Preface

This manual contains reference information for the Cognex Vision Library (CVL). CVL is a powerful C++ class library you can use to write machine vision applications for the Cognex MVS-8000 family of frame grabbers.

Style Conventions Used in This Manual

This manual uses the style conventions described in this section for text and software diagrams.

Text Style Conventions

This manual uses the following style conventions for text:

boldface	Used for C/C++ keywords, function names, class names, structures, enumerations, types, and macros. Also used for user interface elements such as button names, dialog box names, and menu choices.
italic	Used for names of variables, data members, arguments, enumerations, constants, program names, file names. Used for names of books, chapters, and sections. Occasionally used for emphasis.
`courier`	Used for C/C++ code examples and for examples of program output.
`bold courier`	Used in illustrations of command sessions to show the commands that you would type.
<italic>	When enclosed in angle brackets, used to indicate keyboard keys such as *<Tab>* or *<Enter>*.

Microsoft Windows Support

Cognex CVL software runs on Windows operating systems. In this documentation set, these are abbreviated to Windows unless there is a feature specific to one of the variants. Consult the *Getting Started* manual for your CVL release for details on the operating systems, hardware, and software supported by that release.

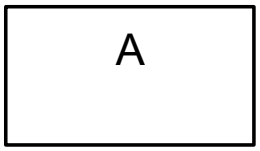
Software Diagramming Conventions

This manual uses the following symbols in class diagrams:

- **Classes** are shown as a box with the class name centered inside the box. For example, a class A with the C++ declaration

  ```
  class A{};
  ```

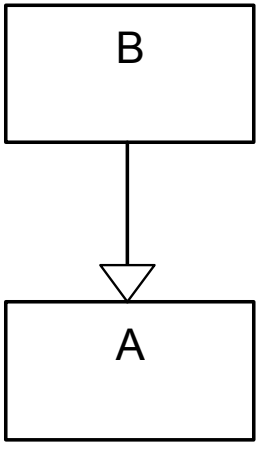
  is shown graphically as follows:



- **Inheritance** relationships between classes are shown using solid-line arrows from the derived class to the base class with a large, hollow triangle pointing toward the base class. For example, a class B that inherits from a class A with the declaration

  ```
  class B : public A {};
  ```

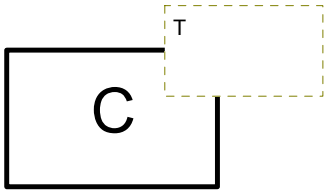
  is shown graphically as follows:



- **Template classes** are shown as a class box with a smaller, dotted-line rectangle representing the template parameter superimposed on the upper right corner of the class box. For example, a template class C with a parameter of type class T with the declaration:

  ```
  template <class T>
  class C{};
  ```

  is shown graphically as follows:



These symbols are based on the Unified Modeling Language (UML), a standard graphical notation for object-oriented analysis and design. See the latest *OMG Unified Modeling Language Specification* (available from the Object Management Group at http://www.omg.org) for more information.

Cognex Offices

Cognex Corporation serves its customers from the following locations:

Corporate Headquarters	Cognex Corporation Corporate Headquarters One Vision Drive Natick, MA 01760-2059 (508) 650-3000
Web Site	http://www.cognex.com

cc1Xform

```
#include <ch_cvl/xform.h>

class cc1Xform;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a one-dimensional transformation object You can use it to scale and offset points along one axis.

Constructors/Destructors

cc1Xform

```
cc1Xform();

cc1Xform(double scale, double offset);
```

- `cc1Xform();`

  Creates a new transformation object. Points are not scaled and not offset.

- `cc1Xform(double scale, double offset);`

  Creates a new transformation object in which points are scaled by *scale* and offset by *offset*.

  Parameters

scale	The amount by which to scale a point.
offset	The amount by which to offset the scaled point.

Operators

operator*

```
cc1Xform operator* (const cc1Xform& xform) const;

double operator* (double pt) const;
```

- `cc1Xform operator* (const cc1Xform& xform) const;`

  Return the transformation object that is the result of composing this transformation object with *xform*, that is, the transformation object that gives the same result as mapping a point first by this transformation object and then by *xform*.

  Parameters

xform	The transformation object to compose with this transformation object.

- `double operator* (double pt) const;`

  Maps the point pt according to the transformation object:

  ```
  result = scale * pt + offset;
  ```

  Parameters

pt	The point to be mapped.

operator==

```
bool operator== (const cc1Xform& that) const;
```

Return true if this transformation object is equal to *that*.

Parameters

that	The other transformation object.

operator!=

```
bool operator!= (const cc1Xform&) const;
```

Return true if this transformation object is not equal to *that*.

Parameters

that	The other transformation object.

Public Member Functions

offset

```
double offset();
void offset(double offset);
```

- `double offset();`

  Returns the offset component of the transformation object. The offset is the amount that the transformation matrix adds or subtracts to a scaled point.

- `void offset(double offset);`

  Sets the offset of the transformation object.

  Parameters

  offset The amount to add or subtract to a point.

scale

```
double scale();
void scale(double scale);
```

- `double scale();`

  Returns the scale component of the transformation object. The scale is the amount by which the transformation object multiplies a point.

- `void scale(double scale);`

  Parameters

  scale The amount by which to multiply a point.

inverse

```
cc1Xform inverse() const;
```

Return the inverse transformation object for this transformation object.

Throws

ccMathError::Singular
The transformation is singular (scale = 0).

cc1Xform

compose `cc1Xform compose(const cc1Xform& xform) const;`

Return the transformation object that is the result of composing this transformation object with *xform*, that is, the transformation object that gives the same result as mapping a point first by this transformation object and then by *xform*.

Parameters

xform The transformation object to compose with this transformation object.

Notes

This is the same function as the multiplication (*) operator when the other operator is a **cc1Xform**.

mapPoint `double mapPoint (double pt) const;`

Map the point *pt* according to the transformation object:

```
result = scale * pt + offset;
```

Parameters

pt The point to be mapped.

Notes

This is the same function as the multiplication (*) operator when the other operator is a point.

invMapPoint `double invMapPoint (double pt) const;`

Maps the point *pt* by the inverse of this transformation object:

```
result = 1/scale * (pt - offset);
```

Throws

ccMathError::Singular
The transformation is singular.

mapVector `double mapVector (double vect) const;`

Scales the vector:

```
result = scale * vect;
```

Parameters

vect The vector to scale.

invMapVector

```
double invMapVector (double vect) const;
```

Scales the vector: result = 1/scale * vect

Parameters

vect

Throws

ccMathError::Singular if the transformation object is singular.

isIdentity

```
bool isIdentity() const;
```

Return true if the transformation object is the identity transform.

isSingular

```
bool isSingular();
```

Return true if the transformation is singular; that is, all points map to the same point.

Data Members

I

```
static const cc1Xform I;
```

The identity transformation object for **cc1Xform**.

cc1Xform

cc2Matrix

```
#include <ch_cvl/matrix.h>

template <int D> class ccMatrix;

typedef ccMatrix<2> cc2Matrix;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class implements a four element, 2 by 2 square matrix that allows for 2D transformations.

Note The template parameter, D, in the class definition specifies the dimension of a **ccMatrix**. For example, **ccMatrix<2>** specifies a 2x2 matrix. **cc2Matrix** is a type definition for a **ccMatrix<>** object instantiated with a template parameter of 2. Similarly, **ccMatrix<3>** specifies a 3x3 matrix. **cc3Matrix** is a type definition for a **ccMatrix<>** object instantiated with a template parameter of 3.

The **cc2Matrix** member functions let you specify the elements of the transformation matrix in three different modalities:

1. The explicit mode. In this modality you explicitly define the four elements of the matrix. When you use this modality, the mapping between image coordinates (I_x, I_y) and client coordinates (C_x, C_y) is:

$$\begin{bmatrix} C_x \\ C_y \end{bmatrix} = \begin{bmatrix} e_{11} & e_{12} \\ e_{21} & e_{22} \end{bmatrix} \begin{bmatrix} I_x \\ I_y \end{bmatrix}$$

   where e_{11}, e_{12}, e_{21}, e_{22} are the matrix elements that you have specified. (For the definition of image coordinates and client coordinates as well as an overview on image transformations see *Images and Coordinates* in the *CVL User's Guide*).

2. The scale-rotation mode. In this modality the matrix is specified by the rotation of the x-axis (r_x), the rotation of the y-axis (r_y), the x-scale (s_x) and the y-scale (s_y). When you use this modality, the mapping between image coordinates (I_x, I_y) and client coordinates (C_x, C_y) is:

$$\begin{bmatrix} C_x \\ C_y \end{bmatrix} = \begin{bmatrix} s_x \cos r_x & -s_y \sin r_y \\ s_x \sin r_x & s_y \cos r_y \end{bmatrix} \begin{bmatrix} I_x \\ I_y \end{bmatrix}$$

3. The shear-aspect mode. In this modality the matrix is specified by the scale of the coordinate system (S), the aspect ratio of the x- and y- axes (A), the shear angle (K) and the rotation angle of the coordinate system(R).When you use this modality, the mapping between image coordinates (I_x, I_y) and client coordinates (C_x, C_y) is:

$$\begin{bmatrix} C_x \\ C_y \end{bmatrix} = \begin{bmatrix} S\cos R & AS(-\sin R - \cos R \tan K) \\ S\sin R & AS(-\cos R - \sin R \tan K) \end{bmatrix} \begin{bmatrix} I_x \\ I_y \end{bmatrix}$$

The scale-rotation and shear-aspect modalities are equivalent, so you can use the one that best suits your application or existing algorithms. However, it is important not mix elements from one modality with elements from the other modality. For example, if you specified a shear angle (K) in the shear-aspect mode, then $A \neq s_y / s_x$. In general the scale-rotation mode is easier to work with.

Note **cc2Matrix** is the name of the class as it is used throughout the Cognex Vision Library. This name is actually a **typedef** for **ccMatrix<2>.** Both forms are valid and entirely equivalent.

Constructors/Destructors

cc2Matrix

```
cc2Matrix();

cc2Matrix(double e11, double e12, double e21, double e22);

cc2Matrix(const ccRadian& xRot, const ccRadian& yRot,
  double xScale, double yScale);

cc2Matrix(double scale, double aspect,
  const ccRadian& shear, const ccRadian& rotation);
```

- `cc2Matrix();`

  The default constructor initializes this matrix to the identity matrix ($\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$)

- `cc2Matrix(double e11, double e12, double e21, double e22);`

  Initializes this matrix according to the explicit mode. The constructor sets the elements of the matrix to *e11*, *e12*, *e21*, *e22*.

  Parameters

e11	The element of the matrix corresponding to the first row and first column.
e12	The element of the matrix corresponding to the first row and second column.
e21	The element of the matrix corresponding to the second row and first column.
e22	The element of the matrix corresponding to the second row and second column.

- `cc2Matrix(const ccRadian& xRot, const ccRadian& yRot, double xScale, double yScale);`

  Initializes this matrix according to the scale-rotation mode.

xRot	The x-rotation; the amount by which to rotate the x-axis in radians.
yRot	The y-rotation; the amount by which to rotate the y-axis in radians.
xScale	The x-scale; the amount by which to scale the x-axis units.
yScale	The y-scale; the amount by which to scale the y-axis units.

- `cc2Matrix(double scale, double aspect, const ccRadian& shear, const ccRadian& rotation);`

Initializes this matrix according to the shear-aspect mode.

scale	The scale element; the amount by which to scale all units.
aspect	The aspect ratio; the ratio of the x-axis units to the y-axis units.
shear	The shear element; the amount by which to rotate the y-axis in radians.
rotation	The rotation element; the amount by which to rotate the entire coordinate system in radians.

Operators

operator+

```
cc2Matrix operator+(const cc2Matrix& m) const;
```

Returns the sum of this matrix and the matrix *m*.

Parameters

m	The matrix added to this matrix.

operator+=

```
cc2Matrix& operator+=(const cc2Matrix& m);
```

Sets this matrix to the sum of this matrix and the matrix *m*.

Parameters

m	The matrix added to this matrix.

operator-

```
cc2Matrix operator-() const;
cc2Matrix operator-(const cc2Matrix& m) const;
```

- `cc2Matrix operator-() const;`

Returns a matrix whose elements are the opposite (i.e. multiplied by -1) of the elements of this matrix.

- `cc2Matrix operator-(const cc2Matrix& m) const;`

Returns the difference between this matrix and the matrix *m*.

Parameters

m	The matrix subtracted from this matrix.

operator-=

```
cc2Matrix& operator-=(const cc2Matrix& m);
```

Sets this matrix to the difference of this matrix and the matrix *m*.

Parameters

m	The matrix subtracted from this matrix.

operator*

```
cc2Matrix operator*(double s) const;
cc2Matrix operator*(const cc2Matrix& m) const;
cc2Vect operator*(const cc2Vect& v);
```

- `cc2Matrix operator*(double s) const;`

  Returns a matrix whose elements are equal to the elements of this matrix times *s*.

  Parameters

s	The value each element of this matrix is multiplied by.

- `cc2Matrix operator*(const cc2Matrix& m) const;`

  Returns the matrix that is the composition of this matrix and the matrix *m*. Mapping a point with the resulting matrix is equivalent to first mapping the point by the matrix *m* and then by this matrix.

  Parameters

m	The matrix composed with this matrix.

- `cc2Vect operator*(const cc2Vect& v) const;`

  Returns the vector resulting from the product of this matrix and the vector *v* (representing a point). The vector returned is the point *v* transformed by this matrix.

  Parameters

v	The vector transformed by this matrix.

operator*=

```
cc2Matrix& operator*=(double s);
cc2Matrix& operator*=(const cc2Matrix& m);
```

- `cc2Matrix& operator*=(double s);`

  Sets this matrix to the product of this matrix and *s*.

Parameters

s The value each element of this matrix is multiplied by.

- `cc2Matrix& operator*=(const cc2Matrix& m);`

Sets this matrix to the composition of this matrix and *m*.

Parameters

m The matrix composed with this matrix

operator/

```
cc2Matrix operator/(double s);
cc2Matrix operator/(const cc2Matrix& m);
```

- `cc2Matrix operator/(double s);`

Returns a matrix whose elements are equal to the elements of this matrix divided by s.

Parameters

s The value each element of this matrix is divided by.

- `cc2Matrix operator/(const cc2Matrix& m);`

Returns the matrix composed by this matrix and the inverse of *m*.

Parameters

m The matrix whose inverse is composed with this matrix.

operator/=

```
cc2Matrix& operator/=(double s);
cc2Matrix operator/=(const cc2Matrix& m);
```

- cc2Matrix& operator/=(double s);

Sets this matrix to the quotient of this matrix and *s*.

Parameters

s The value each element of the matrix is divided by.

- `cc2Matrix operator/=(const cc2Matrix& m);`

Sets this matrix to the matrix composed by this matrix and the inverse of *m*.

Parameters

m The matrix whose inverse is composed with this matrix.

Throws

ccMathError::Singular
The matrix used as a divisor is singular.

operator==

```
bool operator==(const cc2Matrix& m) const;
```

Returns true if all the elements of this matrix are the same as the corresponding elements of the matrix *m*.

m The matrix compared to this matrix.

operator!=

```
bool operator!=(const cc2Matrix& m) const;
```

Returns true if this matrix is not the same as *m*.

Parameters

m The matrix compared to this matrix.

Friends

operator *=

```
friend cc2Vect operator*=(const cc2Vect& v,
  const cc2Matrix& m);
```

Returns the vector resulting from the left-product of the matrix *m* with the vector *v*. If

$v = \begin{bmatrix} V_x \\ V_y \end{bmatrix}$ and $m = \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix}$ the left-product of *m* with *v* is defined as

$$\begin{bmatrix} V_x & V_y \end{bmatrix} \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} = \begin{bmatrix} (V_x m_{11} + V_y m_{21}) & (V_x m_{12} + V_y m_{22}) \end{bmatrix}$$

Parameters

v The vector multiplied with *m*.

m The matrix multiplied with v.

Public Member Functions

determinant

```
double determinant() const;
```

Returns the determinant of this matrix. If ***this*** $= \begin{bmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{bmatrix}$ the value returned is $t_{11}t_{22} - t_{12}t_{21}$.

inverse

```
cc2Matrix inverse() const;
```

Returns the inverse of this matrix. The inverse of this matrix is $\left(\frac{1}{det[this]}\right)\begin{bmatrix} t_{22} & -t_{12} \\ -t_{21} & t_{11} \end{bmatrix}$ where $det[this]$ is the determinant of this matrix.

Throws

ccMathError::Singular
The transformation matrix is singular.

transpose

```
cc2Matrix transpose() const;
```

Returns the transpose of this matrix. If $this = \begin{bmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{bmatrix}$ the transpose of this matrix is $\begin{bmatrix} t_{11} & t_{21} \\ t_{12} & t_{22} \end{bmatrix}$.

isSingular

```
bool isSingular() const;
```

Returns true if this matrix is singular (i.e. if $det[this]$ is exactly equal to zero).

isIdentity

```
bool isIdentity() const;
```

Returns true if this matrix is the identity matrix.

element

```
double element(c_Int32 row,c_Int32 column) const;
void element(c_Int32 row,c_Int32 column, double value);
```

- `double element(c_Int32 row,c_Int32 column) const;`

Returns the element of this matrix specified by the indices *row* and *column*.

Parameters

row — The row-index.

0: Identifies the first row.

1: Identifies the second row.

column — The column-index.

0: Identifies the first column.

1: Identifies the second column.

- `void element(c_Int32 row,c_Int32 column, double value);`

  Sets the element of this matrix specified by the indices *row* and *column* to *s*.

  Parameters

  row — The row-index.

  0: identifies the first row.

  1: identifies the second row.

  column — The column-index.

  0: identifies the first column.

  1: identifies the second column.

  value — The value the matrix element specified by *row* and *column* is set to.

xRot `ccRadian xRot() const;`

Returns the x-rotation element of this matrix when using the scale-rotation specification.

Throws

ccMathError::Singular — This matrix is singular.

yRot `ccRadian yRot() const;`

Returns the y-rotation element of this matrix when using the scale-rotation specification.

Throws

ccMathError::Singular — This matrix is singular.

xScale `double xScale() const;`

Returns the x-scale element of this matrix when using the scale-rotation specification.

Throws

ccMathError::Singular — This matrix is singular.

yScale `double yScale() const;`

Returns the y-scale element of this matrix when using the scale-rotation specification.

Throws
ccMathError::Singular
This matrix is singular.

scale `double scale() const;`

Returns the scale element of this matrix when using the shear-aspect specification.

Throws
ccMathError::Singular
This matrix is singular.

aspect `double aspect() const;`

Returns the aspect element of this matrix when using the shear-aspect specification.

Throws
ccMathError::Singular
This matrix is singular.

shear `ccRadian shear() const;`

Returns the shear element of this matrix when using the shear-aspect specification.

Throws
ccMathError::Singular
This matrix is singular.

rotation `ccRadian rotation() const;`

Returns the rotation element of this matrix when using the shear-aspect specification.

Throws
ccMathError::Singular
This matrix is singular.

Data Members

I `static const cc2Matrix I;`

The identity transformation matrix for **cc2Matrix.**

cc2Point

```
#include <ch_cvl/shapes.h>

class cc2Point : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a point. In most cases, you can use either **cc2Point** or **cc2Vect** to describe locations in a coordinate system. This class, however, is a full-fledged **ccShape** andinherits all of the methods of that class.

Constructors/Destructors

cc2Point

```
cc2Point();

cc2Point(const cc2Vect& v);

cc2Point(double x, double y);
```

- `cc2Point();`

  Default constructor. Constructs a point with coordinates (0,0).

- `cc2Point(const cc2Vect& v);`

  Conversion constructor. Constructs a point with coordinates equal to the coordinates of the supplied vector.

  Parameters

  v The vector.

- `cc2Point(double x, double y);`

  Constructs a point with *x* and *y* coordinates equal to the supplied values.

  Parameters

  x The x value.

y The y value.

Operators

operator==

```
bool operator==(const cc2Point &rhs) const;
```

Returns true if this point is equal to *rhs*, under strict floating point equality.

Parameters

rhs The other **cc2Point**.

operator!=

```
bool operator!=(const cc2Point &rhs) const;
```

Returns true if this point is not equal to *rhs*, under strict floating point equality.

Parameters

rhs The other **cc2Point**.

Public Member Functions

x

```
double x() const;
double x(double val);
```

- ```
  double x() const;
  ```

  Gets the x coordinate of this point.

- ```
  double x(double val);
  ```

  Sets the x coordinate of this point.

  Parameters

  val The value to which the x coordinate is set.

y

```
double y() const;
void y(double val);
```

- ```
  double y() const;
  ```

  Gets the y coordinate of this point.
  ```

- `void y(double val);`

  Sets the y coordinate of this point.

  Parameters

  val The value to which the y coordinate is set.

vect

```
const cc2Vect& vect() const;
void vect(const cc2Vect &val);
```

- `const cc2Vect& vect() const;`

  Returns the vector representation of this point.

- `void vect(const cc2Vect &val);`

  Sets the vector representation of this point.

  Parameters

  val The vector that represents this point.

map

```
cc2Point map(const cc2Xform& c) const;
```

Returns the result of mapping this point with the transformation object *c*.

Parameters

c The transformation object.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this point.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For points, this function always returns true. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For points, this function always returns false. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

For points, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For points, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

For points, this function always returns false. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For points, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For points, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the smallest rectangle that encloses this point.

Notes

This function succeeds the deprecated **encloseRect()**. However, note that **boundingBox()** returns a rectangle of size (0, 0), while **encloseRect()** returned a rectangle of size (1, 1) for points.

See **ccShape::boundingBox()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns this **cc2Point**.

Parameters

p	The point.

perimeter

```
virtual double perimeter() const;
```

Returns 0.0 for any point.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this shape to the given point. For a point, the returned perimeter position specifies the point itself.

Parameters

info Shape information for this point.

point The other point.

Notes

The **ccPerimPos::distAlongPrimitive()** component of the returned perimeter position is equal to 0.0.

See **ccShape::nearestPerimPos()** for more information.

startPoint

```
virtual cc2Vect startPoint() const;
```

Returns this **cc2Point**. See **ccShape::startPoint()** for more information.

endPoint

```
virtual cc2Vect endPoint() const;
```

Returns this **cc2Point**. See **ccShape::endPoint()** for more information.

startAngle

```
virtual ccRadian startAngle() const;
```

Throws

ccShapesError::NoTangent
hasTangent() is always false for **cc2Point**.

See **ccShape::startAngle()** for more information.

endAngle

```
virtual ccRadian endAngle() const;
```

Throws

ccShapesError::NoTangent
hasTangent() is always false for **cc2Point**.

See **ccShape::endAngle()** for more information.

cc2Point

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Throws

ccShapesError::NoTangent
hasTangent() is always false for **cc2Point**.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns 0.0 for a **cc2Point**.

Parameters

p	The start point of the vector *p->t* where *t* is this point.

See **ccShape::windingAngle()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns this **cc2Point**. See **ccShape::reverse()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Adds this **cc2Point** to *result* if **params.computeTangents()** is false.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position chains are appended.

Notes

If **params.computeTangents()** is true, this **cc2Point** does not contribute any samples to *result*.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this point mapped by *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a zero-length line segment with both endpoints coincident with this point. See **ccShape::decompose()** for more information.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to this point.

Parameters

info	Shape information for this point.
range	The perimeter range. If the distance component of this **ccPerimRange** is greater than 0.0, it is internally clipped to 0.0.

See **ccShape::perimeter()** for more information.

cc2Point

cc2Rigid

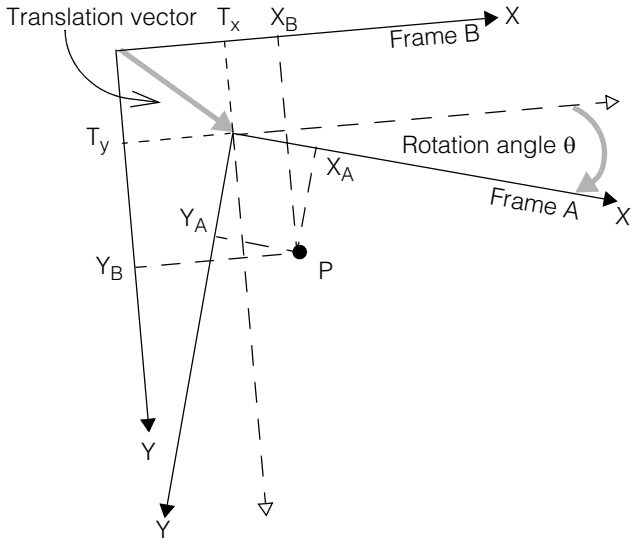
```
#include <ch_cvl/xform.h>

class cc2Rigid;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

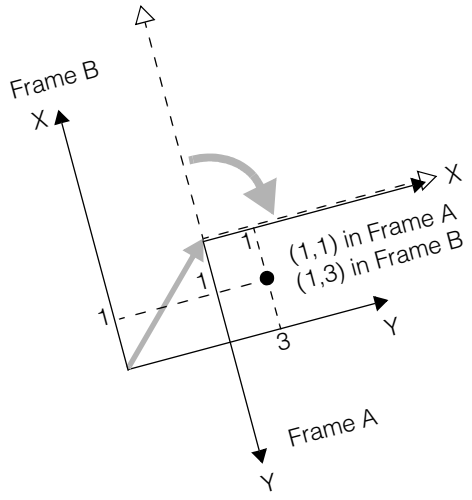
This class implements a rigid transformation of coordinate data.The transformation can be also thought of as a mapping of features from an initial coordinate frame to a second frame. The transformation is called rigid because the data are mapped by a simple rotation and translation, no distortions due to scaling or skews are present. The following figure illustrates a rigid transformation that maps features from Frame A to Frame B. The transformation is defined by a 2-element translation vector and by a rotation angle. The elements of the translation vector specify the amount by which Frame A is translated along the X- and Y- directions of Frame B (T_x and T_y in the following figure), while the rotation angle specifies the angle by which the coordinate axes are rotated from Frame B (θ in the following figure)



If your data are initially represented in Frame A, the member functions of **cc2Rigid** allow you to map them to their representation in Frame B. For example, if (X_A, Y_A) are the coordinates of the point P in Frame A, the class provides you with ways to return the coordinates of the point in Frame B (X_B, Y_B). The two points are mathematically related by the following expression:

$$\begin{bmatrix} X_B \\ Y_B \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} X_A \\ Y_A \end{bmatrix} + \begin{bmatrix} T_x \\ T_y \end{bmatrix}$$

As an illustration, consider the rigid transformation characterized by the translation vector (2,2) and the rotation angle of 90 degrees (see following figure). In this case the point (1,1) in Frame A is mapped to the point (1, 3) in Frame B.



$$\begin{bmatrix} X_B \\ Y_B \end{bmatrix} = \begin{bmatrix} \cos(90) & -\sin(90) \\ \sin(90) & \cos(90) \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} + \begin{bmatrix} 2 \\ 2 \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} + \begin{bmatrix} 2 \\ 2 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 2 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 \\ 3 \end{bmatrix}$$

Constructors/Destructors.

cc2Rigid

```
cc2Rigid();
cc2Rigid(const ccDegree& a, const cc2Vect& t);
```

- `cc2Rigid();`

  The default constructor initializes this rigid transformation to the identity transformation, that is the transformation which maps features to their current location, leaving them unchanged. The identity transformation is defined by a translation vector whose components are both *0* (no translation) and a rotation angle of *0* degrees (no rotation).

- `cc2Rigid(const ccDegree& a, const cc2Vect& t);`

  Initializes the rotation angle and the translation vector of this rigid transformation.

  Parameters

a	The rotation angle assigned to this rigid transformation.
t	The translation vector assigned to this rigid transformation.

Operators

operator*

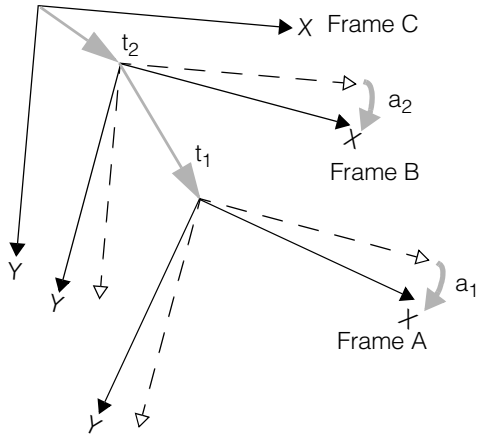
```
cc2Rigid operator*(const cc2Rigid& xform) const;
cc2Xform operator*(const cc2Xform& xform) const;
cc2Vect operator*(const cc2Vect &pt) const;
```

- `cc2Rigid operator*(const cc2Rigid& xform) const;`

  Returns the rigid transformation that is the composition of this rigid transformation and *xform*. Mapping the resulting rigid transformation is equivalent to first mapping *xform* and then this rigid transformation. For example, assume that *xform* is defined by the translation vector t_1 and by the rotation angle a_1 while this rigid transformation is defined by the translation vector t_2 and the rotation angle a_2 (see following figure). The rigid transformation returned by the operator has the same effect as the following sequence of transformations.

  1. *xform* maps data from Frame A to Frame B.

2. This rigid transformation maps data from Frame B to Frame C.



Parameters

xform The rigid transformation composed with this rigid transformation.

- `cc2Xform operator*(const cc2Xform& xform) const;`

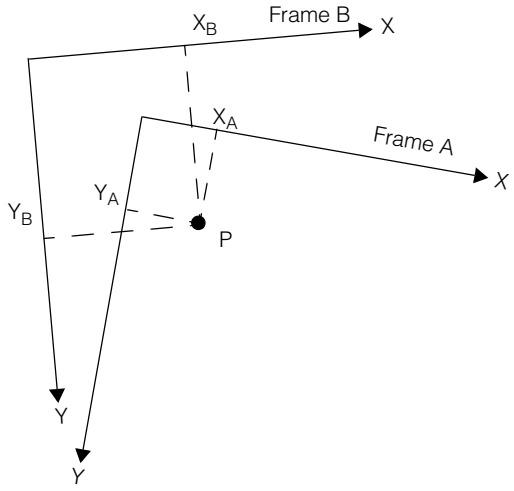
This operator returns the **cc2Xform** transformation object resulting from the composition of this rigid transformation and *xform*. Mapping a point with the resulting **cc2Xform** transformation object is equivalent to first mapping the point by *xform* and then by this rigid transformation.

Parameters

xform The **cc2Xform** transformation object composed with this rigid transformation.

- `cc2Vect operator*(const cc2Vect &pt) const;`

  Maps the coordinates of the point *pt* using this rigid transformation. The point (X_A, Y_A) in Frame A is mapped to (X_B, Y_B) in Frame B (see following figure). The operation performed by this operator is equivalent to the one performed by the function **mapPoint**.



Parameters

pt The point whose coordinates are mapped.

operator == `bool operator==(const cc2Rigid& xform) const;`

Returns true if this rigid transformation is exactly the same as *xform* (that is, if the translation and rotation of the two transformations are the same).

Parameters

xform The rigid transformation compared to this rigid transformation.

operator!= `bool operator!=(const cc2Rigid& xform) const;`

Returns true if this rigid transformation is not the same as *xform*.

Parameters

xform The transformation compared to this rigid transformation.

Friends

operator*

```
cc2Xform operator*(const cc2Xform &x,
  const cc2Rigid &r);
```

Returns the **cc2Xform** resulting from the composition of the **cc2Xform** *x* and the rigid transformation *r*. Mapping a point with the resulting **cc2Xform** transformation object is equivalent to first mapping the point by *r* and then by *x*.

Parameters

x	The **cc2Xform** transformation object to be composed with the rigid transformation *r*.
r	The rigid transformation to be composed with the **cc2Xform** transformation object *x*.

Public Member Functions

angle

```
const ccDegree& angle()const;

void angle(const ccDegree& a);
```

- `const ccDegree& angle() const;`

  Returns the rotation angle of this rigid transformation in degrees.

- `void angle(const ccDegree& a);`

  Sets the rotation angle of this rigid transformation to *a*.

  Parameters

a	The rotation angle assigned to this rigid transformation.

cosAngle

```
double cosAngle()const;
```

Returns the cosine of the rotation angle of this rigid transformation.

sinAngle

```
double sinAngle()const;
```

Returns the sine of the rotation angle of this rigid transformation.

trans

```
const cc2Vect& trans()const;
void trans(const cc2Vect& t);
```

- `const cc2Vect& trans()const;`

  Returns the translation vector of this rigid transformation.

- `void trans(const cc2Vect& t);`

  Sets the translation vector of this rigid transformation to *t*.

  Parameters

t	The translation vector assigned to this rigid transformation.

linear

```
cc2Xform linear() const;
```

Returns the equivalent **cc2Xform** form of this rigid transformation.

compose

```
cc2Rigid compose(const cc2Rigid& xform) const;
cc2Xform compose(const cc2Xform& xform) const;
```

- `cc2Rigid compose(const cc2Rigid& xform)const;`

  Returns the composition of this rigid transformation with *xform*. This function implements the same operation as **operator *(const cc2Rigid& xform)**.

  Parameters

xform	The rigid transformation composed with this transformation.

- `cc2Xform compose(const cc2Xform& xform)const;`

  Returns the composition of this rigid transformation with the **cc2Xform** transformation *xform*. This function implements the same operation as **operator *(const cc2Xform& xform)**.

  Parameters

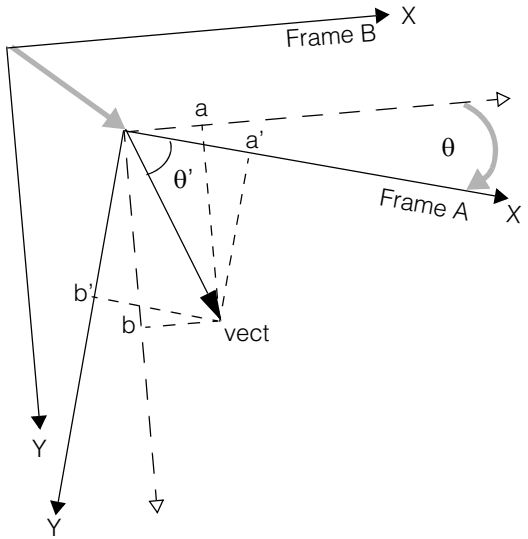
xform	The **cc2Xform** transformation composed with this transformation.

inverse `cc2Rigid inverse() const;`

Returns the inverse of this rigid transformation. The inverse of this rigid transformation is defined as the rigid transformation that, when composed with this rigid transformation, returns the identity transformation. If this rigid transformation maps points from Frame A to Frame B, the inverse of this rigid transformation maps points from Frame B back to Frame A.

mapVector `cc2Vect mapVector (const cc2Vect &vect) const;`

Maps the components of *vect* by this rigid transformation. If (a', b') are the components of *vect* in Frame A and (a, b) are the components of *vect* in Frame B, **mapVector** maps (a', b') to (a, b).



Parameters

vect The vector whose components are mapped by **mapVector**.

Notes.

Although a vector and a point are represented by the same data type (**cc2Vect**) it is important to keep in mind that they represent two distinct notions. A point represents a specific position in the coordinate space. A vector represents a length and direction in the same space but has no fixed location. A vector is depicted in drawings as an arrow. Points and vectors can be represented by the same class because a vector whose tail is placed at the origin specifies a unique point (at the end of the arrow).

invMapVector `cc2Vect invMapVector (const cc2Vect &vect) const;`

Implements the inverse of the mapping operated by **MapVector**. If we refer to the preceding figure, **invMapVector** maps (a, b) (in Frame B), to (a', b') in Frame A.

Parameters

vect The vector mapped by **invMapVector**.

mapAngle `ccRadian mapAngle (const ccRadian& ang) const;`

Maps the polar angle of some feature in coordinate Frame A (see preceding figure) to the polar angle in coordinate Frame B. If θ' is the polar angle of *vect* in Frame A, **mapAngle** maps θ' to ($\theta + \theta$').

Parameters

ang The polar angle of a feature in coordinate Frame A.

invMapAngle `ccRadian invMapAngle (const ccRadian& ang) const;`

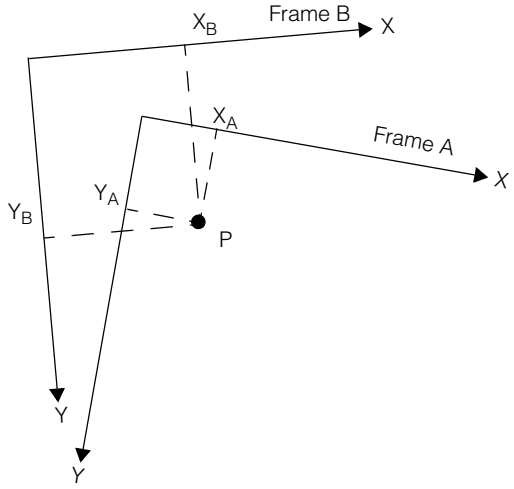
Implements the inverse of the mapping operated by **mapAngle**. If we refer to the preceding figure, **invMapAngle** maps ($\theta + \theta$') (the polar angle of *vect* in Frame B) to θ' (the polar angle of *vect* in Frame A).

Parameters

ang The polar angle of a feature in coordinate Frame B ($(\theta + \theta')$ in the preceding figure).

mapPoint `cc2Vect mapPoint (const cc2Vect &pt) const;`

Maps the point *pt* from its coordinates in Frame A (see following figure) to its coordinates in Frame B. This function implements the same operation as **operator *(const cc2Vect &pt)**. If (x_A, y_A) are the coordinates of *pt* in Frame A and (x_B, y_B) are the coordinates of *pt* in Frame B, **mapPoint** performs the following mapping: (x_A, y_A) -> (x_B, y_B).



Parameters

pt The point mapped by this transformation.

invMapPoint `cc2Vect invMapPoint (const cc2Vect &pt) const;`

Implements the inverse of the mapping operated by **mapPoint**. In the previous figure, **invMapPoint** maps (x_B, y_B) (the coordinates of *pt* in Frame B) to (x_A, y_A) (the coordinates of *pt* in Frame A).

Parameters

pt The point mapped by the inverse of this transformation.

isIdentity `bool isIdentity() const;`

Returns true if this rigid transformation is the identity transformation.

Data Members

```
static const cc2Rigid I;
```

The identity transformation for **cc2Rigid**.

cc2Rigid

cc2Vect

```
#include <ch_cvl/vector.h>

class cc2Vect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Yes

This class describes a two-dimensional vector, a quantity that is determined by its length (magnitude) and direction. Throughout CVL, **cc2Vector** is used to describe points, so you can also think of a vector as an (x,y) coordinate pair.

Notes

cc2Vect is the name of the class as it is used throughout the Cognex Vision Library. This name is actually a **typedef** for **ccVector<2>**. Both forms are valid and entirely equivalent.

Do not confuse the CVL vector classes **cc2Vect** and **cc3Vect** with the C++ Standard Template Library's **vector** template class. Though both have the same mathematical underpinnings, CVL vector classes are generally used to describe the location of points while the STL **vector** class is used to implement flexible arrays.

Constructors/Destructors

cc2Vect

```
cc2Vect();
cc2Vect(double x, double y);
cc2Vect(double r, ccRadian t);
cc2Vect(const ccFPair& p);
cc2Vect(const ccDPair& p);
cc2Vect(const ccIPair& p);
```

- `cc2Vect();`

  The default constructor creates a vector in which both x and y components are set to zero.

- `cc2Vect(double x, double y);`

  Creates a vector with the specified x and y components.

  Parameters

x	The x-component of the vector.
y	The y-component of the vector.

- `cc2Vect(double r, ccRadian t);`

  Creates a vector from the specified radius and angle.

  Parameters

r	The radius of the circle.
t	The angle in radians. Angles are measured from the x-axis.

  Notes

  If the radius is zero, the angle information is not stored. The vector is a null vector.

- `cc2Vect(const ccFPair& p);`

  Creates a vector from the specified pair of **float**s.

  Parameters

p	The pair of **float**s.

- `cc2Vect(const ccDPair& p);`

  Creates a vector from the specified pair of **double**s.

  Parameters

p	The pair of **double**s.

- `cc2Vect(const ccIPair& p);`

  Creates a vector from the specified pair of integers (**c_Int32**).

  Parameters

p	The pair of integers.

Operators

operator[]

```
double& operator[](int d);
double operator[](int d) const;
```

- `double& operator[](int d);`

  Provides array-like access to the vector. Typically you use this form when your application works with both two- and three-dimensional vectors. This form allows you to set the value of a component.

  Parameters

  d The index of the element to return.

  0: The x-component.

  1: The y-component.

- `double operator[](int d) const;`

  Provides array-like access to the vector. Typically you use this form when your application works with both two- and three-dimensional vectors.

  Parameters

  d The index of the element to return.

  0: The x-component.

  1: The y-component.

operator+

```
cc2Vect operator+(const cc2Vect& v) const;
```

Returns a vector that is the result of adding this vector and another vector.

Parameters

v The vector to add to this vector.

operator+=

```
cc2Vect& operator+=(const cc2Vect& v);
```

Adds this vector to another vector and returns the result.

Parameters

v The vector to add to this vector.

operator-

```
cc2Vect operator-() const;
cc2Vect operator-(const cc2Vect&) const;
```

- `cc2Vect operator-() const;`

  The unary minus operator.

- `cc2Vect operator-(const cc2Vect& v) const;`

  Returns a vector that is the result of subtracting the vector v from this vector.

  Parameters

  v The vector to subtract from this vector.

operator-=

```
cc2Vect& operator-=(const cc2Vect& v);
```

Subtracts the vector v from this vector and returns the result.

Parameters

v The vector to subtract from this vector.

operator*

```
cc2Vect operator*(double d) const;
friend cc2Vect operator*(double, const cc2Vect&);
double operator*(const cc2Vect& v) const;
```

- `cc2Vect operator*(double d) const;`

  Returns a vector that is the result of multiplying each element in the vector by *d*.

  Parameters

  d The value by which to multiply each element of the vector.

- `friend cc2Vect operator*(double d, const cc2Vect& v);`

  Returns a vector that is the result of multiplying each element in the vector by *d*.

  Parameters

  d The value by which to multiply each element of the vector.

  v The vector.

- `double operator*(const cc2Vect& v) const;`

  Returns the dot product of this vector and the vector *v*.

  Parameters

v	The other vector.

operator*= `cc2Vect& operator*=(double d);`

Multiplies each element in this vector by *d* and returns the result.

Parameters

d	The value by which to multiply each element of the vector.

operator/ `cc2Vect operator/(double d) const;`

Returns a vector that is the result of dividing each element in this vector by *d*.

Parameters

d	The value by which to divide each element of the vector.

operator/= `cc2Vect& operator/=(double d) const;`

Divides each element in this vector by *d* and returns the result.

Parameters

d	The value by which to divide each element of the vector.

operator== `bool operator==(const cc2Vect& v) const;`

Returns true if this vector is equal to another vector.

Parameters

v	The other vector.

operator!= `bool operator!=(const cc2Vect&) const;`

Returns true if this vector is not equal to another vector.

Parameters

v	The other vector.

Public Member Functions

x

```
double x() const;
void x(double newX);
```

- `double x() const;`

  Returns the vector's x-component.

- `void x(double newX);`

  Sets the vector's x-component.

  Parameters

  newX The new x-component.

y

```
double y() const;
void y(double newY);
```

- `double y() const;`

  Returns the vector's y-component.

- `void y(double newY);`

  Sets the vector's y-component.

  Parameters

  newY The new y-component.

len

```
double len() const;
```

Returns the length (or magnitude) of the vector.

isNull

```
bool isNull() const;
```

Returns true if this is a null vector (both components are zero).

angle `ccRadian angle() const;`

Returns the vector angle in the range $-\pi <$ angle $<= \pi$. Angles are measured from the x-axis.

Throws

ccMathError::NullVector
Both the x-component and the y-component are zero.

unit `cc2Vect unit() const;`

Returns a unit vector parallel to this vector. A unit vector is a vector whose length is 1.

Throws

ccMathError::NullVector
Both the x-component and the y-component are zero.

project `cc2Vect project(const cc2Vect& v) const;`

Returns a vector that is the result of projecting the vector *v* onto this vector.

Parameters

v The vector to project onto this vector.

Throws

ccMathError::NullVector
Both the x-component and the y-component are zero.

An error is not thrown if *v* is null or the two vectors are perpendicular to each other.

perpendicular `cc2Vect perpendicular() const;`

Returns a vector perpendicular (rotated +90 degrees) to this vector. The new vector is the same length as this vector.

Notes

The null vector is considered perpendicular to itself

distance `double distance(const cc2Vect& v) const;`

Returns the distance to the other vector. This is the length of difference between this vector and vector *v*.

Parameters

v The other vector.

cc2Vect

dot

```
double dot(const cc2Vect& v) const;
```

Returns the dot product of this vector and the vector *v*.

Parameters

v	The other vector.

cross

```
double cross(const cc2Vect& v) const;
```

Returns the cross product of this vector and *v*.

Parameters

v	The other vector.

floor

```
ccIPair floor() const ;
```

Returns a **ccIPair** corresponding to **floor**(**cc2Vect::x()**), **floor(cc2Vect::y()**).

ceil

```
ccIPair ceil() const ;
```

Returns a **ccIPair** corresponding to **ceil**(**cc2Vect::x()**), **ceil(cc2Vect::y()**).

cc2Wireframe

```
#include <ch_cvl/wirefrm.h>

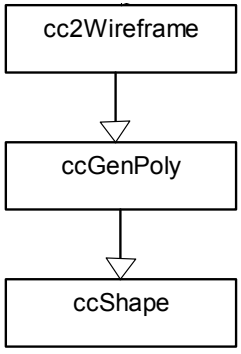
class cc2Wireframe : public ccGenPoly;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	Complex

The **cc2Wireframe** class is a general polygon (**ccGenPoly**) shape with an explicitly defined polarity value plus segment length tolerance information. The weight is implicitly defaulted to 1.0. However, the (deprecated) interface to PatMax allows you to specify weights that are applied to a vector of **cc2Wireframe** objects to be trained.

Note PatMax does not use the tolerance information in a **cc2Wireframe**.

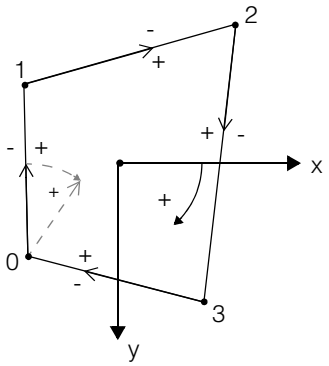


The above figure shows the **cc2Wireframe** class inheritance hierarchy.

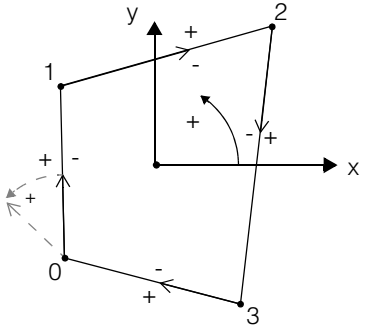
Polarity

Each wireframe has unique *polarity*. As you traverse the wireframe from one vertex to another, each segment has a positive side and a negative side. By default, the positive side of a segment with index N is that side to which the segment would move if it were to rotate in the direction of positive angle when the center of rotation is vertex N. The polarity is dependent on the direction of increasing indices, and the handedness of the coordinate system. Note that when the wireframe is closed, the inside of the wireframe will be of one polarity, and the outside will be of the opposite polarity.

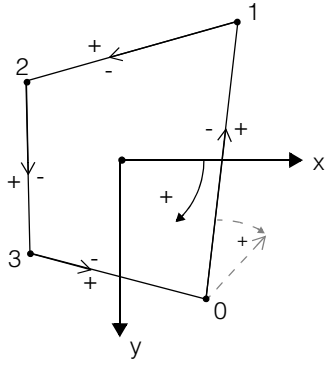
The following closed wireframe diagrams show the wireframe polarity for right-handed and left-handed coordinate systems.



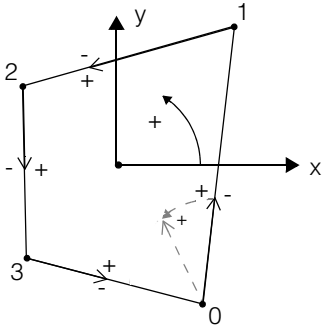
Left-handed coordinate system.
Positive rotation is clockwise.
Positive side of each segment on the right.



Right-handed coordinate system.
Positive rotation is counterclockwise.
Positive side of each segment on the left.

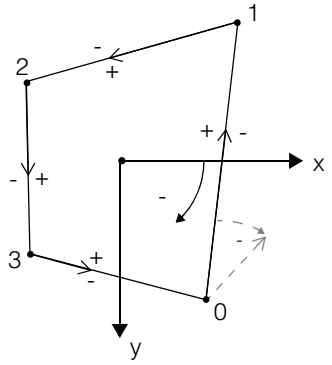


Left-handed coordinate system.
Positive rotation is clockwise.
Positive side of each segment on the right.



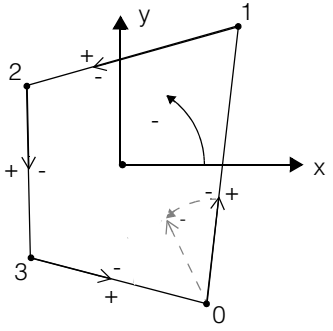
Right-handed coordinate system.
Positive rotation is counterclockwise.
Positive side of each segment on the left.

The diagrams above show the wireframe polarities for the given conditions. These polarities are the default state. Note that you can reverse the wireframe polarity to the *reversed* state by calling **cc2Wireframe::polarity()**. The two examples above are show below with reversed polarity.



Left-handed coordinate system.
Positive rotation is counter-clockwise.
Positive side of each segment on the left.

Reversed polarity



Right-handed coordinate system.
Positive rotation is clockwise.
Positive side of each segment on the right.

Each segment in the wireframe has associated tolerance information contained in a **ccDimTol** object that specifies *nominal*, *maximum,* and *minimum* segment lengths. A description of tolerances is presented in the **ccDimTol** reference page.

When tolerances are defined, the scale type associated with each segment indicates how tolerances change when the wireframe is scaled. The effect of scaling on tolerances is also discussed in the **ccDimTol** reference page.

Using PatMax with Wireframes

For new development, you should use **ccGenPoly** or **ccGenPolyModel** shapes rather than **cc2Wireframe** shapes when training PatMax on synthetic shapes. If you want to move to the new **train()** interface of PatMax but continue to use legacy **cc2Wireframe** shapes that may already exist in your code, you will need to put the wireframes into a shape tree prior to training. See the *Training with Wireframes* section of the *PatMax* chapter of the *CVL Vision Tools Guide* for sample code that demonstrates how to do this.

Constructors/Destructors

cc2Wireframe

```
cc2Wireframe() {};
cc2Wireframe(const ccGenPoly& gp);
cc2Wireframe(const ccGenPoly& gp, const ccDimTol & tol);
virtual ~cc2Wireframe();
```

- `cc2Wireframe() {};`

  Default constructor. Constructs a wireframe object with no vertices or segments.

- `cc2Wireframe(const ccGenPoly& gp);`

  Conversion constructor. Constructs a wireframe object that is equivalent to the supplied generalized polygon.

  Parameters

  gp — The generalized polygon used as a basis for the constructed wireframe object.

- `cc2Wireframe(const ccGenPoly& gp, const ccDimTol & tol);`

  Constructs a wireframe object that is equivalent to the supplied generalized polygon. All segments are set to use the specified segment length tolerance.

  Parameters

  gp — The generalized polygon used as a basis for the constructed wireframe object.

  tol — The segment length tolerance. The nominal tolerance dimension is ignored.

- `virtual ~cc2Wireframe();`

  Destructor. Destroys this wireframe shape.

Operators

operator==

```
bool operator==(const cc2Wireframe&) const;
```

This operator allows you to compare two **cc2Wireframe** objects. For example,

```
if(frame1 == frame2) {.....}
```

The equality expression evaluates to *true* if the objects are equal. It is *false* if they are not equal.

Parameters

cc2Wireframe The right-hand **cc2Wireframe** object. For example, *frame2*.

operator!=

```
bool operator!=(const cc2Wireframe&) const;
```

This operator allows you to compare two **cc2Wireframe** objects. For example,

```
if(frame1 != frame2) {.....}
```

The inequality expression evaluates to *true* if the objects are not equal. It is *false* if they are equal.

Parameters

cc2Wireframe The right-hand **cc2Wireframe** object. For example, *frame2*.

Public Member Functions

isPolarityReversed

```
bool isPolarityReversed() const;
```

Returns *true* if the polarity of the wireframe is reversed from its default state (see general polarity comments above), and false otherwise.

polarity

```
void polarity(bool isReversed);
```

If *isReversed* is true, the polarity of all segments in the wireframe is set to the reversed state. (See the wireframe polarity discussion starting on page 79). If *isReversed* is *false*, the polarity of all segments is set to the default state.

Parameters

isReversed The reverse polarity specifier, *true* or *false*.

Throws

ccShapesError::BadGeom
isMutable() is false.

isInsidePositive

```
bool isInsidePositive() const;
```

Returns *true* if the polarity of the wireframe is such that the inside of the wireframe is positive. Returns *false* otherwise.

Throws

ccShapesError::BadGeom
This wireframe is not closed.

insidePolarity

```
void insidePolarity(bool isPositive);
```

If *isPositive* is *true*, changes the polarity of all segments in this closed wireframe so that the inside of the wireframe is positive. If *isPositive* is *false*, sets the polarity of all segments so that the inside of the wireframe is negative.

Parameters

isPositive The wireframe polarity specifier; *true* or *false*.

Throws

ccShapesError::BadGeom
isMutable() is false.

segmentLengthTol

```
void segmentLengthTol(c_Int32 segmentIndex,
 const ccDimTol & tol);

ccDimTol segmentLengthTol(c_Int32 segmentIndex) const;
```

- ```
  void segmentLengthTol(c_Int32 segmentIndex,
   const ccDimTol & tol);
  ```

Sets the segment length tolerance for the segment with the specified index.

Parameters

segmentIndex The index for the target segment.

tol The new segment length tolerance. The nominal dimension is ignored.

Throws

ccShapesError::BadCoeff
segmentIndex is not a valid segment index.

ccShapesError::BadGeom
isMutable() is false, or the absolute tolerances specified are not possible.

The generalized polygon is unaffected in case of any throw.
  ```

- `ccDimTol segmentLengthTol(c_Int32 segmentIndex) const;`

  Returns the segment length tolerance for the segment with the specified index. The nominal segment length will reflect the actual length of the specified segment.

  Parameters

  segmentIndex The index for the target segment.

  Throws

  ccShapesError::BadCoeff
  If *segmentIndex* is not a valid segment index.

  The generalized polygon is unaffected in case of any throw.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this wireframe.

map

```
cc2Wireframe map(const cc2Rigid& c,
  double scale = 1.0) const;

cc2Wireframe map(const cc2Xform& c) const;
```

- `cc2Wireframe map(const cc2Rigid& c, double scale = 1.0) const;`

  Returns this wireframe scaled by *scale*, and mapped by *c*. The returned wireframe is mutable. For information on scaling of wireframe segment length tolerances see the **ccDimTol** class reference page.

  Parameters

  c The mapping transform used.

  scale The scale factor used.

  Throws

  ccShapesError::BadGeom
  If the scaled nominal segment length for any segment is not within the defined fixed tolerance ranges.

- `cc2Wireframe map(const cc2Xform& c) const;`

  Returns this wireframe mapped by *c*. Wireframe tolerances are scaled according to the scale type of each wireframe segment. Scaling is described in the **ccDimTol** class reference page. The scale factor for a given segment is defined as the ratio of the old segment length to the new segment length along a possibly elliptical arc.

  The returned generalized polygon is immutable unless **c.isIdentity()** is true.

  Parameters

  c The mapping transform used.

  Throws

  ccShapesError::BadGeom
  If the scaled nominal segment length for any segment is not within the defined fixed tolerance ranges.

insertVertex

```
void insertVertex(const cc2Vect & vertexPoint,
  double roundingSize = 0.0,
  const ccRadian& previousSegmentAngleSpan
    = ccRadian(0.0),
  const ccDimTol& previousSegmentLengthTol
    = ccDimTol (-1, -1, -1));

void insertVertex(c_Int32 previousVertexIndex,
  const cc2Vect& vertexPoint,
  double roundingSize = 0.0,
  const ccRadian& previousSegmentAngleSpan
    = ccRadian(0.0),
  const ccDimTol & previousSegmentLengthTol
    = ccDimTol (-1, -1, -1));
```

- ```
  void insertVertex(const cc2Vect & vertexPoint,
    double roundingSize = 0.0,
    const ccRadian & previousSegmentAngleSpan
      = ccRadian(0.0),
    const ccDimTol & previousSegmentLengthTol
      = ccDimTol (-1, -1, -1));
  ```

  Inserts the specified vertex after the last vertex in the generalized polygon. The vertex rounding, previous segment angle span, and previous segment length tolerance are also specified.

  Parameters

  vertexPoint The x,y location of the inserted vertex.

  roundingSize The vertex rounding size.
  ```

previousSegmentAngleSpan
The previous segment angle span.

previousSegmentLengthTol
The previous segment length tolerance.

An override, see the **ccGenPoly** base class.

- ```
  void insertVertex(c_Int32 previousVertexIndex,
    const cc2Vect& vertexPoint,
    double roundingSize = 0.0,
    const ccRadian & previousSegmentAngleSpan
    = ccRadian(0.0),
    const ccDimTol & previousSegmentLengthTol
      = ccDimTol (-1, -1, -1));
  ```

  Inserts the specified vertex after the vertex with index *previousVertexIndex*. The vertex rounding, previous segment angle span, and previous segment length tolerance are also specified.

  If *previousVertexIndex* = -1, the new vertex will become the first vertex.

  In all cases, vertex indices beyond the new vertex increase by 1 as a result of adding a new vertex.

  Parameters

  previousVertexIndex
  The index of the vertex prior to where the new vertex is inserted. A -1 indicates the new vertex should be the first vertex (index 0).

  vertexPoint The x,y location of the inserted vertex.

  roundingSize The vertex rounding size.

  previousSegmentAngleSpan
  The previous segment angle span.

  previousSegmentLengthTol
  The previous segment length tolerance.

  An override, see the **ccGenPoly** base class.
  ```

close

```
void close(
  const ccRadian & segmentAngleSpan = ccDegree(0),
  const ccDimTol& segmentLengthTol = ccDimTol(-1, -1, -1));
```

Closes the generalized polygon. It connects the vertex with the largest index to the vertex with the smallest index using a segment with the specified *segmentAngleSpan*. *segmentLengthTol* sets the new segment length tolerance.

There is no effect if the generalized polygon is already closed.

An override, see the **ccGenPoly** base class.

Parameters

segmentAngleSpan
: The segment angle span for the segment added when the polygon is closed.

segmentLengthTol
: The segment length tolerance.

Throws

ccShapesError::BadGeom
: If *segmentLengthTol* is not valid.

See **ccGenPoly** base class for more throw conditions.

cc2Xform

```
#include <ch_cvl/xform.h>

class cc2Xform;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a two-dimensional transformation object. The transformation object is made up of a four-element matrix and a two-element vector. Together, these two components allow for transformations along six degrees of freedom.

The **cc2Xform** member functions let you specify coordinate transformations two different ways. The difference between the two methods is the way you specify the elements of the four-element matrix. Both methods use the two-element vector for xy-translation.

The scale-rotation method for specifying transformation objects lets you set rotation of the x-axis, rotation of the y-axis, x-scale, and y-scale. The shear-aspect method lets you specify the scale of the coordinate system, the aspect ratio of the x to the y axis, the shear angle, and the rotation of the coordinate system. Both methods are equivalent, so you can use the one that suits your application or your existing algorithms. In general, the scale-rotation method is easier to use.

Note **cc2Xform** is the name of the class as it is used throughout the Cognex Vision Library. This name is actually a **typedef** for **ccXform<2>**. Both forms are valid and entirely equivalent.

Constructors/Destructors

cc2Xform

```
cc2Xform();

cc2Xform(const ccMatrix<2>& c, const cc2Vect& t);

cc2Xform(const cc2Vect& t, const ccRadian& xRot,
  const ccRadian& yRot, double xScale, double yScale);

cc2Xform(const cc2Vect& t, double scale, double aspect,
  const ccRadian& shear, const ccRadian& rotation);
```

- `cc2Xform();`

  The default constructor creates an identity transformation object.

- `cc2Xform(const ccMatrix<2>& c, const cc2Vect& t);`

  Creates a transformation object with a matrix component *c* and a translation component *t*.

  Parameters

c	The matrix component of the transformation object.
t	The translation component of the transformation object.

- `cc2Xform(const cc2Vect& t, const ccRadian& xRot, const ccRadian& yRot, double xScale, double yScale);`

  Creates a transformation object using the scale-rotation method.

  Parameters

t	The translation component; the amount by which to move the origin of the mapped coordinate system.
xRot	The x-rotation; the amount by which to rotate the x-axis in radians.
yRot	The y-rotation; the amount by which to rotate the y-axis in radians.
xScale	The x-scale; the amount by which to scale the x-axis units.
yScale	The y-scale; the amount by which to scale the y-axis unit.

- `cc2Xform(const cc2Vect& t, double scale, double aspect, const ccRadian& shear, const ccRadian& rotation);`

  Creates a transformation object using the shear-aspect method.

Parameters

t	The translation component; the amount by which to move the origin of the mapped coordinate system.
scale	The scale element; the amount by which to scale all units.
aspect	The aspect ratio; the ratio of the x-axis units to the y-axis units.
shear	The shear element; the amount by which to rotate the y-axis in radians.
rotation	The rotation element; the amount by which to rotate the entire coordinate system in radians.

Operators

operator*

```
cc2Xform operator* (const cc2Xform& xform) const;
cc2Vect operator* (const cc2Vect &pt) const;
```

- `cc2Xform operator* (const cc2Xform& xform) const;`

Returns the transformation object that is the composition of this transformation object and the transformation object *xform*. Mapping a point with the resulting transformation object has the same effect as mapping the point by the *xform* transformation object and then by this transformation object.

Parameters

xform	The transformation object to compose with this one.

Notes

Using this operator is the same as using the **compose()** function:

```
xform.compose(xform2) == xform * xform2
```

- `cc2Vect operator* (const cc2Vect &pt) const;`

Return the result of mapping the point *pt* with this transformation object. This is has the same effect as:

```
resultPt = matrix() * pt + trans();
```

Parameters

pt	The point to map.

Notes

This operator is the same as using the **mapPoint()** function:

```
xform.mapPoint(pt) == xform * pt
```

operator==

```
bool operator== (const cc2Xform& that) const;
```

Return true if this transformation object is the same as *that* transformation object.

Parameters

that The other transformation object to compare.

operator!=

```
bool operator!= (const cc2Xform&) const;
```

Parameters

that The other transformation object to compare.

Public Member Functions

matrix

```
const ccMatrix<2>& matrix();
void matrix(const ccMatrix<2>& c);
```

- `const ccMatrix<2>& matrix();`

  Returns the 2x2 matrix component of the transformation object.

- `void matrix(const ccMatrix<2>& c);`

  Sets the matrix component of the transformation object to *c*.

  Parameters

  c The matrix component of the transformation object.

trans

```
const cc2Vect& trans();
void trans(const cc2Vect& t);
```

- `const cc2Vect& trans();`

  Returns the 2-element translation vector of the transformation object.

- `void trans(const cc2Vect& t);`

  Sets the translation vector component of the transformation object to *t*.

Parameters

t The translation component of the transformation object.

inverse

```
cc2Xform inverse() const;
```

Returns the inverse of this transformation object.

Throws

ccMathError::Singular
The transformation is singular.

compose

```
cc2Xform compose (const cc2Xform& xform) const;
```

Returns the transformation object that is the composition of this transformation object and the transformation object *xform*. Mapping a point with the resulting transformation object has the same effect as mapping the point by *xform*, then by this transformation object.

Parameters

xform The transformation object to compose with this one.

Notes

Using this function is the same as using the multiplication operator:

```
xform.compose(xform2) == xform * xform2
```

xRot

```
ccRadian xRot() const;
```

Returns the x-rotation element of the transformation object using the scale-rotation specification.

Notes

Be careful when you mix elements from the scale-rotation specification with elements of the shear-aspect specification. For example, if you specify a value for **shear()** in the shear-aspect specification, **aspect() != yScale() / xScale()**.

Throws

ccMathError::Singular
The transformation is singular.

yRot

```
ccRadian yRot() const;
```

Returns the y-rotation element of the transformation object using the scale-rotation specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

xScale `double xScale() const;`

Returns the x-scale element of the transformation object using the scale-rotation specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

yScale `double yScale() const;`

Returns the y-scale element of the transformation object using the scale-rotation specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

scale `double scale() const;`

Returns the scale element of the transformation object using the shear-aspect specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

aspect `double aspect() const;`

Returns the aspect element of the transformation object using the shear-aspect specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

shear `ccRadian shear();`

Returns the shear element of the transformation object using the shear-aspect specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

rotation `ccRadian rotation() const;`

Returns the rotation element of the transformation object using the shear-aspect specification.

Notes
See note to **xRot()** on page 93.

Throws
ccMathError::Singular
The transformation is singular.

mapAngle `ccRadian mapAngle (const ccRadian& ang) const;`

Return the results of mapping the angle *ang* with this transformation object.

Parameters
ang The angle to map in radians.

invMapAngle `ccRadian invMapAngle (const ccRadian& ang) const;`

Return the results of mapping the angle *ang* with the inverse of this transformation object.

Parameters

ang The angle to map in radians.

Throws

ccMathError::Singular
The transformation is singular.

mapPoint

```
cc2Vect mapPoint (const cc2Vect &pt) const;
```

Return the result of mapping the point *pt* with this transformation object. This is has the same effect as:

```
resultPt = matrix() * pt + trans();
```

Parameters

pt The point to map.

Notes

Using this function is the same as using the multiplication operator:

```
xform.mapPoint(pt) == xform * pt
```

invMapPoint

```
cc2Vect invMapPoint (const cc2Vect &pt) const;
```

Return the result of mapping the point *pt* with the inverse of this transformation object. This is has the same effect as:

```
resultPt = matrix().inverse() * (pt - trans());
```

Parameters

pt The point to map.

Throws

ccMathError::Singular
The transformation is singular.

mapVector

```
cc2Vect mapVector (const cc2Vect &vect) const;
```

Rotates and scales the vector *vect* by the transformation object, ignoring translation:

```
result = matrix() * vect;
```

Parameters

vect The vector to be mapped.

invMapVector

```
cc2Vect invMapVector (const cc2Vect &vect) const;
```

Rotates and scales the vector *vect* by the inverse of the transformation object, ignoring translation:

```
result = matrix().inverse() * vect;
```

Parameters

vect The vector to be mapped.

Throws

ccMathError::Singular
The transformation is singular.

mapArea

```
double mapArea (double area) const;
```

Returns the area after mapping by the *xform*.

Parameters

area The area to be mapped.

Notes

This function computes the mapped area by first calculating the area of a unit square and then multiplying area by that value. You may wish to call this function with the area 1.0 to get a conversion constant you can use without the overhead of calling this function multiple times.

invMapArea

```
double invMapArea (double area) const;
```

Returns the area after mapping by the inverse of the *xform*.

Parameters

area The area to be mapped.

Throws

ccMathError::Singular
The transformation is singular.

isIdentity

```
bool isIdentity() const;
```

Returns true if this transformation object is the identity object: all points map to themselves.

isSingular

```
bool isSingular() const;
```

Returns true if the transformation is singular: all points map to the same line.

Data Members

I

```
static const cc2Xform I;
```

The identity transformation matrix for **cc2Xform**.

cc2XformBase

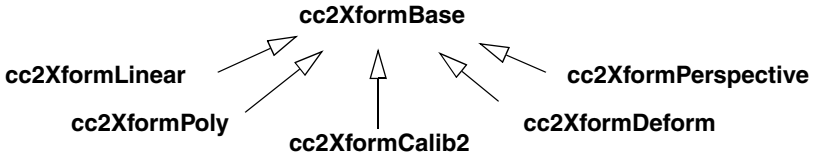
```
#include <ch_cvl/xfbase.h>

class cc2XformBase : public ccRepBase, public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This is the abstract base class for 2D coordinate transforms. From this base class the specialized classes such as **cc2XformPoly** and **cc2XformLinear** are derived.



Constructors/Destructors

Use the constructors of the derived classes.

Operators

operator*

```
cc2Vect operator*(const cc2Vect& pt) const;

cc2XformBasePtrh operator*(const cc2XformBase& rhs) const;
```

- `cc2Vect operator*(const cc2Vect& pt) const;`

  Returns the point *pt* mapped by this transformation. Using this operator is equivalent to using the **mapPoint** function.

  Parameters

pt	The point mapped by the operator.

Notes

Each derived class should make a **using** declaration of this operator. This assures that additional * operator functions overload, rather than hide, the base class operator.

- `cc2XformBasePtrh operator*(const cc2XformBase& rhs) const;`

Returns the composition of this transformation with the transformation *rhs*. Mapping a point with the resulting transformation is equivalent to first mapping the point by the transformation *rhs* and then by this transformation. The use of this operator is equivalent to the use of the **composeBase** function.

Parameters

rhs The transformation to be composed with this transformation.

Notes

The only allowed compositions are: **cc2XformLinear** * **cc2XformLinear**, **cc2XformLinear** * **cc2XformPoly**, **cc2XformPoly** * **cc2XformLinear**

Public Member Functions

mapPoint

```
virtual cc2Vect mapPoint(const cc2Vect& pt) const = 0;
```

Maps the point *pt* by using this transformation.

Parameters

pt The point mapped by this transformation.

isLinear

```
virtual bool isLinear() const = 0;
```

Returns true if this transformation is linear.

Notes

This function is designed to efficiently identify cases where transformations are guaranteed to be linear. The function may return false if it would take too much time to determine otherwise.

linearXform

```
virtual cc2XformLinear linearXform(const cc2Vect& atThisPt)
  const = 0;
```

Returns the linear transformation defined by the linear terms of the Taylor series expansion about the point *atThisPt.*

Parameters

atThisPt The point around which this transformation is linearized.

composeBase

```
virtual cc2XformBasePtrh composeBase(
  const cc2XformBase& rhs) const = 0;
```

Returns the composition of this transformation with the transformation *rhs*. Mapping a point with the resulting transformation is equivalent to first mapping the point by the transformation *rhs* and then by this transformation.

Parameters

rhs The transformation to be composed with this transformation.

Notes

The run-time type of the returned result is not guaranteed to be the same across different CVL releases, so do not write code that depends on the exact run-time type. For example, avoid using a dynamic cast.

It is expected that, for convenience, derived classes may declare functions such as **compose()** that take a particular transform type and return a particular transform type. The return value will not be heap allocated. For example;

```
cc2XformLinear: cc2XformLinear compose(
  const cc2XformLinear& rhs) const;
```

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const = 0;
```

Returns a transformation that is the inverse of this transformation.

Throws

ccMathError::Singular

The transformation is singular and cannot be inverted.

Notes

In the case of nonlinear transformations, the inverse transformation may not be exact.

clone

```
virtual cc2XformBasePtrh clone() const = 0;
```

Returns a newly allocated copy of this transformation.

Notes

This function is required for polymorphic copying.

cc2XformBase

cc2XformCalib2

```
#include <ch_cvl/ccalib.h>

class cc2XformCalib2 : public cc2XformBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class contains a nonlinear calibration transform. It models the effects of perspective distortion and lens distortion. A general reference for terminology used in this description is *Multiple View Geometry in Computer Vision* by Richard Hartley and Andrew Zisserman.

A calibration transform C has the following form when mapping points from physical space to image space:

C = L composed with R_{rad} composed with P

where:

P is a perspective transform and depends on the position and orientation of the object plane with respect to the camera.

R_{rad} is a radial transform and depends on the camera lens used. This transform is modeled as a cubic polynomial transform using one distortion coefficient,

L is a linear transform and depends on camera properties such as focal length (scale), aspect, skew, and position of the optical axis relative to the image center. L does not contain any rotation.

Thus, P depends on the properties of the image acquisition system which are external to the camera. These are known as the *extrinsic* calibration parameters. R_{rad} and L depend on camera properties which are internal to the camera. These are known as *intrinsic* calibration parameters.

The calibration transform mapping image points to physical points is obtained by composition of inverses of L, R_{rad}, and P composed in reverse order.

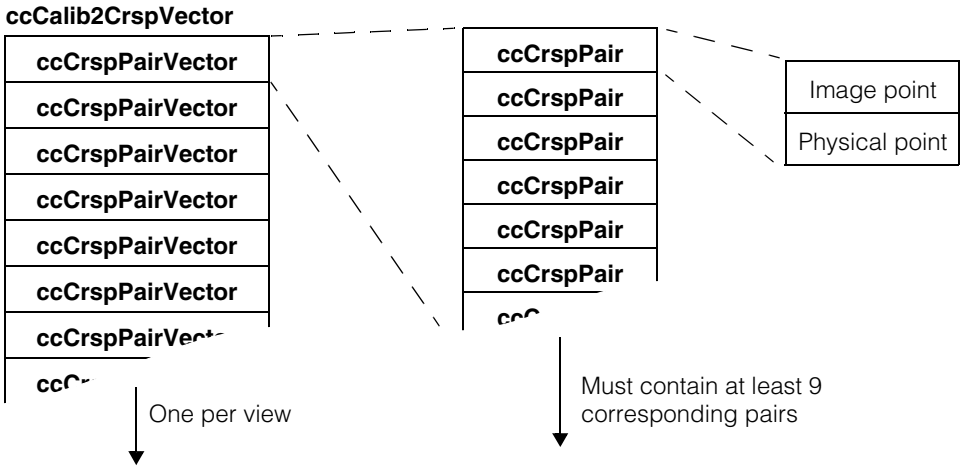
There are two ways to compute this transform:

1. Using known intrinsic and extrinsic calibration parameters.
2. Using correspondences between physical points and client points generated from one or more views. (Client space is usually the same as image space in the calibration image.)

Use **init()** to create the transform in one of these two ways.

Correspondences

The following figure describes how we manage corresponding image points and physical points. Each member of the **ccCalib2CrspVector** vector is a vector of corresponding image point - physical point pairs. The points in each **ccCrspPairVector** vector all come from one image (a view) and must contain at least 9 corresponding point pairs.



Note that the **cc2XformCalib2** is asymmetric between image coordinates and physical coordinates. **cc2XformCalib2** is designed to map from physical coordinates to image coordinates. You should always initialize a **cc2XformCalib2** object so that it maps from physical coordinates to image coordinates and use either **invMapPoint()** or **inverse()** to map from image coordinates to physical coordinates.

Since the **cc2XformCalib2** is asymmetric, it is important to specify the positions in the **ccCrspPairVector** in the proper order. Furthermore, the **ccCrspPairVector** used to initialize a **cc2XformCalib2** transform should always be paired with the image coordinate point first, as shown in the figure above.

Constructors/Destructors

cc2XformCalib2

```
cc2XformCalib2();
cc2XformCalib2(const cc2XformCalib2& calibXform);
~cc2XformCalib2();
```

- `cc2XformCalib2();`

  Constructs an identity transform. The direction of the transform is set to map points from physical space to client space (usually the same as image space).

- `cc2XformCalib2(const cc2XformCalib2& calibXform);`

  Copy constructor.

  Parameters

  calibXform The new object that is a copy of this object.

- `~cc2XformCalib2();`

  Destructor.

Operators

operator=

```
cc2XformCalib2& operator=(
  const cc2XformCalib2& calibXform);
```

Assignment operator. Make this object a copy of *calibXform*.

Parameters

calibXform Source of the assignment.

operator*

```
using cc2XformBase::operator*;
```

Uses the same operator* as the base class.

Public Member Functions

init

```
void init(
  const ccCalib2ParamsIntrinsic& intrinsicParams,
  const ccCalib2ParamsExtrinsic& extrinsicParams);

void init(const ccCalib2CrspVector& correspondences);

void init(
  const ccCalib2CrspVector& correspondences,
  cmStd vector<double>& rmsResiduals,
  cmStd vector<double>& maxResiduals);
```

You initialize the object with intrinsic and extrinsic parameters, or with corresponding image points and physical points. The most recent initialization reflects the active transform. The direction of the transform is set to map points from physical space to client space (usually the same as image space).

- ```
  void init(
    const ccCalib2ParamsIntrinsic& intrinsicParams,
    const ccCalib2ParamsExtrinsic& extrinsicParams);
  ```

  Creates a calibration transform using the provided intrinsic and extrinsic parameters.

  Parameters

  intrinsicParams The intrinsic parameter set.

  extrinsicParams The extrinsic parameter set.

- ```
  void init(const ccCalib2CrspVector& correspondences);
  ```

  Create a calibration transform computed from a vector of corresponding image points and physical points. The direction of the transform is from the second coordinate space in the correspondences to the first coordinate space. If using results returned by the feature extractor provided with CVL (**cfCalib2VertexFeatureExtract()**), the direction of transformation is from physical space to client space (usually the same as image space).

The extrinsic parameters within this transform are set according to the first correspondence in the **ccCalib2CrspVector** input vector (index 0).

The number of views equals the size of input vector, one entry per view. The correspondences are generated from different views of a planar object. The following conditions must be met:

1. All intrinsic camera settings are expected to stay constant over all the views.
2. Two views are considered different if the planes of the objects in two views are not parallel (relative to the camera).

Parameters

correspondences
A vector of corresponding image points and physical points.

Throws

cc2XformCalibDefs::InsufficientPoints
If the number of points in any *ccCrspPairVector* is < 9.

*cc2XformCalibDefs::*NumerircalError
If computation cannot be further carried out. This may happen if conditions above are not met.

*cc2XformCalibDefs::*BadParams
If size of the **ccCalib2CrspVector** vector is 0.

Notes

If the number of views = 1, separation of intrinsic and extrinsic parameters is not possible.

As the number of views increases, the accuracy of computed intrinsic and extrinsic parameters increases.

The **cc2XformCalib2** is not symmetric between image coordinates and physical coordinates. The **cc2XformCalib2** transform should map from physical coordinates to image coordinates. The first cc2Vect in each ccCrspPair should represent the image location of the vertex expressed in image coordinates, and the second cc2Vect should represent the corresponding location in physical coordinates.

- ```
  void init(
    const ccCalib2CrspVector& correspondences,
    cmStd vector<double>& rmsResiduals,
    cmStd vector<double>& maxResiduals);
  ```

  Create a calibration transform computed from a vector of correspondences. All comments following the previous **init()** overload above are valid here too. Additionally, compute the residual errors in mapping points. The vectors *rmsResiduals* and *maxResiduals* are resized to the size of the *correspondences* vector.

  For single view calibration, rms and maximum residual errors of mapped points from "to" points in the single correspondence provided are computed and stored as single elements of *rmsResiduals* and *maxResiduals* respectively.

  For multiple view calibration, residual errors for the i-th correspondence are computed as follows:

  1. A **cc2XformCalib2** object T_i is constructed using intrinsic parameters of this **cc2XformCalib2** object and extrinsic parameters computed from the i-th correspondence.
  2. "from" points in the i-th correspondence are mapped through T_i.
  3. Rms and maximum residual errors of mapped points from "to" points in the i-th correspondence are computed and stored as the i-th element of *rmsResiduals* and *maxResiduals* respectively.

  Notes

  The **cc2XformCalib2** is not symmetric between image coordinates and physical coordinates. The **cc2XformCalib2** transform should map from physical coordinates to image coordinates. The first cc2Vect in each ccCrspPair should represent the image location of the vertex expressed in image coordinates, and the second cc2Vect should represent the corresponding location in physical coordinates.

intrinsicParams

```
const ccCalib2ParamsIntrinsic& intrinsicParams() const;
```

Returns the intrinsic calibration parameters which are part of this calibration transform.

Throws

cc2XformCalibDefs::BadParams

If this transform was initialized with a single view.
```

extrinsicParams

```
const ccCalib2ParamsExtrinsic& extrinsicParams() const;

void extrinsicParams(
  const ccCalib2ParamsExtrinsic& extrinsicParams);

ccCalib2ParamsExtrinsic extrinsicParams (
  const ccCrspPairVector& corr) const;

void extrinsicParams(const ccCrspPairVector& corr);
```

- `const ccCalib2ParamsExtrinsic& extrinsicParams() const;`

  Returns the extrinsic calibration parameters that are part of this calibration transform.

  Throws

  cc2XformCalibDefs::BadParams
  If this transform was initialized with a single view.

- `void extrinsicParams(`
  `  const ccCalib2ParamsExtrinsic& extrinsicParams);`

  Sets new extrinsic calibration parameters.

  Parameters

  extrinsicParams The new extrinsic calibration parameters.

  Throws

  cc2XformCalibDefs::BadParams
  If this transform was initialized with a single view.

- `ccCalib2ParamsExtrinsic extrinsicParams (`
  `  const ccCrspPairVector& corr) const;`

  Returns the extrinsic parameters associated with the view specified by *corr*.

  Notes

  The intrinsic camera calibration parameters used to obtain the provided correspondence must be same parameters that are part of this transform. In other words, the intrinsic camera settings used when **init()** was called must be unchanged when this function is called.

  Parameters

  corr The corresponding image point - physical point vector for one view.

Throws

cc2XformCalibDefs::BadParams
If this transform was initialized with a single view.

- `void extrinsicParams(const ccCrspPairVector& corr);`

Sets the extrinsic parameters associated with the view specified by *corr*.

Notes

The intrinsic camera calibration parameters used to obtain the provided correspondence must be same parameters that are part of this transform. In other words, the intrinsic camera settings used when **init()** was called must be unchanged when this function is called.

Calling **init()** with multiple views sets the extrinsic parameters in the transform to extrinsic parameters for the first view (index 0). If you wish the change the transform to use extrinsic parameters for a different view, you call this function.

Parameters

corr The corresponding image point - physical point vector for one view.

Throws

cc2XformCalibDefs::BadParams
If this transform was initialized with a single view.

extrinsicXform

```
cc3Xform extrinsicXform() const;

void extrinsicXform(const cc3Xform& rigidXform);

cc3Xform extrinsicXform(
  const ccCrspPairVector& corr) const;
```

- `cc3Xform extrinsicXform() const;`

Returns the rigid 3D transform between the physical 3D coordinate system and camera 3D coordinate system that is part this **cc2XformCalib2** transform. The direction of returned transform is same as direction of this **cc2XformCalib2** transform.

- `void extrinsicXform(const cc3Xform& rigidXform);`

Sets the rigid 3D transform between the camera coordinate system and the physical coordinate system to provided a rigid 3D transform. If matrix R_{rot} in *rigidXform* is not exactly a rotation matrix, it attempts to compute a rotation matrix closest to R_{rot} and then sets extrinsic transform. Such a computation should succeed in practical situations.

Parameters

rigidXform The new 3D transform.

Throws

cc2XformCalib2Defs::BadParams
If computation of a rotation matrix (if necessary) does not succeed.

- ```
  cc3Xform extrinsicXform(
    const ccCrspPairVector& corr) const;
  ```

Get the 3D rigid transform between the physical 3D coordinate system and camera 3D coordinate system as specified by the correspondence *coor*. The direction of returned transform is same as direction of this **cc2XformCalib2** transform.

Parameters

corr The correspondence vector.

mapPoint

```
virtual cc2Vect mapPoint(const cc2Vect& pt) const;
```

Maps a given 2-D point through this transform and returns the mapped point.

Parameters

pt The point to be mapped.

Throws

cc2XformCalibDefs::MapsToInfity
If *pt* maps to infinity through this transform.

isLinear

```
virtual bool isLinear() const;
```

Returns true if this transform is an affine transform (a linear transform). For example, the transform is linear if there is no perspective or radial distortion.

Notes

This function is designed to efficiently identify cases where transformations are guaranteed to be linear. The function may return false if it would take too much time to determine if it is linear.

linearXform

```
virtual cc2XformLinear linearXform(
  const cc2Vect& atThisPt) const;
```

Returns a linear transform which is the best approximation to this transform at the point *atThisPt*.
```

Parameters

atThisPt The point where the transform is linearized.

composeBase

```
virtual cc2XformBasePtrh composeBase(
  const cc2XformBase& rhs) const;
```

Returns the transform which is the composition of this transform and the transform *rhs*. Mapping a point with the resulting transformation is equivalent to first mapping the point by the transformation *rhs* and then by this transformation.

Parameters

rhs The transform to compose with this transform.

Notes

The only allowed compositions are: **cc2XformLinear** ***cc2XformLinear**, **cc2XformLinear** ***cc2XformPoly**, **cc2XformPoly** ***cc2XformLinear**

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const;
```

Returns the inverse of this transform.

Notes

In the case of nonlinear transformations, the inverse transformation may not be exact.

clone

```
virtual cc2XformBasePtrh clone() const;
```

Returns a newly allocated copy of this object.

Notes

This function is required for polymorphic copying.

distortionModel

```
cc2XformCalib2Defs::ccCalib2DistortionModel
   distortionModel() const ;
```

Returns a distortion model used by this object.

Typedefs

ccCalib2CrspVector

```
typedef cmStd vector<ccCrspPairVector> ccCalib2CrspVector;
```

ccCrspPair

```
typedef ccPair<cc2Vect> ccCrspPair;
```

ccCrspPairVector

```
typedef cmStd vector<ccCrspPair> ccCrspPairVector;
```

cc2XformCalib2

cc2XformDeform

```
#include <ch_cvl/xfdeform.h>

class cc2XformDeform : public cc2XformBase
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class models a 2D coordinate deformation transform.

Constructors/Destructors

cc2XformDeform

```
cc2XformDeform();

cc2XformDeform(
  const cmStd vector<cc2Vect>& toPoints,
  const cmStd vector<cc2Vect>& fromPoints,
  double smoothness = 0);

cc2XformDeform(const cc2XformDeform& rhs);

~cc2XformDeform();
```

- ```
  cc2XformDeform();
  ```

  Default constructor. Constructs an identity transform.

- ```
  cc2XformDeform(
    const cmStd vector<cc2Vect>& toPoints,
    const cmStd vector<cc2Vect>& fromPoints,
    double smoothness = 0);
  ```

  Constructs a transform that maps *fromPoints* to *toPoints* using a smoothing parameter.

Notes

A smoothness of 0 yields an exact mapping at the specified point while a smoothness of infinity yields an affine transform.

The transform is non singular whenever points in the *fromPoints* vector are pair-wise distinct and not colinear.

Parameters

toPoints A vector of *from* points.

fromPoints A vector of *to* points.

smoothness The smoothing parameter.

Throws

cc2XformDeformDefs::BadParams
If *smoothness* < 0,
or if **toPoints.size()** != **fromPoints.size()**,
or if **fromPoints.size()** < 3.

ccMathError::Singular
If the transform is singular.

- `cc2XformDeform(const cc2XformDeform& rhs);`

Copy constructor.

- `~cc2XformDeform();`

Destructor

Operators

operator= `cc2XformDeform& operator=(const cc2XformDeform& rhs);`

Assignment operator.

operator* `cc2XformBasePtrh operator*(const cc2XformBase& rhs) const;`

Returns the composition of this transformation with the transformation *rhs*. Mapping a point with the resulting transform is equivalent to first mapping the point by the transform *rhs* and then by this transform. The use of this operator is equivalent of **composeBase(***rhs***)**.

Parameters

rhs The transform to be composed with this transform.

Public Member Functions

update

```
void update(
  const cmStd vector<cc2Vect>& toPoints,
  const cmStd vector<c_Bool>& enabled =
                                    cmStd vector<c_Bool>());
```

Updates this transform using the provided set of *toPoints*. *toPoint-fromPoint* correspondence may be enabled or disabled through the *enabled* vector as follows:

If the i-th element in *enabled* is ceTrue, then the i-th point in *fromPoints* (provided through the constructor) is mapped to the i-th point in *toPoints*. Otherwise, the i-th points in the *fromPoints* and *toPoints* vectors are both ignored by this transform.

Parameters

toPoints	The new to points vector.
enabled	The enable/disable vector.

Throws

cc2XformDeformDefs::BadParams
If **toPoints.size()** != **fromPoints.size()**,
or if **enabled.size()** != **fromPoints.size()**,
or if the number of ceTrue elements in *enabled* is < 3.

smoothness

```
double smoothness() const;
```

Returns the current smoothness value.

mapPoint

```
virtual cc2Vect mapPoint(const cc2Vect& pt) const;
```

Returns the point *pt*, mapped by this deformation transform.

This function is an override to the base class **cc2XformBase**.

Parameters

pt	The point to map.

isLinear

```
virtual bool isLinear() const;
```

Returns true if this deformation transform is linear. Returns false otherwise.

This function is an override to the base class **cc2XformBase**.

cc2XformDeform

linearXform

```
virtual cc2XformLinear linearXform(
  const cc2Vect& atThisPt) const;
```

Returns a linear transform which represents the best linearization of this transform at the given point. This linearization will map the given point exactly but will likely be accurate only in a small region around that point.

This function is an override to the base class **cc2XformBase**.

Parameters

atThisPt The point where the deformation transform is to be linearized.

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const;
```

Returns a transform which is the inverse of this transform.

This function is an override to the base class **cc2XformBase**.

Notes

The inverse will not be exact unless this deformation transform is linear.

This function will take time comparable to the time taken to construct the transform to be inverted. It is not a fast operation.

Throws

ccMathError::Singular
If this transform cannot be inverted because of singularity.

clone

```
virtual cc2XformBasePtrh clone() const;
```

Returns a newly allocated copy of this object.

This function is an override to the base class **cc2XformBase**.

Notes

This function is required for polymorphic copying.

isIdentity

```
bool isIdentity() const;
```

Returns true if this transform is an identity transform.

This function is an override to the base class **cc2XformBase**.

cc2XformLinear

```
#include <ch_cvl/xflinear.h>

class cc2XformLinear : public cc2XformBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class implements a linear transformation between coordinate systems. If (C_x, C_y) are the client coordinates of generic image features and (I_x, I_y) their corresponding image coordinates, the mapping performed by the class is:

$$\begin{bmatrix} C_x \\ C_y \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} I_x \\ I_y \end{bmatrix} + \begin{bmatrix} T_x \\ T_y \end{bmatrix}$$

where:

$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ is the matrix component of the linear transformation

$\begin{bmatrix} T_x \\ T_y \end{bmatrix}$ is the translation vector component of the linear transformation

A generic linear transformation L will be referred to as the pair:

$$L = \left(\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \begin{bmatrix} T_x \\ T_y \end{bmatrix} \right)$$

Notes

If you use this class to map image features from frame A to frame B, the components of the translation vector must be the ones of the vector that goes from frame B to frame A expressed in Frame B (see *Math Foundations of Transformations* in the *CVL User's Guide)*. If the translation vector is not specified in this way, the results returned by the mapping functions will not be correct.

Constructors/Destructors

cc2XformLinear

```
cc2XformLinear();

cc2XformLinear(const cc2Matrix& c, const cc2Vect& t);

cc2XformLinear(const cc2Vect& t, const ccRadian& xRot,
  const ccRadian& yRot, double xScale, double yScale);

cc2XformLinear(const cc2Vect& t, double scale,
  double aspect, const ccRadian& shear,
  const ccRadian& rotation);

cc2XformLinear(const cc2Xform&);
```

- `cc2XformLinear();`

  The default constructor initializes this transformation to the identity transformation.The identity transformation maps a point to itself.

  Identity Transformation: $\left(\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}, \begin{bmatrix}0\\ 0\end{bmatrix}\right)$

- `cc2XformLinear(const cc2Matrix& c, const cc2Vect& t);`

  Initializes this transformation to the matrix *c* and the translation vector *t*.

  Parameters

c	The matrix this transformation is set to
t	The translation vector this transformation is set to

- `cc2XformLinear(const cc2Vect& t, const ccRadian& xRot, const ccRadian& yRot, double xScale, double yScale);`

  Initializes the matrix component of this transformation according to the scale-rotation mode (see *Math Foundations of Transformations* and *Images and Coordinates* in the *CVL User's Guide*). The translation vector component of this transformation is set to *t*.

  Parameters

t	The translation vector this transformation is set to.
xRot	The x-rotation; the amount by which to rotate the x-axis in radiants.
yRot	The y-rotation; the amount by which to rotate the y-axis in radiants.
xScale	The x-scale; the amount by which to scale the x-axis units.
yScale	The y-scale; the amount by which to scale the y-axis units.

- `cc2XformLinear(const cc2Vect& t, double scale, double aspect, const ccRadian& shear, const ccRadian& rotation);`

  Initializes the matrix component of this transformation according to the shear-aspect mode (see *Math Foundations of Transformations* and *Images and Coordinates* in the *CVL User's Guide*). The translation vector component of this transformation is set to *t*.

  Parameters

t	The translation vector this transformation is set to.
scale	The scale element; the amount by which to scale all units.
aspect	The aspect ratio; the ratio of the x-axis units to the y-axis units.
shear	The shear element; the amount by which to rotate the y-axis in radiants.
rotation	The rotation element; the amount by which to rotate the entire coordinate system in radiants.

- `cc2XformLinear(const cc2Xform& c);`

  Initializes this transformation to the **cc2Xform** transformation *c*.

  Parameters

c	The **cc2Xform** transformation this transformation is set to

Notes

This constructor is primarily for convenience when using existing CVL code.

Operators

cc2Xform

```
operator cc2Xform() const;
```

Cast this transformation to its equivalent **cc2Xform** form.

operator==

```
bool operator== (const cc2XformLinear& c) const;
```

Returns true if all the components of this transformation are the same as the corresponding components of *m*.

Parameters

c	The transformation compared to this transformation

operator!=

```
bool operator!= (const cc2XformLinear& c) const;
```

Returns true if this transformation is not the same as *c*.

Parameters

c	The transformation compared to this transformation

operator=

```
cc2XformLinear& operator=(const cc2Xform& rhs);
```

Assignment operator. Creates a new **cc2XformLinear** object equal to *rhs*.

Parameters

rhs	The assignment source.

operator*

```
cc2XformLinear operator*(
  const cc2XformLinear& xform) const;

cc2XformBasePtrh operator*(const cc2XformBase& base) const;

cc2Vect operator*(const cc2Vect& pt) const;
```

- ```
  cc2XformLinear operator*(
    const cc2XformLinear& xform) const;
  ```

  Returns the composition of this transform with the transform *xform*. Mapping a point with the resulting transform is equivalent to first mapping the point by the transform *xform* and then by this transform. The use of this operator is equivalent to the use of the **compose()** function.
  ```

Parameters

xform The transform to be composed with this transform

- `cc2XformBasePtrh operator*(const cc2XformBase& base) const;`

Returns the composition of this transform with the base transform *base*. Mapping a point with the resulting transform is equivalent to first mapping the point by the transform *base* and then by this transform. The use of this operator is equivalent to the use of the **composeBase()** function.

Parameters

base The base transform.

- `cc2Vect operator*(const cc2Vect& pt) const;`

Maps the point *pt* by using this transform. This is equivalent to calling **mapPoint()** (see below).

Parameters

pt The point to map.

Public Member Functions

mapPoint `virtual cc2Vect mapPoint(const cc2Vect& pt) const;`

Maps the point *pt* by using this transformation (see *Math Foundations of Transformations* in the *CVL User's Guide*).

If $\left(\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \begin{bmatrix} T_x \\ T_y \end{bmatrix}\right)$ is this transformation and $\begin{bmatrix} pt_x \\ pt_y \end{bmatrix}$ is the point *pt,* the point returned by the function is::

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} pt_x \\ pt_y \end{bmatrix} + \begin{bmatrix} T_x \\ T_y \end{bmatrix}$$

Parameters

pt The point to map.

isLinear `virtual bool isLinear() const;`

Always returns true since this transformation is linear.

cc2XformLinear

linearXform

```
virtual cc2XformLinear linearXform(const cc2Vect& atThisPt)
  const;
```

This function returns a transformation identical to this transformation regardless of *atThisPt*.

Parameters

atThisPt The point around which this transformation is linearized.

composeBase

```
virtual cc2XformBasePtrh composeBase
  (const cc2XformBase& rhs) const;
```

Returns a pointer handle to the transformation that is the composition of this transformation and *rhs*. This transformation can be composed with either a **cc2XformLinear** or a **cc2XformPoly** transformation.

Parameters

rhs The transformation to be composed with this transformation.

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const;
```

Returns a pointer handle to the inverse of this transformation.

Throws

ccMathError::Singular
The transformation is singular.

clone

```
virtual cc2XformBasePtrh clone() const;
```

Returns a newly allocated copy of this transformation.

matrix

```
const cc2Matrix& matrix();

void matrix(const cc2Matrix& c);
```

- ```
  const cc2Matrix& matrix();
  ```

  Returns the matrix component of this linear transformation.

- ```
  void matrix(const ccMatrix<2>& c);
  ```

  Sets the matrix component of this linear transformation to *c*.

  Parameters

  c The matrix this transformation's matrix is set to.

trans

```
const cc2Vect& trans();
void trans(const cc2Vect& t);
```

- `const cc2Vect& trans();`

  Returns the 2-element translation vector of this transformation.

- `void trans(const cc2Vect& t);`

  Sets the translation vector component of this transformation to *t*.

  Parameters

  t — The vector this transformation's vector is set to.

inverse

```
cc2XformLinear inverse() const;
```

Returns the inverse of this transformation

Throws

ccMathError::Singular
The transformation is singular.

compose

```
cc2XformLinear compose(const cc2XformLinear& xform) const;
```

Returns the transformation resulting from the composition of this transformation with *xform*. Mapping a point with the resulting transformation is equivalent to first mapping the point by the transformation *xform* and then by this transformation.

Parameters

xform — The linear transformation to be composed with this transformation.

xRot

```
ccRadian xRot() const;
```

Returns the x-rotation element of this transformation when using the scale-rotation specification.

Throws

ccMathError::Singular
The transformation is singular.

yRot `ccRadian yRot() const;`

Returns the y-rotation element of this transformation when using the scale-rotation specification.

Throws

ccMathError::Singular
The transformation is singular

xScale `double xScale() const;`

Returns the x-scale element of this transformation when using the scale-rotation specification.

Throws

ccMathError::Singular
The transformation is singular.

yScale `double yScale() const;`

Returns the y-scale element of this transformation when using the scale-rotation specification.

ccMathError::Singular
The transformation is singular

scale `double scale() const;`

Returns the scale element of this transformation when using the shear-aspect specification.

Throws

ccMathError::Singular
The transformation is singular.

aspect `double aspect() const;`

Returns the aspect element of this transformation when using the shear-aspect specification.

Notes

Be careful when you mix elements from the scale-rotation specification with elements of the shear-aspect specification. For example, if you specify a shear angle in the shear-aspect specification, then **aspect()**!= **yScale() / xScale()**.

Throws

ccMathError::Singular
The transformation is singular.

shear `ccRadian shear();`

Returns the shear element of this transformation when using the shear-aspect specification.

Throws
ccMathError::Singular
The transformation is singular.

rotation `ccRadian rotation() const;`

Returns the rotation element of this transformation when using the shear-aspect specification.

Throws
ccMathError::Singular
The transformation is singular.

mapAngle `ccRadian mapAngle (const ccRadian& ang) const;`

Return the results of mapping the angle *ang* with this transformation.

Parameters
ang The angle to map in radians.

invMapAngle `ccRadian invMapAngle (const ccRadian& ang) const;`

Return the results of mapping the angle *ang* with the inverse of this transformation.

Parameters
ang The angle to map in radians.

Throws
ccMathError::Singular
The transformation is singular.

invMapPoint `cc2Vect invMapPoint (const cc2Vect &pt) const;`

Returns the result of mapping the point *pt* with the inverse of this transformation

If $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ and $\begin{bmatrix} T_x \\ T_y \end{bmatrix}$ are the matrix and translation vector components of this

transformation and $\begin{bmatrix} pt_x \\ pt_y \end{bmatrix}$ is the point *pt,* the point returned by the function is:

$$\frac{1}{det(A)} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix} \begin{bmatrix} pt_x - T_x \\ pt_y - T_y \end{bmatrix}$$

mapVector

```
cc2Vect mapVector (const cc2Vect &vect) const;
```

Maps the vector *vect* by using the matrix component of this transformation. If $\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ is the matrix component of this transformation, the vector returned by the function is:

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} vect_x \\ vect_y \end{bmatrix}$$

Parameters

vect The vector to be mapped.

invMapVector

```
cc2Vect invMapVector (const cc2Vect &vect) const;
```

Maps the vector *vect* by using the inverse of the matrix component of this transformation. If $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ is the matrix component of this transformation, the vector returned by the function is:

$$\frac{1}{det(A)} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix} \begin{bmatrix} vect_x \\ vect_y \end{bmatrix}$$

Parameters

vect The vector to be mapped.

Throws

ccMathError::Singular
The transformation is singular.

mapArea

```
double mapArea (double area) const;
```

Returns the area after mapping by this transformation.

Parameters

area The area to be mapped.

Notes

This function computes the mapped area by first calculating the area of a unit square and then multiplying area by that value. You may wish to call this function with the area of 1.0 to get a conversion constant you can use without the overhead of calling this function multiple times.

invMapArea

```
double invMapArea (double area) const;
```

Returns the area after mapping by the inverse of this transformation.

Parameters

area The area to be mapped.

Throws

ccMathError::Singular
The transformation is singular.

isIdentity

```
bool isIdentity() const;
```

Returns true if this transformation is the identity transformation (in this case all points map to themselves).

isSingular

```
bool isSingular() const;
```

Returns true if this transformation is singular (in this case all points map to the same point or line).

Data Members

I

```
static const cc2XformLinear I;
```

The identity transformation for **cc2XformLinear**.

cc2XformLinear

cc2XformPerspective

```
#include <ch_cvl/xfpersp.h>

class cc2XformPerspective: public cc2XformBase
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class models a perspective transform used for viewing a planar object. In general, this is a nonlinear transform represented by a 3x3 matrix, for example the matrix M.

The transform maps a 2D point $\begin{bmatrix} x \\ y \end{bmatrix}$ to the 2D point $\begin{bmatrix} u/w \\ v/w \end{bmatrix}$

Where $\begin{bmatrix} u \\ v \\ w \end{bmatrix} = M \times \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$

The matrix *M* is a 3x3 matrix as follows:

$$M = \begin{bmatrix} m11 & m12 & m13 \\ m21 & m22 & m23 \\ m31 & m32 & m33 \end{bmatrix}$$

For more details, please see *Multiple View Geometry in Computer Vision* by Richard Hartley and Andrew Zisserman.

Constructors/Destructors

cc2XformPerspective

```
cc2XformPerspective();

cc2XformPerspective(
  const cmStd vector<cc2Vect>& toPoints,
  const cmStd vector<cc2Vect>& fromPoints);

cc2XformPerspective(
  const cc2Vect& cornerPo,
  const cc2Vect& cornerPx,
  const cc2Vect& cornerPy,
  const cc2Vect& cornerPopp);

cc2XformPerspective(const cc3Matrix& mat);

cc2XformPerspective(const cc2XformPerspective& xform);

~cc2XformPerspective();
```

- `cc2XformPerspective();`

  Constructs the identity transform.

- ```
  cc2XformPerspective(
    const cmStd vector<cc2Vect>& toPoints,
    const cmStd vector<cc2Vect>& fromPoints);
  ```

  Constructs a perspective transformation that achieves a least-squares best fit from *fromPoints* to *toPoints*.

  Parameters

  toPoints The transform to points.

  fromPoints The transform from points.

  Throws

  cc2XformPerspectiveDefs:: BadParams
  If **fromPoint.size()** != **toPoints.size()**, or if **fromPoints.size()** < 4.

  ccMathError::Singular
  If a transform cannot be determined. This can occur if the points all lie on a single point or line.
  ```

- ```
  cc2XformPerspective(
    const cc2Vect& cornerPo,
    const cc2Vect& cornerPx,
    const cc2Vect& cornerPy,
    const cc2Vect& cornerPopp);
  ```

  Constructs a perspective transform that maps:

  (0, 0) --> *cornerPo*
  (1, 0) --> *cornerPx*
  (0, 1) --> *cornerPy*
  (1, 1) --> *cornerPopp*

  Parameters

cornerPo	Location of the *Po* corner.
cornerPx	Location of the *Px* corner.
cornerPy	Location of the *Py* corner.
cornerPopp	Location of the *Popp* corner.

  Notes

  If the provided corners are set to identical points, the derived transform may be unable to map the corner of the unit square.

- ```
  cc2XformPerspective(const cc3Matrix& mat);
  ```

  Constructs a perspective transform with matrix *mat*. Nonzero scalar multiples of a matrix produce the same perspective transform.

  Parameters

mat	The supplied 3D matrix.

- ```
  cc2XformPerspective(const cc2XformPerspective& xform);
  ```

  Copy Constructor

- ```
  ~cc2XformPerspective();
  ```

  Destructor.

Operators

operator=

```
const cc2XformPerspective& operator=(
  const cc2XformPerspective& that);
```

Assignment operator. Make this object a copy of *that*.

Parameters

that The object to copy.

operator==

```
bool operator==(const cc2XformPerspective& that) const;
```

Returns true if each entry in the matrix of *this* is equal to each corresponding entry in the matrix of *that*. Returns false otherwise.

Parameters

that The transform to compare with this transform.

Public Member Functions

matrix

```
cc3Matrix matrix() const;
```

Returns the 3x3 matrix of this perspective transform.

mapPoint

```
virtual cc2Vect mapPoint(const cc2Vect& pt) const;
```

Returns the 2D point *pt mapped* through this transform.

Parameters

pt The point to map.

Throws

ccMathError::Singular
If computation involves division by zero.

isLinear

```
virtual bool isLinear() const;
```

Returns true if this transform is exactly linear; returns false otherwise.

Using the notation in the introduction, this transform is exactly linear if *m31* = *m32* = 0.

linearXform

```
virtual cc2XformLinear linearXform(const cc2Vect& pt)
                                                    const;
```

Returns a linear transform which represents the best approximation to this perspective transform at 2D point *pt*.

Parameters

pt The point where the linear approximation is made.

Throws

ccMathError::Singular
If computation involves division by zero.

composeBase

```
virtual cc2XformBasePtrh composeBase(
  const cc2XformBase& rhs) const;
```

Returns a transform which is the composition of *this* with the given transform. For example, (**this*) * *rhs*.

Parameters

rhs The transform to compose with this transform.

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const;
```

Returns the inverse of this transform.

Throws

ccMathError::Singular
If this transform is singular.

clone

```
virtual cc2XformBasePtrh clone() const;
```

Returns a newly allocated copy of this object.

Notes

This function is required for polymorphic copying.

isSingular

```
bool isSingular() const;
```

Returns true if this transform is singular; returns false otherwise.

cc2XformPerspective

cc2XformPoly

```
#include <ch_cvl/xfpoly.h>

class cc2XformPoly : public cc2XformBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class implements a nonlinear polynomial mapping between coordinate frames to be used in all those instances where a high level of mapping accuracy is required. The class implements polynomial mappings of order 1, 3 and 5 (for more details, see *Math Foundations of Transformations* in the *CVL User's Guide*). If (C_x, C_y) are client coordinates of generic image features and (I_x, I_y) are their corresponding image coordinates, the mapping performed by the class is:

$$C_x = \sum_{i,j \geq 0}^{i+j \leq n} a_{ij} {I_x}^i {I_y}^j \qquad C_y = \sum_{i,j \geq 0}^{i+j \leq n} b_{ij} {I_x}^i {I_y}^j$$

where a_{ij} and b_{ij} are the coefficients of the transformation and n is the degree of the transformation.

Constructors/Destructors

cc2XformPoly

```
cc2XformPoly();

cc2XformPoly(const cmStd vector<cc2Vect>& toPoints,
  const cmStd vector<cc2Vect>& fromPoints,
  c_Int32 order = 5);
```

- `cc2XformPoly();`

  Constructs the identity transformation. The identity transformation is:

  $C_x = I_x \qquad C_y = I_y$

- ```
  cc2XformPoly(const cmStd vector<cc2Vect>& toPoints,
    const cmStd vector<cc2Vect>& fromPoints,
    c_Int32 order = 5);
  ```

  Creates a polynomial transformation of order *order*. The coefficients of the transformation computed by the constructor provide the best least-square fit between the list of points *fromPoints* (typically in image coordinates) and the list of points *toPoints* (typically in client coordinates). Only polynomials of orders 1, 3 and 5 are allowed. The following table lists the minimum number of points for each order

Order	Number of Points
1	3
3	10
5	21

Parameters

toPoints The target list of points in client coordinates.

fromPoints The starting list of points in image coordinates.

order The order of the polynomial transformation. It must be 1, 3 or 5.

Notes

In general, the more points are used the more accurate the resulting polynomial fit will be. It is recommended that a grid of at least 8x8 points, spanning the entire region of interest, is used.

Throws

cc2XformPoly::BadParams

Not enough points in *fromPoints* and *toPoints* for the requested order of the polynomial transformation.

The number of points in *fromPoints* is not equal to the number of points in *toPoint*s.

The requested order of the polynomial transformation is less than 1.

cc2XformDefs::NotImplemented

The requested order of the polynomial is positive and not 1, 3, or 5.

cc2XformPoly::IllDefined

The least-square fit cannot converge to a solution.
  ```

Public Member Functions

mapPoint

```
virtual cc2Vect mapPoint(const cc2Vect& fromPoint) const;
```

Maps the coordinates of the point *fromPoint* using this transformation.

Parameters

fromPoint The point mapped by this transformation

isLinear

```
virtual bool isLinear() const;
```

Returns true if the order of this transformation is 1 or if all the coefficients of the polynomial terms with degree greater than one are exactly zero.

linearXform

```
virtual cc2XformLinear linearXform(const cc2Vect& atThisPt)
  const;
```

Returns the linear transformation defined by the linear terms of the Taylor series expansion of this transformation about the point *atThisPt* (for more details see *Math Foundations of Transformations* in the *CVL User's Guide*).

Parameters

atThisPt The point where the returned **cc2XformLinear** transformation is defined

composeBase

```
virtual cc2XformBasePtrh composeBase(
  const cc2XformBase& rhs)const;
```

Returns a transformation that is the composition of this transformation with *rhs*. Mapping a point with the resulting transformation is equivalent to first mapping the point by *rhs* and then by this transformation. This transformation can only be composed with a **cc2XformLinear** object.

Parameters

rhs The transformation composed with this transformation

Throws

cc2XformDefs::NotImplemented
This transformation is composed with an object other than **cc2XformLinear**.

inverseBase

```
virtual cc2XformBasePtrh inverseBase() const;
```

Returns the inverse of this transformation. The inverse of this transformation maps points in client coordinates to points in image coordinates.

Notes

This function may not provide an exact inverse mapping.

Throws

ccMathError::Singular

The transformation is singular and cannot be inverted.

clone

```
virtual cc2XformBasePtrh clone() const;
```

Returns a newly allocated copy of this object.

cc3AngleVect

```
#include <ch_cvl/ccalib.h>

class cc3AngleVect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class represents a rotation in 3-D space. It holds three angles which express rotations of the axes of a 3-D coordinate system. It is used to express the orientation of one coordinate system with respect to another. We use the convention of *Givens* rotations (see *Multiple View Geometry in Computer Vision*, Appendix A3.1.1, by *Hartley & Zisserman*).

A rotation R of 3-D coordinate axes is expressed as:

R = Rx * Ry * Rz

where

Rz = rotation of x,y-axes about a fixed z-axis,
Ry = rotation of z,x-axes about a fixed y-axis,
Rx = rotation of y,z-axes about a fixed x-axis.

The order of applying rotations is: Rz first, Ry second, and Rx third.

Constructors/Destructors

cc3AngleVect

```
cc3AngleVect(
  const ccRadian& angleX,
  const ccRadian& angleY,
  const ccRadian& angleZ);

cc3AngleVect();
```

- ```
  cc3AngleVect(
    const ccRadian& angleX,
    const ccRadian& angleY,
    const ccRadian& angleZ);
  ```

  Constructs an object with angles initialized to the provided values.
  ```

Parameters

angleX	The y,z-axes rotation angle about a fixed x-axis.
angleY	The z,x-axes rotation angle about a fixed y-axis.
angleZ	The x,y-axes rotation angle about a fixed z-axis.

- `cc3AngleVect();`

  Constructs an object with all three angles initialized to 0.

Public Member Functions

x

```
ccRadian x();
void x(const ccRadian& angleX);
```

- `ccRadian x();`

  Returns the y,z-axes rotation angle about a fixed x-axis.

- `void x(const ccRadian& angleX);`

  Sets a new y,z-axes rotation angle about a fixed x-axis.

  Parameters

angleX	The new y,z-axes rotation angle about a fixed x-axis.

y

```
ccRadian y() const;
void y(const ccRadian& angleY);
```

- `ccRadian y() const;`

  Returns the z,x-axes rotation angle about a fixed y-axis.

- `void y(const ccRadian& angleY);`

  Sets a new z,x-axes rotation angle about a fixed y-axis.

  Parameters

angleY	The new z,x-axes rotation angle about a fixed y-axis.

z

```
ccRadian z() const;
void z(const ccRadian& angleZ);
```

- `ccRadian z() const;`

  Returns the x,y-axes rotation angle about a fixed z-axis.

- `void z(const ccRadian& angleZ);`

  Sets a new x,y-axes rotation angle about a fixed z-axis.

  Parameters

  angleZ The new x,y-axes rotation angle about a fixed z-axis.

matrix

```
cc3Matrix matrix() const;
void matrix(const cc3Matrix& R);
```

- `cc3Matrix matrix() const;`

  Returns the rotation matrix associated with rotation of the 3-D coordinate axes through angles in this object. See the introduction to this reference page for the rotation order applied.

- `void matrix(const cc3Matrix& R);`

  Set the angles in this object to angles computed from rotation matrix *R*. Theoretically, *R* must satisfy determinant (*R*) = 1 and *R** (Transpose of *R*) = Identity. If R is not exactly a rotation matrix it attempts to compute a rotation matrix closest to *R* and then sets the angles. Such a computation should succeed in practical situations.

  Parameters

  R The new rotation matrix.

  Throws

  cc2XformCalib2Defs::BadParams
  If computation of a rotation matrix (if necessary) does not succeed.

cc3AngleVect

cc3PlanePel

```
#include <ch_cvl/colorpel.h>

class cc3PlanePel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **cc3PlanePel** class describes a three-plane pixel that can be used to create multi-planar pel buffers. The planes of the three-plane pixel are named plane 0, plane 1, and plane 2. The way the three planes are used depends on the application. One typical use is RGB, although HLS and HSV can also be supported.

In addition to this three-plane pixel class, CVL also defines additional pointer, **const** pointer, reference, and **const** reference classes that provide transparent pointer and reference semantics:

- **cc3PlanePtr**
- **cc3PlanePtr_const**
- **cc3PlaneRef**
- **cc3PlaneRef_const**

Constructors/Destructors

cc3PlanePel

```
cc3PlanePel();
cc3PlanePel(c_UInt8 ch1, c_UInt8 ch2, c_UInt8 ch3);
```

- `cc3PlanePel();`

  The default constructor creates a pixel with uninitialized elements.

- `cc3PlanePel(c_UInt8 ch1, c_UInt8 ch2, c_UInt8 ch3);`

  Creates a pixel with the specified values for each plane.

  Parameters

  ch1 Value for plane 0.

ch2	Value for plane 1.
ch3	Value for plane 2.

Public Member Functions

plane0

```
c_UInt8& plane0();
const c_UInt8& plane0() const;
```

- `c_UInt8& plane0();`

  Returns a read-write reference to the plane 0 element of the pixel.

- `const c_UInt8& plane0() const;`

  Returns a read-only reference to the plane 0 element of the pixel.

plane1

```
c_UInt8& plane1();
const c_UInt8& plane1() const;
```

- `c_UInt8& plane1();`

  Returns a read-write reference to the plane 1 element of the pixel.

- `const c_UInt8& plane1() const;`

  Returns a read-only reference to the plane 1 element of the pixel.

plane2

```
c_UInt8& plane2();
const c_UInt8& plane2() const;
```

- `c_UInt8& plane2();`

  Returns a read-write reference to the plane 2 element of the pixel.

- `const c_UInt8& plane2() const;`

  Returns a read-only reference to the plane 2 element of the pixel.

cc3PlanePelBuffer

```
#include <ch_cvl/colorbuf.h>

class cc3PlanePelBuffer : public ccPelBuffer<cc3PlanePel>;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **cc3PlanePelBuffer** class is an instance of the template class **ccPelBuffer** that uses three-plane pixels (see **cc3PlanePel** on page 145).

Constructors/Destructors

cc3PlanePelBuffer

```
cc3PlanePelBuffer();

cc3PlanePelBuffer(c_Int32 width, c_Int32 height,
  c_Int32 alignModulus=32);

cc3PlanePelBuffer(ccPelRoot<cc3PlanePel>* pelroot);
```

- `cc3PlanePelBuffer();`

  Creates an unbound window, that is, one that is not associated with any root image. Height and width are set to 0 and all offsets are set to (0,0). The window's transform is set to identity.

- `cc3PlanePelBuffer(c_Int32 width, c_Int32 height, c_Int32 alignModulus=32);`

  Allocates contiguous storage for a root image of *width* x *height* pixels of type *P* and a window that encompasses the entire root image. The pixels are default-constructed. This storage will be freed by the destructor. The byte address of the first row's first pixel is zero modulo the *alignModulus*. The allocated row width (in pixels) is increased if necessary to make the row size (in bytes) a multiple of the specified *alignModulus*. Up to (*alignModulus*-1) pad pixels may be allocated for each row. Pad pixels, if any, occur to the right (greater x) of the pixels that belong to the root image. Pixel processing routines are permitted to overwrite pad pixels.

Parameters

width	The width, in pixels, of the root image. (*width* > 0)
height	The height, in rows, of the root image. (*height* > 0)
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 means that memory is aligned on byte boundaries, 2 aligns on word boundaries, 4 aligns on long word boundaries, and so on. (*alignModulus* >= 1)

- `cc3PlanePelBuffer(ccPelRoot<cc3PlanePel>* pelroot);`

Creates a window bound to the root image *pelroot*. Height and width are set to encompass the entire root image. Offset is set to (0,0) and the transform is set to identity.

Parameters

pelroot	The root image the window is bound to.

Notes

If *pelroot* is *NULL*, the effect is the same as **cc3PlanePelBuffer()**; this window becomes unbound.

Public Member Functions

plane0

```
ccPelBuffer_const<c_UInt8> plane0() const;
ccPelBuffer<c_UInt8> plane0();
```

- `ccPelBuffer_const<c_UInt8> plane0() const;`

Returns plane 0 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

- `ccPelBuffer<c_UInt8> plane0();`

Returns plane 0 of this pel buffer as a read-write grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

plane1

```
ccPelBuffer_const<c_UInt8> plane1() const;
ccPelBuffer<c_UInt8> plane1();
```

- `ccPelBuffer_const<c_UInt8> plane1() const;`

  Returns plane 1 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

- `ccPelBuffer<c_UInt8> plane1();`

  Returns plane 1 of this pel buffer as a read-write grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

plane2

```
ccPelBuffer_const<c_UInt8> plane2() const;
ccPelBuffer<c_UInt8> plane2();
```

- `ccPelBuffer_const<c_UInt8> plane2() const;`

  Returns plane 2 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

- `ccPelBuffer<c_UInt8> plane2();`

  Returns plane 2 of this pel buffer as a read-write grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

colorSpace

```
ccColorSpaceDefs::ColorSpace colorSpace() const;
void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);
```

- `ccColorSpaceDefs::ColorSpace colorSpace() const;`

  Returns the color space (RGB or HSI) of the image.

- `void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);`

  Sets the color space (RGB or HSI) of the image.

  Parameters

colorSpace	The color space: **ccColorSpaceDefs::eRGB** or **ccColorSpaceDefs::eHSI**

cc3PlanePelBuffer_const

```
#include <ch_cvl/colorbuf.h>

class cc3PlanePelBuffer_const : public
                          ccPelBuffer_const<cc3PlanePel>
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **cc3PlanePelBuffer** class is an instance of the template class **ccPelBuffer** on page 2371 that uses three-plane pixels (see **cc3PlanePel** on page 145). This class allows read-only access to the planes of the pel buffer.

Constructors/Destructors

cc3PlanePelBuffer_const

```
cc3PlanePelBuffer_const();

cc3PlanePelBuffer_const(const ccPelRoot<cc3PlanePel>*);
```

- `cc3PlanePelBuffer_const();`

  Creates an unbound window, that is, one that is not associated with any root image. Height and width are set to 0 and all offsets are set to (0,0). The window's transform is set to identity.

- ```
  cc3PlanePelBuffer_const(
    const ccPelRoot<cc3PlanePel>* pelroot);
  ```

  Creates a window bound to the root image *pelroot*. Height and width are set to encompass the entire root image. Offset is set to (0,0) and the transform is set to identity.

  Parameters

  pelroot The root image the window is bound to.

  Notes

  If *pelroot* is *NULL*, the effect is the same as **cc3PlanePelBuffer_const()**; this window becomes unbound.
  ```

Public Member Functions

plane0

```
ccPelBuffer_const<c_UInt8> plane0() const;
```

Returns plane 0 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

plane1

```
ccPelBuffer_const<c_UInt8> plane1() const;
```

Returns plane 1 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

plane2

```
ccPelBuffer_const<c_UInt8> plane2() const;
```

Returns plane 2 of this pel buffer as a read-only grey-scale pel buffer. The returned pel buffer has the same window size, offset, root offset, and transform as this pel buffer. The returned pel buffer exists even if this pel buffer is destroyed.

colorSpace

```
ccColorSpaceDefs::ColorSpace colorSpace() const;
void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);
```

- `ccColorSpaceDefs::ColorSpace colorSpace() const;`

  Returns the color space (RGB or HSI) of the image.

- `void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);`

  Sets the color space (RGB or HSI) of the image.

  Parameters

colorSpace	The color space: **ccColorSpaceDefs::eRGB** or **ccColorSpaceDefs::eHSI**

cc3PlanePelPtr

```
#include <ch_cvl/colorpel.h>

class cc3PlanePelPtr : public cc3PlanePelPtr_const;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **cc3PlanePelPtr** class provides pointer semantics for the three-plane pixel class **cc3PlanePel** (see page 145). It is used by the **ccPelTraits** class (see page 2403).

Constructors/Destructors

cc3PlanePelPtr

```
cc3PlanePelPtr();
cc3PlanePelPtr(c_UInt8 *ch1, c_UInt8 *ch2, c_UInt8 *ch3);
explicit cc3PlanePelPtr(cc3PlanePel *pelPtr);
explicit cc3PlanePelPtr(const cc3PlanePelPtr_const &cPtr);
```

- `cc3PlanePelPtr();`

  Creates a three-plane pixel pointer that does not point to any pixel.

- `cc3PlanePelPtr(c_UInt8 *ch1, c_UInt8 *ch2, c_UInt8 *ch3);`

  Creates a three-plane pixel pointer that points to the three values supplied.

  Parameters

ch1	A pointer to the plane 0 value.
ch2	A pointer to the plane 1 value
ch3	A pointer to the plane 2 value.

- `explicit cc3PlanePelPtr(cc3PlanePel *pelPtr);`

  Creates a three-plane pixel pointer that points to the same three-plane pixel pointed to by *pelPtr*.

Parameters

pelPtr A pointer to a three-plane pixel object.

- `explicit cc3PlanePelPtr(const cc3PlanePelPtr_const &cPtr);`

  Converts a **cc3PlanePelPtr_const** object to **cc3PlanePelPtr** object.

  Parameters

  cPtr The **const** pointer to convert.

Public Member Functions

pPlane0 `c_UInt8* pPlane0() const;`

Returns a pointer to the plane 0 element of the pixel.

pPlane1 `c_UInt8* pPlane1() const;`

Returns a pointer to the plane 1element of the pixel.

pPlane2 `c_UInt8* pPlane2() const;`

Returns a pointer to the plane 2 element of the pixel.

Operators

These operators allow pointer arithmetic on pointers to three-plane pixels. As for pointers to scalars, the pixels are expected to be contiguous.

operator+ `cc3PlanePelPtr operator+(int d) const;`

Returns a pointer to the *d*th pixel beyond this one.

Parameters

d The distance from this pixel.

operator+= `cc3PlanePelPtr& operator+=(int d);`

Returns a reference the *d*th pixel beyond this one.

Parameters

d The distance from this pixel.

operator-

```
cc3PlanePelPtr operator-(int d) const;
```

Returns a pointer to the *d*th pixel before this one.

Parameters

d	The distance from this pixel.

operator-=

```
cc3PlanePelPtr& operator-=(int d);
```

Returns a reference the *d*th pixel before this one.

Parameters

d	The distance from this pixel.

operator++

```
cc3PlanePelPtr& operator++();
const cc3PlanePelPtr operator++(int);
```

- ```
  cc3PlanePelPtr& operator++();
  ```

  Implements the prefix **++** operator for this class.

- ```
  const cc3PlanePelPtr operator++(int);
  ```

  Implements the postfix **++** operator for this class.

operator--

```
cc3PlanePelPtr& operator--();
const cc3PlanePelPtr operator--(int);
```

- ```
  cc3PlanePelPtr& operator--();
  ```

  Implements the prefix **– –** operator for this class.

- ```
  const cc3PlanePelPtr operator--(int);
  ```

  Implements the postfix **– –** operator for this class.

operator[]

```
cc3PlanePelRef operator[] (int d) const;
```

Implements the subscript operator for this class.

cc3PlanePelPtr

operator* `cc3PlanePelRef operator*() const;`

Implements the pointer dereferencing operator for this class.

operator-> `cc3PlanePelRef *operator->() const;`

Implements the member dereferencing operator for this class.

cc3PlanePelPtr_const

```
#include <ch_cvl/colorpel.h>

class cc3PlanePelPtr_const : public cc_3Ptrs;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **cc3PlanePelPtr_const** class provides **const** pointer semantics for the three-plane pixel class **cc3PlanePel** (see page 145). It is used by the **ccPelTraits** class (see page 2403).

Constructors/Destructors

cc3PlanePelPtr_const

```
cc3PlanePelPtr_const();

cc3PlanePelPtr_const(const c_UInt8 *ch1,
  const c_UInt8 *ch2, const c_UInt8 *ch3);

explicit cc3PlanePelPtr_const(const cc3PlanePel *pelPtr);
```

- `cc3PlanePelPtr_const();`

  Creates a three-plane pixel **const** pointer that does not point to any pixel.

- ```
  cc3PlanePelPtr_const(const c_UInt8 *ch1,
    const c_UInt8 *ch2, const c_UInt8 *ch3);
  ```

  Creates a three-plane pixel **const** pointer that points to the three values supplied.

  Parameters

ch1	A pointer to the plane 0 value.
ch2	A pointer to the plane 1 value
ch3	A pointer to the plane 2 value.
  ```

- `explicit cc3PlanePelPtr_const(const cc3PlanePel *pelPtr);`

  Creates a three-plane pixel **const** pointer that points to the same three-plane pixel pointed to by *pelPtr*.

  Parameters

pelPtr	A pointer to a three-plane pixel object.

Public Member Functions

pPlane0 `const c_UInt8* pPlane0() const;`

Returns a read-only pointer to the plane 0 element of the pixel.

pPlane1 `const c_UInt8* pPlane1();`

Returns a read-only pointer to the plane 1 element of the pixel.

pPlane2 `const c_UInt8* pPlane2() const;`

Returns a read-only pointer to the plane 2 element of the pixel.

Operators

These operators allow pointer arithmetic on pointers to three-plane pixels. As for pointers to scalars, the pixels are expected to be contiguous.

operator+ `cc3PlanePelPtr_const operator+(int d) const;`

Returns a read-only pointer to the *d*th pixel beyond this one.

Parameters

d	The distance from this pixel.

operator+= `cc3PlanePelPtr_const& operator+=(int d);`

Returns a reference the *d*th pixel beyond this one.

Parameters

d	The distance from this pixel.

operator- `cc3PlanePelPtr_const operator-;`

Returns a read-only pointer to the *d*th pixel before this one.

Parameters

d The distance from this pixel.

operator-=

```
cc3PlanePelPtr_const& operator-=(int d)
```

Returns a reference the *d*th pixel before this one.

Parameters

d The distance from this pixel.

operator-

```
int operator-(const cc3PlanePelPtr_const &r);
```

Returns the number of pixels between this pixel and another pixel.

Parameters

r A reference to the other pixel.

operator++

```
cc3PlanePelPtr_const& operator++();
const cc3PlanePelPtr_const operator++(int);
```

- ```
  cc3PlanePelPtr_const& operator++();
  ```

  Implements the prefix **++** operator for this class.

- ```
  const cc3PlanePelPtr_const operator++(int);
  ```

  Implements the postfix **++** operator for this class.

operator--

```
cc3PlanePelPtr_const& operator--();
const cc3PlanePelPtr_const operator--(int);
```

- ```
  cc3PlanePelPtr_const& operator--();
  ```

  Implements the prefix **– –** operator for this class.

- ```
  const cc3PlanePelPtr_const operator--(int);
  ```

  Implements the postfix **– –** operator for this class.

cc3PlanePelPtr_const

operator[]

```
cc3PlanePelRef_const operator[] (int d) const;
```

Implements the subscript operator for this class.

operator*

```
cc3PlanePelRef_const operator*() const;
```

Implements the pointer dereferencing operator for this class.

operator->

```
cc3PlanePelRef_const *operator->() const;
```

Implements the member dereferencing operator for this class.

operator==

```
bool operator==(const cc3PlanePelPtr_const &other) const;
```

Returns true if the three-plane pixel that this object points to has the same values as the three-plane pixel that *other* points to.

Parameters

other The pointer to the other three-plane pixel.

operator!=

```
bool operator!=(const cc3PlanePelPtr_const &other) const;
```

Returns true if the three-plane pixel that this object points to does not have the same values as the three-plane pixel that *other* points to.

Parameters

other The pointer to the other three-plane pixel.

operator const void*

```
operator const void*() const;
```

Returns this pointer only if none of the planes is null.

operator!

```
bool operator!() const;
```

Returns true if one of the planes is null.

cc3PlanePelRef

```
#include <ch_cvl/colorpel.h>

class cc3PlanePelRef : public cc3PlanePelRef_const;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **cc3PlanePelRef** class provides reference semantics for the three-plane pixel class **cc3PlanePel** (see page 145). It is used by the **ccPelTraits** class (see page 2403).

Constructors/Destructors

cc3PlanePelRef `cc3PlanePelRef(const cc3PlanePel& pel);`

Creates a reference to a three-plane pixel.

Parameters

pel The pixel.

Public Member Functions

plane0 `c_UInt8& plane0() const;`

Returns a read-write reference to the plane 0 element of the pixel.

plane1 `c_UInt8& plane1() const;`

Returns a read-write reference to the plane 1 element of the pixel.

plane2 `c_UInt8& plane2() const;`

Returns a read-write reference to the plane 1 element of the pixel.

Operators

operator&

```
cc3PlanePelPtr operator&() const;
```

Returns a pointer class object referring to the same byte locations as this object.

operator=

```
cc3PlanePelRef operator=
   (const cc3PlanePelRef_const& cRef) const;

cc3PlanePelRef operator= (const cc3PlanePelRef& ref) const;

cc3PlanePelRef operator= (const cc3PlanePel& p) const;
```

Assignment operator.

The semantics are different from compiler-generated assignment operator. Rather than copying member objects, the byte locations pointed to by the member objects (which are of type **c_UInt8 ***) are copied. The semantics are consistent with the usage of this class as a proxy object (or reference class) to the **cc3PlanePel** class.

- ```
  cc3PlanePelRef operator=
     (const cc3PlanePelRef_const& cRef) const;
  ```

  Parameters

  cRef The const object to assign.

- ```
  cc3PlanePelRef operator= (const cc3PlanePelRef& ref) const;
  ```

  Parameters

  ref The object to assign.

- ```
  cc3PlanePelRef operator= (const cc3PlanePel& p) const;
  ```

  Parameters

  p The object to assign.
  ```

cc3PlanePelRef_const

```
#include <ch_cvl/colorpel.h>

class cc3PlanePelRef_const : public cc_3Ptrs;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **cc3PlanePelRef_const** class provides **const** reference semantics for the three-plane pixel class **cc3PlanePel** (see page 145). It is used by the **ccPelTraits** class (see page 2403).

Constructors/Destructors

cc3PlanePelRef_const

```
cc3PlanePelRef_const(const cc3PlanePel& pel);
```

Creates a **const** reference to a three-plane pixel.

Parameters

pel The pixel.

Public Member Functions

plane0

```
const c_UInt8& plane0();
```

Returns a read-only reference to the plane 0 element of the pixel.

plane1

```
const c_UInt8& plane1() const;
```

Returns a read-only reference to the plane 1 element of the pixel.

plane2

```
const c_UInt8& plane2() const;
```

Returns a read-only reference to the plane 2 element of the pixel.

Operators

operator==

```
bool operator==(const cc3PlanePel& p) const;
bool operator==(const cc3PlanePelRef_const& p) const;
```

- `bool operator==(const cc3PlanePel& p) const;`

  Returns true if the pixel referred to by this object has the same values as the pixel *p*.

  Parameters

  p The three-plane pel to compare to.

- `bool operator==(const cc3PlanePelRef_const& p) const;`

  Returns true if the pixel referred to by this object has the same values as the pixel *p*.

  Parameters

  p The three-plane pel to compare to.

operator!=

```
bool operator!=(const cc3PlanePel& p) const;
bool operator!=(const cc3PlanePelRef_const& p) const;
```

- `bool operator!=(const cc3PlanePel& p) const;`

  Returns true if the pixel referred to by this object does not have the same values as the pixel *p*.

  Parameters

  p The three-plane pel to compare to.

- `bool operator!=(const cc3PlanePelRef_const& p) const;`

  Returns true if the pixel referred to by this object does not have the same values as the pixel *p*.

  Parameters

  p The three-plane pel to compare to.

operator&

```
cc3PlanePelPtr_const operator&() const;
```

Returns a pointer class object referring to the same byte locations as this object.

cc3Vect

```
#include <ch_cvl/vector.h>

class cc3Vect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a three-dimensional vector, a quantity that is determined by its length (magnitude) and direction. Throughout the CVL, **cc3Vector** is used to describe points in three-dimensional space, so you can also think of a vector as an (x,y,z) coordinate.

Notes

cc3Vect is the name of the class as it is used throughout the Cognex Vision Library. This name is actually a **typedef** for **ccVector<3>**. Both forms are valid and entirely equivalent.

Do not confuse the CVL vectors classes **cc2Vect** and **cc3Vect** with the C++ Standard Template Library's **vector** template class. Though both have the same mathematical underpinnings, the CVL vector classes are generally used to describe the location of points while the STL **vector** class is used to implement flexible arrays.

Constructors/Destructors

cc3Vect

```
cc3Vect();

cc3Vect(double x, double y, double z);
```

- `cc3Vect();`

  The default constructor creates a vector in which all three components are set to zero.

- `cc3Vect(double x, double y, double z);`

  Creates a vector with the specified components.

Parameters

x	The x-component of the vector.
y	The y-component of the vector.
z	The z-component of the vector.

Operators

operator[]

```
double& operator[](int d);
double operator[](int d) const;
```

- `double& operator[](int d);`

Provides array-like access to the vector. Typically you use this form when your application works with both two- and three-dimensional vectors. This form allows you to set the value of a component.

Parameters

d	The index of the element to return.
	0: The x-component.
	1: The y-component.
	2: The z-component.

- `double operator[](int d) const;`

Provides array-like access to the vector. Typically you use this form when your application works with both two- and three-dimensional vectors.

Parameters

d	The index of the element to return.
	0: The x-component.
	1: The y-component.
	2: The z-component.

operator+

```
cc3Vect operator+(const cc3Vect& v) const;
```

Returns a vector that is the result of adding this vector and another vector.

Parameters

v The vector to add to this vector.

operator+=

```
cc3Vect& operator+=(const cc3Vect& v);
```

Adds this vector to another vector and returns the result.

Parameters

v The vector to add to this vector.

operator-

```
cc3Vect operator-() const;
cc3Vect operator-(const cc3Vect& v) const;
```

- ```
  cc3Vect operator-() const;
  ```

  The unary minus operator.

- ```
  cc3Vect operator-(const cc3Vect& v) const;
  ```

  Returns a vector that is the result of subtracting the vector v from this vector.

  Parameters

  v The vector to subtract from this vector.

operator-=

```
cc3Vect& operator-=(const cc3Vect& v);
```

Subtracts the vector v from this vector and returns the result.

Parameters

v The vector to subtract from this vector.

operator*

```
cc3Vect operator*(double d) const;
friend cc3Vect operator*(double d, const cc3Vect& v);
double operator*(const cc3Vect& v) const;
```

- ```
  cc3Vect operator*(double d) const;
  ```

  Returns a vector that is the result of multiplying each element in the vector by *d*.

  Parameters

  d The value by which to multiply each element of the vector.
  ```

- `friend cc3Vect operator*(double d, const cc3Vect& v);`

  Returns a vector that is the result of multiplying each element in the vector by *d*.

  Parameters

d	The value by which to multiply each element of the vector.
v	The vector.

- `double operator*(const cc3Vect& v) const;`

  Returns the dot product of this vector and the vector *v*.

  Parameters

v	The other vector.

operator*= `cc3Vect& operator*=(double d);`

Multiplies each element in this vector by *d* and returns the result.

Parameters

d	The value by which to multiply each element of the vector.

operator/ `cc3Vect operator/(double d) const;`

Returns a vector that is the result of dividing each element in this vector by *d*.

Parameters

d	The value by which to divide each element of the vector.

operator/= `cc3Vect& operator/=(double d) const;`

Divides each element in this vector by *d* and returns the result.

Parameters

d	The value by which to divide each element of the vector.

operator== `bool operator==(const cc3Vect& v) const;`

Returns true if this vector is equal to another vector.

Parameters

v	The other vector.

operator!=

```
bool operator!=(const cc3Vect& v) const;
```

Returns true if this vector is not equal to another vector.

Parameters

v	The other vector.

Public Member Functions

x

```
double x() const;
void x(double newX);
```

- ```
  double x() const;
  ```

  Returns the vector's x-component.

- ```
  void x(double newX);
  ```

  Sets the vector's x-component.

  Parameters

newX	The new x-component.

y

```
double y() const;
void y(double newY);
```

- ```
  double y() const;
  ```

  Returns the vector's y-component.

- ```
  void y(double newY);
  ```

  Sets the vector's y-component.

  Parameters

newY	The new y-component.

z

```
double z() const;
void z(double newZ);
```

- `double z() const;`

  Returns the vector's z-component.

- `void z(double newZ);`

  Sets the vector's z-component.

  Parameters

  newZ The new z-component.

len

```
double len() const;
```

Returns the length (or magnitude) of the vector.

isNull

```
bool isNull() const;
```

Returns true if this is a null vector (all components are zero).

unit

```
cc3Vect unit() const;
```

Returns a unit vector parallel to this vector. A unit vector is a vector whose length is 1.

Throws

ccMathError::NullVector
The x-component, the y-component, and the z-component are zero.

project

```
cc3Vect project(const cc3Vect&) const;
```

Returns a vector that is the result of projecting the vector *v* onto this vector.

Parameters

v The vector to project onto this vector.

Throws

ccMathError::NullVector
The x-component, the y-component, and the z-component are zero.

An error is not thrown if *v* is null or the two vectors are perpendicular to each other.

distance

```
double distance(const cc3Vect& v) const;
```

Returns the distance to the other vector. This is the length of difference between this vector and vector *v*.

Parameters

v	The other vector.

dot

```
double dot(const cc3Vect& v) const;
```

Returns the dot product of this vector and the vector *v*.

Parameters

v	The other vector.

cross

```
cc3Vect cross(const cc3Vect& v) const;
```

Returns the cross product of this vector and *v*.

Parameters

v	The other vector.

cc3Vect

cc8500l

```
#include <ch_cvl/vp8500l.h>

class cc8500l : public ccUnknownFG,
                public ccUnknownPIO;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes the Cognex MVS-8500L frame grabber. There is one instance of this class for each MVS-8500L board in a system. When you write your application you create the frame grabber object you will use, with code similar to the following:

```
cc8500l& fg = cc8500l::get(i);
```

In this example, *i* is the MVS-8500L board number in your system, starting with 0. If you have only one MVS-8500L in your system *i* will always be 0. If you have more than one MVS-8500L board in your system you will need to know the board number you wish to use so you can code the above line properly.

Constructors/Destructors

A single instance of this class is created automatically for each MVS-8500L installed in your system.

Public Member Functions

inputLine

```
virtual ccInputLine inputLine(c_Int32 line);
```

Returns a **ccInputLine** object that represents the specified logical input line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line number. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

The MVS-8500L provides eight bidirectional TTL lines. Each line can be independently enabled as an input or output line using **ccOutputLine::enable()** or **ccInputLine::enable()**.

The eight lines are numbered 8 through 15.

At power-on of the MVS-8500L, all lines are enabled as input lines; they must be explicitly enabled for use as output lines. At power-on, all lines are pulled high by an internal pull-up resistor.

The MVS-8500L's parallel I/O lines have three connection options. They can be used as TTL lines, can be converted to opto-isolated line pairs, or a combination of TTL and opto-isolated lines. These connection options are described in the *MVS-8500 Hardware Manual.* Consult that manual for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

Line 8 has a dual purpose as either programmable TTL line or as a trigger line for the currently active camera. If the acquisition FIFO's **triggerEnable()** function is invoked for line 8, then line 8 is not available for use as an input line with this function.

Similarly, line 9 has a dual purpose as either programmable TTL line or strobe control line for the currently active camera. If the acquisition FIFO's **strobeEnable()** function is invoked for line 9, then line 9 is not available for use as an input line with this function.

The following table shows the logical *line* numbers for the eight parallel I/O lines on the MVS-8500L, when each bidirectional line is configured as an input line.

inputLine *line* parameter	**Signal name on MVS-8500L**	**Device Connection**
8	TTL_BI_8	Trigger for the currently active camera, if enabled. Otherwise a bidirectional line, controls any TTL input device when this line is enabled for input.
9	TTL_BI_9	Strobe for the currently active camera, if enabled. Otherwise a bidirectional line, controls any TTL input device when this line is enabled for input.
10	TTL_BI_10	Bidirectional line, controls any TTL input device when this line is enabled for input
11	TTL_BI_11	Bidirectional, as above

inputLine *line* parameter	Signal name on MVS-8500L	Device Connection
12	TTL_BI_12	Bidirectional, as above
13	TTL_BI_13	Bidirectional, as above
14	TTL_BI_14	Bidirectional, as above
15	TTL_BI_15	Bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL, opto-isolated, or combination connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

outputLine

```
virtual ccOutputLine outputLine(c_Int32 line);
```

Returns a **ccOutputLine** object that represents the specified logical output line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

See the *Notes* above for **inputLine()**. Remember that at power-on of the MVS-8500L, all lines are enabled as input lines; they must be explicitly enabled for use as output lines, using **ccOutputLine::enable()**.

The eight lines are numbered 8 through 15.

Consult the *MVS-8500 Hardware Manual* for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

The following table shows the logical *line* numbers for the eight parallel I/O lines on the MVS-8500L, when each bidirectional line is configured as an output line.

outputLine *line* parameter	**Signal name on MVS-8500L**	**Device Connection**
8	TTL_BI_8	Trigger for the currently active camera, if enabled. Otherwise a bidirectional line, controls any TTL input device when this line is enabled for input.
9	TTL_BI_9	Strobe for the currently active camera, if enabled. Otherwise a bidirectional line, controls any TTL input device when this line is enabled for input.
10	TTL_BI_10	Bidirectional line, controls any TTL input device when this line is enabled for input
11	TTL_BI_11	Bidirectional, as above
12	TTL_BI_12	Bidirectional, as above
13	TTL_BI_13	Bidirectional, as above
14	TTL_BI_14	Bidirectional, as above
15	TTL_BI_15	Bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL, opto-isolated, or combination connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

numInputLines `virtual c_Int32 numInputLines() const;`

Returns the number of total input lines for this hardware. The total depends upon the configuration set by **setIOConfig()**.

This is an override from class **ccParallelIO**.

numOutputLines `virtual c_Int32 numOutputLines() const;`

Returns the number of total output lines for this hardware.

This is an override from class **ccParallelIO**.

getIOConfig `virtual ccIOConfig& getIOConfig() const;`

Returns the parallel I/O board configuration.

This is an override from class **ccParallelIO**.

setIOConfig `virtual void setIOConfig(ccIOConfig& config);`

Sets the parallel I/O board configuration. See **ccIOConfig** and its derived classes, as discussed in **ccIOConfig** on page 1799 and in *ch_cvl/pioconfg.h*.

This is an override from class **ccParallelIO**.

Parameters

config The I/O board configuration.

Notes

The *config* parameter is one of the following classes derived from **ccIOConfig**:

ccIO8500l (for use with cable 300-0390)
ccIOExternal8500l (for use with cable 300-0389)
ccIOSplit8500l (for use with cable 300-0399)

Example

This example sets the I/O configuration for an MVS-8500L frame grabber using cable 300-0390 and the pass-through TTL connection module.

```
cc8500l& fg = cc8500l::get(0);
ccParallelIO* pio = dynamic_cast<ccParallelIO*> (&fg);
pio->setIOConfig(ccIO8500l());
```

Static Functions

count

```
static c_Int32 count();
```

Returns the number of Cognex MVS-8500L frame grabbers installed in the system.

get

```
static cc8500l& get(c_Int32 i = 0);
```

Returns the **cc8500l** object associated with the Cognex MVS-8500L frame grabber whose index is *i*. Index numbers begin with 0. See the introduction to this reference page for additional information.

Parameters

i The Cognex MVS-8500L board index.

Throws

ccBoard::BadParams
If *i* is not a valid index.

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding
The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse
The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error,

a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occured while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

cc8500l

cc8501

```
#include <ch_cvl/vp8501.h>

class cc8501 : public ccBoard,
               public ccFrameGrabber,
               public ccParallelIO;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes the Cognex MVS-8501 frame grabber and the Cognex MVS-8511 (and MVS-8511e) frame grabber.

Note The information contained in this section for Cognex MVS-8511 frame grabbers is valid for Cognex MVS-8511e frame grabbers.

There is one instance of this class for each MVS-8501 or MVS-8511 board in a system. When you write your application you create the frame grabber object you will use, with code similar to the following:

```
cc8501& fg = cc8501::get(i);
```

In this example, *i* is the MVS-8501 board number in your system, starting with 0. If you have only one MVS-8501 in your system *i* will always be 0. If you have more than one MVS-8501 board in your system you will need to know the board number you wish to use so you can code the above line properly.

Generally, MVS-8501 board 0 is the MVS-8501 board in the lower numbered PCI slot. However, this can vary with different motherboard manufacturers, and can be BIOS dependent. Consult your system hardware documentation to verify the system's PCI slot numbering system when you use more than one MVS-8501 or MVS-8511 in your system.

Constructors/Destructors

A single instance of this class is created automatically for each MVS-8501 and MVS-8511 installed in your system.

Public Member Functions

inputLine

```
virtual ccInputLine inputLine(c_Int32 line);
```

Returns a **ccInputLine** object that represents the specified logical input line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line number. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

The MVS-8501 or MVS-8511 provide sixteen bidirectional TTL lines. On some Cognex frame grabber families, the input or output direction of all bidirectional lines is set as a group. By contrast, on the MVS-8500 series, each line can be independently enabled as an input or output line using **ccOutputLine::enable()** or **ccInputLine::enable()**.

At power-on of the MVS-8501 or MVS-8511, all sixteen lines are enabled as input lines; they must be explicitly enabled for use as output lines. At power-on, all lines are pulled high by an internal pull-up resistor. By contrast, on other Cognex frame grabbers, parallel I/O lines are pulled low or allowed to float.

The MVS-8501's or MVS-8511's parallel I/O lines have three connection options. They can be used as TTL lines, can be converted to opto-isolated line pairs, or a combination of TTL and opto-isolated lines. These connection options are

described in the *MVS-8500 Hardware Manual*. Consult that manual for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

Line 8 has a dual purpose as either programmable TTL line or as a trigger line for the currently active camera. If the acquisition FIFO's **triggerEnable()** function is invoked for line 8, then line 8 is not available for use as an input line with this function.

Similarly, line 9 has a dual purpose as either programmable TTL line or strobe control line for the currently active camera. If the acquisition FIFO's **strobeEnable()** function is invoked for line 9, then line 9 is not available for use as an input line with this function.

The following table shows the logical *line* numbers for the sixteen parallel I/O lines on the MVS-8501 or MVS-8511, when each bidirectional line is configured as an input line.

inputLine *line* parameter	**Signal name on MVS-8501**	**Device Connection**
0	TTL_BI_0	Bidirectional line, controls any TTL input device when this line is enabled for input
1	TTL_BI_1	Bidirectional, as above
2	TTL_BI_2	Bidirectional, as above
3	TTL_BI_3	Bidirectional, as above
4	TTL_BI_4	Bidirectional, as above
5	TTL_BI_5	Bidirectional, as above
6	TTL_BI_6	Bidirectional, as above
7	TTL_BI_7	Bidirectional, as above
8	TTL_BI_8	Trigger for the currently active camera, if enabled, or bidirectional, as above
9	TTL_BI_9	Strobe for the currently active camera, if enabled, or bidirectional, as above
10	TTL_BI_10	Bidirectional line, controls any TTL input device when this line is enabled for input
11	TTL_BI_11	Bidirectional, as above

inputLine *line* parameter	Signal name on MVS-8501	Device Connection
12	TTL_BI_12	Bidirectional, as above
13	TTL_BI_13	Bidirectional, as above
14	TTL_BI_14	Bidirectional, as above
15	TTL_BI_15	Bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL, opto-isolated, or combination connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

outputLine

```
virtual ccOutputLine outputLine(c_Int32 line);
```

Returns a **ccOutputLine** object that represents the specified logical output line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

See the *Notes* above for **inputLine()**. Remember that at power-on of the MVS-8501 or MVS-8511, all sixteen lines are enabled as input lines; they must be explicitly enabled for use as output lines, using **ccOutputLine::enable()**.

Consult the *MVS-8500 Hardware Manual* for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

The following table shows the logical *line* numbers for the sixteen parallel I/O lines on the MVS-8501 or MVS-8511, when each bidirectional line is configured as an output line.

outputLine *line* parameter	**Signal name on MVS-8501**	**Device Connection**
0	TTL_BI_0	Bidirectional line, controls any TTL output device when this line is enabled for output
1	TTL_BI_1	Bidirectional, as above
2	TTL_BI_2	Bidirectional, as above
3	TTL_BI_3	Bidirectional, as above
4	TTL_BI_4	Bidirectional, as above
5	TTL_BI_5	Bidirectional, as above
6	TTL_BI_6	Bidirectional, as above
7	TTL_BI_7	Bidirectional, as above
8	TTL_BI_8	Trigger for the currently active camera if enabled, or bidirectional, as above
9	TTL_BI_9	Strobe for the currently active camera if enabled, or bidirectional, as above
10	TTL_BI_10	Bidirectional line, controls any TTL output device when this line is enabled for output
11	TTL_BI_11	Bidirectional, as above
12	TTL_BI_12	Bidirectional, as above
13	TTL_BI_13	Bidirectional, as above

outputLine *line* parameter	Signal name on MVS-8501	Device Connection
14	TTL_BI_14	Bidirectional, as above
15	TTL_BI_15	Bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL, opto-isolated, or combination connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

numInputLines

```
virtual c_Int32 numInputLines() const;
```

Returns the number of total input lines for this hardware. The total depends upon the configuration set by **setIOConfig()**.

This is an override from class **ccParallelIO**.

numOutputLines

```
virtual c_Int32 numOutputLines() const;
```

Returns the number of total output lines for this hardware.

This is an override from class **ccParallelIO**.

getIOConfig

```
virtual ccIOConfig& getIOConfig() const;
```

Returns the parallel I/O board configuration.

This is an override from class **ccParallelIO**.

setIOConfig

```
virtual void setIOConfig(ccIOConfig& config);
```

Sets the parallel I/O board configuration. See **ccIOConfig** and its derived classes, as discussed in **ccIOConfig** on page 1799 and in *ch_cvl/pioconfg.h*.

This is an override from class **ccParallelIO**.

Parameters

config The I/O board configuration.

Notes

The *config* parameter is one of the following classes derived from **ccIOConfig**:

ccIO8501 (for use with cable 300-0390)
ccIOExternal8501 (for use with cable 300-0389)
ccIOSplit8501 (for use with cable 300-0399)

Example

This example sets the I/O configuration for an MVS-8501 frame grabber using cable 300-0390 and the pass-through TTL connection module.

```
cc8501& fg = cc8501::get(0);
ccParallelIO* pio = dynamic_cast<ccParallelIO*> (&fg);
pio->setIOConfig(ccIO8501());
```

is8510

```
bool is8510() const;
```

Returns whether the 'gotten' object returned by **cc8501::get(*i*)** is an 8501 or 8511 frame grabber.

Notes

This function offers an alternate approach to differentiating by means of the grabber's 'pretty' name, for example, “8501” versus “8511”.

Static Functions

count

```
static c_Int32 count();
```

Returns the number of Cognex MVS-8501 and MVS-8511 frame grabbers installed in the system.

get

```
static cc8501& get(c_Int32 i = 0);
```

Returns the **cc8501** object associated with the Cognex MVS-8501 or MVS-8511 frame grabber whose index is *i*. Index numbers begin with 0. See the introduction to this reference page for additional information.

Parameters

i The Cognex MVS-8501 or MVS-8511 board index.

Throws

ccBoard::BadParams
If *i* is not a valid index.

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occured while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

cc8504

```
#include <ch_cvl/vp8504.h>

class cc8504 : public ccBoard,
               public ccFrameGrabber,
               public ccParallelIO;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes the Cognex MVS-8504 (and MVS-8504e) frame grabber and the Cognex MVS-8514 (and MVS-8514e) frame grabber.

Note The information contained in this section for Cognex MVS-8504 and MVS-8514 frame grabbers is valid for Cognex MVS-8504e and MVS-8514e frame grabbers respectively.

There is one instance of this class for each MVS-8504 and MVS-8514 board in a system. When you write your application you create the frame grabber object you will use, with code similar to the following:

```
cc8504& fg = cc8504::get(i);
```

In this example, *i* is the MVS-8504 board number in your system, starting with 0. If you have only one MVS-8504 in your system *i* will always be 0. If you have more than one MVS-8504 board in your system you will need to know the board number you wish to use so you can code the above line properly.

Generally, MVS-8504 (or MVS-8514) board 0 is the MVS-8504 (or MVS-8514) board in the lower numbered PCI slot. However, this can vary with different motherboard manufacturers, and can be BIOS dependent. Consult your system hardware documentation to verify the system's PCI slot numbering system when you use more than one MVS-8504 or MVS-8514 in your system.

Constructors/Destructors

A single instance of this class is created automatically for each MVS-8504 and MVS-8514 installed in your system.

Public Member Functions

inputLine

```
virtual ccInputLine inputLine(c_Int32 line);
```

Returns a **ccInputLine** object that represents the specified logical input line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line number. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

The MVS-8504 or MVS-8514 provide sixteen bidirectional TTL lines. On some Cognex frame grabber families, the input or output direction of all bidirectional lines is set as a group. By contrast, on the MVS-8500 series, each line can be independently enabled as an input or output line using **ccOutputLine::enable()** or **ccInputLine::enable()**.

At power-on of the MVS-8504 or MVS-8514, all sixteen lines are enabled as input lines; they must be explicitly enabled for use as output lines. At power-on, all lines are pulled high by an internal pull-up resistor. By contrast, on other Cognex frame grabbers, parallel I/O lines are pulled low or allowed to float.

The MVS-8504's or MVS-8514's parallel I/O lines have three connection options. They can be used as TTL lines, can be converted to opto-isolated line pairs, or a combination of TTL and opto-isolated lines. These connection options are

described in the *MVS-8500 Hardware Manual*. Consult that manual for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

Lines 8, 10, 12, and 14 have a dual purpose as either programmable TTL lines or dedicated trigger lines. If the acquisition FIFO's **triggerEnable()** function is invoked for a given camera channel, the dedicated trigger line for that channel is not available for use as an input line with this function.

Similarly, lines 9, 11, 13, and 15 have a dual purpose as either programmable TTL lines or dedicated strobe control lines. If the acquisition FIFO's **strobeEnable()** function is invoked for a given camera channel, the dedicated strobe line for that channel is not available for use as an input line with this function.

The following table shows the logical *line* numbers for the sixteen parallel I/O lines on the MVS-8504 or MVS-8514, when each bidirectional line is configured as an input line.

inputLine *line* parameter	**Signal name on MVS-8504**	**Device Connection**
0	TTL_BI_0	Bidirectional line, controls any TTL input device when this line is enabled for input
1	TTL_BI_1	Bidirectional, as above
2	TTL_BI_2	Bidirectional, as above
3	TTL_BI_3	Bidirectional, as above
4	TTL_BI_4	Bidirectional, as above
5	TTL_BI_5	Bidirectional, as above
6	TTL_BI_6	Bidirectional, as above
7	TTL_BI_7	Bidirectional, as above
8	TTL_BI_8	Trigger for camera channel 1 if enabled, or bidirectional, as above
9	TTL_BI_9	Strobe for camera channel 1 if enabled, or bidirectional, as above
10	TTL_BI_10	Trigger for camera channel 2 if enabled, or bidirectional, as above
11	TTL_BI_11	Strobe for camera channel 2 if enabled, or bidirectional, as above

inputLine *line* parameter	Signal name on MVS-8504	Device Connection
12	TTL_BI_12	Trigger for camera channel 3 if enabled, or bidirectional, as above
13	TTL_BI_13	Strobe for camera channel 3 if enabled, or bidirectional, as above
14	TTL_BI_14	Trigger for camera channel 4 if enabled, or bidirectional, as above
15	TTL_BI_15	Strobe for camera channel 4 if enabled, or bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL, opto-isolated, or combination connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

outputLine

```
virtual ccOutputLine outputLine(c_Int32 line);
```

Returns a **ccOutputLine** object that represents the specified logical output line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

See the *Notes* above for **inputLine()**. Remember that at power-on of the MVS-8504, all sixteen lines are enabled as input lines; they must be explicitly enabled for use as output lines, using **ccOutputLine::enable()**.

Consult the *MVS-8500 Hardware Manual* for the correspondence between the signal names used in the table below and the pin numbers to which you connect device wiring.

The following table shows the logical *line* numbers for the sixteen parallel I/O lines on the MVS-8504 or MVS-8514, when each bidirectional line is configured as an output line.

outputLine *line* parameter	**Signal name on MVS-8504**	**Device Connection**
0	TTL_BI_0	Bidirectional line, controls any TTL output device when this line is enabled for output
1	TTL_BI_1	Bidirectional, as above
2	TTL_BI_2	Bidirectional, as above
3	TTL_BI_3	Bidirectional, as above
4	TTL_BI_4	Bidirectional, as above
5	TTL_BI_5	Bidirectional, as above
6	TTL_BI_6	Bidirectional, as above
7	TTL_BI_7	Bidirectional, as above
8	TTL_BI_8	Trigger for camera channel 1 if enabled, or bidirectional, as above
9	TTL_BI_9	Strobe for camera channel 1 if enabled, or bidirectional, as above
10	TTL_BI_10	Trigger for camera channel 2 if enabled, or bidirectional, as above
11	TTL_BI_11	Strobe for camera channel 2 if enabled, or bidirectional, as above
12	TTL_BI_12	Trigger for camera channel 3 if enabled, or bidirectional, as above

outputLine *line* parameter	Signal name on MVS-8504	Device Connection
13	TTL_BI_13	Strobe for camera channel 3 if enabled, or bidirectional, as above
14	TTL_BI_14	Trigger for camera channel 4 if enabled, or bidirectional, as above
15	TTL_BI_15	Strobe for camera channel 4 if enabled, or bidirectional, as above

The *line* numbers in the table above are the same whether devices are wired with the TTL or opto-isolated connection options. Consult the *MVS-8500 Hardware Manual* for the pin numbers for each connection option that correspond to the signal names in the table above.

numInputLines `virtual c_Int32 numInputLines() const;`

Returns the number of total input lines for this hardware. The total depends upon the configuration set by **setIOConfig()**.

This is an override from class **ccParallelIO**.

numOutputLines `virtual c_Int32 numOutputLines() const;`

Returns the number of total output lines for this hardware.

This is an override from class **ccParallelIO**.

getIOConfig `virtual ccIOConfig& getIOConfig() const;`

Returns the parallel I/O board configuration.

This is an override from class **ccParallelIO**.

setIOConfig `virtual void setIOConfig(ccIOConfig& config);`

Sets the parallel I/O board configuration. See **ccIOConfig** and its derived classes, as discussed in **ccIOConfig** on page 1799 and in *ch_cvl/pioconfg.h*.

This is an override from class **ccParallelIO**.

Parameters

config The I/O cable and connection box configuration, in the form of a class derived from **ccIOConfig**.

Notes

The *config* parameter is one of the following classes derived from **ccIOConfig**:

ccIO8504 (for use with cable 300-0390)
ccIOExternal8504 (for use with cable 300-0389)
ccIOSplit8504 (for use with cable 300-0399)

Example

This example sets the I/O configuration for an MVS-8504 frame grabber using cable 300-0390 and the pass-through TTL connection module.

```
cc8504& fg = cc8504::get(0);
ccParallelIO* pio = dynamic_cast<ccParallelIO*> (&fg);
pio->setIOConfig(ccIO8504());
```

is8510

```
bool is8510() const;
```

Returns whether the 'gotten' object returned by **cc8504::get(*i*)** is an 8504 or 8514 frame grabber.

Notes

This function offers an alternate approach to differentiating by means of the grabber's 'pretty' name, for example, “8504” versus “8514”.

Static Functions

count

```
static c_Int32 count();
```

Returns the number of Cognex MVS-8504 frame grabbers and Cognex MVS-8514 frame grabbers installed in the system.

get

```
static cc8504& get(c_Int32 i = 0);
```

Returns the **cc8504** object associated with the Cognex MVS-8504 frame grabber or the Cognex MVS-8514 frame grabber whose index is *i*. Index numbers begin with 0. See the introduction to this reference page for additional information.

Parameters

i The Cognex MVS-8504 or MVS-8514 board index.

Throws

ccBoard::BadParams
If *i* is not a valid index.

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occured while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

cc8600

```
#include <ch_cvl/vp8600.h>

class cc8600 : public ccBoard,
               public ccFrameGrabber,
               public ccParallelIO;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes the Cognex MVS-8600 and MVS-8600e frame grabbers. There is one instance of this class for each frame grabber board in a system.

The MVS-8600 and MVS-8600e series frame grabbers consist of three frame grabber boards that plug into your PC. The MVS-8601 and MVS-8602 plug into the PCI bus and the MVS-8602e plugs into the PCI Express bus. The MVS-8601 has one camera port and can support one camera. The MVS-8602 and MVS-8602e have two camera ports and can support one or two cameras each. In this class reference we use the term MVS-8600, or just 8600, to refer to all three of the MVS-8600 and MVS-8600e frame grabber boards.

When you write your application, you create the frame grabber object you will use with code like this example:

```
cc8600& fg = cc8600::get(i);
```

In this example, *i* is the MVS-8600 or MVS-8600e board number in your system, starting with 0. If you have only one MVS-8600 or MVS-8600e in your system *i* will always be 0. If you have more than one, you will need to know the board number you wish to address so you can code the above line properly.

Generally, board 0 is the MVS-8600 or MVS-8600e board in the lower numbered PCI slot. However, this can vary with different motherboard manufacturers, and can be BIOS dependent. Consult your system hardware documentation to verify the system's PCI slot numbering system when you use more than one MVS-8600 or MVS-8600e in your system.

Constructors/Destructors

A single instance of this class is created automatically for each MVS-8600 installed in your system.

Public Member Functions

inputLine

```
virtual ccInputLine inputLine(c_Int32 line);
```

Returns a **ccInputLine** object that represents the specified logical input line. This is an override from class **ccParallelIO**.

Parameters

line — The logical line number. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

The MVS-8600 provides six or eight pairs of opto-isolated input lines, depending on the I/O configuration you specify with **setIOConfig()**.

I/O Configuration	Number of programmable input lines
ccIO8600LVDS	8
ccIO8600TTL	8
ccIO8600DualLVDS	6

The following table shows the logical *line* numbers for the eight opto-isolated input line pairs. Match the signal names to connection pin numbers by using the *MVS-8600 Hardware Manual*.

inputLine *line* parameter	Signal name on MVS-8600	Notes
0	OPTO_IN_0±	Not available when connecting two line scan cameras with two LVDS encoders (that is, when using **ccIO8600DualLVDS**).
1	OPTO_IN_1±	
2	OPTO_IN_2±	
3	OPTO_IN_3±	
4	OPTO_IN_4±	
5	OPTO_IN_5±	
6	OPTO_IN_6±	
7	OPTO_IN_7±	

outputLine

```
virtual ccOutputLine outputLine(c_Int32 line);
```

Returns a **ccOutputLine** object that represents the specified logical output line. This is an override from class **ccParallelIO**.

Parameters

line The logical line. *line* must be a valid value for the configuration set by **setIOConfig()**.

Notes

The MVS-8600 provides six or eight pairs of opto-isolated output lines, depending on the I/O configuration you specify with **setIOConfig()**.

I/O Configuration	Number of programmable output lines
ccIO8600LVDS	8
ccIO8600TTL	8
ccIO8600DualLVDS	6

The following table shows the logical *line* numbers for the eight opto-isolated output line pairs. Match the signal names to connection pin numbers by using the *MVS-8600 Hardware Manual*.

outputLine *line* parameter	Signal name on MVS-8600	Notes
0	OPTO_OUT_0±	Not available when connecting two line scan cameras with two LVDS encoders (that is, when using **ccIO8600DualLVDS**).
1	OPTO_OUT_1±	
2	OPTO_OUT_2±	
3	OPTO_OUT_3±	
4	OPTO_OUT_4±	
5	OPTO_OUT_5±	
6	OPTO_OUT_6±	
7	OPTO_OUT_7±	

numInputLines `virtual c_Int32 numInputLines() const;`

Returns the number of total input lines for this hardware. The total depends upon the configuration set by **setIOConfig()**.

This is an override from class **ccParallelIO**.

numOutputLines `virtual c_Int32 numOutputLines() const;`

Returns the number of total output lines for this hardware.

This is an override from class **ccParallelIO**.

getIOConfig `virtual ccIOConfig& getIOConfig() const;`

Returns the parallel I/O board configuration.

This is an override from class **ccParallelIO**.

setIOConfig `virtual void setIOConfig(ccIOConfig& config);`

Sets the parallel I/O board configuration. See **ccIOConfig** and its derived classes, as discussed in **ccIOConfig** on page 1799 and in *ch_cvl/pioconfg.h*.

This is an override from class **ccParallelIO**.

Parameters

config	The I/O cable and connection box configuration, in the form of a class derived from **ccIOConfig**.

Notes

The *config* parameter is one of the following classes derived from **ccIOConfig**:

ccIO8600LVDS (for use with cable 300-0539)
ccIO8600TTL (for use with cable 300-0540)
ccIO8600DualLVDS (for use with cable 300-0538)

In all cases, the same I/O connection module is used, Cognex part number 800-5885-1.

Example

This example sets the I/O configuration for an MVS-8600 frame grabber using cable 300-0539 and the MVS-8600 I/O connection module.

```
cc8600& fg = cc8600::get(0);
ccParallelIO* pio = dynamic_cast<ccParallelIO*> (&fg);
pio->setIOConfig(ccIO8600LVDS());
```

sizePelPool

```
c_Int32 sizePelPool();
```

```
void sizePelPool(c_Int32 desiredSize);
```

The pel pool is a special pool used to store images acquired using the MVS-8600 and MVS-8600e frame grabbers. Each frame grabber has its own pel pool. The default size is 32 MB each.

- `c_Int32 sizePelPool();`

  Returns the current pel pool size, in bytes.

- `void sizePelPool(c_Int32 desiredSize);`

  Sets a new pel pool size, in bytes.

  Parameters

  desiredSize The new pel pool size.

  Notes

  When you set a new pel pool size, you set the size for all MVS-8600 and MVS-8600e frame grabbers.

Static Functions

count

```
static c_Int32 count();
```

Returns the number of Cognex MVS-8600 frame grabbers installed in the system.

get

```
static cc8600& get(c_Int32 i = 0);
```

Returns the **cc8600** object associated with the Cognex MVS-8600 frame grabber whose index is *i*. Index numbers begin with 0. See the introduction to this reference page for additional information.

Parameters

i The Cognex MVS-8600 board index.

Throws

ccBoard::BadParams

If *i* is not a valid index.

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8600**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occurred while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from

an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

cc8BitInputLutProp

```
#include <ch_cvl/prop.h>

class cc8BitInputLutProp;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes the 8-bit lookup table, a 256-element array. The digitizer converts each pixel into an 8-bit value. This value is used as an index into the input lookup table. The resulting value is stored in the root image. For dual-tap cameras, which use one digitizer for the even field and another for the odd field, two lookup tables are used.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

cc8BitInputLutProp

```
cc8BitInputLutProp();

explicit cc8BitInputLutProp(const c_UInt8* ilut);

explicit cc8BitInputLutProp(const c_UInt8* ilut0,
  const c_UInt8* ilut1);
```

- `cc8BitInputLutProp();`

  Creates a new input lookup table property not associated with any FIFO. Uses *cc8BitInputLutProp::default8BitInputLut* as the lookup table.

- `explicit cc8BitInputLutProp(const c_UInt8* ilut);`

  Creates a new input lookup table property not associated with any FIFO. This function uses a copy of *ilut* as the lookup table.

Parameters

ilut — An array of 256 8-bit values (**c_UInt8**) to use as the lookup table.

- `explicit cc8BitInputLutProp(const c_UInt8* ilut0, const c_UInt8* ilut1);`

Creates a new input lookup table property not associated with any FIFO. This function uses a copy of *ilut0* as the lookup table for the fist (even) digitizer and *ilut1* as the lookup table for the second (odd) digitizer.

Parameters

ilut0 — An array of 256 8-bit values (**c_UInt8**) to use as the lookup table for the first (even) digitizer.

ilut1 — An array of 256 8-bit values (**c_UInt8**) to use as the lookup table for the second (odd) digitizer.

Enumerations

LutChannel

```
enum LutChannel;
```

This enumeration lets you specify the digitizer that an input lookup table refers to.

Value	Meaning
eOnly	The input lookup table is the only lookup table and applies to all digitizers.
eEven	The input lookup table applies to the digitizer for the even field. For single-tap cameras, *eEven* is the same as *eOnly*.
eOdd	The input lookup table applies to the digitizer for the odd field.

Public Member Functions

inputLut

```
void inputLut(const c_UInt8* ilut);
void inputLut(const c_UInt8* ilut, LutChannel lutCh);
const c_UInt8* inputLut(LutChannel lut=eOnly) const;
```

- `void inputLut(const c_UInt8* ilut);`

Sets the 8-bit input lookup table to a copy of *ilut*.

Parameters

ilut An array of 256 8-bit values (**c_UInt8**) to use as the lookup table.

- `void inputLut(const c_UInt8* ilut, LutChannel lutCh);`

  Sets the 8-bit lookup table for the specified digitizer to a copy of *ilut*.

  Parameters

  ilut An array of 256 8-bit values (**c_UInt8**) to use as the lookup table.

  lutCh The digitizer to which *ilut* applies. Must be one of:

  cc8BitInputLutProp::eOnly
  cc8BitInputLutProp::eEven
  cc8BitInputLutProp::eOdd

- `const c_UInt8* inputLut(LutChannel lut=eOnly) const;`

  Returns the 8-bit input lookup table for the specified digitizer.

Constants

default8BitInputLut

`static const c_UInt8 default8BitInputLut[256];`

The default input lookup table is a positive linear mapping in the range 15 to 240. Values below 15 are mapped to 15; values above 240 are mapped to 240.

positive8BitLut `static const c_UInt8 positive8BitLut[256];`

This table is a positive linear mapping from 0 to 255.

shifted8BitLut `static const c_UInt8 shifted8BitLut[256];`

This table is a positive linear mapping with values in the range 0 to 225 shifted to 15 to 240. Values in the range 226 to 255 are clamped to 240. Use this LUT instead of the **default8BitInputLut** when you are using an 8-bit desktop for display and you want to preserve as much information as possible in the low end of the pixel values.

cc8BitInputLutProp

ccAcqFailure

```
#include <ch_cvl/acqfail.h>

class ccAcqFailure;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class returns information about why an acquisition failed.

Constructors/Destructors

ccAcqFailure

```
ccAcqFailure();
~ccAcqFailure();
```

- `ccAcqFailure();`

  Creates an instance of this class. The initial state of this class is successful (no failures).

- `~ccAcqFailure();`

  Destructor.

Operators

bool

```
operator bool();
```

Casting this class to **bool** returns true if the acquisition failed or false otherwise.

Public Member Functions

isMissed

```
bool isMissed();

void isMissed(bool missedState);
```

- `bool isMissed() const;`

  Returns true if the acquisition failed because of a missed trigger. Otherwise returns false. A missed trigger is a hardware trigger which failed to cause an acquisition to occur.

  In general, this failure is an indication that triggers are occurring faster than the acquisition system can process them.

  If you try to start an acquisition on a **ccAcqFifo** object that already has the maximum number of outstanding acquisitions, (*ccAcqFifo::kMaxOutstanding*) the acquisition will fail. When you eventually try to complete the acquisition, the resulting **ccAcqFailure** will be **isMissed()**.

  In semi-trigger mode, you must call **ccAcqFifo::start()** for each acquire. If a trigger occurs and start was not called, the trigger will cause an **isMissed()** error.

  Notes

  On a CVM4 (Cognex CVC-1000 camera), **ccAcqFailure** may report either **isOverrun()** or **isMissed()**.

  If a master FIFO fails because of **isMissed()**, its slaves never receive notification of the missed trigger. To the slave FIFOs, it is as if the triggers never occurred.

- `void isMissed(bool missedState);`

  Sets the missed state of the acquisition.

  Parameters

  missedState The new missed state.

isOverrun

```
bool isOverrun() const;
void isOverrun(bool overrun);
```

- `bool isOverrun() const;`

  Returns true if the acquisition failed because a trigger was received, but an image could not be acquired. Otherwise returns false.

  This error occurs when a trigger caused image integration by the camera, but the image could not be acquired from the camera. Generally, **isOverrun()** errors occur when triggers are arriving too frequently.

  If a master FIFO fails because of an **isOverrun()** condition, the slave FIFOs may successfully complete their acquisitions.

  Notes

  This function always returns false on a Cognex MVS-8120 with CVM1 or CVM6.

  On a CVM4 (Cognex CVC-1000 camera), **ccAcqFailure** may report either **isOverrun()** or **isMissed()**.

- `void isOverrun(bool overrun);`

  Sets the overrun property of the acquisition.

  Parameters

  overrun The overrun state.

isAbnormal

```
bool isAbnormal();
void isAbnormal(bool abnormalState);
```

- `bool isAbnormal();]`

  Returns true if the acquisition failed because a trigger was received, but an image could not be acquired. Otherwise returns false.

  This error occurs when a trigger caused image integration by the camera, but the image could not be acquired from the camera. Generally, **isAbnormal()** errors are caused by factors unrelated to trigger rate, such as PCI bus saturation, blown camera fuse, overheating, and so on. If you are experiencing **isAbnormal()** errors, consult the release notes and hardware-specific documentation to determine the possible causes of the errors.

  For the 8100L, **isAbnormal()** can return true if the camera is not connected, or if the hardware is dropping pixel data because of excessive PCI bus latencies.

Notes

This failure should never happen in a properly functioning system. Some examples of abnormal failures are a blown camera fuse or a temperature alert that indicates that the frame grabber is overheating.

- `void isAbnormal(bool abnormalState);`

Sets the abnormal state of the acquisition.

Parameters

abnormalState The new abnormal state.

isIncomplete

```
bool isIncomplete() const;
void isIncomplete(bool incompleteState);
```

- `bool isIncomplete() const;`

Returns true if the acquisition failed because the **ccAcqFifo::baseComplete()** *maxWait* interval expired before the acquisition entered the complete state (**ccAcqFifo::isComplete()** returns true).

Notes

Although using *maxWait* as a timeout timer is one possible design choice, the preferred approach is to leave *maxWait* set to the default (HUGE_VAL) and the use **ccAcqFifo::isComplete()** to determine when an acquisition is completed. This will avoid **isIncomplete()** errors entirely.

- `void isIncomplete(bool incompleteState);`

Sets the incomplete state of the acquisition.

Parameters

incompleteState The new incomplete state.

isTooFastEncoder

```
bool isTooFastEncoder() const;
void isTooFastEncoder(bool tooFastState);
```

- `bool isTooFastEncoder() const;`

  Returns true if the acquisition failed because of a line overrun situation. This situation is the result of one or more of the following conditions:

  - The line rate being dictated by the position counter is exceeding the output line rate of the camera.
  - The value given to **ccEncoderProp::stepsPerLine()** is too small given the rate at which the position counter increments or decrements/.
  - The value given to **ccExposureProp::exposure()** maps to a line exposure interval that exceeds the length of a line as specified by the position counter and **ccEncoderProp::stepsPerLine()**. This condition applies only when using cameras that support a variable line exposure interval.

  Notes

  This error occurs only with line scan cameras.

- `void isTooFastEncoder(bool tooFastState);`

  Sets the “too fast” state of the acquisition.

  Parameters

  tooFastState The new “too fast” state.

isInvalidRoi

```
bool isInvalidRoi() const;
void isInvalidRoi(bool invalid);
```

`bool isInvalidRoi() const;`

Returns true if an acquisition could not be performed because the region of interest property was invalid (see **ccRoiProp** on page 2763). Typically, a region of interest that is too large will generate this error.

Notes

Some cameras, such as line scan cameras, are implemented with a direct relationship between the ROI property and the image acquired. In these cases, it is possible to specify a ROI outside of the physical bounds of the camera and frame grabber combination.

```
void isInvalidRoi(bool invalid);
```

Sets the invalid region of interest property of the acquisition.

Parameters

invalid The invalid state.

abnormalErrorCode

```
c_Int32 abnormalErrorCode() const;
void abnormalErrorCode(c_Int32);
```

For Cognex use only. In some circumstances, technical support may ask you to use this function to gather more data to help them locate the problem.

- `c_Int32 abnormalErrorCode() const;`

  Returns error information specific to a particular hardware platform thrown by acquisition hardware because of some unusual condition.

- `void abnormalErrorCode(c_Int32);`

  Sets an abnormal error code.

  Parameters

  c_Int32 The error code.

isTimingError

```
bool isTimingError() const;
void isTimingError(bool flag);
```

- `bool isTimingError() const;`

  Returns true if there is a grievous video timing error that prevented the acquisition from occurring. This is commonly caused by attempting to acquire when the camera is not plugged in, or when the video format is not appropriate for the camera.

Notes

This error will occur only for mismatches that prevent the acquire hardware from working at all. Other mismatches may cause corrupted images but not this error.

- `void isTimingError(bool);`

  Sets the timing error flag.

  Parameters

  flag The timing error flag.

Deprecated Members

isOtherFifoError

```
bool isOtherFifoError() const;
void isOtherFifoError(bool error);
```

This function has been deprecated and is maintained for backward compatibility only. It should not be used in new applications.

- `bool isOtherFifoError() const;`

  Returns true if the acquisition failed because of a failure on a master or slave acquisition FIFO.

- `void isOtherFifoError(bool error);`

  Sets the other error property of the acquisition.

  Parameters

  error The error state.

isTimeout

```
bool isTimeout();
void isTimeout(bool timeoutState);
```

This function has been deprecated and is maintained for backward compatibility only. It should not be used in new applications.

- `bool isTimeout();`

  Returns true if the acquisition failed because the timeout period elapsed before the acquisition system was able to obtain the required resources. Returns false otherwise. Timeout errors can occur when the required hardware is being used by another FIFO.

  Notes

  This error is never returned in combination with **isMissed()** or **isOverrun()**.

- `void isTimeout(bool timeoutState);`

  Sets the timeout state of the acquisition.

  Parameters

  timeoutState The new timeout state.

ccAcqFifo

```
#include <ch_cvl/acqbase.h>

class ccAcqFifo : public virtual ccRepBase;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

You create **ccAcqFifo** objects by calling **ccStdVideoFormat::newAcqFifoEx()** which returns various instantiations derived from this class. You use **ccAcqFifo** methods to acquire images for all concrete fifo types.

Notes

Using **ccAcqFifo::complete()** in derived classes to handle acquired images is now replaced by **ccAcqFifo::completeAcq()**. The older method is retained for backward compatibility, but you should use **ccAcqFifo::completeAcq()** for all new code.

Constructors/Destructors

ccAcqFifo

```
virtual ~ccAcqFifo();

ccAcqFifo(ccAcqFifo&);
```

- `virtual ~ccAcqFifo();`

  Destroys the FIFO and cancels all outstanding acquisitions on it.

- `ccAcqFifo(ccAcqFifo&);`

  Copy constructor.

Enumerations

ceStartReqStatus

```
enum ceStartReqStatus;
```

These constants provide additional information about the state of an acquisition request after a call to **baseComplete()** or **complete()** in the derived classes.

Value	Meaning
ckStartReqWasServiced	• A new call to **start()** is needed to get the next image. • The returned *appTag* is valid. • The **complete()** call is in sync with the other FIFOs of the master-slave sequence.
ckStartReqNotServiced	• A new call to **start()** is not needed to get the next image. • The returned *appTag* is not valid. • The **complete()** call is out of sync with the other FIFOs of the master-slave sequence.

enum

```
enum {kMaxOutstanding = 32};
```

The maximum number of outstanding acquisitions supported per FIFO. Attempting to have more than this number of acquisitions outstanding at one time causes either **start()** to return false (if the trigger model specifies *ckRequestAcquireOrFail* as its **startAction()**) or a *ccAcqFailure::isMissed* failure otherwise.

Public Member Functions

start

```
bool start(c_UInt32 appTag = 0);
```

Requests that an acquisition be started as soon as possible. The request is added to the FIFO of outstanding acquisitions. A copy of the current property values is stored with the request, so that subsequent changes to this FIFO's properties have no effect on the outstanding acquisitions.

Returns true to indicate the start request was successful. A return of false means the resources were not available and the requested acquisition will not take place.

appTag is an arbitrary value supplied by the application for identifying this acquisition request. The value is returned by the matching **complete()** or **baseComplete()** invocation. The value is not interpreted by **ccAcqFifo**. Typically, the *appTag* is used to facilitate FIFO order integrity verification.

Parameters

appTag — An application defined value that identifies this acquisition request.

Notes

The exact behavior of **start()** is controlled by **ccTriggerModel::startAction()**. See **ceStartAction** on page 3148.

See **prepare()** for a description of what it means to start an acquisition "as soon as possible."

triggerEnabled() must be true for acquisitions to proceed.

Throws

ccAcqFifo::StartNotAllowed

The selected trigger model does not allow **start()** to be invoked. See **ceStartAction** on page 3148.

baseComplete

```
cc_PelBuffer* baseComplete (
  const ccAcqFifo::CompleteArgs& args);

cc_PelBuffer* baseComplete (
  ccAcqFailure* failure=0,
  c_UInt32* appTag = 0,
  bool makeLocal = true,
  double maxWait = HUGE_VAL,
  bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Notes

Using **baseComplete()** or **complete()** in derived classes to handle acquired images is now replaced by **ccAcqFifo::completeAcq()**. The older method is retained for backward compatibility, but you should use **ccAcqFifo::completeAcq()** for all new code.

Classes derived from this class override this function to return a more specific **ccPelBuffer<P>** type. Derived classes typically also supply a function, **complete()**, which is similar to **baseComplete()** but which returns a **ccPelBuffer** object rather than a pointer to one.

The returned pel buffer is a window onto the valid pixels of a pelroot. The underlying pelroot may be larger than this window. For example, the width of the underlying pelroot is often larger to accommodate DMA transfer alignment restrictions imposed by each frame grabber. In this case, the returned pel buffer is a window onto the valid pixels, and the underlying pelroot is larger and contains invalid pixel data. Avoid resizing or repositioning the pel buffer to include the invalid pixel data, since there is no guarantee on the contents of this memory.

The first **baseComplete()** overload takes a **ccAcqFifo::CompleteArgs** object to specify its parameters. Using **CompleteArgs** allows you to specify any parameter in any order without having to specify the preceding parameters. For more information on the **baseComplete()** parameters see **CompleteArgs** on page 3881.

Using the second **baseComplete()** overload you specify individual parameters as call arguments. This syntax has the following limitations, compared to the first overload:

1. Arguments must be specified in the given order, even when not making use of a particular argument. For example, if you wish only to change the *maxWait* timeout value, you must also specify the three preceding parameters.
2. You cannot specify the use of a **ccAcquireInfo** object to contain the results of the image acquisition. The **ccAcquireInfo::triggerNum()** feature does not have an analogous argument in the old form, and thus cannot be used with the old form.

The recommended way to examine or test the results of an image acquisition is to specify a **ccAcquireInfo** object to contain the results. This object is specified as a **CompleteArgs** parameter, as shown in the second example on page 222. For more information on **ccAcquireInfo** objects, see **ccAcquireInfo** on page 261.

- ```
  cc_PelBuffer* baseComplete (
    const ccAcqFifo::CompleteArgs& args);
  ```

  Specify parameters in a **CompleteArgs** object. See **CompleteArgs** on page 3881.

  Returns the image of the oldest completed outstanding image acquisition in the FIFO, and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one.

  Returns null if the acquisition failed or if the **ccAcqFifo::CompleteArgs().maxWait()** period has elapsed. In this case, the **ccAcquireInfo** object you specified with **ccAcqFifo::CompleteArgs** contains the reason the acquisition failed.

  Parameters

  args A completion arguments object.

  Throws

  ccPel::BadWindow

  You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.
  ```

Example

This code fragment gets an image from an outstanding acquisition:

```
auto_ptr<cc_PelBuffer> pb(fifo->baseComplete());
if (pb.get())
  processImage(*pb);
```

This code fragment determines how the acquisition failed:

```
ccAcquireInfo info;
ccPtrHandle<cc_PelBuffer> pb = fifo->baseComplete
  (ccAcqFifo::CompleteArgs().acquireInfo(&info));
if (pb)
  processImage(*pb);
else if (info.failure().isTimeout())
  // Clean up after the timeout
else
  // Report or log an unexpected acquisition failure
```

-
```
cc_PelBuffer* baseComplete (
  ccAcqFailure* failure=0,
  c_UInt32* appTag = 0,
  bool makeLocal = true,
  double maxWait = HUGE_VAL,
  bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Specify the parameters as arguments.

Parameters

failure	See the description of **ccAcquireInfo::**failure() on page 262.
appTag	See the description of **ccAcquireInfo::**appTag() on page 262.
makeLocal	See the description of **ccAcqFifo::CompleteArgs().makeLocal()** on page 3883.
maxWait	See the description of **ccAcqFifo::CompleteArgs().maxWait()** on page 3884.
autoStart	Deprecated parameter. See the description of **ccAcqFifo::CompleteArgs().autoStart()** on page 3885.
startReqStatus	See the description of **ccAcqFifo::CompleteArgs().startReqStatus()** on page 3884.

completeAcq

```
virtual ccAcqImagePtrh completeAcq(
  const CompleteArgs& args = CompleteArgs()) = 0;
```

Gets the image of the oldest outstanding acquisition. This call blocks if there is no outstanding completed acquisition.

The function returns the acquired image. If the acquisition failed or the *maxWait* period elapsed the image will be unbound.

Parameters

args A completion arguments object.

isValid

```
bool isValid(ccAcqProblem* problem = 0) const;
```

Returns true if the FIFO is configured properly and is able to perform an image acquisition.

Parameters

problem If this function returns false, this optional argument contains the reason that the FIFO was not configured properly.

Notes

isValid() performs a more comprehensive check of a FIFO's master/slave configuration than the **ccTriggerProp::triggerMaster()** and **ccTriggerProp::couldSlaveTo()** methods. If a master/slave configuration does not perform as expected, use **isValid()** to check whether the FIFOs are configured properly. If **isValid()** returns false, use **ccAcqProblem::hasInvalidMaster()** or **ccAcqProblem::hasInvalidSlave()** to diagnose the problem.

isIdle

```
bool isIdle() const;
```

Returns true if there are no outstanding acquisitions on the FIFO.

isWaiting

```
bool isWaiting() const;
```

Becomes true when the FIFO begins waiting for **start()**, and returns to false when hardware resources are allocated and all setup delays are finished.

isAcquiring

```
bool isAcquiring() const;
```

Returns true if the oldest outstanding acquisition is waiting for a trigger signal or is acquiring an image. For master/slave acquisitions, it becomes true only after the master and all slaves are ready for acquisition.

isMovable `bool isMovable() const;`

Returns true if the oldest outstanding acquisition has progressed to the point where the camera's field of view can be changed without affecting the acquired image. For example, for strobed and shuttered acquisitions, this means that the strobe or the shutter has been fired.

When an acquisition enters this state, the acquisition software invokes the move-part callback function that you can specify with the move-part callback property. See **ccMovePartCallbackProp** on page 1899.

isComplete `bool isComplete() const;`

Returns true if the oldest outstanding acquisition has completed, perhaps unsuccessfully. The next invocation of **baseComplete()** returns the image if the acquisition was successful or a null pointer if it was not.

When an acquisition enters this state, the acquisition software invokes the acquisition complete callback function that you can specify with the acquisition complete callback property. See **ccCompleteCallbackProp** on page 1049.

pendingAcqs `c_Int32 pendingAcqs() const;`

Returns the number of acquisitions in the *pending* state. This is the number of acquisitions requested by **start()** for which acquisition has not started. To achieve high frame rate acquisition in manual trigger mode, the FIFO must always have one or more pending acquisitions.

completedAcqs `c_Int32 completedAcqs() const;`

Returns the number of acquisitions in the *completed* state. This is the number of completed acquisitions for which the user has not called **complete()**. This is similar to **isComplete()**, except it indicates if more than one completed acquisition is available. If images are being acquired faster than they are being consumed, the number returned by **completedAcqs()** will begin increasing. If left unchecked, this will eventually result in *isMissed* or other errors. **completedAcqs()** can be used to control production line speed to maximize the inspection rate without generating errors.

availableAcqs `c_Int32 availableAcqs() const;`

Returns the number of acquisitions in the *available* state. This method returns an upper bound on the number of additional acquisitions that may be added to the FIFO before errors occur. In manual or semi-automatic trigger mode, calling **start()** decreases the

number of available acquisitions. In auto trigger mode, each trigger decreases the number of available acquisitions. In all trigger modes, calling **complete()** and releasing pel buffers increases available acquisitions.

Notes

The number returned by **availableAcqs()** is an upper bound and not a guaranteed minimum. It is intended to be used to detect resource leaks during debugging.

The sum of (pending + completed + available) is not a constant. Acquisitions in progress are neither pending nor completed.

Calling **start()** does not always decrease **availableAcqs()** by one.

Actions of other FIFOs may affect **availableAcqs()**.

pendingAcqs() and **completedAcqs()** function the same on all platforms and CVL revisions. **availableAcqs()** may behave differently between platforms and CVL revisions. For example, the way available image memory affects **availableAcqs()** can vary.

prepare

```
public: bool prepare(ccCvlString& result,
  double maxWait = 0.0);

bool prepare(double maxWait = HUGE_VAL);
```

This function prepares the video subsystem as needed for this FIFO, waiting up to *maxWait* seconds before returning. It returns true if successful and false if not successful. If **prepare()** returns false, do not attempt an acquisition with this FIFO, as it will fail and likely hang.

Calling **prepare()** does not eliminate or reduce the setup time, but allows the same setup time to occur prior to calling **start()**. This is useful if an acquisition cannot be started immediately, but you want to get the hardware ready now. If an acquisition can start

immediately, there is no performance benefit to calling **prepare()** before **start()**. In this case, the primary use of **prepare()** is to detect hardware setup problems, such as a missing camera.

For an acquisition to take place, the FIFO requires that a certain subset of the video subsystem be in the proper state. For example, a FIFO created to acquire images in RS-170 640x480 format, requires that the video subsystem switch to RS-170 640x480 timing. If the video subsystem section selected by this FIFO is already in this state, the FIFO is considered prepared, and acquisitions can begin immediately.

If the FIFO is not prepared when an acquisition starts, the acquisition software starts preparing the video subsystem automatically and blocks all subsequent acquisitions for that FIFO until the FIFO is prepared or until the timeout limit is reached. Be aware that certain state transitions of the video subsystem take a significant amount of time (up to hundreds of milliseconds) to complete.

The **prepare()** and **isPrepared()** functions let you make sure that an acquisition can start immediately.

Notes

isPrepared() is deprecated..

In a typical application, the acquisition FIFOs are always prepared and all acquisitions start immediately, so most applications do not need to use the **prepare()** function.

Parameters

maxWait	The number of seconds to wait until the video subsystem is prepared before returning. The value *HUGE_VAL* (defined in *<math.h>)* indicates that the system should wait indefinitely. The FIFO should be idle before calling **prepare()**. If it is not idle (starts are queued, or you are in auto trigger mode with triggers enabled), **prepare()** will assume the hardware is already prepared and will return true immediately. When the FIFO is idle there should be no wait, so Cognex recommends you always set *maxWait* to 0.
result	Additional information about what happened during the prepare.

Notes

On most platforms, *maxWait* has a granularity between 1 millisecond and 1 microsecond.

If **ccTriggerProp::triggerEnable()** is false and **start()** calls are queued, **prepare()** will return immediately without preparing the FIFO. If you use **prepare()** you should call **prepare()** and then **start()**, not the reverse.

Calling **prepare()** on a master or slave FIFO prepares all the associated master and slave FIFOs. You could prepare each master and slave FIFO individually, but that would be redundant.

You do not need to call **prepare()** when using automatic triggering. The acquisition software performs hardware preparation for you when **triggerEnable()** is true.

Additional information about what happened during the prepare is available via the result string.

flush

```
void flush();
```

Discards all outstanding acquisitions, leaving this FIFO in the idle state. If an acquisition is in progress, it is cancelled and discarded. If **ccTriggerProp::triggerEnable()** is true, this function disables triggers before discarding all acquisitions, then re-enables triggers.

properties

```
virtual ccAcqProps& properties()= 0;
```

Returns a reference to the FIFO's properties object.

Notes

The reference that this function returns is not **const** so that you can invoke appropriate **ccAcqProps** member functions to set individual properties. Derived classes typically override this function to return a more specific type derived from **ccAcqProps**.

propertyQuery

```
ccAcqPropertyQuery& propertyQuery();
```

Returns a property query object that you can use to test whether the FIFO supports a particular property. If the property is supported, this function returns a valid property object. The returned object may be used to set property values. Both pointer and reference semantics are supported.

Example

To set the timeout property only if this FIFO supports it, you would write:

```
ccTimeoutProp* timeoutProp = fifo->propertyQuery();
if (timeoutProp)
  timeoutProp->timeout(10.0);
```

Or, using reference semantics, you would write:

```
try
{
  ccTimeoutProp& timeoutProp = fifo->propertyQuery();
  timeoutProp.strobeEnable(true);
}
catch (cmStd bad_cast&)
{
  // The timeout property is not supported.
}
```

---

triggerModel

```
void triggerModel(const ccTriggerModel& model);

void triggerModel(ccTriggerModelPtrh model);

const ccTriggerModel& triggerModel() const;
```

- `void triggerModel(const ccTriggerModel& model);`

  Sets the trigger model for the current FIFO. The default model is **cfManualTrigger()**. See **ccTriggerModel** on page 3145.

  Parameters

  model — A trigger model object, usually created with one of the global functions **cfManualTrigger()**, **cfAutoTrigger()**, **cfSemiTrigger()**, or **cfSlaveTrigger()**.

- `void triggerModel(ccTriggerModelPtrh model);`

  Sets the trigger model for the current FIFO. Cognex recommends that custom trigger models be set using the **ccTriggerModelPtrh** overload. Built-in trigger models (such as **cfManualTrigger**) can only be set using the **ccTriggerModel&** overload.

  Parameters

  model — The name of your custom trigger model object.

- `const ccTriggerModel& triggerModel() const;`

  Returns the currently set trigger model for this FIFO.

  See also **cfManualTrigger()** on page 3733, **cfAutoTrigger()** on page 3533, **cfSemiTrigger()** on page 3853, and **cfSlaveTrigger()** on page 3861.

triggerEnable

```
void triggerEnable(bool enable);

bool triggerEnable() const;
```

- `void triggerEnable(bool enable);`

  Enables or disables triggers. The default is true.

  Invoking **triggerEnable()** for a master camera channel or any of its slaves has the effect of invoking **triggerEnable()** for all. That is, masters and slaves have the same **triggerEnable()** setting.

  Parameters

  enable — In general, true allows acquisitions to happen and false prevents acquisitions from happening, depending on the current trigger model and its state. For more information on each trigger model, see **cfManualTrigger()** on page 3733, **cfAutoTrigger()** on page 3533, **cfSemiTrigger()** on page 3853, and **cfSlaveTrigger()** on page 3861.

- `bool triggerEnable() const;`

  Returns true if triggers are enabled, false otherwise.

movePartInfoCallback

```
void movePartInfoCallback(const ccCallbackAcqInfoPtrh&);
const ccCallbackAcqInfoPtrh& movePartInfoCallback() const;
```

- `void movePartInfoCallback(const ccCallbackAcqInfoPtrh&);`

This function is one of two ways to register a callback class for the movable state:

Method	Features	See
ccAcqFifo:: movePartInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	this section
ccMovePartCallbackProp	Calls your callback function.	*ccMovePartCallbackProp* on page 1899

This function effectively registers a callback function that you want the acquisition engine to call when the acquisition enters the movable state (that is, when **ccAcqFifo::isMovable()** returns true). The movable state is when the camera's field of view can be changed without affecting the acquired image.

An unbound handle means no callback will occur.

This function actually registers, not a function, but a callback class you define. Your callback class contains your callback function, defined as an override of **operator()()** of that class.

A **ccCallbackAcqInfo** class is a special case of a **ccCallback1** class in which an instance of **ccAcquireInfo** is passed as an argument. This allows your callback function to use the information about the current state of the acquisition stored in the **ccAcquireInfo** object.

The callback function you write should set flags or semaphores in your application that allow your program to proceed to another state the next time it executes. Your callback function is executed internally by the acquisition engine, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

In general, an acquisition enters the movable state during the acquisition's next-to-last vertical blank interval. With an RS-170 camera, for example, an acquisition would enter the movable state 17 ms (one field time) before it enters the complete state.

Not all frame grabbers can detect the next-to-last vertical blank interval. When using one of these frame grabbers, the acquisition enters the movable and complete states at the same time. In such cases, the move-part callback is always invoked first, followed immediately by the completion callback.

On the MVS-8100M, MVS-8100C, and MVS-8100C/CPCI (but not the MVS-8100M+ when using CCF-based video formats), you can select between default and optimum timing of the move-part callback function's execution. See **cc8100m::movePartTimingChoice** on page 210.

For a further discussion, see *Using Callback Functions* in the *Acquiring Images* chapter of the *CVL User's Guide.*

Parameters

ccCallbackAcqInfoPtrh

Pointer handle referencing an instance of a callback class you've defined, that contains the callback function you have defined as an override of **operator()()** for that class.

- `const ccCallbackAcqInfoPtrh& movePartInfoCallback() const;`

  Returns a pointer handle to the registered callback class instance for this acquisition.

completeInfoCallback

```
void completeInfoCallback(const ccCallbackAcqInfoPtrh&);
const ccCallbackAcqInfoPtrh& completeInfoCallback() const;
```

- `void completeInfoCallback(const ccCallbackAcqInfoPtrh&);`

This function is one of two ways to register a callback class for the complete state:

Method	Features	See
ccAcqFifo:: completeInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	this section
ccCompleteCallbackProp	Calls your callback function.	*ccCompleteCallbackProp* on page 1049

This function effectively registers a callback function that you want the acquisition engine to call when the image acquisition is complete. An acquisition enters the complete state (**ccAcqFifo::isComplete()** returns true) when the next invocation of **ccAcqFifo::baseComplete()** would return the acquired image (if the acquisition was successful) or null (if the acquisition was not successful).

An unbound handle means no callback will occur.

This function actually registers, not a function, but a callback class you define. Your callback class contains your callback function, defined as an override of **operator()()** of that class.

A **ccCallbackAcqInfo** class is a special case of a **ccCallback1** class in which an instance of **ccAcquireInfo** is passed as an argument. This allows your callback function to use the information about the current state of the acquisition stored in the **ccAcquireInfo** object.

The callback function you write should set flags or semaphores in your application that allow your program to proceed to another state the next time it executes. Your callback function is executed internally by the acquisition engine, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

For a further discussion, see *Using Callback Functions* in the *Acquiring Images* chapter of the *CVL User's Guide.*

Parameters

ccCallbackAcqInfoPtrh

Pointer handle referencing an instance of a callback class you've defined, that contains the callback function you have defined as an override of **operator()()** for that class.

- `const ccCallbackAcqInfoPtrh& completeInfoCallback() const;`

  Returns a pointer handle to the registered callback class instance for this acquisition.

overrunInfoCallback

```
void overrunInfoCallback(const ccCallbackAcqInfoPtrh&);
const ccCallbackAcqInfoPtrh& overrunInfoCallback() const;
```

- `void overrunInfoCallback(const ccCallbackAcqInfoPtrh&);`

This function is one of two ways to register a callback class for the overrun state:

Method	Features	See
ccAcqFifo:: overrunInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	this section
ccOverrunCallbackProp	Calls your callback function.	*ccOverrunCallbackProp* on page 2345

This function effectively registers a callback function that you want the acquisition engine to call if an overrun occurs. Generally, overrun errors and **isMissed()** errors occur when triggers occur too fast. See **ccAcqFailure::isOverrun()** and **ccAcqFailure::isMissed()** for more information about the overrun state.

An unbound handle means no callback will occur.

This function actually registers, not a function, but a callback class you define. Your callback class contains your callback function, defined as an override of **operator()()** of that class.

A **ccCallbackAcqInfo** class is a special case of a **ccCallback1** class in which an instance of **ccAcquireInfo** is passed as an argument. This allows your callback function to use the information about the current state of the acquisition stored in the **ccAcquireInfo** object.

The callback function you write should set flags or semaphores in your application that allow your program to handle the overrun condition the next time it executes. Your callback function is executed internally by the acquisition engine, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

For a further discussion, see *Using Callback Functions* in the *Acquiring Images* chapter of the *CVL User's Guide*.

Parameters

ccCallbackAcqInfoPtrh

Pointer handle referencing an instance of a callback class you've defined, that contains the callback function you have defined as an override of **operator()()** for that class.

- `const ccCallbackAcqInfoPtrh& overrunInfoCallback() const;`

  Returns a pointer handle to the registered callback class instance for this acquisition.

videoFormat

```
virtual const ccVideoFormat& videoFormat() const = 0;
```

Returns the video format for which this FIFO was constructed.

frameGrabber

```
virtual ccFrameGrabber& frameGrabber() const = 0;
```

Returns the frame grabber for which this FIFO was constructed.

hardwareImagePoolSize

```
c_Int32 hardwareImagePoolSize() const;
void hardwareImagePoolSize(c_Int32 numberOfImages);
```

- `c_Int32 hardwareImagePoolSize() const;`

  Returns the size of the MVS-8600 hardware image pool in number of images.

- `void hardwareImagePoolSize(c_Int32 numberOfImages);`

  Sets the size, in number of images, of the MVS-8600 hardware image pool used the by the acquisition FIFO. A larger image pool size reduces the likelihood of acquisition errors due to system latency or high CPU load. A smaller pool size conserves memory.

  For area scan cameras the amount of memory, in bytes, used for the image pool is:

  videoFormatWidth * videoFormatHeight * bytesPerPixel * numberOfImages.

  For line scan cameras the amount of memory in bytes is:

  videoFormatWidth * imageROIHeight * bytesPerPixel * numberOfImages.

  In most cases, a minimum pool size of 4 images is recommended. In the case of images larger than 32MB, a pool size of 2 or 3 images may be used to conserve memory if the acquisition rate allows..

Parameters

numberOfImages

The number of images to allocate in the hardware pool. The lowest number allowed is 2 images. Specifying zero sets the number of images to **defaultHardwareImagePoolSize()**.

Notes

This function applies only to the MVS-8600 and MVS-8600e frame grabbers.

If there isn't enough memory available to create an image pool of the given size, **prepare()** returns False, **completeAcq()** fails, and **isAbnormal()** is True with error code 2. In this case, try reducing the pool size. If the pool is exhausted at runtime, **completeAcq()** fails, and **isAbnormal()** is True with error code 7. In this case, try increasing the pool size.

Throws

ccAcqFifo::BadParams

numberOfImages is 1 or less than zero,.

defaultHardwareImagePoolSize

```
c_Int32 defaultHardwareImagePoolSize() const;
```

Returns the default number of images available in the MVS-8600 image pool. For line scan acquisition default the number of images depends on the image height which you can adjust with the region of interest (ROI) setting.

Notes

This function applies only to the MVS-8600 and MVS-8600e frame grabbers.

Deprecated Members

isPrepared

```
bool isPrepared() const;
```

Returns true if the resources that the FIFO needs to perform an acquisition are ready. If **isPrepared()** returns true, an acquisition request begins immediately.

This function is deprecated in CVL 6.2 cr10.

Friends

ccDirectDrawSurfacePool
```
friend class ccDirectDrawSurfacePool;
```

cc_FGDisplay
```
friend class cc_FGDisplay;
```

Typedefs

ccAcqFifoPtrh
```
typedef ccPtrHandle<ccAcqFifo> ccAcqFifoPtrh;
```

ccAcqFifoPtrh_const
```
typedef ccPtrHandle_const<ccAcqFifo> ccAcqFifoPtrh_const;
```

ccAcqImage

```
#include <acqimage.h>

class ccAcqImage : public virtual ccRepBase
```

Class Properties

Copyable	No
Derivable	Not Intended
Archiveable	Yes

ccAcqImage holds the information for an acquired image. A **ccAcqImage** object containing the acquired image is returned when you call **ccAcqFifo::completeAcq()**.

This class contains the public member functions you can call to convert the acquired image into various formats. If the requested format is different from the acquired image format, the acquired image is converted to the requested format and the new image is returned. The acquired image is unchanged.

If the requested format is the same as the acquired format, the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

When there is an acquisition error, the returned **ccAcqImage** object will be unbound. In this case, calling any of the conversion routines will also result in unbound images. Check whether an image is bound before making conversion calls.

Note Image format conversions are done completely in software and can have a significant impact on system performance. For a one megapixel image, the conversion can take over 100 milliseconds on a 1 GHz processor.

The **ceImageFormat** enum on page 240 lists the possible acquired image formats. All acquired image formats with the exception of *ceImageFormat_Bayer16* can be converted into formats acceptable to CVL by calling conversion routines in this class.

Constructors/Destructors

ccAcqImage

```
ccAcqImage() {}

ccAcqImage(
  const ccPelBuffer<c_UInt8>& buf,
  ceImageFormat formatAcquired);

ccAcqImage(const ccPelBuffer<ccPackedRGB16Pel>& buf);

ccAcqImage(const ccPelBuffer<ccPackedRGB32Pel>& buf);

ccAcqImage(const cc3PlanePelBuffer& buf);

~ccAcqImage() {}
```

Notes

Since **ccAcqImage** objects are returned to you when you call **ccAcqFifo::completeAcq()** there is no need for you to create **ccAcqImage** objects in your program.

Enumerations

ceImageFormat

```
enum ceImageFormat;
```

These values specify all of the possible acquired image formats.

Value	Format	Bit Depth
ceImageFormat_Grey8	Monochrome	8 bits/pixel
ceImageFormat_Grey10	Monochrome	10 bits/pixel
ceImageFormat_Grey12	Monochrome	12 bits/pixel
ceImageFormat_Grey16	Monochrome	16 bits/pixel
ceImageFormat_PackedRGB16	[R,G,B]=[5,6,5]	16 bits/pixel
ceImageFormat_PackedRGB32	[a,R,G,B]=[8,8,8,8]	32 bits/pixel
ceImageFormat_Bayer8	Bayer8	8 bits/pixel
ceImageFormat_Bayer16	Bayer16	16 bits/pixel
ceImageFormat_UYYVYY	YUV 4:1:1	12 bits/pixel (average)
ceImageFormat_UYVY	YUV 4:2:2	16 bits/pixel (average)

Value	Format	Bit Depth
ceImageFormat_UYV	YUV 4:4:4	24 bits/pixel
ceImageFormat_PackedRGB24	[R,G,B]=[8,8,8]	24 bits/pixel
ceImageFormat_PackedRGB48	[R,G,B]=[16,16,16]	48 bits/pixel
ceImageFormat_PlanarRGB8	R=G=B=8 bits	8 bits/pixel * 3
ceImageFormat_PackedBGR24	[B,G,R]=[8,8,8]	24 bits/pixel
ceImageFormat_Grey16BigEndian	Monochrome	16 bits/pixel
ceImageFormat_Grey14	Monochrome	14 bits/pixel
ceImageFormat_Grey10_Packed	Monochrome	10 bits/pixel (2 pixels/3 bytes)
ceImageFormat_Grey12_Packed	Monochrome	14 bits/pixel (2 pixels/3 bytes)
ceImageFormat_Grey8_2Byte	Monochrome	14 bits/pixel(1pixel/2 bytes)
ceImageFormat_Unknown	Unknown video format	

Public Member Functions

getGrey8PelBuffer

```
ccPelBuffer<c_UInt8> getGrey8PelBuffer();
```

Return the acquired image in *ceImageFormat_Grey8* format. If the acquired image format is not *ceImageFormat_Grey8* the acquired image is converted to *ceImageFormat_Grey8* and the new image is returned. The acquired image is unchanged.

If the acquired image format is *ceImageFormat_Grey8,* the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

Throws

ccAcqImage::NotSupported

The conversion of the acquired image format to *ceImageFormat_Grey8* is not supported.

getGrey16PelBuffer

```
ccPelBuffer<c_UInt16> getGrey16PelBuffer();
```

Return the acquired image in *ceImageFormat_Grey16* format. If the acquired image format is not *ceImageFormat_Grey16* the acquired image is converted to *ceImageFormat_Grey16* and the new image is returned. The acquired image is unchanged.

If the acquired image format is *ceImageFormat_Grey16,* the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

Throws

ccAcqImage::NotSupported
The conversion of the acquired image format to *ceImageFormat_Grey16* is not supported.

getPackedRGB16PelBuffer

```
ccPelBuffer<ccPackedRGB16Pel> getPackedRGB16PelBuffer();
```

Return the acquired image in *ceImageFormat_PackedRGB16* format. If the acquired image format is not *ceImageFormat_PackedRGB16* the acquired image is converted to *ceImageFormat_PackedRGB16* and the new image is returned. The acquired image is unchanged.

If the acquired image format is *ceImageFormat_PackedRGB16,* the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

Throws

ccAcqImage::NotSupported
The conversion of the acquired image format to *ceImageFormat_PackedRGB16* is not supported.

getPackedRGB32PelBuffer

```
ccPelBuffer<ccPackedRGB32Pel> getPackedRGB32PelBuffer();
```

Return the acquired image in *ceImageFormat_PackedRGB32* format. If the acquired image format is not *ceImageFormat_PackedRGB32* the acquired image is converted to *ceImageFormat_PackedRGB32* and the new image is returned. The acquired image is unchanged.

If the acquired image format is *ceImageFormat_PackedRGB32,* the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

Throws

ccAcqImage::NotSupported

The conversion of the acquired image format to *ceImageFormat_PackedRGB32* is not supported.

get3PlanePelBuffer

```
cc3PlanePelBuffer get3PlanePelBuffer();
```

Return the acquired image in *ceImageFormat_PlanarRGB8* format. If the acquired image format is not *ceImageFormat_PlanarRGB8* the acquired image is converted to *ceImageFormat_PlanarRGB8* and the new image is returned. The acquired image is unchanged.

If the acquired image format is *ceImageFormat_PlanarRGB8,* the acquired image is returned directly without copying. Be aware that in this case you are working with the acquired image, not a copy.

Throws

ccAcqImage::NotSupported

The conversion of the acquired image format to *ceImageFormat_PlanarRGB8* is not supported.

isBound

```
bool isBound() const;
```

Return true if the image is bound to a root image. Return false otherwise.

isConversionSupported

```
bool isConversionSupported(
  ceImageFormat formatConverted) const;
```

Return true if the *formatConverted* conversion is supported. Return false otherwise.

Parameters

formatConverted

The format to test.

isColor

```
bool isColor() const;
```

Returns true if the image was acquired using a color video format. Returns false otherwise.

width

```
c_Int32 width() const;
```

Return the width of the acquired image in pixels (if the image is bound).

height `c_Int32 height() const;`

Return the height of the acquired image in rows (if the image is bound).

alignModulus `c_Int32 alignModulus() const;`

Return the row alignment of the acquired image in bytes (if the image is bound).

rowUpdate `c_Int32 rowUpdate() const;`

Return the row update of the acquired image in bytes (if the image is bound).

formatAcquired `ceImageFormat formatAcquired() const;`

Return the format of the acquired image (if the image is bound).

intensityBits `c_Int32 intensityBits() const;`

Returns the number of bits of intensity data per pixel if the image is bound or 8 if the image is unbound.

For color images, this function indicates the number of bits per pixel per color. That is, if the image contains 8-bits each of red, green, and blue data, this function returns 8 even though the total number of data bits per pixel is 24.

Notes

For *ceImageFormat_PackedRGB16* images, this function returns 8, rather than the theoretically correct value of 5.33333...

Static Functions

isColor `static bool isColor(ceImageFormat imgfmt);`

Returns true if the supplied image format is a color image.

Typedefs

ccAcqImagePtrh `typedef ccPtrHandle<ccAcqImage> ccAcqImagePtrh;`

ccAcqProblem

```
#include <ch_cvl/acqprob.h>

class ccAcqProblem;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains member functions that help you identify why a FIFO is improperly configured. You should use these functions when **ccAcqFifo::isValid()** returns false. For more information about valid FIFOs and using **ccAcqProblem**, see the *CVL User's Guide* and the *acqprob.cpp* sample program.

Attempting to acquire from an invalid FIFO is not recommended, and can result in image corruption and may hang your program. However, this is a recommendation and is not strictly enforced.

Note that member functions in this class attempt to identify a set of common problems and may not identify every possible problem. You may encounter problems in your application that **ccAcqProblem** does not specifically identify.

Constructors/Destructors

ccAcqProblem

```
ccAcqProblem();

ccAcqProblem(const ccAcqProblem&);

virtual ~ccAcqProblem();
```

- `ccAcqProblem();`

  Default constructor.

- `ccAcqProblem(const ccAcqProblem&);`

  Copy constructor.

- `virtual ~ccAcqProblem();`

  Destructor.

Operators

bool `operator bool() cons;`

Casting this class to **bool** returns true if the acquisition is configured improperly. It returns false otherwise.

operator= `ccAcqProblem& operator=(const ccAcqProblem& prob);`

Assignment operator. Assigns the value of *prob* to this object.

Parameters

prob The value to assign.

Public Member Functions

slavePortInvalid

```
bool slavePortInvalid() const;
```

Returns true if the camera port settings are invalid. While the individual camera port settings for each FIFO may be valid, two FIFOs may be erroneously assigned to the same camera. Another possibility is that the master/slave arrangement may violate a platform-specific requirement. For example, a platform may require the slave FIFO to be on the next higher port from the master.

slaveNotSlaveTrigger

```
bool slaveNotSlaveTrigger() const;
```

Returns true if a FIFO has been assigned a trigger master but not assigned a slave trigger model.

slaveTriggerNoMaster

```
bool slaveTriggerNoMaster() const;
```

Returns true if the FIFO has a slave trigger model but has not been assigned a trigger master.

masterIsSlaveTrigger

```
bool masterIsSlaveTrigger() const;
```

Returns true if trigger master is assigned the slave trigger model. A trigger master cannot be slaved to another FIFO.

mismatchedExposures

```
bool mismatchedExposures() const;
```

Returns true if the master and slaves are using different exposure settings. The exposures for all master/slaved FIFOs must be set to identical values to ensure the cameras stay synchronized for shared strobe applications.

This problem can be ignored when using the CVC-1000 and non-strobed acquisitions.

mismatchedFormats

```
bool mismatchedFormats() const;
```

Returns true if master and slave FIFOs are using different camera formats. In most cases you application will hang when you attempt to acquire images with this condition.

It may be possible to master/slave compatible cameras, for example two different RS-170 type cameras that have identical CTIs. This can occur when individual cameras are replaced with a later model or different brand. However *any* differences in video timing will cause problems in master/slave applications.

invalidCameraPort

```
bool invalidCameraPort() const;
```

Returns true if the camera port setting is outside the range of 0 - **numCameraPort()**-1

invalidAuxLightPort

```
bool invalidAuxLightPort() const;
```

Returns true if lighting is enabled and the aux light port setting is outside the range of 0 - 4, or if it is in conflict with the camera port setting. If an acquire is attempted the aux light will not work.

tooFewPorts

```
bool tooFewPorts() const;
```

Returns true if, in a master/slave configuration, there are not enough camera ports to support the number of taps needed for all the cameras.

badSyncModel

```
bool badSyncModel() const;
```

Returns true if, in a master/slave configuration, a slave is set to an improper sync model.

Deprecated Members

The following functions are deprecated and are maintained for backward compatibility only. These functions should not be used in new applications.

hasInvalidSlave

```
bool hasInvalidSlave() const;
```

Returns true when the FIFO is invalid due to some master/slave problem. Other methods in this class provide information regarding why the master/slave setup is invalid.

This problem can occur due to limitations or constraints of the frame grabber associated with selecting master and slave **ccAcqFifo**s. Check your frame grabber-specific documentation for constraints regarding **ccAcqFifo**s. For example, check the camera port intended for master/slave acquisitions.

hasInvalidMaster

```
bool hasInvalidMaster() const;
```

Returns true when the FIFO is invalid due to some master/slave problem. Other methods in this class provide information regarding why the master/slave setup is invalid.

This problem can occur due to limitations or constraints of the frame grabber associated with selecting master and slave **ccAcqFifo**s. Check your frame grabber-specific documentation for constraints regarding **ccAcqFifo**s. For example, check the camera port intended for master/slave acquisitions.

ccAcqPropertyQuery

```
#include <ch_cvl/prop.h>

class ccAcqPropertyQuery;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class is used with **ccAcqFifo::propertyQuery()** to determine whether a FIFO supports a particular property. When cast implicitly or explicitly to any of the property classes, the resulting cast returns a pointer or a reference to the property class. If the property is not supported, it returns a null pointer, or, in the case of reference semantics, throws *std::bad_cast*.

For example, to set the timeout property only if a FIFO supports it, you would write:

```
ccContrastBrightnessProp* contrastBrightnessProp =
                                          fifo->propertyQuery();
if (contrastBrightnessProp)
    contrastBrightnessProp->contrastBrightness(0.5, 0.5);
```

Or, using reference semantics, you would write:

```
try
{
    ccContrastBrightnessProp& contrastBrightnessProp =
                                          fifo->propertyQuery();
    contrastBrightnessProp.contrastBrightness(0.5, 0.5);
}
catch (cmStd bad_cast&)
{
    // The contrast/brightness property is not supported.
}
```

The constructor and destructor for this class are protected.

Operators

All of the cast operators for the **ccAcqPropertyQuery** class are public.

The cast-to-pointer operators all return a pointer to a property object, if the FIFO supports that property. If not, they return a null pointer.

The cast-to-reference operators all return a reference to a property object, if the FIFO supports that property. If not, they throw an *std::bad_cast* exception. Table 1 lists the type-safe property cast operators and their signatures.

```

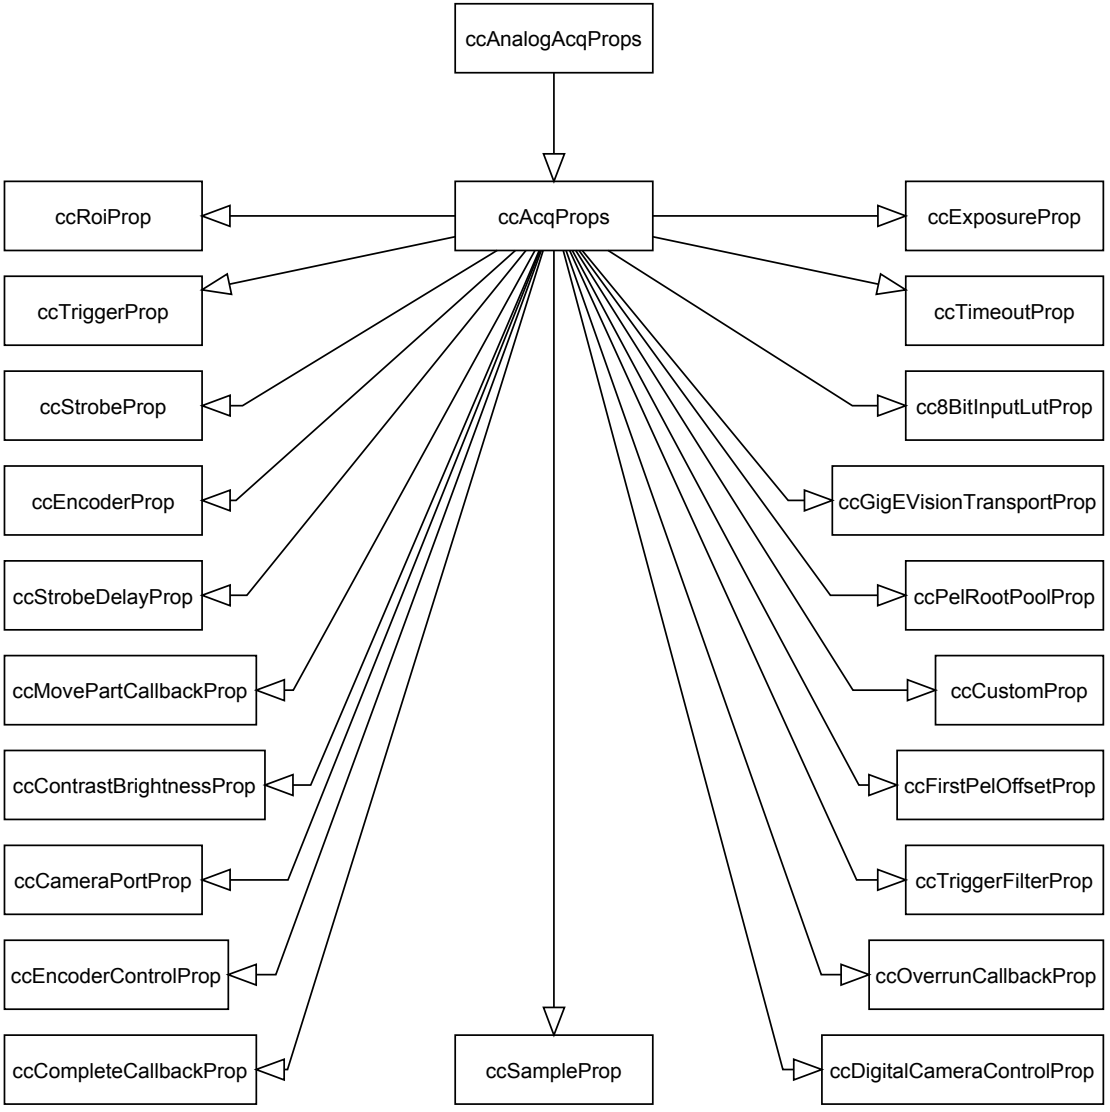
Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This is the base class for all properties that are common to all **ccAcqFifo** types.

ccAcqProps



The above figure shows the **ccAcqProps** class inheritance hierarchy.

Constructors/Destructors

ccAcqProps `ccAcqProps();`

Creates a properties object not associated with any FIFO. All values are default values.

ccAcqProps

ccAcuBarCodeCalibrationResult

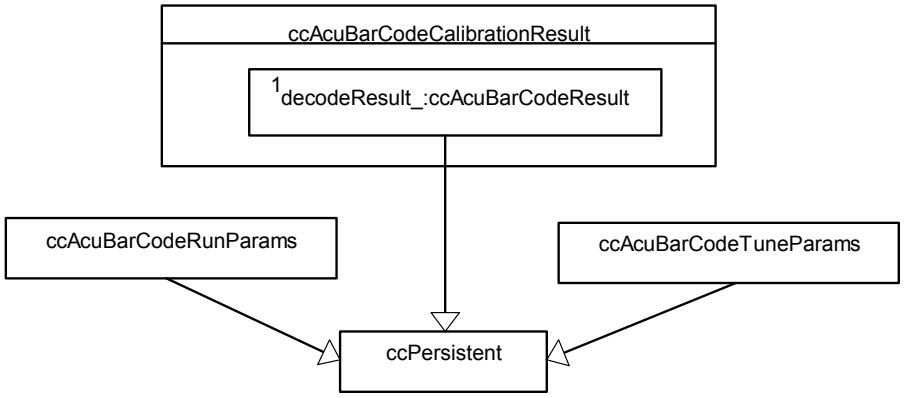
```
#include <ch_cvl/acubar.h>

class ccAcuBarCodeCalibrationResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the results of applying the calibrate operation to the Barcode tool.



Constructors/Destructors

Uses the compiler-generated default constructor, copy constructor, destructor, and assignment operator.

Public Member Functions

isCalibrated

```
bool isCalibrated() const;
```

Returns true if calibration is successful, false otherwise. Calibration is considered successful if the associated decode operation, using the calibrated barcode properties, is successful, that is if the score of the decode operation is greater than or equal to the accept threshold.

symbolType

```
ccAcuBarCodeDefs::Symbology symbolType() const;
```

Returns the type of 1D symbology found. The symbology must have been computed as a result of calibration.

resultWindow

```
ccPelRect resultWindow(bool includeQuietZone) const;
```

Returns an image-coordinate-aligned rectangle that best fits the limits of the barcode.

Parameters

includeQuietZone

If *includeQuietZone* is true, the rectangle returned includes the leading and trailing quiet zones. If *includeQuietZone* is false, the rectangle returned encloses just the barcode and does not include the leading and trailing quiet zones.

Notes

The position of the barcode is the center of this best-fit rectangle.

pitch

```
double pitch() const;
```

Returns the pitch of the barcode in pixels. The pitch of the barcode is the average spacing between consecutive bars.

stringLength

```
c_Int32 stringLength() const;
```

Returns the length of the encoded string. This includes the check character, if any. For Code128, the check character is not present in the returned string.

scanDirection

```
ccAcuBarCodeDefs::ScanDirection scanDirection() const;
```

Returns *eLeftToRight* or *eRightToLeft* to indicate the orientation of the barcode. The orientation must have been computed as a result of calibration.

clientFromImageXform

```
const cc2Xform &clientFromImageXform() const;
```

Returns the client-from-image transform required to translate image coordinates to client coordinates.

time

```
double time() const;
```

Returns the time in seconds required to compute this result.

decodeResult

```
const ccAcuBarCodeResult &decodeResult() const;
```

Returns the result of decoding the barcode using the calibrated barcode properties. The result object must have been computed as a result of calibration.

operator==

```
bool operator== (const ccAcuBarCodeCalibrationResult& that)
const;
```

Returns true if **this* equals *that*, false otherwise. Two **ccAcuBarCodeCalibrationResult** objects are considered equal if all of their corresponding data members are equal except the time. Doubles are compared using **cfRealEq()** (see ch_cvl/math.h) with 1.e-8 as the tolerance.

Parameters

that	**ccAcuBarCodeCalibrationResult** object being compared to the current one.

ccAcuBarCodeCalibrationResult

ccAcquireInfo

```
#include <ch_cvl/acqbase.h>

class ccAcquireInfo;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class stores information about an image acquisition, which can be retrieved when calling **completeAcq()** for that acquisition, or when calling a callback function.

You can examine or test the results of an image acquisition by declaring a **ccAcquireInfo** object to contain the results. You pass this object as a **ccAcqFifo::CompleteArgs** parameter to **completeAcq()** as shown in this code fragment:

```
ccAcquireInfo info;
ccAcqImagePtrh img = fifo->completeAcq
  (ccAcqFifo::CompleteArgs().acquireInfo(&info));
```

To pass a **ccAcquireInfo** object to a callback function, use the **ccAcqFifo** member function **completeInfoCallback()**, **movePartInfoCallback()**, or **overrunInfoCallback()**, as appropriate. These functions register a callback function that the acquisition engine calls at certain times. These callback functions can use member functions of the **ccAcquireInfo** instance passed to them by the acquisition engine.

Constructors/Destructors

ccAcquireInfo

```
ccAcquireInfo();
```

Default constructor, used when creating an object to supply to **completeAcq()**.

Public Member Functions

appTag

```
c_UInt32 appTag() const;
```

Returns the apptag for this acquisition, if one was specified by **ccAcqFifo::start()**.

An apptag is an arbitrary integer optionally applied to each image acquisition initiated with **ccAcqFifo::start()**. An application can assign a tag to each acquisition, and match it to the tag returned by **appTag()** on completion of the acquisition, or on invocation of a callback function.

triggerNum

```
c_UInt32 triggerNum() const;
```

Returns the FIFO's current trigger number count.

A trigger number is a monotonically increasing integer value (excepting integer wraparound) that counts the number of triggers processed by the acquisition FIFO. The trigger number count is maintained automatically by the image acquisition engine, to the best of its ability. You do not need to initialize or start the count of trigger numbers. The trigger number count starts over when the acquisition FIFO object is instantiated.

For some applications, using the trigger number provides an easier method of tracking missed triggers than using **failure().IsMissed()** errors. Tracking the trigger number is particularly useful if the trigger model is semi-automatic or custom, where **failure().IsMissed()** errors require extra calls to **complete()** relative to the number of calls to **start()**.

failure

```
ccAcqFailure failure() const;
```

Returns the **ccAcqFailure** object associated with this image acquisition.

Member functions of **ccAcqFailure** allow you to query the reason an image acquisition failed. See **ccAcqFailure** on page 209. The **ccAcqFailure** object is passed as part of the **ccAcquireInfo** object you associate with each image acquisition.

You can test the success of an acquisition as shown in this code fragment:

```
ccAcquireInfo info;
ccAcqImagePtrh img = fifo->completeAcq
  (ccAcqFifo::CompleteArgs().acquireInfo(&info));
...
if (info.failure())
// Acquisition failed, find out why
    if (info.failure().isIncomplete())
    ...
```

Typedefs

ccCallbackAcqInfo

```
typedef ccCallback1<const ccAcquireInfo&>
    ccCallbackAcqInfo;
```

ccCallbackAcqInfoPtrh

```
typedef ccPtrHandle<ccAcquireInfoCB>
    ccCallbackAcqInfoPtrh;
```

ccAcquireInfo

ccAcuBarCodeDefs

```
#include <ch_cvl/acubar.h>

class ccAcuBarCodeDefs;
```

A name space that holds enumerations used with the Barcode tool classes.

Enumerations

FieldType

```
enum FieldType;
```

Field string specifiers.

Value	Meaning
eLastField	Termination of field map
eAlpha	Character A-Z
eNumeric	Character 0-9
eAlphanumeric	Any alphanumeric
eDash	'-' character
ePeriod	'.' character
eSpace	' ' character
eSemiAlpha	Semichecksum character (0 through 7, and A through H)
eAll	All characters supported by a particular symbology
eOther	All characters specified by *eAll*, but not by any of the other field types

Symbology `enum Symbology;`

Supported symbologies.

Value	Meaning
eCode39	Code 39 or Code 3-of-9; supports all 36 alphanumeric characters, seven additional characters, a variable symbol length, and an optional checksum.
eBC412	Supports alphanumeric characters, A through Z, 0 through 9, dash (-), and the semichecksum characters 0 through 7 and A through H.
eIBM412	Supports alphanumeric characters, A through Z, 0 through 9, dash (-), and the semichecksum characters 0 through 7 and A through H.
eCode128	Supports the entire ASCII character set, plus a packed decimal representation (2 digits per byte).

ScanDirection `enum ScanDirection;`

The scan direction for the symbol. This enumeration can be used to set the intended scan direction and it is used to report the actual scan direction.

Value	Meaning
eLeftToRight	Left-to-right scan.
eRightToLeft	Right-to-left scan.
eBoth	Scan in either direction.

Constants

The following constants specify the maximum number of fields represented by a barcode. This includes the NULL character.

Value	Meaning
kMaxNFieldsCode39 = 21	Maximum number of fields for Code39
kMaxNFieldsIBM412 = 19	Maximum number of fields for IBM412

Value	Meaning
kMaxNFieldsBC412 = 19	Maximum number of fields for BC412
kMaxNFieldsCode128 = 45	Maximum number of fields for Code 128
kMaxNFieldChars = 45	Maximum number of acceptable characters in any field

ccAcuBarCodeDefs

ccAcuBarCodeResult

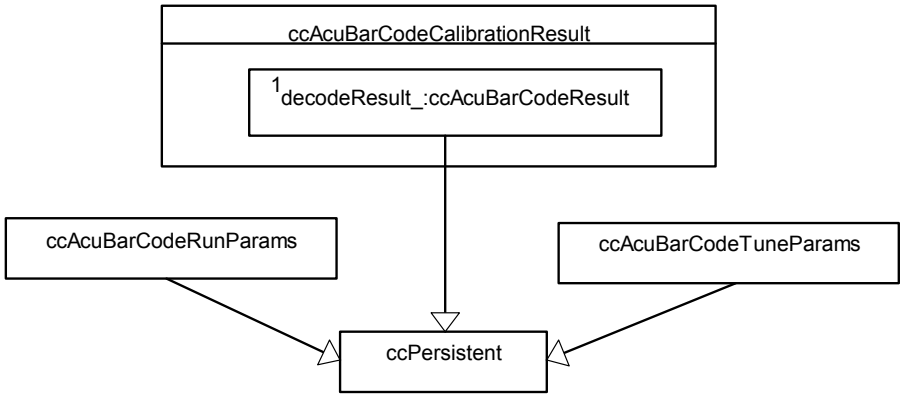
```
#include <ch_cvl/acubar.h>

class ccAcuBarCodeResult : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains results obtained from a single decoding operation executed by a **ccAcuBarCodeTool** object. An instance of this class is contained within a **ccAcuBarCodeCalibrationResult** object.



Constructors/Destructors

ccAcuBarCodeResult

```
ccAcuBarCodeResult();
virtual ~ccAcuBarCodeResult();
```

- `ccAcuBarCodeResult();`

  Constructs a **ccAcuBarCodeResult** object with the data members initialized to the following values:

Parameter	Initial Value
isFound	false
score	0
decoded string	' '
symbol type	*eBC412*
time	0.0
checksumValid	false
scanDirection	*eLeftToRight*
decodedData	Empty vector

- `virtual ~ccAcuBarCodeResult();`

  Destroys an instance of this class.

Operators

operator==

```
bool operator==(const ccAcuBarCodeResult& that) const;
```

Returns true if all of the data members except *time* of this **ccAcuBarCodeResult** object are equal to the data members of a second **ccAcuBarCodeResult** object.

Parameters

that The other parameter set

Public Member Functions

isFound

```
bool isFound() const;
```

Returns true if the string was decoded correctly and the score exceeded the acceptance threshold, false otherwise.

score

```
double score() const;
```

Returns the score that measures the decoding level in the range 0.0 through 1.0. A score of 1.0 indicates perfect decoding, while a score of 0 indicates decoding that was totally unsuccessful.

Notes

For any barcode with a checksum, failure to read the checksum sets the score to 0 (always fails).

decodedString

```
ccCvlString decodedString() const;
```

Returns the decoded string.

decodedData

```
cmStd vector<c_UInt8> decodedData() const;
```

Returns the raw bytes which make up the barcode. For Code 128 symbols, the bytes returned by this function include all of the characters plus the shift and control codes defined in the Code 128 symbology.

symbolType

```
ccAcuBarCodeDefs::Symbology symbolType()
   const;
```

Returns the type of 1D Symbology that was decoded to produce this result.

time

```
double time() const;
```

Returns the time required in seconds to compute this result.

checksumValid

```
bool checksumValid() const;
```

Returns true if *checksum* is valid. As defined under “Some Useful Definitions” in the Barcode Tool chapter of the *CVL Vision Tools Guide*, a checksum is a “character used in calculating a check for correct decoding.”

Notes

For any barcode with a checksum, failure to read the checksum sets the score to 0, which causes the *decode()* operation to fail. **checksumValid()** returns true only if a checksum was present, and the tool was successful in reading the checksum irrespective of whether the tool passed the acceptance threshold.

scanDirection

```
ccAcuBarCodeDefs::ScanDirection scanDirection() const;
```

Returns the direction in which the symbol was scanned. This function returns one of the following values:

ccAcuBarCodeDefs::eRightToLeft
ccAcuBarCodeDefs::eLeftToRight

ccAcuBarCodeRunParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuBarCodeRunParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccAcuBarCodeRunParams** class contains a set of common parameters required to support the Barcode tool. After you have set up a **ccAcuBarCodeRunParams** object, you pass it to **ccAcuBarCodeTool::decode()**, which performs the decoding operation.

You can set up the lighting parameters yourself, or you can use **ccAcuBarCodeTool::tune()** to iterate over several possibilities to create a set of lighting parameters for you.

Constructors/Destructors

ccAcuBarCodeRunParams

```
ccAcuBarCodeRunParams(
  ccAcuBarCodeDefs::Symbology symbolType =
    ccAcuBarCodeDefs::eBC412,
  ccAcuBarCodeDefs::FieldType defaultType =
    ccAcuBarCodeDefs::eAlphanumeric,
  double accept = 0.5,
  ccAcuBarCodeDefs::ScanDirection scanDirection =
    ccAcuBarCodeDefs::eLeftToRight);
```

Constructs a **ccAcuBarCodeRunParams** object, and initializes the symbology type to that specified by *symbolType* and the field strings at all positions to those specified by *defaultType*. Requires that *defaultType* be a valid field type for the specified symbology.

The other parameters are initialized to the following values:

- checksum is false for Code39 and true for Code128, BC412, and IBM412, which have built-in error-correcting checksums.
- *lightPower* = 0.0.
- *brightFieldPowerRatio* = 0.0.

Parameters

symbolType The format for encoding and decoding a specific type of barcode.

defaultType The type of character that each field may contain.

accept The acceptance threshold. Valid range: 0.0 through 1.0. The acceptance threshold is the percentage of scan lines crossing the barcode that must correctly decode for the read to pass.

scanDirection The direction in which to scan the barcode. If you specify *ccAcuBarCodeDefs::eBoth*, then the tool attempts to decode the barcode in both left-to-right and right-to-left directions; it returns the best score. *scanDirection* must be one of the following values:

ccAcuBarCodeDefs::eRightToLeft
ccAcuBarCodeDefs::eLeftToRight
ccAcuBarCodeDefs::eBoth

Notes

BC412 and IBM412 symbologies support the *ccAcuBarCodeDefs::eLastField*, *ccAcuBarCodeDefs::eAlpha*, *ccAcuBarCodeDefs::eNumeric*, *ccAcuBarCodeDefs::eAlphanumeric*, *ccAcuBarCodeDefs::eDash, ccAcuBarCodeDefs::eSemiAlpha*, and *ccAcuBarCodeDefs::eAll* field types. Code39 and Code128 support all of the aforementioned plus *ccAcuBarCodeDefs::ePeriod, ccAcuBarCodeDefs::eSpace*, and *ccAcuBarCodeDefs::eOther*.

Throws

*ccAcuBarCodeDefs::BadParam*s
An invalid field type is specified for the symbology type, or *accept* is out of range 0.0 through 1.0.

Public Member Functions

accept

```
double accept() const;

void accept(double acceptVal);
```

- `double accept() const;`

Gets the accept threshold, which is the percentage of scan lines crossing the barcode that must correctly decode for the read to pass.

- `void accept(double acceptVal);`

  Sets the accept threshold.

  Parameters

  acceptVal The accept threshold; requires that *acceptVal* be between 0.0 and 1.0 inclusive.

  Throws

  ccAcuBarCodeDefs::BadParams
  The value being set is outside the valid range.

changeSymbolAndFieldType

```
void changeSymbolAndFieldType (
  ccAcuBarCodeDefs::Symbology symbolType,
  ccAcuBarCodeDefs::FieldType type);
```

Changes the type of 1D Symbology to be decoded and sets the field strings at all positions to the type specified by *type*.

Parameters

symbolType The format for encoding and decoding a specific type of barcode.

type The type of character that each field may contain.

Throws

ccAcuBarCodeDefs::BadParams
An invalid field type is specified for the symbology type.

Notes

BC412 and IBM412 symbologies support the *ccAcuBarCodeDefs::eLastField*, *ccAcuBarCodeDefs::eAlpha*, *ccAcuBarCodeDefs::eNumeric*, *ccAcuBarCodeDefs::eAlphanumeric*, *ccAcuBarCodeDefs::eDash, ccAcuBarCodeDefs::eSemiAlpha*, and *ccAcuBarCodeDefs::eAll* field types. Code39 and Code128 support all of the aforementioned plus *ccAcuBarCodeDefs::ePeriod, ccAcuBarCodeDefs::eSpace*, and *ccAcuBarCodeDefs::eOther*.

ccAcuBarCodeRunParams::changeSymbolAndFieldType() invalidates all previously set field string specifications for the object.

Whenever the symbology of a **ccAcuBarCodeRunParams** object is changed to *ccAcuBarCodeDefs::eBC412, ccAcuBarCodeDefs::eIBM412*, *ccAcuBarCodeDefs::eCode39*, or *ccAcuBarCodeDefs::eCode128*, the checksum is enabled.

checksum

```
bool checksum() const;
void checksum(bool val);
```

- `bool checksum() const;`

  Gets the checksum enable state.

- `void checksum(bool val);`

  Sets the checksum enable state. (For BC412, IBM412, and Code128 symbologies, *val* is always true.)

  Parameters

  val — True or false depending on whether the tool should perform a checksum operation.

  Notes

  For any symbology that has an optional checksum, you can set this parameter to true or false. For other symbologies, such as BC412 and IBM412 which have built-in error-correcting checksums, it is always set to true. You cannot toggle this value.

  Throws

  ccAcuBarCodeDefs::BadParams — The given symbology is *ccAcuBarCodeDefs::eBC412*, *ccAcuBarCodeDefs::eIBM412*, or *ccAcuBarCodeDefs::eCode128*, and the setter is passed false.

brightFieldPowerRatio

```
double brightFieldPowerRatio() const;
void brightFieldPowerRatio(double val);
```

- `double brightFieldPowerRatio() const;`

  Returns the bright field power ratio for this object. The bright field power ratio is the portion (in the range 0.0 through 1.0) of the total light energy allocated to the bright field lights.

- `void brightFieldPowerRatio(double val);`

  Sets the bright field power ratio for this object. The bright field power ratio is the portion (in the range 0.0 through 1.0) of the total light energy allocated to the bright field lights.

Parameters

val The power ratio. Must be in the range 0.0 (full darkfield) through 1.0 (full brightfield).

Throws

ccAcuBarCodeDefs::BadParams
val was out of range.

fieldString

```
cmStd string fieldString (c_UInt32 position) const;

void fieldString(c_UInt32 position,
 const cmStd string &str);

void fieldString(c_UInt32 position,
 ccAcuBarCodeDefs::FieldType type);
```

- `cmStd string fieldString (c_UInt32 position) const;`

Returns the acceptable characters in the given field position.

Parameters

position The character position. Character positions must be between the following values:

0 and *kMaxNFieldsCode39* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode39*
0 and *kMaxNFieldsBC412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eBC412*
0 and *kMaxNFieldsIBM412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eIBM412*
0 and *kMaxNFieldsCode128* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode128*

Throws

ccAcuBarCodeDefs::BadParams
The position specified is invalid for the symbology type of this **ccAcuBarCodeRunParams** object.

- `void fieldString(c_UInt32 position,`
  `const cmStd string &str);`

Sets the field string at certain positions.

Parameters

position The character position. Character positions must be between the following values:

0 and *kMaxNFieldsCode39* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode39*
0 and *kMaxNFieldsBC412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eBC412*
0 and *kMaxNFieldsIBM412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eIBM412*
0 and *kMaxNFieldsCode128* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode128*

str — Valid characters for the symbology type.

Throws

*ccAcuBarCodeDefs::BadParam*s
Position is not in the valid range, or the string contains invalid characters.

- `void fieldString(c_UInt32 position, ccAcuBarCodeDefs::FieldType type);`

Sets the field string at a particular position to a predefined *fieldType* value.

Parameters

position — The character position. Character positions must be between the following values:

0 and *kMaxNFieldsCode39* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode39*
0 and *kMaxNFieldsBC412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eBC412*
0 and *kMaxNFieldsIBM412* - 1 inclusive for symbology *ccAcuBarCodeDefs::eIBM412*
0 and *kMaxNFieldsCode128* - 1 inclusive for symbology *ccAcuBarCodeDefs::eCode128*

type — Valid field type for the symbology type of this **ccAcuBarCodeRunParams** object.

Notes

BC412 and IBM412 symbologies support the *ccAcuBarCodeDefs::eLastField*, *ccAcuBarCodeDefs::eAlpha*, *ccAcuBarCodeDefs::eNumeric*, *ccAcuBarCodeDefs::eAlphanumeric*, *ccAcuBarCodeDefs::eDash, ccAcuBarCodeDefs::eSemiAlpha*, and *ccAcuBarCodeDefs::eAll* field types. Code39 and Code128 support all of the aforementioned plus *ccAcuBarCodeDefs::ePeriod, ccAcuBarCodeDefs::eSpace*, and *ccAcuBarCodeDefs::eOther*.

Throws

ccAcuBarCodeDefs::BadParams

Position is not in the valid range, or the field type does not agree with the symbology type of this **ccAcuBarCodeRunParams** object.

lightPower

```
double lightPower() const;

void lightPower(double val);
```

- `double lightPower() const;`

  Gets the light power to be used.

- `void lightPower(double val);`

  Sets the light power to be used.

  Parameters

  val The light power. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuBarCodeDefs::BadParams

  val lies outside the valid range.

symbolType

```
ccAcuBarCodeDefs::Symbology symbolType() const;
```

Gets the type of 1D Symbology to be decoded using the parameters contained in the **ccAcuBarCodeRunParams** object.

scanDirection

```
ccAcuBarCodeDefs::ScanDirection scanDirection() const;

void scanDirection(ccAcuBarCodeDefs::ScanDirection
   scanDirection);
```

- `ccAcuBarCodeDefs::ScanDirection scanDirection() const;`

  Returns the scan direction of this **ccAcuBarCodeRunParams** object. The function returns one of the following values:

  ccAcuBarCodeDefs::eRightToLeft
  ccAcuBarCodeDefs::eLeftToRight
  ccAcuBarCodeDefs::eBoth

- `void scanDirection(ccAcuBarCodeDefs::ScanDirection scanDirection);`

  Sets the scan direction of this **ccAcuBarCodeRunParams** object.

  Parameters

  scanDirection The direction in which to scan the barcode. If you specify *ccAcuBarCodeDefs::eBoth*, then the tool attempts to decode the barcode in both left-to-right and right-to-left directions; it returns the best score. *scanDirection* must be one of the following values:

  ccAcuBarCodeDefs::eRightToLeft
  ccAcuBarCodeDefs::eLeftToRight
  ccAcuBarCodeDefs::eBoth

Operators

operator== `bool operator==(const ccAcuBarCodeRunParams& that) const;`

Returns true if these **ccAcuBarCodeRunParams** are the same as another set of **ccAcuBarCodeRunParams**. Two parameter sets are considered equal if all of their attributes are the same.

Parameters

that The other parameter set

ccAcuBarCodeTool

```
#include <ch_cvl/acubar.h>

class ccAcuBarCodeTool;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class represents the base class for the 1D symbology tools. Tools for decoding specific 1D symbologies are derived from the base class.

The class **ccAcuBarCodeTool** and the related classes **ccAcuBarCodeRunParams**, **ccAcuBarCodeTuneParams**, and **ccAcuBarCodeResult** support the following two types of 1D barcode decoders:

- Decoders used for BC412 and IBM412 symbologies, which may require an intermediate tuning step based on light settings to estimate optimal parameters.
- Decoders used for the Code39 and Code 128 symbologies, which do not normally require any tuning prior to decoding except in some special cases (for example, when reading wafers).

To create the Barcode tool, you create a **ccAcuBarCodeTool** object and then perform the following steps:

1. Create a **ccAcuBarCodeResult** object.

   ```
   ccAcuBarCodeResult result;
   ```

2. Create a **ccAcuBarCodeRunParams** object.

   ```
   ccAcuBarCodeRunParams bestParams(ccAcuBarCodeDefs::eIBM412);
   bestParams.lightPower(0.5);
   bestParams.fieldString(7, ccAcuBarCodeDefs::eLastField);
   ```

3. Create a **ccAcuBarCodeTuneParams** object.

   ```
   ccAcuBarCodeTuneParams stTuneParams;
   ```

4. Extract the region of interest to be used for tuning.

```
cc8120& fg = cc8120::get(0);
const ccStdVideoFormat& fmt =
        ccStdVideoFormat::getFormat(cmT("Sony XC75 640x480"))
ccStdGreyAcqFifo *fifo = fmt.newAcqFifo(fg);

fifo->properties().triggerEnable( true);
cc2Xform xform(cc2Matrix(1, 0, 0, 1), cc2Vect(0, 0));
ccAffineRectangle affrect(cc2Vect(110, 180),
          cc2Vect(210, 190), cc2Vect(110, 290));
ccAffineSamplingParams affparams(affrect, 100, 100);
```

5. Call **tune()** to perform the tuning step.

```
ccAcuBarCodeTool mbct;
mbct.tune (*fifo, xform, affparams, stTuneParams,
   bestParams, result);
```

To perform a barcode decoding operation, perform the following steps:

1. Acquire the image.

```
ccPelBuffer_const<c_UInt8> img = fifo->complete();
```

Note Make sure that the acquired image includes the entire barcode, including the quiet zone. For more information on quiet zones, see the chapter *The Barcode Tool* in the *CVL Vision Tools Manual*.

2. Create a **ccAcuBarCodeResult** object.

```
ccAcuBarCodeResult result;
```

3. Create a **ccAcuBarCodeRunParams** object.

```
ccAcuBarCodeRunParams params;
```

4. If necessary, change symbol and field type.

```
params.changeSymbolAndFieldType(ccAcuBarCodeDefs::eIBM412,
          ccAcuBarCodeDefs::eAlpha);
params.fieldString(0, ccAcuBarCodeDefs::eAlphanumeric);
params.fieldString(7, ccAcuBarCodeDefs::eLastField);
params.accept(0.1);
```

5. Decode the barcode.

```
mbct.decode (img, params, result);
```

For more detailed information about decoding barcodes, see the chapter *The Barcode Tool* in the *CVL Vision Tools Manual*.

In addition to the tune and decode functions, the Barcode tool supports a calibrate function, which automatically determines the properties and location of a barcode in an image. After a successful calibration, the **ccAcuBarCodeCalibrationResult** class holds the result.

To calibrate the Barcode tool, perform the following steps:

1. Acquire the image.

```
ccPelBuffer_const<c_UInt8> img = fifo->complete();
```

Note Make sure that the acquired image includes the entire barcode, including the quiet zone. For more information on quiet zones, see the chapter *The Barcode Tool* in the *CVL Vision Tools Manual*

2. Create a **ccAcuBarCodeRunParams** object to specify the runtime parameters for each symbology to be included in the calibration process. For example, to calibrate the Barcode tool for Code39 and BC412 symbologies, create two **ccAcuBarCodeRunParams** objects, one for eCode39 and one for eBC412. By creating only these two objects, you can exclude the other supported symbologies (for example, IBM412 and Code128) from the calibration process.

```
ccAcuBarCodeRunParams code39Params;
ccAcuBarCodeRunParams bc412Params;
```

3. Set the runtime parameters for each symbology, if desired. Runtime parameters can include *accept threshold*, *character set* for each field, *length* of encoded string, *scan direction*, and presence of *checksum* character.

   Set the *length* of the encoded string using the *eLastField* character to mark the end of the string. Not specifying an *eLastField* character in the field map implies that the encoded string length is to be determined.

   Setting the *scan direction* to *eBoth* implies that the barcode scan direction is to be determined.

   See the chapter on the **ccAcuBarCodeRunParams** class for details.

4. Create a vector of the **ccAcuBarCodeRunParams** objects created in the last step.

```
cmStd vector<ccAcuBarCodeRunParams> runParamsSet[2];
runParamsSet[0] = code39Params;
runParamsSet[1] = bc412Params;
```

5. Create a **ccAcuBarCodeCalibrationResult** object.

```
ccAcuBarCodeCalibrationResult calResult;
```

6. Calibrate the Barcode tool.

```
ccAcuBarCodeTool mbct;
mbct.calibrate(img, runParamsSet, calResult);
```

Constructors/Destructors

ccAcuBarCodeTool

```
ccAcuBarCodeTool();

virtual ~ccAcuBarCodeTool();
```

- `ccAcuBarCodeTool();`

  Default constructor.

- `virtual ~ccAcuBarCodeTool();`

  Destroys instances of this class.

Public Member Functions

decode

```
virtual void decode (ccGreyAcqFifo &fifo,
  const cc2Xform &xform,
  const ccAffineSamplingParams &affParams,
  const ccAcuBarCodeRunParams &runParams,
  ccAcuBarCodeResult &result, bool autoRetry = true) const;

virtual void decode (
  const ccPelBuffer_const<c_UInt8> &image,
  const ccAcuBarCodeRunParams &runParams,
  ccAcuBarCodeResult &result, bool autoRetry = true) const;
```

- ```
  virtual void decode (ccGreyAcqFifo &fifo,
    const cc2Xform &xform,
    const ccAffineSamplingParams &affParams,
    const ccAcuBarCodeRunParams &runParams,
    ccAcuBarCodeResult &result, bool autoRetry = true) const;
  ```

  Decodes the barcode located within the region of interest (ROI) specified by *affParams* and returns the results of the decode operation in the object specified by *result*.

  The *fifo* object acquires an image containing the barcode symbol. The light properties of the FIFO are based on the light power and dark level parameters contained in the *runParams* object. You set these parameters prior to acquiring the image. The *xform* object specifies the *clientFromImage* transform of the acquired image. The affine sampling parameters are used to extract the region of interest containing the target
  ```

barcode symbol. The tool then uses this region of interest for decoding the string. When the decoding operation finishes, the properties of the FIFO are left in the state specified by *runParams*.

If the decode operation returns a score for the barcode below the accept threshold you specify in *runParams*, the tool will automatically attempt to decode the barcode using an advanced decoding strategy. If the tool invokes the advanced decoding strategy, the decode will take about 10 times longer to perform, but the advanced strategy may be able to handle barcodes that could not otherwise be decoded.

If you need to ensure that calls to decode take a consistent amount of time, you can prevent the tool from automatically invoking the advanced decode strategy by specifying a value of false for the *autoRetry* argument to this function.

Requires that *xform* be nonsingular and the region of interest be nonnull.

The decode operation supports timeouts via the use of ccTimeout.

Parameters

fifo	An acquisition FIFO.
xform	A coordinate transformation to convert pixel coordinates to client coordinates.
affParams	Affine sampling parameters used to extract the region of interest containing the target barcode symbol.
runParams	A set of parameters used to support the decoding operation including symbol type, field type, and accept threshold.
result	Results obtained from a single decoding operation including score, the decoded string, and the result of the checksum operation.
autoRetry	Specify false to prevent the tool from automatically retrying failed decodes using the advanced decoding strategy. Specify true to allow the tool to automatically retry failed decodes.

Notes

To extract the ROI, the tool performs a windowing operation based on the affine rectangle if you specify the following affine sampling parameters:

- No subsampling
- Image alignment of image coordinates

Otherwise, the tool samples the acquired image as specified.

Throws

ccAcuBarCodeDefs::BadParams

The *xform* is singular or the region of interest specified by *affParams* is null or the field string in *runParams* does not contain a *ccAcuBarCodeDefs::eLastField* character marking the end of the string.

ccAcuBarCodeDefs::NotImplemented

The *symbolType* of *runParams* is not *eBC412*, *eIBM412*, *eCode39*, or *eCode128*.

- ```
  virtual void decode (
    const ccPelBuffer_const<c_UInt8> &image,
    const ccAcuBarCodeRunParams &runParams,
    ccAcuBarCodeResult &result, bool autoRetry = true) const;
  ```

Decodes the string from the source image, and returns the result in the specified result object. Requires that the image be bound, and its window be adjusted to fit the region of interest containing the target barcode symbol and the quiet zone.

If the decode operation returns a score for the barcode below the accept threshold you specify in *runParams*, the tool will automatically attempt to decode the barcode using an advanced decoding strategy. If the tool invokes the advanced decoding strategy, the decode will take about 10 times longer to perform, but the advanced strategy may be able to handle barcodes that could not otherwise be decoded.

If you need to ensure that calls to **decode()** take a consistent amount of time, you can prevent the tool from automatically invoking the advanced decode strategy by specifying a value of false for the *autoRetry* argument to this function.

The decode operation supports timeouts via the use of ccTimeout.

Parameters

image — The pel buffer that contains the image being read.

runParams — A set of parameters used to support the decoding operation including symbol type, field type, and accept threshold.

result — Results obtained from a single decoding operation including score, the decoded string, and the result of the checksum operation.

autoRetry — Specify false to prevent the tool from automatically retrying failed decodes using the advanced decoding strategy. Specify true to allow the tool to automatically retry failed decodes.
  ```

Throws

ccAcuBarCodeDefs::BadParams
The image is not bound or the field string in *runParams* does not contain an *ccAcuBarCodeDefs::eLastField* character marking the end of the string.

ccAcuBarCodeDefs::NotImplemented
The *symbolType* of *runParams* is not *eBC412*, *eIBM412*, *eCode39*, or *eCode128*.

---

calibrate

```
virtual void calibrate (
  const ccPelBuffer_const<c_UInt8> &image,
  ccAcuBarCodeCalibrationResult &result,
  const cmStd vector<ccAcuBarCodeDefs::Symbology>
    &symbolTypes =
    cmStd vector<ccAcuBarCodeDefs::Symbology>());

virtual void calibrate (
  const ccPelBuffer_const<c_UInt8> &image,
  const cmStd vector<ccAcuBarCodeRunParams> &runParamsSet,
  ccAcuBarCodeCalibrationResult &result);
```

-
```
virtual void calibrate (
  const ccPelBuffer_const<c_UInt8> &image,
  ccAcuBarCodeCalibrationResult &result,
  const cmStd vector<ccAcuBarCodeDefs::Symbology>
&symbolTypes =
  cmStd vector<ccAcuBarCodeDefs::Symbology>());
```

Given an image containing a barcode, this calibrate method determines all of the barcode properties using an accept threshold of 0.5 and disabling the checksum for eCode39, for which the checksum is optional. Calibration determines the barcode symbology (Code39, BC412, IBM412, or Code128), encoded string length, orientation (left-to-right or right-to-left), pitch, and location (ROI in the image that encloses the barcode).

Parameters

image — Pelbuffer containing the barcode to be used for calibration.

result — Result object containing information on the result of the calibration.

symbolTypes — Specifies a vector of the symbologies to be included in the calibration. For example, to exclude eCode128 from calibration, specify a vector of the other three supported symbol types (eCode39, eBC412, and eIBM412). Specifying an empty vector for symbolTypes causes the calibrate method to take all supported symbologies into consideration.

Throws

ccAcuBarCodeDefs::NotImplemented
The symbology specified by the vector of symbol types is not one of eCode39, eBC412, eIBM412, or eCode128.

ccAcuBarCodeDefs::BadParams
Two or more elements in the symbolTypes vector correspond to the same symbology.

ccAcuBarCodeDefs::BadImage
The image is not bound or does not satisfy the minimum window size requirement of 32x10 pixels.

- ```
  virtual void calibrate (
    const ccPelBuffer_const<c_UInt8> &image,
    const cmStd vector<ccAcuBarCodeRunParams> &runParamsSet,
    ccAcuBarCodeCalibrationResult &result);
  ```

Given an image containing a barcode, the calibrate method determines the barcode symbology (Code39, BC412, IBM412, or Code128), encoded string length, orientation (left-to-right or right-to-left), pitch, and location (that is, the ROI in the image that encloses the barcode).

Parameters

image — Pelbuffer containing the barcode to be used for calibration.

runParamsSet — Specifies a vector of runtime parameters for each symbology to be included in the calibration process. For example, to exclude eIBM412 and eCode128 from calibration, specify a vector of two runparams objects, one for eCode39 and one for eBC412, each containing a set of parameters to control the calibration of the corresponding symbology. For each symbology, you can control any or all of the following runtime parameters:
- *accept threshold*
- *character set* for each field
- *length* of the encoded string (by using the eLastField character to mark the end of the string; not specifying an eLastField character in the field map implies that the encoded string length is to be determined)
- *scan direction* (eBoth implies that the barcode orientation is to be determined)
- presence or absence of *checksum* character

result — Result object containing information on the result of the calibration.
  ```

Throws

ccAcuBarCodeDefs::NotImplemented
The symbology specified by the *runParamsSet* vector is not one of eCode39, eBC412, eIBM412, or eCode128.

ccAcuBarCodeDefs::BadParams
The *runParamsSet* vector is empty, or two or more elements in the vector correspond to the same symbology.

ccAcuBarCodeDefs::BadImage
The image is not bound or does not satisfy the minimum window size requirement of 32x10 pixels.

---

tune

```
virtual void tune (
  ccGreyAcqFifo &fifo,
  const cc2Xform &xform,
  const ccAffineSamplingParams &affParams,
  const ccAcuBarCodeTuneParams &startTuneParams,
  ccAcuBarCodeRunParams &bestParams,
  ccAcuBarCodeResult &result);

virtual void tune(
  const ccAcuBarCodeTuneParams &startTuneParams,
  ccAcuBarCodeRunParams &bestParams,
  ccAcuBarCodeResult &result);
```

-
```
virtual void tune (
  ccGreyAcqFifo &fifo,
  const cc2Xform &xform,
  const ccAffineSamplingParams &affParams,
  const ccAcuBarCodeTuneParams &startTuneParams,
  ccAcuBarCodeRunParams &bestParams,
  ccAcuBarCodeResult &result);
```

Estimates optimal decoding parameters for the Barcode tool based on various light settings, which you specify in *startTuneParams*.

Images are acquired using the FIFO object specified by *fifo*. The *xform* object specifies the *clientFromImage* transform for the acquired image. The affine sampling parameters are used to extract the region of interest to be used for tuning. The optimal light parameters are returned via the *bestParams* object. The result of decoding using optimal parameters is returned via the *result* object. Upon completion of the tune operation, the tool sets the light properties of the FIFO object to the optimal values returned via *bestParams*.

Requires that *xform* be nonsingular and the region of interest be nonnull.

The tune operation supports timeouts via the use of ccTimeout.

Parameters

fifo	An acquisition FIFO.
xform	A coordinate transformation to convert pixel coordinates to client coordinates.
affParams	Affine sampling parameters used to extract the region of interest containing the target barcode symbol.
startTuneParams	Tuning parameters including dark field and bright field properties.
bestParams	A set of parameters used to support the decoding operation including symbol type, field type, and accept threshold.
result	Results obtained from a single decoding operation including the score, the decoded string, and the result of the checksum operation.

Notes

To extract the ROI, the tool performs a windowing operation based on the affine rectangle if you specify the following affine sampling parameters:

- No subsampling
- Image alignment of image coordinates

Otherwise, the tool samples the acquired image as specified.

Use this function only if you need to tune light parameters in applications such as Wafer ID where the symbology type is either BC412 or IBM412.

Throws

ccAcuBarCodeDefs::BadParams
: The *xform* is singular, the region of interest specified by *affparams* is null, or the field string in *bestParams* does not contain an *ccAcuBarCodeDefs::eLastField* character marking the end of the string.

ccAcuBarCodeDefs::NotImplemented
: The *symbolType* of *bestParams* is not *eBC412*, *eIBM412*, *eCode39*, or *eCode128*.

- ```
  virtual void tune(
    const ccAcuBarCodeTuneParams &startTuneParams,
    ccAcuBarCodeRunParams &bestParams,
    ccAcuBarCodeResult &result);
  ```

  Estimates optimal decoding parameters for the Barcode tool based on various light settings, which you specify in *startTuneParams*.

  You supply the images used for tuning by overriding the **ccAcuBarCodeTool::acquireImage()** function.

  The optimal light parameters are returned via the *bestParams* object. The result of decoding using optimal parameters is returned via the *result* object. Upon completion of the tuning operation, the tool sets the light properties of the FIFO object to the optimal values returned via *bestParams*.

  Requires that *xform* be nonsingular and the region of interest be nonnull.

  The tune operation supports timeouts via the use of ccTimeout.

  Parameters

  startTuneParams Tuning parameters including dark field and bright field properties.

  bestParams A set of parameters used to support the decoding operation including symbol type, field type, and accept threshold.

  result Results obtained from a single decoding operation including the score, the decoded string, and the result of the checksum operation.

  Notes

  Use this function only if you need to tune light parameters in applications such as Wafer ID where the symbology type is either BC412 or IBM412.

  Throws

  ccAcuBarCodeDefs::NotImplemented
  The *symbolType* of *bestParams* is not *eBC412*, *eIBM412*, *eCode39*, or *eCode128*.

  ccAcuBarCodeDefs::BadParams
  The field string in *bestParams* does not contain an *ccAcuBarCodeDefs::eLastField* character marking the end of the string.
  ```

acquireImage

```
virtual ccPelBuffer<c_UInt8> acquireImage(
  const ccAcuBarCodeRunParams& currentParams);
```

You should not call this function directly. To use this function, override it in a class that you derive from **ccAcuBarCodeTool**.

This function lets you tune lighting parameters without using an acquisition FIFO to acquire images. When you use the second overload of **ccAcuBarCodeTool::tune()**, this function is called to obtain images. Your overload of this function should return the image to use for tuning.

Parameters

currentParams The current acquisition parameters.

---

update

```
virtual bool update () const;

virtual bool update(
  const ccAcuBarCodeRunParams &currentParams,
  const ccAcuBarCodeRunParams &bestParams,
  const ccAcuBarCodeResult &currentResult,
  const ccAcuBarCodeResult &bestResult)
```

- ```
  virtual bool update () const;
  ```

  Returns bool, indicating whether the tuning process should continue or not.

- ```
  virtual bool update(
    const ccAcuBarCodeRunParams &currentParams,
    const ccAcuBarCodeRunParams &bestParams,
    const ccAcuBarCodeResult &currentResult,
    const ccAcuBarCodeResult &bestResult)
  ```

  You should not call this function directly. To use this function, override it in a class that you derive from **ccAcuBarCodeTool**.

  Provides a hook that lets you update intermediate **tune()** results. The tuning process continues as long as this function returns true. The default **update()** function always returns true.

  Notes

  A user-overloaded **update()** function may abort tuning by returning false.

  Parameters

  currentParams The current acquisition parameters.

  bestParams The best acquisition parameters.

  currentResult The results of decoding using *currentParams*.

bestResult	The results of decoding using *bestParams*.

ccAcuBarCodeTool

ccAcuBarCodeTuneParams

```
#include <ch_cvl/acubar.h>

class ccAcuBarCodeTuneParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class provides tuning parameters for the tuning process of the Barcode tool. You pass the **ccAcuBarCodeTuneParams** object to **ccAcuBarCodeTool::tune()**. That function uses the information in the tuning parameters to generate a **ccAcuBarCodeRunParams** object that contains the optimal light parameters for the decoding operation.

Constructors/Destructors

ccAcuBarCodeTuneParams

```
ccAcuBarCodeTuneParams (
  bool enableDark = true,
  double darkLow = 0.062745,
  double darkHigh = 1.0,
  double darkStep = 0.12157,
  bool enableBright = true,
  double brightLow = 0.062745,
  double brightHigh = 1.0,
  double brightStep = 0.12157);
```

Creates a tune-parameters object with the specified values.

Parameters

enableDark	True to enable darkfield tuning.
darkLow	The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkHigh	The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkStep	The darkfield step value. Must be in the range 0.0 through 1.0.
enableBright	True to enable brightfield tuning.

brightLow The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

brightHigh The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

brightStep The brightfield step value. Must be in the range 0.0 through 1.0.

Throws

ccAcuBarCodeDefs::BadParams
darkLow, darkHigh, darkStep, brightLow, brightHigh, brightStep are set to be outside the valid range 0.0 through 1.0.

Notes

The default dark field and light field values are set as specified.

Operators

operator==

```
bool operator==(const ccAcuBarCodeTuneParams& that) const;
```

Returns true if these **ccAcuBarCodeTuneParams** are the same as another set of **ccAcuBarCodeTuneParams**. Two parameter sets are considered equal if all of their attributes are the same.

Parameters

that The other parameter set

Public Member Functions

brightLow

```
double brightLow() const;
void brightLow(double val);
```

- `double brightLow() const;`

Returns the minimum light power for brightfield tuning.

- `void brightLow(double val);`

Sets the minimum light power for brightfield tuning.

Parameters

val The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0 where the light power increases monotonically.

Throws
ccAcuBarCodeDefs::BadParams
val is out of range.

brightHigh

```
double brightHigh() const;
void brightHigh(double val);
```

- `double brightHigh() const;`

Returns the maximum light power for brightfield tuning.

- `void brightHigh(double val);`

Sets the maximum light power for brightfield tuning.

Parameters

val	The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0 where the light power increases monotonically.

Throws
ccAcuBarCodeDefs::BadParams
val is out of range.

brightStep

```
double brightStep() const;
void brightStep(double val);
```

- `double brightStep() const;`

Returns the brightfield step for tuning.

- `void brightStep(double val);`

Sets the brightfield step for tuning.

Parameters

val	The brightfield step value. Must be in the range 0.0 through 1.0 where the light power increases monotonically.

Throws
ccAcuBarCodeDefs::BadParams
val is out of range.

ccAcuBarCodeTuneParams

darkLow

```
double darkLow() const;
void darkLow(double val);
```

- `double darkLow() const;`

  Returns the minimum light power for darkfield tuning.

- `void darkLow(double val);`

  Sets the minimum light power for darkfield tuning.

  Parameters

  val — The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuBarCodeDefs::BadParams
  val is out of range.

darkHigh

```
double darkHigh() const;
void darkHigh(double val);
```

- `double darkHigh() const;`

  Returns the maximum light power for darkfield tuning.

- `void darkHigh(double val);`

  Sets the maximum light power for darkfield tuning.

  Parameters

  val — The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuBarCodeDefs::BadParams
  val is out of range.

darkStep

```
double darkStep() const;
void darkStep(double val);
```

- `double darkStep() const;`

  Returns the darkfield step for tuning.

- `void darkStep(double val);`

  Sets the darkfield step for tuning.

  Parameters

  val The darkfield step value. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuBarCodeDefs::BadParams
  val is out of range.

enableBright

```
bool enableBright() const;
void enableBright(bool val);
```

- `bool enableBright() const;`

  Returns true if brightfield tuning is enabled.

- `void enableBright(bool val);`

  Enables or disables brightfield tuning.

  Parameters

  val True if brightfield tuning is enabled. False otherwise.

enableDark

```
bool enableDark() const;
void enableDark(bool val);
```

- `bool enableDark() const;`

  Returns true if darkfield tuning is enabled.

- `void enableDark(bool val);`

  Enables or disables darkfield tuning.

Parameters

val	True if darkfield tuning is enabled. False otherwise.

ccAcuRead

```
#include <ch_cvl/acuread.h>

class ccAcuRead;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class provides access to basic OCR reading and tuning functions. In your application, you would create an instance of this class and use the **read()** function to read a string. You can use the **tune()** function to obtain the optimum reading parameters for your application. The mechanism for enabling Non-Linear OCR is to pass a **ccAcuReadFont** that has been initialized with a nonlinear font to the **read()** or **tune()** function.

You can control some aspects of the tuning function by creating a class derived from this class and overriding the functions **update()** and **userPreprocessAcquiredImage()**.

For more detailed information about OCR, reading, and tuning, see the chapter *acuRead* in the *CVL Vision Tools Guide*.

Constructors/Destructors

You can use the default constructor and destructor to create and destroy instances of this class.

Public Member Functions

tune

```
void tune(const ccPelBuffer_const<c_UInt8> &image,
  const cc_AcuReadFont &font,
  const cc_AcuReadFont &fontNL,
  const ccAcuReadTuneParams &tuneParams,
  const ccAcuReadRunParams &initial,
  ccAcuReadRunParams &best,
  ccAcuReadResultSet &resultSet);

void tune(ccGreyAcqFifo &fifo,
  const cc2Xform &xform,
  const ccPelRect &rect,
  const cc_AcuReadFont &font,
  const cc_AcuReadFont &fontNL,
```

```
  const ccAcuReadTuneParams &tuneParams,
  const ccAcuReadRunParams &initial,
  ccAcuReadRunParams &best,
  ccAcuReadResultSet &resultSet);
```

- ```
  void tune(const ccPelBuffer_const<c_UInt8> &image,
    const cc_AcuReadFont &font,
    const cc_AcuReadFont &fontNL,
    const ccAcuReadTuneParams &tuneParams,
    const ccAcuReadRunParams &initial,
    ccAcuReadRunParams &best,
    ccAcuReadResultSet &resultSet);
  ```

  Cycles through the preprocessing and size parameters, using the image in *image* and invoking **read()** for each setting. Outputs the best read results and, if **resultSet.found()** is true, the run parameters used to generate them.

  Parameters

image	The pel buffer that contains the image being read.
font	The font of the characters being read.
fontNL	To enable non-linear OCR, specify a **ccAcuReadFont** object initialized with a non-linear font. To disable non-linear OCR, set this parameter to a default-constructed **ccAcuReadFont** object. If *font* is a user-defined font, use a default-constructed **ccAcuReadFont** object for *fontNL*.
tuneParams	The tuning parameters.
initial	The initial run parameters.
best	The run parameters that generated the best read result.
resultSet	The best read result.

  Throws

  ccAcuReadDefs::BadParams
  font is uninitialized,
  the checksum specified in *initial* is not *eNone* and *isVariableLength* is set to true, or
  fontNL is initialized and *font* is initialized to be a user-defined font.

  ccAcuReadDefs::BadImage
  image is unbound.
  ```

- ```
  void tune(ccGreyAcqFifo &fifo,
    const cc2Xform &xform,
    const ccPelRect &rect,
    const cc_AcuReadFont &font,
    const cc_AcuReadFont &fontNL,
    const ccAcuReadTuneParams &tuneParams,
    const ccAcuReadRunParams &initial,
    ccAcuReadRunParams &best,
    ccAcuReadResultSet &resultSet);
  ```

  Cycles through the preprocessing, size, and lighting parameters, using the specified region of interest of an acquired image and invoking **read()** for each setting. Outputs the best read results and, if **resultSet.found()** is true, the run parameters used to generate them.

  Parameters

fifo	An acquisition FIFO.
xform	A coordinate transformation to convert pixel coordinates to client coordinates.
rect	The region of interest.
font	The font of the characters being read.
fontNL	To enable Non-Linear OCR, specify a **ccAcuReadFont** object initialized with a nonlinear font. To disable Non-Linear OCR, set this parameter to a default-constructed **ccAcuReadFont** object.
tuneParams	The tuning parameters.
initial	The initial run parameters.
best	The run parameters that generated the best read result.
resultSet	The best read result.

  Throws

  ccAcuReadDefs::BadParams
  font is uninitialized,
  the checksum specified in *initial* is not *eNone* and *isVariableLength* is set to true, or
  fontNL is initialized and *font* is initialized to be a user-defined font.

---

read

```
void read(ccGreyAcqFifo &fifo,
  const cc2Xform &xform,
  const ccPelRect &rect,
  const cc_AcuReadFont &font,
```
```

```
  const cc_AcuReadFont &fontNL,
  const ccAcuReadRunParams &params,
  ccAcuReadResultSet &resultSet);

void read(const ccPelBuffer_const<c_UInt8> &image,
  const cc_AcuReadFont &font,
  const cc_AcuReadFont &fontNL,
  const ccAcuReadRunParams &params,
  ccAcuReadResultSet &resultSet);
```

- ```
  void read(ccGreyAcqFifo &fifo,
    const cc2Xform &xform,
    const ccPelRect &rect,
    const cc_AcuReadFont &font,
    const cc_AcuReadFont &fontNL,
    const ccAcuReadRunParams &params,
    ccAcuReadResultSet &resultSet);
  ```

  Performs a single read operation on the specified region of interest of an acquired image using the specified parameters. Employs the following sub-functions, in the following order:

  1. Acquisition
  2. Preprocessing
  3. Character segmentation
  4. Character identification
  5. Checksum computation.

  Parameters

fifo	An acquisition FIFO.
xform	A coordinate transformation to convert pixel coordinates to client coordinates.
rect	The region of interest.
font	The font of the characters being read. See *ccAcuReadFont* on page 313.
fontNL	To enable Non-Linear OCR, specify a **ccAcuReadFont** object initialized with a non-linear font. To disable non-linear OCR, set this parameter to a default-constructed **ccAcuReadFont** object.
params	The run parameters.
resultSet	The read result.
  ```

Throws

ccAcuReadDefs::BadParams
font is uninitialized,
the checksum specified in *initial* is not *eNone* and *isVariableLength* is set to true, or
fontNL is initialized and *font* is initialized to be a user-defined font.

- ```
  void read(const ccPelBuffer_const<c_UInt8> &image,
    const cc_AcuReadFont &font,
    const cc_AcuReadFont &fontNL,
    const ccAcuReadRunParams &params,
    ccAcuReadResultSet &resultSet);
  ```

Performs a single read operation on the specified image using the specified parameters. Employs the following sub-functions, in the following order:

1. Preprocessing, using the passed-in image
2. Character segmentation
3. Character identification
4. Checksum computation.

Parameters

image — The pel buffer that contains the image being read.

font — The font of the characters being read. See *ccAcuReadFont* on page 313.

fontNL — To enable non-linear OCR, specify a **ccAcuReadFont** object initialized with a non-linear font. To disable non-linear OCR, set this parameter to a default-constructed **ccAcuReadFont** object.

params — The run parameters.

resultSet — The read result.

Throws

ccAcuReadDefs::BadParams
font is uninitialized,
the checksum specified in *params* is not *eNone* and *isVariableLength* is set to true, or
fontNL is initialized and *font* is initialized to be a user-defined font.

ccAcuReadDefs::BadImage
If *image* is unbound.
  ```

update

```
virtual bool update(const ccAcuReadRunParams &current,
  const ccAcuReadRunParams &best,
  const ccAcuReadResultSet &currentRes,
  const ccAcuReadResultSet &bestRes);
```

Provides a hook that lets you update intermediate **tune()** results. The tuning process continues as long as this function returns true. The default **update()** function always returns true.

Parameters

current	The current acquisition parameters.
best	The best acquisition parameters.
currentRes	The result of the current read operation.
bestRes	The results of the best read operation so far.

userPreprocessAcquiredImage

```
virtual bool userPreprocessAcquiredImage(
  ccPelBuffer<c_UInt8>& src, const ccPelRect& rect,
  ccPelBuffer<c_UInt8>& dst);
```

Allows preprocessing of the acquired image in a custom-defined manner during **tune()** and **read()**. The tune or read process continues as long as this function returns true.

The default implementation assigns the source pel buffer to the destination pel buffer, and sets the window of the destination pel buffer to *rect.* The OCR tool uses the window and client coordinate transform of the destination pel buffer for subsequent processing. You can override the default behavior in a derived class of your own to define other custom preprocessing transformations.

Unless a throw occurs, the default implementation is always to return true. You can override this behavior in a derived class of your own to return false, and abort the **tune()** or **read()** operation in progress, if your custom image preprocessing is unsuccessful. This has nothing to do with the image preprocessing that the OCR tool applies internally, which happens only after this function returns true.

Parameters

src	The acquired image. This pel buffer must be bound.
rect	The region of interest within *src*.
dst	The destination pel buffer. The OCR tool uses the window and client coordinate transform returned in this pel buffer for subsequent processing.

Throws

ccPel::BadWindow

src is not bound, either the **width()** or **height()** of *rect* is not positive, or *rect* is not entirely contained within the window of *src*.

Notes

The default implementation throws under the conditions listed above. You can override this behavior in a derived class of your own.

ccAcuRead

ccAcuReadDefs

```
#include <ch_cvl/acuread.h>

class ccAcuReadDefs;
```

A name space that holds enumerations and constants used with the acuRead classes.

Enumerations

Checksum

```
enum Checksum;
```

Values for the checksum parameter.

Value	Meaning
eNone	No checksum.
eSemi	SEMI checksum.
eBC412	BC412 checksum.
eIBM412	IBM412 checksum.
eVirtual	Virtual checksum.

Fields

```
enum Fields;
```

Convenience enumerations for identifying potential characters in a field.

Value	Meaning
eLastField	Termination of field map.
eAlpha	Uppercase alphabetic character (A through Z).
eNumeric	Numeric character (0 through 9).
eAlphanumeric	Uppercase alphabetic or numeric character.
eDash	A dash or minus (–).
ePeriod	A period or decimal point (.).
eSpace	A space ( ).
eSemiAlpha	A SEMI checksum character (0 through 7 and A through H).

ccAcuReadDefs

Color

```
enum Color;
```

Flags describing character and background colors.

Value	Meaning
eBlack	Black characters on white background.
eWhite	White characters on black background.
eLightInverse	Character color is the inverse of the light mode. This option is for use during light tuning. It allows the character color to change when tuning changes the light mode. It should not be used when the image is stored in a pel buffer.

OcrfFlags

```
enum OcrfFlags;
```

Flags enabling tuning of the filtering modes. These values can be ORed together.

Value	Meaning
eLoPass	Low-pass filter.
eHiPass	High-pass filter.
eTopHat	Top-hat filter.
eClip	Clipping filter.
eAll	All filters combined.

Notes

Use these flags with **ccAcuReadTuneParams** objects only. Do not use them as *preprocessing* options with **ccAcuReadRunParams** objects.

ExitCode

```
enum ExitCode;
```

Codes that indicate how the **ccAcuRead::read()** and **ccAcuRead::tune()** methods terminated.

Notes

ccAcuread::read() only terminates with *eNormal*. **ccAcuRead::tune()** may terminate with any of the values.

Value	Meaning
eNormal = 0	Normal termination.
eValidLimit	The required number of successful reads occurred.
eTimeToValid	The maximum allowed time limit expired.
eScoreLimit	The minimum time limit expired and the score did not exceed the score threshold.

Constants

The following constants are used with the optical character recognition classes:

Value	Meaning
kMaxStringLength = 30	The maximum number of actual characters in a string being read not including the end of field map position.
kMaxFieldStringLength = 39	The maximum length of a field string. (A field string lists the character(s) expected at a specific position.) With field strings that contain multiple special characters, the maximum length is 39 not including the terminating NULL character.

ccAcuReadDefs

ccAcuReadFont

```
#include <ch_cvl/acurdfnt.h>

class ccAcuReadFont: public cc_AcuReadFont;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

ccAcuReadFont encapsulates a font used by the acuRead tool. You populate the object by calling **ccAcuReadFont::access()** and passing it a predefined font name or an **ccOCAlphabetPtrh** object that contains a font set definition.

Constructors/Destructors

ccAcuReadFont

```
ccAcuReadFont();

virtual ~ccAcuReadFont();
```

- `ccAcuReadFont();`

  Default constructor. Initializes the object, but does not provide access to any font.

- `virtual ~ccAcuReadFont();`

Operators

operator==

```
bool operator==(const ccAcuReadFont& rhs) const;
```

Returns true if the font in this object is identical to the font in *rhs*. Returns false otherwise.

Public Member Functions

access

```
virtual bool access(
  const ccCvlString & fontName);

virtual bool access(
  const ccCvlString & fontBaseName,
  bool enableNonLinear);

bool access(
  const ccOCAlphabetPtrh_const & alphabet);
```

- ```
  virtual bool access(
    const ccCvlString & fontName);
  ```

  Searches the list of predefined fonts and provides access to the first such font whose name matches *fontName*. The predefined fonts currently supported are semi_nrm, semi_nln, ocra_nrm, ocra_nln, trip_nrm, trip_nln, cano_nrm and cano_nln.

  Returns true if successful and returns false if unable to find the specified name.

  Parameters

  fontName The font name.

  Notes

  fontName should contain the suffix nrm or nln specifying whether the nonlinear mode or normal mode is selected. For example semi_nrm and semi_nln.

- ```
  virtual bool access(
    const ccCvlString & fontBaseName,
    bool enableNonLinear);
  ```

  You specify the font name to access and the nonlinear or normal mode. The function then searches the list of predefined fonts and provides access to the first such font whose name matches *fontBaseName* with the specified mode enabled.

  Returns true if successful and false if unable to find the specified font name.

  Parameters

  fontBaseName The name of the font you wish to access.

  enableNonLinear
  True for nonlinear mode, and false for normal mode.

  Notes

  fontBaseName should not contain the extension *nrm* or *nln*. It should be one of *semi*, *ocra*, *trip* or *cano*.

- ```
  bool access(
    const ccOCAlphabetPtrh_const & alphabet);
  ```

  Creates a user-defined OCR font from an **ccOCAlphabet** object.

  Returns true if successful. If *alphabet* is invalid, an exception is thrown.

  Parameters

  alphabet An OC alphabet.

  Notes

  Fonts can be either fixed width or proportional width.

  Nonlinear mode is not supported for user-defined fonts. A user-defined font cannot be used as a nonlinear font in a read or tune operation.

  Requirements:

  alphabet must contain no more than 39 characters. Only the characters with the following ASCII codes are allowed: 32 (space), 45 (dash), 46 (period), 48 through 57 (digits), 65 through 90 (uppercase letters).

  The key used must be the ASCII code of the character.

  The character bitmap must be binary. That is, the bitmap must contain only two distinct values. The two values can be anything in the range of 0 through 255. The lower of the two values specifies the background and the higher value specifies the foreground.

  All character bitmaps in the alphabet must have the same height.

  A blank character must be specified with type **eBlank** only. If the alphabet contains a space character, it must be specified with type **eBlank** and have the value 32 as its key.

  Masking is not allowed.

  The area of each character must be less than or equal to 1024 pixels.

  There must be no more than one representation of any character.

  The client transform of all character pel buffers must be the identity transform.

  The string returned by **alphabet->name()** must be less than or equal to 31 characters (not including the NULL terminator).

  Throws

  ccAcuReadDefs::BadParams

  Any of the above requirements are not met.
  ```

ccAcuReadFont

fontName

```
virtual ccCvlString fontName() const;
```

Returns an ANSI string containing the name of the font being accessed. If no font is accessed, a null string is returned,

isAccessed

```
bool isAccessed() const;
```

Returns true if the most recent call to the **access()** method successfully populated the object with font information. Returns false if the call failed, or if **access()** has not yet been called.

isUserDefined

```
bool isUserDefined() const;
```

Returns true if the this font was created from an **ccOCAlphabet** and returns false otherwise.

ccAcuReadResult

```
#include <ch_cvl/acuread.h>

class ccAcuReadResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class holds the results from reading an individual character. You access instances of this class as part of a result set returned by **ccAcuRead::tune()** or **ccAcuRead::read()**. See **ccAcuReadResultSet** on page 321 of the *CVL Class Reference*.

Note You should not construct a **ccAcuReadResult** object directly.

Constructors/Destructors

ccAcuReadResult

```
ccAcuReadResult();
```

Creates a character result. Instances of this class are created automatically as part of a result set.

Operators

operator==

```
bool operator== (const ccAcuReadResult& that) const;
```

Returns true if this object equals *that*. Returns false otherwise.

Two **ccAcuReadResult** objects are considered equal if their **character()**, **location()**, **score()**, and **found()** values are equal. Doubles are compared using **cfRealEq()** with 1.e-8 as the tolerance.

Parameters

that The other **ccAcuReadResult** object.

Public Member Functions

found

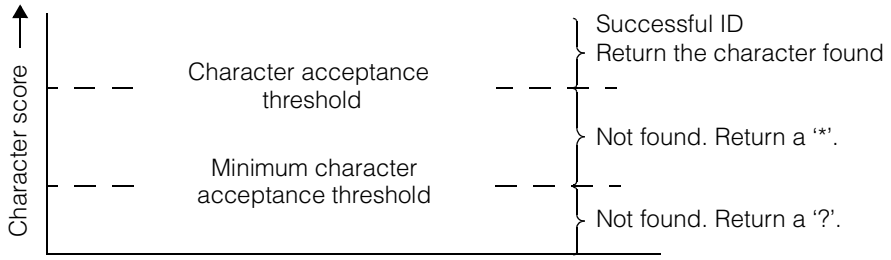
```
bool found() const;
```

Returns true if the character's score was above the *character acceptance threshold*. Returns false otherwise. See the following description.

character

```
c_Int32 character() const;
```

Returns the ASCII code of the found character. If the character was not found but the character score was above the *minimum character acceptance threshold*, it returns an asterisk '*'. If the character score was below the *minimum character acceptance threshold* it returns a question mark '?'. See the following diagram:



You specify an acceptance threshold for the entire string by calling **ccAcuReadRunParams::accept()**. acuRead derives the character acceptance threshold and the minimum character acceptance threshold from this value.

location

```
cc2Vect location() const;
```

Returns the coordinates of identified character in the client coordinate system.

Notes

The returned coordinates are invalid for prefix characters.

score

```
double score() const;
```

Returns the score of the identified character in the range 0.0 through 1.0. A value of 0.0 is always returned for force fitted fields. The value returned for characters that the OCR actually reads, as opposed to those that are force fitted, is a measure of how closely the actual character image data match the identified character. Scores returned for the special characters " " (space), "-" (dash), and "." (period) do not contribute to the overall string score.

ccAcuReadResult

ccAcuReadResultSet

```
#include <ch_cvl/acuread.h>

class ccAcuReadResultSet : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class holds the results of reading a string. In addition to the results for the string as a whole, the result set also includes a vector of results for the individual characters. The functions **ccAcuRead::tune()** and **ccAcuRead::read()** take parameters of type **ccAcuReadResultSet** and fill them with the appropriate results.

Constructors/Destructors

ccAcuReadResultSet

```
ccAcuReadResultSet();
```

Creates a result set. Default-constructed instances of this class can be passed to **ccAcuRead::tune()** and to **ccAcuRead::read()**.

Operators

operator==

```
bool operator== (const ccAcuReadResultSet& that) const;
```

Returns true if this result set is the same as another result set. Two result sets are considered equal if the following attributes are the same: string, angle, checksum, score, acquisition count, and individual character results.

Parameters

that	The other result set.

Public Member Functions

found

```
bool found() const;
```

Returns true if the character string is found. This function returns false if the score for this result is less than the accept threshold *or* if no checksum was valid (and you had enabled at least one checksum).

Notes

Always use **found()** to determine whether or not a read or tune was successful. Do not compare the value of **score()** with an accept threshold to determine success or failure.

readString

```
ccCvlString readString() const;
```

Returns the identified string.

The characters '*' or '?' are placed in positions in the string where incorrect matches were determined during the read or tune operation. See the **acuReadResult::character()** reference material for an explanation of the "*" and "?" characters.

angle

```
ccDegree angle() const;
```

Returns the angle of the identified string in the client coordinate system of the run-time image.

score

```
double score() const;
```

Returns the string score, in the range 0.0 through 1.0.

checksum1Valid

```
bool checksum1Valid() const;
```

Returns true if only one checksum was enabled (either a standard checksum or the Virtual Checksum) and that checksum passed successfully; or if two checksums were enabled (a standard checksum and Virtual Checksum), but only one of them passed.

checksum2Valid

```
bool checksum2Valid() const;
```

Returns true if a standard checksum (SEMI, BC412, or IBM412) was specified with Non-Linear OCR enabled (thereby enabling both the standard checksum and the Virtual Checksum), and both checksums passed.

acquireCount

```
c_Int32 acquireCount() const;
```

Returns the number of acquisitions completed.

result

```
const cmStd vector<ccAcuReadResult> &result() const;
```

Returns a vector of **ccAcuReadResult** objects that represent the results for each individual character. See **ccAcuReadResult** on page 317.

Notes

When running with a fixed string length the size of this vector is set by where you place the *ccAcuReadDefs::eLastField* in the **ccAcuReadRunParams** object. See **ccAcuReadRunParams::fieldString()**.

You set fixed string length mode by setting **isVariableLength()** = false in the **ccAcuReadRunParams** object passed to **ccAcuRead::tune()** or **ccAcuRead::read()**,

time

```
double time() const;
```

Returns the number of seconds the read operation took.

exitCode

```
ccAcuReadDefs::ExitCode exitCode() const;
```

When reading, this function always returns *ccAcuReadDefs::eNormal*.

When tuning it returns one of the following codes indicating how the tuning operation terminated.

ccAcuReadDefs::eNormal
ccAcuReadDefs::eValidLimit
ccAcuReadDefs::eTimeToValid
ccAcuReadDefs::eScoreLimit

runParams

```
const ccAcuReadRunParams &runParams() const;
```

Returns the **ccAcuReadRunParams** used to obtain this result.

nonlinearMode

```
bool nonlinearMode() const;
```

Returns true if nonlinear OCR was used to obtain this result, false otherwise.

ccAcuReadResultSet

ccAcuReadRunParams

```
#include <ch_cvl/acuread.h>

class ccAcuReadRunParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class lets you specify parameters used to perform optical character recognition. After you have set up a **ccAcuReadRunParams** object, you pass it to **ccAcuRead::read()**, which performs the reading operation. See **ccAcuRead** on page 301 of the *CVL Class Reference*.

You can set up the reading parameters yourself, or you can use **ccAcuRead::tune()**, which iterates over several possibilities to create a set of parameters for you.

For more detailed information about OCR, reading, and tuning, see the chapter *acuRead* in the *CVL Vision Tools Manual*.

Constructors/Destructors

ccAcuReadRunParams

```
ccAcuReadRunParams();

ccAcuReadRunParams(double accept,
  double acceptNL,
  c_Int32 lineError,
  c_Int32 spaceError,
  c_Int32 charHeight,
  c_Int32 charWidth,
  c_Int32 checksum,
  c_Int32 color,
  c_Int32 preprocessing,
  double lightPower,
  double brightFieldPowerRatio,
```

```
  const ccCvlString & prefix,
  bool isVariableLength = false,
  c_Int32 refine = 3);

ccAcuReadRunParams(const ccAcuReadRunParams &src);

~ccAcuReadRunParams();
```

- `ccAcuReadRunParams();`

  Creates a default parameters object with the following initial values:

Parameter	Initial Value
accept	0.40
acceptNL	0.7
lineError	2
spaceError	4
charHeight	28
charWidth	14
checksum	*ccAcuReadDefs::eNone*
color	*ccAcuReadDefs::eLightInverse*
preprocessing	0
lightPower	0
brightFieldPowerRatio	0
prefix	““
isVariableLength	false
refine	3

  The field map contains the string “0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ” for positions 0 through *kMaxStringLength* - 1, and *eLastField* for position *kMaxStringLength*.

-
```
ccAcuReadRunParams(
  double accept,
  double acceptNL,
```

```
c_Int32 lineError,
c_Int32 spaceError,
c_Int32 charHeight,
c_Int32 charWidth,
c_Int32 checksum,
c_Int32 color,
c_Int32 preprocessing,
double lightPower,
double brightFieldPowerRatio,
const ccCvlString & prefix,
bool isVariableLength = false,
c_Int32 refine = 3);
```

Creates a parameters object with the specified values.

Parameters

accept	The acceptance threshold for standard OCR. Valid range, 0.0 through 1.0.
acceptNL	The acceptance threshold in nonlinear mode. Valid range, 0.0 through 1.0.
lineError	The line error tolerance in pixels. Valid range, 0 through 20.
spaceError	The space error tolerance in pixels. Valid range, 0 through 20.
charHeight	The initial character height in pixels. Valid range, 8 through 128.
charWidth	The initial character width in pixels. Valid range, 8 through 64.
checksum	The checksum method. Must be one of the following values: *ccAcuReadDefs::eNone* *ccAcuReadDefs::eSemi* *ccAcuReadDefs::eVirtual* For details, see *checksum* on page 336.
color	The character color. Must be one of: *ccAcuReadDefs::eBlack* *ccAcuReadDefs::eWhite* *ccAcuReadDefs::eLightInverse* For details, see *Color* on page 310.
preprocessing	The preprocessing filters to apply. Must be one of the following values:

0: 1D TopHat
1: 1D TopHat + Low Pass
2: 1D High Pass
3: 1D High Pass + Low Pass
4: 2D Top Hat
5: 2D Top Hat + Low Pass
6: 2D High Pass
7: 2D High Pass + Low Pass
8: Clip + 1D TopHat
9: Clip + 1D TopHat + Low Pass
10: Clip + 1D High Pass
11: Clip + 1D High Pass + Low Pass
12: Clip + 2D Top Hat
13: Clip + 2D Top Hat + Low Pass
14: Clip + 2D High Pass
15: Clip + 2D High Pass + Low Pass

lightPower The light power level to be used. Valid range is 0.0 through 1.0.

brightFieldPowerRatio
The bright field power ratio specifies the fraction of the total light power allocated to the bright field.

Also see the description under *brightFieldPowerRatio* on page 338.

prefix The prefix string prepended to each read string before calculating the checksum.

isVariableLength
Set to true if the length of the string(s) to be read is not known. Set to false otherwise.

Also see description under *isVariableLength* on page 339.

refine The refinement strategy. Must be one of the following values:

0: no refinement
1: scale refinement
2: field string compliance
3: scale refinement and field string compliance (the default)

Also see notes under *refine* on page 339.

ccAcuReadDefs::BadParams
A parameter value was out of range.

- `ccAcuReadRunParams(const ccAcuReadRunParams &src);`

  Copy constructor.

  Parameters

  src The source **ccAcuReadRunParams** object.

- `~ccAcuReadRunParams();`

  Destroys a **ccAcuReadRunParams** object.

Operators

operator== `bool operator== (const ccAcuReadRunParams& that) const;`

Returns true if the attribute values in the current run parameters object are equal to those in the other.

Parameters

that The other **ccAcuReadRunParams** object.

Public Member Functions

accept

```
double accept() const;
void accept(double val);
```

- `double accept() const;`

  Returns the acceptance threshold value. This is the string acceptance threshold used by the normal mode OCR. A string must achieve at least this score to be reported as found.

  The acceptance threshold is the minimum score that a character needs to achieve to be considered a valid character.

- `void accept(double val);`

  Sets the acceptance threshold value.

  Parameters

  val The acceptance threshold. Must be a value in the range 0.0 through 1.0.

Throws

ccAcuReadDefs::BadParams
val was out of range.

acceptNL

```
double acceptNL() const;
void acceptNL(double val);
```

- `double acceptNL() const;`

  Returns the acceptance threshold for nonlinear mode.

- `void acceptNL(double val);`

  Sets the acceptance threshold for nonlinear mode.

  Parameters

  val The acceptance threshold. Must be a value in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

lineError

```
c_Int32 lineError() const;
void lineError(c_Int32 val);
```

- `c_Int32 lineError() const;`

  Returns the line error tolerance. The line error tolerance is the number of pixels that a character can be from an ideal baseline and still be considered a match.

- `void lineError(c_Int32 val);`

  Sets the line error tolerance.

  Parameters

  val The line error tolerance in pixels. Must be a value in the range 0 through 20.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

spaceError

```
c_Int32 spaceError() const;

void spaceError(c_Int32 val);
```

- `c_Int32 spaceError() const;`

  Returns the space error tolerance. The space error tolerance is the number of pixels that a character can deviate left or right from an ideal center line that spaces all of the characters equally.

- `void spaceError(c_Int32 val);`

  Sets the space error tolerance.

  Parameters

  val The space error tolerance in pixels. Must be a value in the range 0 through 20.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

fieldString

```
ccCvlString fieldString(c_Int32 position) const;

void fieldString(c_Int32 position,
 const ccCvlString &str);

void fieldString(c_Int32 position,
 ccAcuReadDefs::FieldType type);
```

- `ccCvlString fieldString(c_Int32 position) const;`

  Returns the string that lists the characters that are valid at the specified position in the string to be read.

  Parameters

  position The character position. Must be in the range 0 through *kMaxStringLength*.

  Throws

  ccAcuReadDefs::BadParams
  position was out of range.

- `void fieldString(c_Int32 position, const ccCvlString &str);`

  Specifies the characters that are valid at the specified *position* in the string to be read. "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ" is the default field string for character positions 0 through *KMaxStringLength* - 1.

  Parameters

position	The character position. Must be in the range 0 through *kMaxStringLength*.
str	String containing the acceptable characters at the specified field position. For positions 0 through *kMaxStringLength* - 1, the string can either be empty (if this field is intended to be the end of the string to be read) or contain any combination of alphanumeric characters 'A' through 'Z', '0' through '9', or special characters '–' (dash), ' ' (space), or '.' (period), without repetition. For position *kMaxStringLength*, the string must be empty.

  Example

  The following code sets the field string at field position 3 to accept numerics and special characters:

  ```
  {...
   ccAcuReadRunParams rp;
   rp.fieldString(3, "0123456 -.");
   ...
  }
  ```

  Throws

  ccAcuReadDefs::BadParams

  position was out of range, *str* included an invalid or duplicate character, a non-empty *str* is specified for position kMaxStringLength, or the length of *str* was greater than *ccAcuReadDefs::kMaxFieldStringLength–1*.

- `void fieldString(c_Int32 position, ccAcuReadDefs::FieldType type);`

  Sets the field string at the specified *position* to a predefined *fieldType* value.

  Parameters

position	The character position to be set. Must be in the range 0 through *kMaxStringLength*.
type	The type of field that is valid at the specified position.

For positions 0 through *kMaxStringLength* - 1, the following are valid field types:
ccAcuReadDefs::eAlpha ('A' through 'Z')
ccAcuReadDefs::eNumeric, ('0' through '9')
ccAcuReadDefs::eAlphanumeric, (any alphanumeric)
ccAcuReadDefs::eDash, ('-' character)
ccAcuReadDefs::ePeriod, ('.' character)
ccAcuReadDefs::eSpace, (' ' character)
ccAcuReadDefs::eSemiAlpha (Semi checksum character '0' through '7' or 'A' through 'H')

For position *kMaxStringLength*, the only valid field type is *ccAcuReadDefs::eLastField*.

See *Fields* on page 309.

Throws

ccAcuReadDefs::BadParams
position was out of range, *type* was an unknown or invalid type, or a type other than *ccAcuReadDefs::eLastField* was specified for position *kMaxStringLength*.

charHeight

```
c_Int32 charHeight() const;
void charHeight(c_Int32 val);
```

- `c_Int32 charHeight() const;`

Returns the height of the characters to be read.

- `void charHeight(c_Int32 val);`

Sets the height of the characters to be read. Values larger than the height of the region of interest cause failed reads.

Parameters

val — The expected height, in pixels, of the characters to be read. Values must be in the range 8 through 128.

Notes

If this object is being used to pass the initial parameters to **ccAcuRead::tune()**, it is recommended that *val* be equal to the *heightNominal* value of the **ccAcuReadTuneParams** object being used to pass the tuning parameters.

Throws

ccAcuReadDefs::BadParams
val was out of range.

charWidth

```
c_Int32 charWidth() const;
void charWidth(c_Int32 val);
```

- `c_Int32 charWidth() const;`

  Returns the width of the characters to be read.

- `void charWidth(c_Int32 val);`

  Sets the width of the characters to be read. Values larger than the width of the region of interest cause failed reads.

  Parameters

  val — The expected width, in pixels, of the characters to be read. Values must be in the range 8 through 64.

  Notes

  If this object is being used to pass the initial parameters to **ccAcuRead::tune()**, it is recommended that *val* be equal to the *widthNominal* value of the **ccAcuReadTuneParms** object being used to pass the tuning parameters.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

color

```
ccAcuReadDefs::Color color() const;
void color(ccAcuReadDefs::Color val);
```

- `ccAcuReadDefs::Color color() const;`

  Returns the character color.

- `void color(ccAcuReadDefs::Color val);`

  Sets the character color.

Notes

The default color, *ccAcuReadDefs::eLightInverse*, should not be used with the overloads of **ccAcuRead::read()** and **ccAcuRead::tune()** that examine images stored in pel buffers.

Parameters

val The character color. Must be one of:

ccAcuReadDefs::eBlack
ccAcuReadDefs::eWhite
ccAcuReadDefs::eLightInverse

For details, see *Color* on page 310.

Throws

ccAcuReadDefs::BadParams
val was an unsupported value.

preprocessing

```
c_UInt32 preprocessing() const;

void preprocessing(c_UInt32 val);
```

- `c_UInt32 preprocessing() const;`

Returns the preprocessing options.

- `void preprocessing(c_UInt32 val);`

Sets the preprocessing options to use when reading a string.

Parameters

val The preprocessing options. Must be one of the following values:

0: 1D TopHat
1: 1D TopHat + Low Pass
2: 1D High Pass
3: 1D High Pass + Low Pass
4: 2D Top Hat
5: 2D Top Hat + Low Pass
6: 2D High Pass
7: 2D High Pass + Low Pass
8: Clip + 1D TopHat
9: Clip + 1D TopHat + Low Pass
10: Clip + 1D High Pass
11: Clip + 1D High Pass + Low Pass
12: Clip + 2D Top Hat

13: Clip + 2D Top Hat + Low Pass
14: Clip + 2D High Pass
15: Clip + 2D High Pass + Low Pass

The 1D and 2D versions of the top-hat and high-pass filters enable you to choose between one-dimensional and two-dimensional operations on pixel values. The 2D options are more accurate, but slower than the 1D options.

Notes

If this runparams object was initialized by **ccAcuRead::tune()**, changing the preprocessing options is not recommended.

Throws

ccAcuReadDefs::BadParams
val was an unsupported value.

checksum

```
ccAcuReadDefs::Checksum checksum() const;
void checksum(ccAcuReadDefs::Checksum val);
```

- `ccAcuReadDefs::Checksum checksum() const;`

Returns the checksum method.

- `void checksum(ccAcuReadDefs::Checksum val);`

Sets the checksum method or methods.

Parameters

val The checksum method. Must be one of the following values:

Checksum selected	Interpretation
ccAcuReadDefs::eNone	*eNone*
ccAcuReadDefs::eSemi	*eSemi + eVirtual*
ccAcuReadDefs::eBC412	*eBC412 + eVirtual*
ccAcuReadDefs::eIBM412	*eIBM412 + eVirtual*
ccAcuReadDefs::eVirtual	*eVirtual*

Throws

ccAcuReadDefs::BadParams
val was an unsupported value.

Notes

ccAcuReadDefs::eNone disables all checksums.

ccAcuReadDefs::eVirtual enables Virtual Checksum if Non-Linear OCR is enabled, and is ignored if Non-Linear OCR is not enabled.

ccAcuReadDefs::eSemi enables the SEMI checksum if Non-Linear OCR is disabled, and enables both the SEMI checksum and the Virtual Checksum when Non-Linear OCR is enabled.

eVirtual is ignored when using user-defined fonts.

Checksum is not supported for variable length strings. If the checksum method is set, the **ccAcuRead::tune()** and **ccAcuRead::run()** member functions will throw an exception. Refer to the **ccAcuRead::tune()** and **ccAcuRead::read()** methods for information on enabling Non-Linear OCR.

lightPower

```
double lightPower() const;
void lightPower(double val);
```

- `double lightPower() const;`

Returns the light power value.

- `void lightPower(double val);`

Sets the light power.

Parameters

val The light power. Must be in the range 0.0 through 1.0.

Throws

ccAcuReadDefs::BadParams
val was out of range.

brightFieldPowerRatio

```
double brightFieldPowerRatio() const;
void brightFieldPowerRatio(double val);
```

The bright field power ratio specifies the fraction of the total light power allocated to the bright field. The setting must be in the range 0.0 through 1.0. A value of 0.0 indicates bright field is completely off, and a value of 1.0 indicates bright field is fully on.

This is a tunable parameter.

- `double brightFieldPowerRatio() const;`

  Returns the current bright field power ratio setting.

- `void brightFieldPowerRatio(double val);`

  Sets a new bright field power ratio setting.

  Parameters

  val The new bright field power ratio setting.

  Throws

  ccAcuReadDefs::BadParams
  If *val* is outside the valid range.

prefix

```
ccCvlString prefix() const;
void prefix(const ccCvlString & str);
```

- `ccCvlString prefix() const;`

  Returns the prefix string prepended to each read string before calculating the checksum.

- `void prefix(const ccCvlString & str);`

  Sets the prefix string prepended to each read string before calculating the checksum.

  Parameters

  str The prefix string.

refine

```
c_Int32 refine() const;
void refine(c_Int32 val);
```

The result refinement strategy. Controls the scale refinement and field string compliance as described below:

Value	Scale refinement	Field string compliance
0	Disabled	Disabled
1	Enabled	Disabled
2	Disabled	Enabled
3 (default)	Enabled	Enabled

- `c_Int32 refine() const;`

  Returns the refinement strategy.

- `void refine(c_Int32 val);`

  Sets a new refinement strategy.

  Parameters

  val The new refinement strategy.

  Throws

  ccAcuReadDefs::BadParams
  If *val* is outside the valid range.

  Notes

  Turning off string compliance causes acuRead to ignore any specified field strings and to use the default field string (‘0’ through ‘9’, ‘A’ through ‘Z’) to read all characters.

  This function is included for backward compatibility; its use is not recommended.

isVariableLength

```
bool isVariableLength() const;
void isVariableLength(bool isVarLen);
```

Set *isVariableLength* to true if the length of the string(s) to be read is not known. When set to true, the tool considers the length of the field map as the maximum possible value. Consequently, the read operation can result in a string that is smaller than the field map. If set to false, the resulting string length will always be equal to that of the field map.

- `bool isVariableLength() const;`

  Returns the *isVariableLength* flag; true or false.

- `void isVariableLength(bool isVarLen);`

  Sets the *isVariableLength* flag.

  Parameters

  isVarLen The new flag value, true of false.

  Notes

  Characters at the rightmost and leftmost positions of a string are termed end characters. The tool will not report any end characters whose score is below the accept threshold. These will not affect the overall score of the string. However, non-end (middle) characters with a “?” or a “*” will be reported and will affect the overall score. For information about characters reported as “?” or “*” see the **ccAcuReadResult::character()** reference material.

  It may not be possible to provide certain types of information using the field string API for variable length strings. For example, if a single “-” is expected in a string but its position varies from one string to another, and you do not want the “-” to be a choice for other positions in the field string, there is no way to specify this case with the API.

  Checksum is not supported for variable length strings. If the checksum method is set, the **ccAcuRead::tune()** and **ccAcuRead::run()** member functions will throw an exception. Refer to the **ccAcuRead::tune()** and **ccAcuRead::read()** methods for information.

Deprecated Members

The following function is deprecated and is now maintained for backward compatibility only. For new code development use **brightFieldPowerRatio()**.

darkLevel

```
double darkLevel() const;

void darkLevel(double val);
```

- `double darkLevel() const;`

  Returns the dark level to be used. The range must be between 0.0 and 1.0.

- `void darkLevel(double val);`

  Sets the darkLevel to be used. The range must be between 0.0 and 1.0.

  Parameters

  val Dark level in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

ccAcuReadRunParams

ccAcuReadTuneParams

```
#include <ch_cvl/acuread.h>

class ccAcuReadTuneParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class lets you specify the parameters used to tune the lighting, filtering, and character-scaling parameters that affect optical character recognition.

In addition to passing **ccAcuRead::tune()** a **ccAcuReadRunParams** object with initial reading parameters, you pass a **ccAcuReadTuneParams** object to specify how the tuning function should alter the initial parameters as it attempts to find the run parameters that yield the best string score. See **ccAcuRead** on page 301.

For more detailed information about OCR, reading, and tuning, see the chapter *acuRead* in the *CVL Vision Tools Manual*.

Constructors/Destructors

ccAcuReadTuneParams

```
ccAcuReadTuneParams();

ccAcuReadTuneParams(bool enableDark,
  double darkLow,
  double darkHigh,
  double darkStep,
  bool enableBright,
  double brightLow,
  double brightHigh,
  double brightStep,
  bool enableHeight,
  c_Int32 heightNominal,
  c_Int32 heightRange,
  bool enableWidth,
  c_Int32 widthNominal,
  c_Int32 widthRange,
  c_UInt32 enableOcrf,
  c_Int32 validLimit,
  double timeToValid,
```

```
  double scoreLimit,
  bool scoreLimitChecksum,
  double timeToScore);

~ccAcuReadTuneParams();
```

- `ccAcuReadTuneParams();`

  Creates a default tune-parameters object. The initial parameters are set as follows:

Parameter	Value
enableDark	true
darkLow	0.062745
darkHigh	1.0
darkStep	0.12157
enableBright	true
brightLow	0.062745
brightHigh	1.0
brightStep	0.12157
enableHeight	true
heightNominal	28
heightRange	4
enableWidth	true
widthNominal	14
widthRange	2
enableOcrf	*ccAcuReadDefs::eAll*
validLimit	255
timeToValid	30000
scoreLimit	0.10
scoreLimitChecksum	false
timeToScore	30000

- ```
  ccAcuReadTuneParams(bool enableDark,
    double darkLow,
    double darkHigh,
    double darkStep,
    bool enableBright,
    double brightLow,
    double brightHigh,
    double brightStep,
    bool enableHeight,
    c_Int32 heightNominal,
    c_Int32 heightRange,
    bool enableWidth,
    c_Int32 widthNominal,
    c_Int32 widthRange,
    c_UInt32 enableOcrf,
    c_Int32 validLimit,
    double timeToValid,
    double scoreLimit,
    bool scoreLimitChecksum,
    double timeToScore);
  ```

  Parameters

enableDark	True to enable darkfield tuning.
darkLow	The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkHigh	The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkStep	The darkfield step value. Must be in the range 0.0 through 1.0.
enableBright	True to enable brightfield tuning.
brightLow	The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0.
brightHigh	The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0.
brightStep	The brightfield step value. Must be in the range 0.0 through 1.0.
enableHeight	True to enable tuning for character height.
heightNominal	The nominal character height, in pixels. Must be in the range 8 through 128.
heightRange	The character height range, in pixels. Must be in the range 0 through 16.
enableWidth	True to enable tuning of character width.
  ```

widthNominal The nominal character width, in pixels. Must be in the range 8 through 64.

widthRange The character width range, in pixels. Must be in the range 0 through 16.

enableOcrf One of the following values that specify which filters to tune (or zero to disable filter tuning):

ccAcuReadDefs::eLoPass
ccAcuReadDefs::eHiPass
ccAcuReadDefs::eTopHat
ccAcuReadDefs::eClip
ccAcuReadDefs::eAll

validLimit The maximum number of successful reads that can occur without producing a new best score.

timeToValid The maximum number of seconds to spend tuning.

scoreLimit The score threshold for early termination of tuning. Must be in the range 0.0 through 1.0.

scoreLimitChecksum
True terminates tuning if the checksum passes.

timeToScore The maximum time, in seconds, that can elapse before tuning reaches *scoreLimit*.

Throws

ccAcuReadDefs::BadParams
A parameter value was out of range.

- `~ccAcuReadTuneParams();`

Destroys a tune-parameters object.

Operators

operator== `bool operator== (const ccAcuReadTuneParams& that) const;`

Returns true if these tuning parameters are the same as another set. Two tuning parameter sets are considered equal if all of their attributes are the same.

Parameters

that The other tuning parameter set.

Public Member Functions

enableDark

```
bool enableDark() const;
void enableDark(bool val);
```

- `bool enableDark() const;`

  Returns true if darkfield tuning is enabled.

- `void enableDark(bool val);`

  Enables or disables darkfield tuning.

  Parameters

  val — True to enable darkfield tuning, false to disable.

darkLow

```
double darkLow() const;
void darkLow(double val);
```

- `double darkLow() const;`

  Returns the minimum light power for darkfield tuning.

- `void darkLow(double val);`

  Sets the minimum light power for darkfield tuning.

  Parameters

  val — The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

darkHigh

```
double darkHigh() const;
void darkHigh(double val);
```

- `double darkHigh() const;`

  Returns the maximum light power for darkfield tuning.

- `void darkHigh(double val);`

  Sets the maximum light power for darkfield tuning.

  Parameters

  val The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

darkStep

```
double darkStep() const;
void darkStep(double val);
```

- `double darkStep() const;`

  Returns the darkfield step for tuning.

- `void darkStep(double val);`

  Sets the darkfield step for tuning.

  Parameters

  val The darkfield step value. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

enableBright

```
bool enableBright() const;
void enableBright(bool val);
```

- `bool enableBright() const;`

  Returns true if brightfield tuning is enabled.

- `void enableBright(bool val);`

  Enables or disables brightfield tuning.

  Parameters

  val True to enable brightfield tuning, false to disable.

brightLow

```
double brightLow() const;
void brightLow(double val);
```

- `double brightLow() const;`

  Returns the minimum light power for brightfield tuning.

- `void brightLow(double val);`

  Sets the minimum light power for brightfield tuning.

  Parameters

  val The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

brightHigh

```
double brightHigh() const;
void brightHigh(double val);
```

- `double brightHigh() const;`

  Returns the maximum light power for brightfield tuning.

- `void brightHigh(double val);`

  Returns the maximum light power for brightfield tuning.

  Parameters

  val The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

ccAcuReadTuneParams

brightStep

```
double brightStep() const;
void brightStep(double val);
```

- `double brightStep() const;`

  Returns the brightfield step for tuning.

- `void brightStep(double val);`

  Sets the brightfield step for tuning.

  Parameters

  val The brightfield step value. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

enableHeight

```
bool enableHeight() const;
void enableHeight(bool val);
```

- `bool enableHeight() const;`

  Returns true if character height tuning is enabled.

- `void enableHeight(bool val);`

  Enables or disables character height tuning.

  Parameters

  val True to enable character height tuning, false to disable.

heightNominal

```
c_Int32 heightNominal() const;
void heightNominal(c_Int32 val);
```

- `c_Int32 heightNominal() const;`

  Returns the nominal (initial) character height.

- `void heightNominal(c_Int32 val);`

  Sets the nominal (initial) character height.

  Parameters

  val — The nominal character height, in pixels. Must be in the range 8 through 128. It is recommended that *val* be equal to the *charHeight* value of the **ccAcuReadRunParams** object being used to pass the initial parameters to **ccAcuRead::tune()**.

  Throws

  ccAcuReadDefs::BadParams — *val* was out of range.

heightRange

`c_Int32 heightRange() const;`

`void heightRange(c_Int32 val);`

- `c_Int32 heightRange() const;`

  Returns the tolerance that controls the range of character heights tested during tuning. The range is twice this value, which is a plus-and-minus tolerance applied to the nominal height.

- `void heightRange(c_Int32 val);`

  Sets the tolerance that controls the range of character heights tested during tuning. The range is twice this value, which is a plus-and-minus tolerance applied to the nominal height.

  Parameters

  val — The character height tolerance, in pixels. Must be in the range 0 through 16.

  Throws

  ccAcuReadDefs::BadParams — *val* was out of range.

  Notes

  During tuning, acuRead sometimes tests values outside the range you specify, with the result that the character height returned after tuning may fall outside the range (*heightNominal* – *heightRange*, *heightNominal* + *heightRange*).

ccAcuReadTuneParams

enableWidth

```
bool enableWidth() const;
void enableWidth(bool val);
```

- `bool enableWidth() const;`

  Returns true if character width tuning is enabled.

- `void enableWidth(bool val);`

  Enables or disables character width tuning.

  Parameters

  val — True to enable character width tuning, false to disable.

widthNominal

```
c_Int32 widthNominal() const;
void widthNominal(c_Int32 val);
```

- `c_Int32 widthNominal() const;`

  Returns the nominal (initial) character width.

- `void widthNominal(c_Int32 val);`

  Sets the nominal (initial) character width.

  Parameters

  val — The nominal character width, in pixels. Must be in the range 8 through 64. It is recommended that *val* be equal to the *charWidth* value of the **ccAcuReadRunParams** object being used to pass the initial parameters to **ccAcuRead::tune()**.

  Throws

  ccAcuReadDefs::BadParams — *val* was out of range.

widthRange

```
c_Int32 widthRange() const;

void widthRange(c_Int32 val);
```

- `c_Int32 widthRange() const;`

  Returns the tolerance that controls the range of character widths tested during tuning. The range is twice this value, which is a plus-and-minus tolerance applied to the nominal width.

- `void widthRange(c_Int32 val);`

  Sets the tolerance that controls the range of character widths tested during tuning. The range is twice this value, which is a plus-and-minus tolerance applied to the nominal width.

  Parameters

  val — The character width tolerance, in pixels. Must be in the range 0 through 16.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

  Notes

  During tuning, acuRead sometimes tests values outside the range you specify, with the result that the character width returned after tuning may fall outside the range (*widthNominal* – *widthRange*, *widthNominal* + *widthRange*).

enableOcrf

```
c_UInt32 enableOcrf() const;

void enableOcrf(c_UInt32 code);
```

- `c_UInt32 enableOcrf() const;`

  Returns zero if filter tuning is disabled or, when filter tuning is enabled, a value formed by ORing together one or more of the following values:

  ccAcuReadDefs::eLoPass
  ccAcuReadDefs::eHiPass
  ccAcuReadDefs::eTopHat
  ccAcuReadDefs::eClip
  ccAcuReadDefs::eAll

  The returned value indicates which filters will be considered during filter tuning.

- `void enableOcrf(c_UInt32 code);`

  Specifies which filters will be considered during filter tuning.

  Parameters

  code The preprocessing options. Use zero to disable filter tuning. Use any of the following values, which can be ORed together, to enable filter tuning:

  ccAcuReadDefs::eLoPass
  ccAcuReadDefs::eHiPass
  ccAcuReadDefs::eTopHat
  ccAcuReadDefs::eClip
  ccAcuReadDefs::eAll

  For details, see *OcrfFlags* on page 310.

  Throws

  ccAcuReadDefs::BadParams
  If *code* is an invalid value.

  Notes

  Either *ccAcuReadDefs::eTopHat* or *ccAcuReadDefs::eHiPass* must be selected for tuning to take place. If one of these filters is not chosen, filter tuning is not performed.

validLimit

```
c_Int32 validLimit() const;
void validLimit(c_Int32 val);
```

- `c_Int32 validLimit() const;`

  Returns the maximum number of successful reads that can be performed during tuning without producing a new best score.

- `void validLimit(c_Int32 val);`

  Sets the maximum number of successful reads that can occur during tuning without producing a new best score.

  Parameters

  val The maximum number of successful reads. Must be in the range 0 through 255.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

timeToValid

```
double timeToValid() const;
void timeToValid(double val);
```

- `double timeToValid() const;`

  Returns the maximum number of seconds to spend tuning.

- `void timeToValid(double val);`

  Sets the maximum number of seconds to spend tuning.

  Parameters

  val The maximum number of seconds to spend tuning. Must be nonnegative

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

scoreLimit

```
double scoreLimit() const;
void scoreLimit(double val);
```

- `double scoreLimit() const;`

  Returns the string score that tuning must reach within **timeToScore()** seconds in order for tuning to continue.

- `void scoreLimit(double val);`

  Sets the string score that tuning must reach within **timeToScore()** seconds to continue.

  If **scoreLimitChecksum()** is true, the string being read will also need to pass its checksum for tuning to continue beyond **timeToScore()** seconds.

  Parameters

  val The score threshold for early termination of tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuReadDefs::BadParams
  val was out of range.

scoreLimitChecksum

```
bool scoreLimitChecksum() const;
void scoreLimitChecksum(bool val);
```

- `bool scoreLimitChecksum() const;`

  Returns true if the tuning operation considers the checksum in addition to the string score to determine whether tuning should continue beyond **timeToScore()** seconds.

- `void scoreLimitChecksum(bool val);`

  Specifies whether or not the string must pass its checksum within **timeToScore()** seconds for tuning to continue.

  Parameters

  val — True to use the checksum, false to exclude the checksum.

  Notes

  If no checksum is enabled by the *initial* run parameters you pass to **ccAcuRead::tune()**, setting **scoreLimitChecksum()** true has no effect.

timeToScore

```
double timeToScore() const;
void timeToScore(double val);
```

- `double timeToScore() const;`

  Returns the maximum number of seconds that tuning can continue before the string reaches **scoreLimit()** and, if **scoreLimitChecksum()** is true, passes its checksum.

- `void timeToScore(double val);`

  Sets the maximum number of seconds that tuning can continue before the string reaches **scoreLimit()** and, if **scoreLimitChecksum()** is true, passes its checksum.

  Parameters

  val — The maximum number of seconds to tune without reaching the desired string score and, if required, passing the checksum. Must be nonnegative.

  Throws

  ccAcuReadDefs::BadParams — *val* was out of range.

ccAcuSymbolDataMatrixDefs

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolDataMatrixDefs: public ccAcuSymbolDefs;
```

A name space that holds enumerations and constants used with the Symbol tool classes.

Enumerations

ECCType

```
enum ECCType;
```

Values for the ECCType parameter:

Value	Meaning
eECC0	ECC level 0
eECC050	ECC level 50
eECC080	ECC level 80
eECC100	ECC level 100
eECC140	ECC level 140
eECC200	ECC level 200
kDefaultECC	*eECC200*

LearnFlags

```
enum LearnFlags;
```

Setting the following LearnFlags determines which parameters the tool learns:

Value	Meaning
eNone = 0	Tool learns no parameters.
eECC = 1	Tool learns ECC level.
eGrid = 2	Tool learns Grid size.
eNominalGrid = 4	Tool learns nominal grid.
ePolarity = 8	Tool learns polarity.
eModel = 16	Turns optimization on.

Value	Meaning
eAll = 31	Tool learns all learning parameters.
kDefaultLearn = eAll	Default is for the tool to learn all learning parameters.

kMaxDataMatrixModelSize

```
enum kMaxDataMatrixModelSize;
```

Maximum size for a Data Matrix symbol:

Value	Meaning
kMaxDataMatrixModelSize = 48	The maximum supported symbol size is 48.

Polarity

```
enum Polarity;
```

Values for the Polarity parameter:

Value	Meaning
eDarkOnLight	Dark symbol on a light background
eLightOnDark	Light symbol on a dark background

ccAcuSymbolDataMatrixLearnParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolDataMatrixLearnParams:
  public ccAcuSymbolLearnParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The class **ccAcuSymbolDataMatrixLearnParams** supplies the parameters that the Symbol tool uses to create a Data Matrix symbol model. The tool can acquire values for the parameters in this class in the following ways:

- You can set the Learn parameters to their default values by using the default constructor.
- You can specify values for specific Learn parameters using the overload constructor.
- You can set values for the Learn parameters using the setters of the class.
- You can have the tool learn the parameters specified by **learnFlags**. For those parameters not learned by the tool, you use this class to specify the values.

Constructors/Destructors

ccAcuSymbolDataMatrixLearnParams

```
ccAcuSymbolDataMatrixLearnParams();

virtual ~ccAcuSymbolDataMatrixLearnParams();

ccAcuSymbolDataMatrixLearnParams(
   const ccAffineRectangle& nominalGrid,
   c_UInt8 nrows,
   c_UInt8 ncols,
   ccAcuSymbolDataMatrixDefs::ECCType ecc =
      ccAcuSymbolDataMatrixDefs::kDefaultECC,
   ccAcuSymbolDataMatrixDefs::Polarity symbolPolarity =
   ccAcuSymbolDataMatrixDefs::eDarkOnLight,
   ccRadian angle = ccRadian(0.0),
```

```
   double scale = 1.0,
   bool aimFlag = true,
   bool mirror = false);
```

- `ccAcuSymbolDataMatrixLearnParams();`

  Default constructor. The members are initialized to their default values, which are:

Parameter	Value
nRows	10
nCols	10
nominalGrid	Points at (0, 10), (10, 10), (0, 0)
eccType	*ccAcuSymbolDataMatrixDefs::kDefaultECC*
symbolPolarity	*ccAcuSymbolDataMatrixDefs::eDarkOnLight*
aimFlag	True

  Notes

  The nominal grid as well as the number of rows and columns are set to match the smallest symbol size (10 x 10) allowed for an AIM-compliant Data Matrix symbol (version ECC 200). The transform of the nominal grid is set to identity.

- `virtual ~ccAcuSymbolDataMatrixLearnParams();`

  Destroys instances of this class.

- ```
  ccAcuSymbolDataMatrixLearnParams(
     const ccAffineRectangle& nominalGrid,
     c_UInt8 nrows,
     c_UInt8 ncols,
     ccAcuSymbolDataMatrixDefs::ECCType ecc =
        ccAcuSymbolDataMatrixDefs::kDefaultECC,
     ccAcuSymbolDataMatrixDefs::Polarity symbolPolarity =
     ccAcuSymbolDataMatrixDefs::eDarkOnLight,
     ccRadian angle = ccRadian(0.0),
     double scale = 1.0,
     bool aimFlag = true,
     bool mirror = false);
  ```

  Constructor overload with specified values.
  ```

Parameters

nominalGrid The affine rectangle that encloses the symbol.

nrows The number of rows in the symbol. For AIM-compliant symbols, the number of rows must be the same as the number of columns for the symbol grid for all versions except *eECC200*.

For AIM-compliant square symbols, *nrows* should be:

Odd and in the range 9 through *kMaxDataMatrixModelSize* if the ECC type specified is *eECC0-eECC140*.

Even and in the range 10 through *kMaxDataMatrixModelSize* if the version specified is *eECC200*.

For AIM-compliant rectangular symbols (version ECC 200 only), *nrows* must be one of the following combinations:

nrows	ncols
8	18
8	32
12	26
12	36
16	36
16	48

ncols The number of columns in the symbol. For AIM-compliant symbols, the number of rows must be the same as the number of columns for the symbol grid for all versions except *eECC200*.

For AIM-compliant square symbols, *ncols* should be:

Odd and in the range 9 through *kMaxDataMatrixModelSize* if the ECC type specified is *eECC0-eECC140*.

Even and in the range 10 through *kMaxDataMatrixModelSize* if the version specified is *eECC200*.

For AIM-compliant rectangular symbols (version ECC 200 only), *ncols* must be one of the following combinations:

nrows	ncols
8	18
8	32
12	26
12	36
16	36
16	48

ecc The ECC level.

symbolPolarity The polarity of the symbol, either dark-on-light or light-on-dark.

angle The angle of the symbol relative to the model. Should be specified in radians.

scale The scale of the symbol relative to the model. *scale* should be greater than 0.

aimFlag If true, then the symbol is AIM-compliant.

mirror If true, then the tool reverses the image of the symbol after acquisition.

Throws

ccAcuSymbolDefs::BadParams
The conditions described above are not met.

Operators

operator==

```
bool operator== (
   const ccAcuSymbolDataMatrixLearnParams &that) const;
```

Compares this object with another. Two **ccAcuSymbolDataMatrixLearnParams** objects are considered equal if all their corresponding data members are identical.

Public Member Functions

aimFlag

```
bool aimFlag() const;
```

Gets the AIM-compliance flag.

cols

```
c_UInt8 cols() const;
```

Gets the number of columns in the symbol grid.

ecc

```
ccAcuSymbolDataMatrixDefs::ECCType ecc()
   const;
```

Gets the Data Matrix version specified by ECC level.

modelTypeAndSize

```
void modelTypeAndSize (
   ccAcuSymbolDataMatrixDefs::ECCType ecc,
   c_UInt8 rows,
   c_UInt8 cols
   bool aimFlag);
```

Sets the version, number of rows, and number of columns in the symbol grid; it also specifies AIM compliance.

Parameters

ecc — The Data Matrix version specified by ECC level.

nrows — The number of rows in the symbol. For AIM-compliant symbols, the number of rows must be the same as the number of columns for the symbol grid for all versions except *eECC200*.

For AIM-compliant square symbols, *nrows* should be:

Odd and in the range 9 through *kMaxDataMatrixModelSize* if the ECC type specified is *eECC0-eECC140*.

Even and in the range 10 through *kMaxDataMatrixModelSize* if the version specified is *eECC200*.

For AIM-compliant rectangular symbols (version ECC 200 only), *nrows* must be one of the following combinations:

nrows	ncols
8	18
8	32
12	26
12	36
16	36
16	48

rows and *cols* should be in the range 9 through *kMaxDataMatrixModelSize*, but need not be equal or have a pre-determined size.

ncols

The number of columns in the symbol. For AIM-compliant symbols, the number of rows must be the same as the number of columns for the symbol grid for all versions except *eECC200*.

For AIM-compliant square symbols, *ncols* should be:

Odd and in the range 9 through *kMaxDataMatrixModelSize* if the ECC type specified is *eECC0-eECC140*.

Even and in the range 10 through *kMaxDataMatrixModelSize* if the version specified is *eECC200*.

For AIM-compliant rectangular symbols (version ECC 200 only), *ncols* must be one of the following combinations:

nrows	ncols
8	18
8	32
12	26
12	36
16	36
16	48

rows and *cols* should be in the range 9 through *kMaxDataMatrixModelSize*, but need not be equal or have a pre-determined size.

aimFlag The AIM-compliance flag. It is learned only when the tool operates in high-contrast mode. Otherwise, you must supply a flag value. For AIM-compliant square symbols, *aimFlag* must be set true. For non-AIM-compliant symbols, *aimFlag* must be set false.

Throws

ccAcuSymbolDefs::BadParams
The conditions described above are not met.

Notes

For all versions except ECC 200, the number of rows must be the same as the number of columns for the symbol grid.

The row and column specification does not include the quiet zone.

rows

```
c_UInt8 rows() const;
```

Gets the number of rows in the symbol grid.

symbolPolarity

```
ccAcuSymbolDataMatrixDefs::Polarity symbolPolarity()
   const;

void symbolPolarity (
   ccAcuSymbolDataMatrixDefs::Polarity pol);
```

- ```
  ccAcuSymbolDataMatrixDefs::Polarity symbolPolarity()
     const;
  ```

  Gets the symbol polarity.

- ```
  void symbolPolarity (
     ccAcuSymbolDataMatrixDefs::Polarity pol);
  ```

  Sets the symbol polarity.

  Parameters

  pol The polarity of the symbol, either dark on light or light on dark.

ccAcuSymbolDataMatrixLearnParams

ccAcuSymbolDataMatrixTool

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolDataMatrixTool: public ccAcuSymbolTool;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

You use this class to create the central object for the Data Matrix tool, which contains the trained representation of a Data Matrix symbol, and the functions for the learn and decode phases of the tool's operation.

Constructors/Destructors

ccAcuSymbolDataMatrixTool

```
ccAcuSymbolDataMatrixTool(
  ccAcuSymbolDefs::OperatingMode opMode =
  ccAcuSymbolDefs::eAutoDetect);

virtual ~ccAcuSymbolDataMatrixTool();

ccAcuSymbolDataMatrixTool(
  const ccAcuSymbolDataMatrixLearnParams& learnParams,
  c_UInt32 learnFlags,
  ccAcuSymbolDefs::OperatingMode opMode =
  ccAcuSymbolDefs::eAutoDetect );
```

- `ccAcuSymbolDataMatrixTool(`
  `ccAcuSymbolDefs::OperatingMode opMode =`
  `ccAcuSymbolDefs::eAutoDetect);`

  Constructs a Symbol tool for decoding Data Matrix symbols. The tool is in an unlearned state, the operating mode defaults to *eAutoDetect*, and all members are initialized to the following defaults:

Parameter	Value
initialLearnParams	default constructed **ccAcuSymbolDataMatrixLearnParams**
bestLearnedParams	default constructed **ccAcuSymbolDataMatrixLearnParams**
learnFlags	*ccAcuSymbolDataMatrixDefs::eAll*
isLearned	false

- `virtual ~ccAcuSymbolDataMatrixTool();`

  Destroys instances of this class.

- ```
  ccAcuSymbolDataMatrixTool(
    const ccAcuSymbolDataMatrixLearnParams& learnParams,
    c_UInt32 learnFlags,
    ccAcuSymbolDefs::OperatingMode opMode =
    ccAcuSymbolDefs::eAutoDetect);
  ```

  Creates a Symbol tool that learns those parameters in the **ccAcuSymbolDataMatrixLearnParams** object specified by *learnFlags* and sets the remaining parameters to their defaults or to those values supplied by the setters of the **ccAcuSymbolDataMatrixLearnParams** class. (Constructor overload)

  Requires that **learnFlags** be a bitwise combination of any of the **ccAcuSymbolDataMatrixDefs::LearnFlags** values. *learnFlags* must be in the range [0, 31].

  Parameters

  learnParams — Parameters that the tool can learn or that you can set. Examples include ECC level, grid size, nominal grid, and polarity. You must set the Learn parameter *mirrorFlag* or use the default.

  learnFlags — Flags that when set direct the tool to learn a specific Learn parameter.

  opMode — Determines the operating mode for the tool, which can be one of:
  ccAcuSymbolDefs::eStandard
  ccAcuSymbolDefs::eHighContrast
  ccAcuSymbolDefs::eAutoDetect

  Throws

  ccAcuSymbolDefs::BadParams
  learnFlags is not in the range 0 through 31.

Public Member Functions

bestLearnedParams

```
const ccAcuSymbolDataMatrixLearnParams&
  bestLearnedParams() const;
```

Returns the final learned parameters after the tool, which is in Learn and Decode mode, has performed the following actions:

1. Found a symbol in the image
2. Learned the parameters specified by **learnFlags**
3. Created a model from the parameters specified by **learnFlags** and those specified by the **ccAcuSymbolDataMatrixLearnParams** object
```

4. Decoded the symbol

Notes

This function should be used to get the learned parameters after the tool has undergone learning successfully as indicated by **isLearned()** returning true.

Throws

ccAcuSymbolDefs::NotLearned

This function is invoked when the tool has not undergone the learning phase successfully and **isLearned()** returns false.

decode

```
bool decode (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAcuSymbolFinderParams& findParams,
  ccAcuSymbolResult& result) const;
```

Finds the symbol in the given image and decodes it using the specified Find parameters and internally stored Learn parameters. The result of decoding is returned via the result object. Returns true if successful, false if the operation failed. Requires that the image be bound.

This function places the tool in Standard Decode mode for Data Matrix symbology.

Parameters

image The acquired image. The pel buffer must be bound.

findParams The Find parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.

result The result object that contains data derived from the decoding operation including angle, score, and scale.

Notes

In high-contrast mode, the tool ignores the *findParams* value, and instead uses 5% as a scale range and 180 degrees (or **ckPI**/2) as an angle range.

This function supports the use of a **ccTimeout**-based timeout.

Throws

ccAcuSymbolDefs::BadImage

The image is not bound.

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

initialLearnParams

```
const ccAcuSymbolDataMatrixLearnParams&
  initialLearnParams() const;

void initialLearnParams(
  const ccAcuSymbolDataMatrixLearnParams& learnParams);
```

- ```
  const ccAcuSymbolDataMatrixLearnParams&
    initialLearnParams() const;
  ```

  Gets the initial parameters used for learning prior to estimation by the learn and decode phase.

- ```
  void initialLearnParams(
    const ccAcuSymbolDataMatrixLearnParams& learnParams);
  ```

  Sets the initial parameters used for learning, prior to estimation by the learn and decode phase.

  Parameters

  learnParams — Parameters that the tool can learn or that you can set. Examples include ECC level, grid size, nominal grid, and polarity. You must set the Learn parameter **mirrorFlag** or use the default.

  Notes

  The setter function should be used to initialize the learn parameters in preparation for the learning phase.

  When operating in high-contrast mode, the tool ignores all initial learn parameters except the cell size range.

learn

```
void learn (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAcuSymbolFinderParams& findParams,
  ccAcuSymbolResult& result);
```

Estimates the optimal configuration of selected symbol learning parameters as specified by *initialLearnParams* and *learnFlags*. If learning is successful, the tool updates *bestLearnedParams* and decodes the symbol using the internally learned parameters and the *findParams* object. Finally, the tool returns decoding results via the result object. Requires that the image be bound.

This function places the tool in Learn and Decode mode for Data Matrix symbology.

Parameters

image — The acquired image. The pel buffer must be bound.

findParams The Find parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.

result The result object that contains data derived from the decoding operation including angle, score, and scale.

Notes

In high-contrast mode, the tool ignores the *findParams* value, and instead uses 5% as a scale range and 180 degrees (or **ckPI**/2) as an angle range.

This function supports the use of a **ccTimeout**-based timeout.

Throws

ccAcuSymbolDefs::BadImage
The image is not bound.

ccSecurityViolation
Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

learnFlags

```
c_UInt32 learnFlags() const;

void learnFlags(c_UInt32 flags);
```

- `c_UInt32 learnFlags() const;`

Gets the learnable parameter flags. The parameter *flags* must be a bitwise combination of any of the *ccAcuSymbolDataMatrixDefs::LearnFlags* values. *flags* must be in the range 0 through 31.

- `void learnFlags(c_UInt32 flags);`

  Sets the learnable parameter flags, which are:

Value	Meaning
eNone = 0	Tool learns no parameters.
eECC = 1	Tool learns ECC level.
eGrid = 2	Tool learns Grid size.
eNominalGrid = 4	Tool learns nominal grid.
ePolarity = 8	Tool learns polarity.
eModel = 16	Turns optimization on.
eAll = 31	Tool learns all learning parameters.
kDefaultLearn = eAll	Default is for the tool to learn all learning parameters.

  The parameter *flags* must be a bitwise combination of any of the *ccAcuSymbolQRCodeDefs::LearnFlags* values. *flags* must be in the range 0 through 31.

  Parameters

  flags — The *learnFlags* that if set, direct the tool to learn a specific Learn parameter.

  Notes

  In high-contrast mode, the tool ignores the *flags* value, unless it is *ccAcuSymbolDataMatrixDefs::eNone,* and uses *ccAcuSymbolDataMatrixDefs::eAll*.

  Throws

  ccAcuSymbolDefs::BadParams
  flags is not in the range 0 through 31.

tune

```
virtual void tune (ccGreyAcqFifo &fifo,
   const cc2Xform &xform,
   const ccAffineSamplingParams &affParams,
```

```
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &tuneParams,
   ccAcuSymbolTuneResult &tuneResult);

virtual void tune (
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &startTuneParams,
   ccAcuSymbolTuneResult &tuneResult);
```

- ```
  virtual void tune (ccGreyAcqFifo &fifo,
     const cc2Xform &xform,
     const ccAffineSamplingParams &affParams,
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &tuneParams,
     ccAcuSymbolTuneResult &tuneResult);
  ```

  This function automatically determines the optimal lighting properties using the supplied **ccGreyAcqFifo** to acquire images. The supplied **cc2Xform** and **ccAffineSamplingParams** are used to extract the region of interest from each acquired image. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

  If the tool is currently in the learned state (**isLearned()** returns true), this function uses the best learned parameters and calls **decode()**; otherwise, this function invokes the **learn()** function.

  The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object. If tuning is successful, the lighting properties of the supplied **ccGreyAcqFifo** are set to the tuned values. If tuning fails, the original values are restored.

  Parameters

fifo	The fifo to acquire images with.
xform	A **cc2xform** that describes the region of interest.
affParams	The sampling parameters to use to construct the region of interest image.
findParams	The search parameters to use to find the symbol.
tuneParams	The tuning parameters to use for tuning.
tuneResult	A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.
  ```

Notes

You can override the **update()** function to control the tuning process.

This function supports the use of a **ccTimeout**-based timeout.

Throws

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

- ```
  virtual void tune (
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &startTuneParams,
     ccAcuSymbolTuneResult &tuneResult);
  ```

This function automatically determines the optimal lighting properties using images acquired by calling your override of the **ccAcuSymbolTool::acquireImage()** function. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object.

Parameters

findParams The search parameters to use to find the symbol.

tuneParams The initial tuning parameters to use for tuning (supplied to your callback function).

tuneResult A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.

Notes

This function supports the use of a **ccTimeout**-based timeout.

Throws

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.
  ```

ccAcuSymbolDataMatrixTool

ccAcuSymbolDefs

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolDefs;
```

A name space that holds enumerations and constants used with the Symbol tool classes.

Enumerations

TuneMethod

```
enum TuneMethod;
```

An enumeration that describes which method (learn or decode) was used during tuning.

Value	Meaning
eLearn	The learn method was used during tuning.
eDecode	The decode method was used during tuning.

TuneExitCode

```
enum TuneExitCode;
```

An enumeration that indicates why tuning was stopped.

Value	Meaning
eNormal	Tuning completed normally.
eTime	Tuning timed out.
eNumSuccess	Tuning was stopped because the specified number of successful decodes without score improvement was reached.

OperatingMode `enum OperatingMode;`

An enumeration that describes operating modes for the Symbol tool.

Value	Meaning
eHighContrast	An operating mode suitable for label, PCB, and high-contrast, direct-mark applications where there is high-contrast within the symbol region and possibly high clutter/confusion outside the symbol region.
eStandard	An operating mode intended for wafer and degraded direct-mark applications where there is the possibility of low contrast or degradation within the symbol region and low clutter/confusion outside the symbol region.
eAutoDetect	The Symbol tool automatically selects and runs in an appropriate operating mode based on your system's security. Use *eAutoDetect* for general, direct-mark applications.

System behavior is dependent on the level of hardware security present in your machine. Two security levels are available: Standard security uses the *2DSymbol* security bit, and High Contrast security uses the *2DSymbolHighContrast* security bit. If you wish to run in *eStandard* mode, you require Standard security in your machine. If you wish to run in *eHighContrast* mode, you require High Contrast security in your machine. *eAutoDetect* mode checks your system security and runs in the appropriate mode.

The following table summarizes the operating modes, hardware security, and system behavior.

Run Mode	Security	System behavior
eStandard	Standard	Runs in *eStandard* mode
	High Contrast	Throws an exception
	Standard and High Contrast	Runs in *eStandard* mode
eHighContrast	Standard	Throws an exception
	High Contrast	Runs in *eHighContrast* mode
	Standard and High Contrast	Runs in *eHighContrast* mode

Run Mode	Security	System behavior
eAutoDetect	Standard	Runs in *eStandard* mode
	High Contrast	Runs in *eHighContrast* mode
	Standard and High Contrast	Runs in combined mode

ccAcuSymbolDefs

ccAcuSymbolFinderParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolFinderParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class holds a set of parameters used to locate and decode both Data Matrix and QR Code symbols. The parameters are defaulted at construction, and may be read using getters and written using setters.

Constructors/Destructors

ccAcuSymbolFinderParams

```
ccAcuSymbolFinderParams();
```

Creates a **ccAcuSymbolFinderParams** object and sets all parameters to the following default values:.

Parameter	Value
accept	0.5
confusion	0.7
contrast	0.5
angleRange	ckPI/90.0
scaleRange	0.0
aspectDistortion	1.0
angleRef	cc2Vect(1.0, 0.0)

Operators

operator==

```
bool operator== (const ccAcuSymbolFinderParams &that)
const;
```

Returns true if these finder parameters are the same as another set. Two parameter sets are considered equal if all of their attributes are the same.

Public Member Functions

accept

```
double accept() const;
```

Returns the acceptance threshold.

acceptAndConfusion

```
void acceptAndConfusion(double accept, double confusion);
```

Sets the acceptance and confusion thresholds during the search phase, the period when the tool searches for a symbol. Both *accept* and *confusion* must be between 0.0 and 1.0 inclusive, and *accept* must be less than or equal to *confusion*.

Parameters

accept — The acceptance threshold, a score below which the tool rejects a candidate symbol as a symbol.

confusion — The confusion threshold, a score above which the tool accepts the candidate symbol as a symbol.

Notes

Features which return a score below the accept threshold are not considered during the search phase.

The **confusion** parameter specifies the maximum score that an erroneous feature can have and not be considered a symbol. Features that return scores greater than or equal to the confusion threshold are considered to be valid instances of the symbol.

Features that return scores below the confusion threshold but greater than or equal to the accept threshold may or may not be valid instances of the symbol.

Throws

ccAcuSymbolDefs::BadParams
The above conditions are not met.

angleRange

```
ccRadian angleRange() const;
void angleRange(ccRadian range);
```

- `ccRadian angleRange() const;`

  Gets the angle range specified in radians. The angle range is a range of angles through which the Symbol tool rotates the symbol model during the search phase. If the angle of the runtime symbol matches the angle of the symbol model after being rotated, the Symbol tool considers the runtime symbol to be an instance of the symbol if all other Find parameters have acceptable values. Requires that the range must be greater than or equal to 0.0.

- `void angleRange(ccRadian range);`

  Sets the angle range, specified in radians. Requires that the range must be greater than or equal to 0.0.

  Parameters

  range The allowed deviation in radians of the **angle** parameter from its expected value

  Throws

  ccAcuSymbolDefs::BadParams
  The range is not greater than or equal to 0.0.

  Notes

  This parameter sets the range of angles to be considered while locating the symbol. The range of angles considered is:

  - *nominal angle - range*
  - *nominal angle + range*

angleRef

```
cc2Vect angleRef () const;
void angleRef (const cc2Vect &ref);
```

- `cc2Vect angleRef () const;`

  Gets the angle that specifies the reference coordinate system of the symbol. This coordinate system is relative to the x-axis of the current coordinate system of the tool. Requires both **angleRef.x()** and **angleRef.y()** must be in the range -1.0 through 1.0.

- `void angleRef (const cc2Vect &ref);`

  Sets the angle that specifies the reference coordinate system of the symbol. This coordinate system is relative to the x-axis of the current coordinate system of the tool. Requires both **angleRef.x()** and **angleRef.y()** must be in the range -1.0 through1.0.

  Parameters

  ref A vector that specifies the reference angle with respect to the x-axis of the current coordinate system.

  Notes

  You use the **angleRef** parameter when a symbology is aligned with a specific reference orientation. For such cases, you can specify the x and y components of the **angleRef** vector in the reference direction with respect to the x-axis of the current coordinate system. All angles are then be measured with respect to the specified reference orientation.

  Using the **angleRef** parameter assumes that the current coordinate system is orthogonal.

  Throws

  ccAcuSymbolDefs::BadParams
  The above condition is not met.

aspectDistortion

```
double aspectDistortion() const;

void aspectDistortion(double aspectDistortion);
```

- `double aspectDistortion() const;`

  Gets the expected aspect distortion while determining the location of the symbol, with respect to the client coordinate space of the image presented for learn/decode. Requires that the **aspectDistortion** be greater than 0.0.

- `void aspectDistortion(double aspectDistortion);`

  Sets the expected aspect distortion while determining the location of the symbol, with respect to the client coordinate space of the image presented for learn/decode. Requires that the **aspectDistortion** be greater than 0.0.

  Parameters

  aspectDistortion The expected ratio of pixel width to pixel height.

Notes

You should use the default value except with unusual cameras or single-field acquires.

Throws

ccAcuSymbolDefs::BadParams
The above condition is not met.

confusion

```
double confusion() const;
```

Returns the confusion threshold.

contrast

```
double contrast() const;
void contrast(double contrast);
```

- `double contrast() const;`

  Gets minimum acceptable model contrast expressed as a fraction of the trained symbol's contrast.

- `void contrast(double contrast);`

  Sets minimum acceptable model contrast expressed as a fraction of the trained symbol's contrast. Requires the specified value must be between 0.0 and 1.0 inclusive.

  Parameters

  contrast The minimum acceptable image contrast where contrast is the difference in pixel value between the symbol and the background

  Throws

  ccAcuSymbolDefs::BadParams
  The above condition is not met.

scaleRange

```
double scaleRange() const;
void scaleRange(double range);
```

- `double scaleRange() const;`

  Gets the scale range, which is a range of percentages by which the Symbol tool multiplies the size of the model during the search phase. If size of the runtime symbol matches the size of the symbol model after being multiplied by any of these

percentages, the Symbol tool considers the runtime symbol to be an instance of the symbol if all other Find parameters have acceptable values. Requires that the scale must be greater than or equal to 0.0.

- `void scaleRange(double range);`

  Sets the scale range. Requires that the scale must be greater than or equal to 0.0.

  Parameters

  range — The range of variation in the scale parameter while locating the symbol expressed as a percentage. To specify a value of 5%, supply a value of 0.05.

  Throws

  ccAcuSymbolDefs::BadParams — The above condition is not met.

ccAcuSymbolLearnParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolLearnParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

The **ccAcuSymbolLearnParams** class is an abstract base class from which the tool specific classes, **ccAcuSymbolDataMatrixLearnParams** and **ccAcuSymbolQRCodeLearnParams**, are derived. These classes provide symbology specific parameters for learning.

Constructors/Destructors

The constructors and destructors are used by the derived classes. You should not need to use them in your own applications.

Public Member Functions

angle

```
ccRadian angle() const;

void angle(ccRadian ang);
```

- `ccRadian angle() const;`

  Gets the expected orientation of the symbol to be located.

- `void angle(ccRadian ang);`

  Sets the expected orientation of the symbol to be located. (The expected angle is relative to the client coordinate system of the image.)

  Parameters

  ang The expected angle of the symbol to be located.

cellSizeRange

```
const ccRange &cellSizeRange() const;

void cellSizeRange(const ccRange &range);
```

- `const ccRange &cellSizeRange() const;`

  Returns the range of the cell size for the 2-D symbol. The range is measured in the client units of the learn-time image.

- `void cellSizeRange(const ccRange &range);`

  Sets the range of the cell size for the 2-D symbol. The range is measured in the client units of the learn-time image.

Parameters

range The cell size range.

Throws

ccAcuSymbolDefs::BadParams
The start or end of the cell size range is less than 0.

Notes

The cell size range is not learned. It applies to high-contrast and standard operating modes.

If you supply an empty range (**ccRange::EmptyRange()**, the default value) the tool determines an optimal cell size range. The optimal cell size range varies with operating mode and symbology. The following table shows these default ranges for standard and high-contrast operating modes.

Mode	Symbol type	Range (min)	Range (max)
eStandard	QR Code symbols	7 pixels	14 pixels
	Data Matrix symbols	4.5 pixels	9 pixels
eHighContrast	Continuous symbols	7 pixels	21 pixels
	Dot-matrix symbols	7 pixels	14 pixels

Setting a cell size range larger than these default ranges can substantially increase the tool execution time during learning operations.

When loading from older archives, the cell size range is set to its default value.

mirrorFlag

```
bool mirrorFlag() const;
void mirrorFlag(bool mirror);
```

- `bool mirrorFlag() const;`

  Gets the mirror flag.

- `void mirrorFlag(bool mirror);`

  Sets the mirror flag. If **mirror** is true, then mirroring is present, and the tool automatically reverses the image after acquisition.

  Parameters

  mirror — Indicates whether the images containing the symbols to be decoded are mirrored or not.

  Notes

  The *mirror* parameter is learned only when the tool operates in high-contrast mode. Otherwise, a user input is required.

nominalGrid

```
const ccAffineRectangle& nominalGrid () const;
void nominalGrid (const ccAffineRectangle& affRect);
```

- `const ccAffineRectangle& nominalGrid () const;`

  Gets the affine rectangle which defines the 2D symbol grid.

- `void nominalGrid (const ccAffineRectangle& affRect);`

  Sets the affine rectangle which defines the 2D symbol grid.

  Parameters

  affRect — The affine rectangle that defines the 2D symbol grid.

  Notes

  The affine rectangle specified should be defined to enable the tool to determine the dimensions and orientation of the finder pattern and the 2D symbol grid of the symbol to be located. The specification of an affine rectangle allows variations in the scale, orientation, and aspect from the symbol model used to locate the symbol

in the runtime image. These variations typically arise from two sources: (1) From the characteristics of the camera used to acquire the image of the printed symbol, and (2) during printing of the symbol.

The nominal grid of a Data Matrix symbol is defined by the 3 corners of its L-shaped finder pattern. The nominal grid of a Model 1 or Model 2 QR Code symbol is defined by the centers of the 3 finder patterns, whereas the nominal grid of a Micro QR Code symbol is defined by the corners formed by the single finder pattern and the 2 timing patterns running along the top row and left column of the symbol.

scale

```
double scale() const;
void scale(double scale);
```

- `double scale() const;`

Gets the ratio of the expected scale of the symbol to be located in relation to the scale of the model. Requires *scale* must be greater than 0.0.

- `void scale(double scale);`

Sets the ratio of the expected scale of the symbol to be located in relation to the scale of the model. Requires *scale* must be greater than 0.0. (The scale of the symbol used in the learning phase becomes the scale of the model.)

Parameters

scale — The expected scale of the symbol to be located in relation to the scale of the model.

Throws

ccAcuSymbolDefs::BadParams — The scale is not greater than 0.0.

Notes

This parameter is relative to the client coordinate space of the image presented for learn/decode. For example, specifying scale to be 1.2 implies that the expected scale of the symbol (in client coordinate space) is 1.2 times the scale of the model (in client coordinate space).

Operators

operator==

```
bool operator== (const ccAcuSymbolLearnParams &that) const;
```

Returns true if these learn parameters are the same as another set. Two parameter sets are considered equal if all of their attributes are the same.

ccAcuSymbolLearnParams

ccAcuSymbolQRCodeDefs

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolQRCodeDefs: public ccAcuSymbolDefs;
```

A name space that holds enumerations and constants used with the Symbol tool classes.

Enumerations

Polarity

```
enum Polarity;
```

Values for the Polarity parameter:

Value	Meaning
eDarkOnLight	Dark symbol on a light background
eLightOnDark	Light symbol on a dark background

QRModelType

```
enum QRModelType;
```

Values for the QRModelType parameter:

Value	Meaning
eQRModelUnknown = 0	Unknown model
eQRModel1 = 1	*Model 1*
eQRModel2 = 2	*Model 2*
eMicroQR = 4	*Micro QR code*
kDefaultQRModel = eQRModel2	*Model 2*

LearnFlags

```
enum LearnFlags;
```

Setting the following LearnFlags determines which parameters the tool learns:

Value	Meaning
eNone = 0	Tool learns no parameters.
eQRModel = 1	Tool learns QR model.

Value	Meaning
eGrid = 2	Tool learns grid size.
eNominalGrid = 4	Tool learns nominal grid.
ePolarity = 8	Tool learns polarity.
eModel = 16	Turns optimization on.
eAll = 31	Tool learns all learning parameters.
kDefaultLearn = eAll	Default is for the tool to learn all parameters.

kMaxQRModelSize

```
enum kMaxQRModelSize;
```

Maximum size for a QR Code symbol:

Value	Meaning
kMaxQRModelSize = 49	The maximum supported symbol size is 49.

ccAcuSymbolQRCodeLearnParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolQRCodeLearnParams:
  public ccAcuSymbolLearnParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The class **ccAcuSymbolQRCodeLearnParams** supplies the parameters that the Symbol tool uses to create a QR Code symbol model. The tool can acquire values for the parameters in this class in the following ways:

- You can set the Learn parameters to their default values by using the default constructor.
- You can specify values for specific Learn parameters using the overload constructor.
- You can set values for the Learn parameters using the setters of the class.
- You can have the tool learn the parameters specified by *learnFlags*. For those parameters not learned by the tool, you use this class to specify the values.

Constructors/Destructors

ccAcuSymbolQRCodeLearnParams

```
ccAcuSymbolQRCodeLearnParams();

virtual ~ccAcuSymbolQRCodeLearnParams();

ccAcuSymbolQRCodeLearnParams(
   const ccAffineRectangle& nominalGrid,
   c_Int32 size,
   ccAcuSymbolQRCodeDefs::QRModelType model =
      ccAcuSymbolQRCodeDefs::kDefaultQRModel,
   ccAcuSymbolQRCodeDefs::Polarity symbolPolarity =
      ccAcuSymbolQRCodeDefs::eDarkOnLight,
```

```
   ccRadian angle = ccRadian(0.0),
   double scale = 1.0,
   bool mirror = false);
```

- `ccAcuSymbolQRCodeLearnParams();`

  Default constructor. The members are initialized to their default values, which are:

Parameter	Value
size	21
nominalGrid	points at (0, 21), (21, 21), (0, 0)
qrModelType	*ccAcuSymbolQRCodeDefs::kDefaultQRModel*
symbolPolarity	*ccAcuSymbolQRCodeDefs::eDarkOnLight*

  Notes

  The nominal grid as well as the number of rows and columns are set to match the smallest symbol size (21 x 21) allowed for a QR Code model 2 symbol. The transform of the nominal grid is set to identity. *qrModelsToLearn* is set to *eQRModel2 | eMicroQR* by default.

- `virtual ~ccAcuSymbolQRCodeLearnParams();`

  Destroys instances of this class.

- ```
  ccAcuSymbolQRCodeLearnParams(
     const ccAffineRectangle& nominalGrid,
     c_Int32 size,
     ccAcuSymbolQRCodeDefs::QRModelType model =
        ccAcuSymbolQRCodeDefs::kDefaultQRModel,
     ccAcuSymbolQRCodeDefs::Polarity symbolPolarity =
        ccAcuSymbolQRCodeDefs::eDarkOnLight,
  ```
  ```

```
ccRadian angle = ccRadian(0.0),
double scale = 1.0,
bool mirror = false);
```

Constructor overload with specified values. *qrModelsToLearn* is set to its default value of *eQRModel2 | eMicroQR*.

The function has the following requirements:

- *model* should be one of the predefined types: *unknown*, *model1, model 2*. or *microQR*
- *size* should be:
  - in the range 21 through *kMaxQRModelSize* for *eQRModel1*
  - in the range 21 through *kMaxQRModelSize* for *eQRModel2*
  - in the range 11 through 17 for *eMicroQR*

Parameters

nominalGrid	The affine rectangle that encloses the symbol.
size	The grid size where the length and width of the symbol are equal.
model	*unknown*, *model1, model 2*. or *microQR*.
symbolPolarity	The polarity of the symbol, either dark on light or light on dark.
angle	The angle of the symbol relative to the model.
scale	The scale of the symbol relative to the model.
mirror	If true, then the tool reverses the image of the symbol after acquisition.

Throws

ccAcuSymbolDefs::BadParams
The conditions described above are not met.

Operators

operator==

```
bool operator== (
   const ccAcuSymbolQRCodeLearnParams &that) const;
```

Compares this object with another. Two **ccAcuSymbolQRCodeLearnParams** objects are considered equal if all their corresponding data members are identical.

Public Member Functions

modelTypeAndSize

```
void modelTypeAndSize (
   ccAcuSymbolQRCodeDefs::QRModelType modelType,
   c_Int32 size);
```

Sets the QR Code model type and grid size. The function has the following requirements:

- *modelType* should be one of the predefined types: *unknown*, *model1, model 2*. or *microQR*
- *size* should be:
  - in the range 21 through *kMaxQRModelSize* for *eQRModel1*
  - in the range 21 through *kMaxQRModelSize* for *eQRModel2*
  - in the range 11 through 17 for *eMicroQR*

Parameters

modelType *unknown*, *model1, model 2*. or *microQR*.

size The grid size where the length and width of the symbol are equal.

Notes

The number of rows is always equal to the number of columns.

Throws

ccAcuSymbolDefs::BadParams
The conditions described above are not met.

qrModel

```
ccAcuSymbolQRCodeDefs::QRModelType qrModel()
   const;
```

Gets the QR Code model type.

size

```
c_Int32 size() const;
```

Gets the grid size.

Notes

The number of rows is always equal to the number of columns.

symbolPolarity

```
ccAcuSymbolQRCodeDefs::Polarity symbolPolarity()
   const;

void symbolPolarity (
   ccAcuSymbolQRCodeDefs::Polarity pol);
```

- ```
  ccAcuSymbolQRCodeDefs::Polarity symbolPolarity()
     const;
  ```

  Gets the symbol polarity, which is either dark-on-light or light-on-dark.

- ```
  void symbolPolarity (
     ccAcuSymbolQRCodeDefs::Polarity pol);
  ```

  Sets the symbol polarity.

  Parameters

  pol The polarity of the symbol, either dark-on-light or light-on-dark.

qrModelsToLearn

```
c_UInt32 qrModelsToLearn() const;

void qrModelsToLearn(c_UInt32 modelsToLearn);
```

Get/Set the QR Code model types to look for at learn time when the model type of the symbol is to be determined by the tool. When the model type need not be learned, this parameter is ignored and *qrModelType* is used instead.

The model types are specified as a bitwise-OR of the appropriate entries from *ccAcuSymbolQRCodeDefs::QRModelType*.

- ```
  c_UInt32 qrModelsToLearn() const;
  ```

  Returns the QR Code model types.

- ```
  void qrModelsToLearn(c_UInt32 modelsToLearn);
  ```

  Sets the QR Code model types.

  Parameters

  modelsToLearn The model types.

Throws

ccAcuSymbolDefs::BadParams

If *modelsToLearn* = 0,
or if *modelsToLearn* is a value not created by the bitwise-OR of values from *ccAcuSymbolQRCodeDefs::QRModelType*.

Notes

This parameter is not learned.

At decode time the tool can only decode a symbol with a model type that it has learned, as specified by the internally stored learned params.

ccAcuSymbolQRCodeTool

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolQRCodeTool : public ccAcuSymbolTool;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

You use this class to create the central object for the QR Code tool, which contains the trained representation of a QR Code symbol, and the functions for the learn and decode phases of the tool's operation.

Constructors/Destructors

ccAcuSymbolQRCodeTool

```
ccAcuSymbolQRCodeTool (
  ccAcuSymbolDefs::OperatingMode opMode =
  ccAcuSymbolDefs::eAutoDetect);

virtual ~ccAcuSymbolQRCodeTool();

ccAcuSymbolQRCodeTool (
  const ccAcuSymbolQRCodeLearnParams& learnParams,
  c_UInt32 learnFlags,
  ccAcuSymbolDefs::OperatingMode opMode =
  ccAcuSymbolDefs::eAutoDetect );
```

- ```
  ccAcuSymbolQRCodeTool (
    ccAcuSymbolDefs::OperatingMode opMode =
    ccAcuSymbolDefs::eAutoDetect);
  ```

  Constructs a Symbol tool for decoding QR Code symbols. The tool is in an unlearned state, the operating mode defaults to *eAutoDetect*, and all members are initialized to the following defaults:

Parameter	Value
initialLearnParams	default constructed **ccAcuSymbolQRCodeLearnParams**
bestLearnedParams	default constructed **ccAcuSymbolQRCodeLearnParams**
learnFlags	*ccAcuSymbolQRCodeDefs::eAll*
isLearned	false

- ```
  virtual ~ccAcuSymbolQRCodeTool();
  ```

  Destroys instances of this class.

- ```
  ccAcuSymbolQRCodeTool (
    const ccAcuSymbolQRCodeLearnParams& learnParams,
    c_UInt32 learnFlags,
    ccAcuSymbolDefs::OperatingMode opMode =
    ccAcuSymbolDefs::eAutoDetect);
  ```

  Creates a Symbol tool that learns those parameters in the **ccAcuSymbolQRCodeLearnParams** object specified by *learnFlags* and sets the remaining parameters to their defaults or to those values supplied by the setters of the **ccAcuSymbolQRCodeLearnParams** class. (Constructor overload)

  Requires that *learnFlags* be a bitwise combination of any of the *ccAcuSymbolQRCodeDefs::LearnFlags* values. *learnFlags* must be in the range 0 through 31.

  Parameters

  learnParams — Parameters that the tool can learn or you can set. Examples include QRModel type, grid size, nominal grid, and polarity. You must set the Learn parameter *mirrorFlag* or use the default.

  learnFlags — Flags that when set direct the tool to learn a specific Learn parameter. Values set in the **ccAcuSymbolQRCodeLearnParams** object are ignored by the **learn()** function unless the appropriated *learnFlags* value is set.

  opMode — Determines the operating mode for the tool, which can be one of:
  ccAcuSymbolDefs::eStandard
  ccAcuSymbolDefs::eHighContrast
  ccAcuSymbolDefs::eAutoDetect

  Throws

  ccAcuSymbolDefs::BadParams
  learnFlags is not in the range 0 through 31.

Public Member Functions

bestLearnedParams

```
const ccAcuSymbolQRCodeLearnParams&
   bestLearnedParams() const;
```

Returns the final learned parameters after the tool, which is in Learn and Decode mode, has performed the following actions:

1. Found a symbol in the image.
2. Learned the parameters specified by *learnFlags*.
```

3. Created a model from the parameters specified by *learnFlags* and those specified by the **ccAcuSymbolQRCodeLearnParams** object.
4. Decoded the symbol.

Notes

This function should be used to get the learned parameters after the tool has undergone learning successfully as indicated by **isLearned()** returning true.

Throws

ccAcuSymbolDefs::NotLearned
This function is invoked when the tool has not undergone the learning phase successfully and **isLearned()** returns false.

decode

```
bool decode (
   const ccPelBuffer_const<c_UInt8>& image,
   const ccAcuSymbolFinderParams& findParams,
   ccAcuSymbolResult& result) const;
```

Finds the symbol in the given image and decodes it using the specified Find parameters and internally stored Learn parameters. The result of decoding is returned via the result object. Returns true if successful; false if the operation failed. Requires that the image be bound.

This function places the tool in Standard Decode mode for QR Code symbology.

Parameters

image	The acquired image. The pel buffer must be bound.
findParams	The Find parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.
result	The result object that contains data derived from the decoding operation including angle, score, and scale.

Notes

In high-contrast mode, the tool ignores the *findParams* value, and instead uses 5% as a scale range and 180 degrees (or **ckPI**/2) as an angle range.

This function supports the use of a ccTimeout-based timeout.

Throws

ccAcuSymbolDefs::BadImage
The image is not bound.

ccSecurityViolation
Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

initialLearnParams

```
const ccAcuSymbolQRCodeLearnParams& initialLearnParams()
   const;

void initialLearnParams(
   const ccAcuSymbolQRCodeLearnParams& learnParams);
```

- `const ccAcuSymbolQRCodeLearnParams& initialLearnParams()`
  `const;`

  Gets the initial parameters used for learning prior to estimation by the learn and decode phase.

- `void initialLearnParams(`
  `const ccAcuSymbolQRCodeLearnParams& learnParams);`

  Sets the initial parameters used for learning prior to estimation by the learn and decode phase.

  Parameters

  learnParams Parameters that the tool can learn or that you can set. Examples include QRModel type, grid size, nominal grid, and polarity. You must set the Learn parameter *mirrorFlag* or use the default.

  Notes

  The setter function should be used to initialize the learn parameters in preparation for the learning phase.

  When operating in high-contrast mode, the tool ignores all initial learn parameters except for the cell size range and *qrModelsToLearn*.

learn

```
void learn (const ccPelBuffer_const<c_UInt8>& image,
   const ccAcuSymbolFinderParams& findParams,
   ccAcuSymbolResult& result);
```

Estimates the optimal configuration of selected symbol learning parameters as specified by *initialLearnParams* and *learnFlags*. If learning is successful, the tool updates *bestLearnedParams* and decodes the symbol using the internally learned parameters and the *findParams* object. Finally, the tool returns decoding results via the result object. Requires that the image be bound.

This function places the tool in Learn and Decode mode for QR Code symbology.

Parameters

image The acquired image. The pel buffer must be bound.

findParams The Find parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.

result The result object that contains data derived from the decoding operation including angle, score, and scale.

Notes

In high-contrast mode, the tool ignores the *findParams* value, and instead uses 5% as a scale range and 180 degrees (or **ckPI**/2) as an angle range.

This function supports the use of a ccTimeout-based timeout.

Throws

ccAcuSymbolDefs::BadImage
The image is not bound.

ccSecurityViolation
Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

ccAcuSymbolDefs::BadParams
If there are any inconsistencies between the learnable parameter flags and the appropriate learn parameters. For example, the *eQRModel* bit of the learn flags is set to 0 (meaning the model type of the symbol should not be learned) but the model type provided by the initial learn parameters is *eQRModelUnknown*.

learnFlags

```
c_UInt32 learnFlags() const;
void learnFlags(c_UInt32 flags);
```

- `c_UInt32 learnFlags() const;`

  Gets the learnable parameter flags, a bitwise combination of any of the *ccAcuSymbolQRCodeDefs::LearnFlags* values. *learnFlags_* must be in the range 0 through 31.

- `void learnFlags(c_UInt32 flags);`

  Sets the learnable parameter flags, which are:

Value	Meaning
eNone = 0	Tool learns no parameters.
eQRModel = 1	Tool learns QR model.
eGrid = 2	Tool learns grid size.
eNominalGrid = 4	Tool learns nominal grid.
ePolarity = 8	Tool learns polarity.
eModel = 16	Turns optimization on.
eAll = 31	Tool learns all parameters.
kDefaultLearn = eAll	Default is for the tool to learn all parameters.

  The parameter *flags* must be a bitwise combination of any of the *ccAcuSymbolQRCodeDefs::LearnFlags* values. *flags* must be in the range 0 through 31.

  Parameters

  flags — The *learnFlags* that when set direct the tool to learn a specific Learn parameter.

  Notes

  In high-contrast mode, the tool ignores the *flags* value, unless it is *ccAcuSymbolQRCodeDefs::eNone*, and uses *ccAcuSymbolQRCodeDefs::eAll*.

  Throws

  ccAcuSymbolDefs::BadParams — *flags* is not in the range 0 through 31.

tune

```
virtual void tune (ccGreyAcqFifo &fifo,
   const cc2Xform &xform,
   const ccAffineSamplingParams &affParams,
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &tuneParams,
   ccAcuSymbolTuneResult &tuneResult);

virtual void tune (
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &startTuneParams,
   ccAcuSymbolTuneResult &tuneResult);
```

- ```
  virtual void tune (ccGreyAcqFifo &fifo,
     const cc2Xform &xform,
     const ccAffineSamplingParams &affParams,
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &tuneParams,
     ccAcuSymbolTuneResult &tuneResult;
  ```

  This function automatically determines the optimal lighting properties using the supplied **ccGreyAcqFifo** to acquire images. The supplied **cc2Xform** and **ccAffineSamplingParams** are used to extract the region of interest from each acquired image. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

  If the tool is currently in the learned state (**isLearned()** returns true), this function uses the best learned parameters and calls **decode()**; otherwise, this function invokes the **learn()** function.

  The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object. If tuning is successful, the lighting properties of the supplied **ccGreyAcqFifo** are set to the tuned values. If tuning fails, the original values are restored.

  Parameters

fifo	The fifo to acquire images with.
xform	A **cc2xform** that describes the region of interest.
affParams	The sampling parameters to use to construct the region of interest image.
findParams	The search parameters to use to find the symbol.
tuneParams	The tuning parameters to use for tuning.
tuneResult	A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.
  ```

Notes

You can override the **update()** function to control the tuning process.

This function supports the use of a ccTimeout-based timeout.

Throws

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

ccAcuSymbolDefs::BadParams

if, when **learn()** is invoked, there are any inconsistencies between the learnable parameter flags and the appropriate learn parameters. For example, the *eQRModel* bit of the learn flags is set to 0 (meaning the model type of the symbol should not be learned) but the model type provided by the initial learn parameters is *eQRModelUnknown*.

- ```
  virtual void tune (
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &startTuneParams,
     ccAcuSymbolTuneResult &tuneResult);
  ```

This function automatically determines the optimal lighting properties using images acquired by calling your override of the **ccAcuSymbolTool::acquireImage()** function. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object.

Parameters

findParams The search parameters to use to find the symbol.

tuneParams The initial tuning parameters to use for tuning (supplied to your callback function).

tuneResult A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.

Notes

This function supports the use of a ccTimeout-based timeout.

Throws
  ```

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

ccAcuSymbolDefs::BadParams

if, when **learn()** is invoked, there are any inconsistencies between the learnable parameter flags and the appropriate learn parameters. For example, the *eQRModel* bit of the learn flags is set to 0 (meaning the model type of the symbol should not be learned) but the model type provided by the initial learn parameters is *eQRModelUnknown*.

ccAcuSymbolResult

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolResult : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the results for either Data Matrix and QR Code symbols.

Constructors/Destructors

ccAcuSymbolResult

```
ccAcuSymbolResult();
```

Constructs a **ccAcuSymbolResult** object with all members initialized to the following default values:

Parameter	Value
isFound	False
decodedFlag	False
decodedMBCSString	empty vector
decodedString	" "
decodedData	0
location	cc2Vect(0.0, 0.0)
score	0.0
scale	1.0
angle	0.0
aspect	1.0
time	0.0

Parameter	Value
imgFromClient	Identity transform
resultGrid	Default constructed affine rectangle
numErrors	0
numErrorBits	0
learnParams	Default constructed **ccAcuSymbolLearnParams**

Operators

operator==

```
bool operator==(const ccAcuSymbolResult&) const;
```

Returns true if all result parameters except for *time* are the same as another set. Two parameter sets are considered equal if all of their attributes are the same.

Public Member Functions

angle

```
ccRadian angle() const;
```

Returns the angle with respect to the reference angle if any.

aspect

```
double aspect() const;
```

Returns the aspect ratio of the 2D symbol that was found with respect to the client coordinate space. The aspect ratio is the expected ratio of pixel height to pixel width.

decodedData

```
cmStd vector<c_UInt8> decodedData() const;
```

Returns the raw bit-stream to be decoded as a sequence of bytes. You can use this function to return a sequence of uninterpreted bytes, from which the original string encoded in the symbol can be reconstructed using an alternate custom string decoder.

Throws

ccAcuSymbolDefs::BadString
This function is invoked when **isFound()** returns false.

Notes

The raw decoded data corresponds to the encoded bit-stream. It typically contains sub-streams, which begin with a ECI header that contains information about the mode used for encoding and the number of characters in the sub-stream. The

header is followed by the data bit-stream. A raw bit-stream corresponding to a QR Code symbol may be composed of two sub-streams, the first encoded in AlphaNumeric mode, and the second in Kanji (2 bytes per character).

Conceptually, the raw bit-stream could be represented as follows:

```
|AlphaNumeric mode indicator|char count| -- Data bit-stream
--| |Kanji Mode indicator |char count| -- Data bit-stream --|
```

The sequence of bytes in the raw bit-stream should not be altered prior to decoding as this may corrupt any multi-byte encoded data.

decodedString `ccCvlString decodedString() const;`

Returns the decoded string of the symbol just found.

Throws

ccAcuSymbolDefs::BadString
This function is invoked when **isDecoded()** returns false.

Notes

This function processes the raw uninterpreted bit-stream and generates an ANSI string. Use this function only for symbols that you know do not contain multibyte characters.

decodedMBCSString

```
cmStd vector<c_UInt8> decodedMBCSString() const;
```

Returns the decoded data as a null-terminated, multi-byte string. The size of the vector includes the null terminator.

For symbologies that encode 8-bit characters, this function returns a string of single-byte characters. For example, for the Data Matrix symbology, this function returns a single-byte stream of ASCII and extended ASCII characters.

For symbologies that encode single-byte and double-byte characters, this function returns a stream of multi-byte characters. For example, for the QR Code symbology, this function returns a stream of JIS8 characters (8-bit character set) and Shift JIS characters (double-byte character set that encodes Kanji characters).

You can convert multi-byte characters to unicode using the **mbtowc()** and **mbstowcs()** C library routines.

Throws

ccAcuSymbolDefs::BadString
If this function is invoked when **isDecoded()** returns *false*.

imageFromClientXform

```
const cc2Xform& imageFromClientXform () const;
```

Returns the transform required to translate client coordinates to image coordinates.

isDecoded

```
bool isDecoded() const;
```

Returns true if this symbol is decoded, false otherwise.

isFound

```
bool isFound() const;
```

Returns true if this runtime symbol is found, false otherwise. A symbol is found if its score equals or exceeds the accept threshold, implying that the symbol location was determined with sufficient confidence.

location

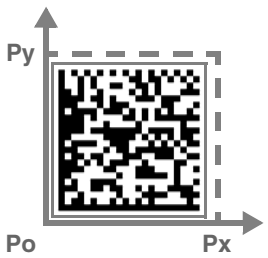
```
cc2Vect location() const;
```

Returns the location of center of the found symbol in the client coordinate system of the runtime image.

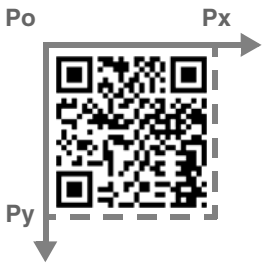
resultGrid

```
const ccAffineRectangle& resultGrid () const;
```

Returns the affine rectangle applied to compute this result. The affine rectangle returned by this function reflects the “natural” orientation and handedness of the symbol being decoded, as shown in the following figure:



Data Matrix (right-handed)



QR Code (left handed)

scale

```
double scale() const;
```

Returns the scale of the 2D symbol that was found, as a fraction of the scale of the model size.

score

```
double score() const;
```

Returns the result score in the range 0.0 through 1.0, which is the correlation between the runtime symbol and the model.

Notes

If the score is 0.0 after the Symbol tool attempts to locate the symbol, the tool does not perform the decoding step. In this case, the **angle**, **scale** and **aspect** are set to their nominal values.

time

```
double time() const;
```

Returns the time (in seconds) required to decode the symbol.

numErrors

```
c_Int32 numErrors () const;
```

Returns the number of erroneous data words encountered while decoding the symbol. The function returns -1 if this information is not available.

numErrorBits

```
c_Int32 numErrorBits () const;
```

Returns the number of erroneous bits encountered while decoding the symbol. This function returns -1 if this information is not available

learnParams

```
const ccAcuSymbolLearnParams& learnParams () const;
```

Returns the **ccAcuSymbolLearnParams** used to compute this result.

Throws

ccAcuSymbolDefs::BadParams

The symbol is neither decoded nor found: both **isFound()** and **isDecoded()** return false.

ccAcuSymbolResult

ccAcuSymbolTool

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolTool : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccAcuSymbolTool is an abstract the base class from which the following tool classes representing specific 2D matrix symbologies are derived:

- ccAcuSymbolDataMatrixTool
- ccAcuSymbolQRCodeTool

The Symbol tool operates in two modes:

- Standard Decode mode where the tool uses a set of externally specified parameters to locate and decode the target symbol
- Learn and Decode mode, which consists of a learning phase and a decode phase

  During the learning phase, the application acquires a source image with the target symbol. The tool then locates a candidate symbol in the image and analyzes it, and learns optimal parameters based on learning flags provided. The objective of the learning phase is to estimate a set of parameters when incomplete information regarding best parameters is available.The learned parameters are stored inside the tool along with parameters that you specify as part of a model of the symbol.

  During the decode phase, the tool decodes the symbol using the internally stored parameters. Results of decoding are returned via a **ccAcuSymbolResult** object.

For more detailed information about the Symbol tool, see the chapter *Symbol Tool* in the *CVL Vision Tools Guide*.

Constructors/Destructors

The constructors and destructors are used by the derived classes. You should not need to use them in your own applications.

Public Member Functions

decode

```
virtual bool decode (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAcuSymbolFinderParams& findParams,
    ccAcuSymbolResult& result) const = 0;
```

Finds the symbol in the given image and decodes it using the specified *findParams* and internally stored learned parameters. The result of decoding is returned via *result*. Returns true if the decoding operation was successful; false if not. Requires that the image be bound.

Notes

The function **decode()** should be over-ridden in the derived tool class. Because this function is pure virtual, you need to define this function in all the classes derived from this class corresponding to the standard decode phase of this tool.

After a symbol is found within a defined area, **Decode()** begins symbol recognition. If the size in found symbols differs significantly (greater than ±5 percent), the function can fail. To prevent this failure, avoid using *eHighContrast* operating mode and adjust the *ScaleRange*, which is one of the *findParams,* in proportion to the difference in size.

Parameters

image	The pel buffer that contains the image being read.
findParams	The finder parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.
result	The result object that contains data derived from the decoding operation including angle, score, and scale.

Throws

ccAcuSymbolDefs::BadImage
The image is not bound.

ccSecurityViolation
Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

isLearned

```
bool isLearned() const;
```

Gets the learned state of this tool. True indicates that the tool has undergone the learning phase successfully, while false indicates an unsuccessful learning phase.

learn

```
virtual void learn (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAcuSymbolFinderParams& findParams,
    ccAcuSymbolResult& result) = 0;
```

Estimates the optimal configuration of selected symbol learning parameters as specified by the **initialLearnParams** and **learnFlags**. The result of decoding is returned via the result object. Requires that the image be bound.

Notes

The function **learn()** should be over-ridden in the derived tool class. Because this function is pure virtual, you need to define this function in all the classes derived from this class corresponding to the standard decode phase of this tool.

Parameters

image The pel buffer that contains the image being read.

findParams The finder parameters, which the tool uses to locate and orient each runtime symbol. Examples include angle, scale, confusion threshold, and acceptance threshold.

result The result object that contains data derived from the decoding operation including angle, score, and scale.

Throws

ccAcuSymbolDefs::BadImage
The image is not bound.

ccSecurityViolation
Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

operatingMode

```
ccAcuSymbolDefs::OperatingMode operatingMode() const;
```

Returns the current operating mode for the tool, which can be one of the following values:

ccAcuSymbolDefs::eStandard
ccAcuSymbolDefs::eHighContrast
ccAcuSymbolDefs::eAutoDetect

---

tune

```
virtual void tune (ccGreyAcqFifo &fifo,
   const cc2Xform &xform,
   const ccAffineSamplingParams &affParams,
```

```
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &tuneParams,
   ccAcuSymbolTuneResult &tuneResult) = 0;

virtual void tune (
   const ccAcuSymbolFinderParams &findParams,
   const ccAcuSymbolTuneParams &startTuneParams,
   ccAcuSymbolTuneResult &tuneResult) = 0;
```

- ```
  virtual void tune (ccGreyAcqFifo &fifo,
     const cc2Xform &xform,
     const ccAffineSamplingParams &affParams,
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &tuneParams,
     ccAcuSymbolTuneResult &tuneResult) = 0;
  ```

  This function automatically determines the optimal lighting properties using the supplied **ccGreyAcqFifo** to acquire images. The supplied **cc2Xform** and **ccAffineSamplingParams** are used to extract the region of interest from each acquired image. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

  If the tool is currently in the learned state (**isLearned()** returns true), this function uses the best learned parameters and calls **decode()**; otherwise, this function invokes the **learn()** function.

  The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object. If tuning is successful, the lighting properties of the supplied **ccGreyAcqFifo** are set to the tuned values. If tuning fails, the original values are restored.

  Parameters

fifo	The fifo to acquire images with.
xform	A **cc2xform** that describes the region of interest.
affParams	The sampling parameters to use to construct the region of interest image.
findParams	The search parameters to use to find the symbol.
tuneParams	The tuning parameters to use for tuning.
tuneResult	A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.

  Notes

  You can override the **update()** function to control the tuning process.
  ```

Throws

ccSecurityViolation

Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

- ```
  virtual void tune (
     const ccAcuSymbolFinderParams &findParams,
     const ccAcuSymbolTuneParams &startTuneParams,
     ccAcuSymbolTuneResult &tuneResult) = 0;
  ```

  This function automatically determines the optimal lighting properties using images acquired by calling your override of the **acquireImage()** function. The supplied **ccAcuSymbolTuneParams** object is used to set the tuning parameters and the supplied **ccAcuSymbolFinderParams** object is used to locate the symbols.

  The tuned parameters (and the decode results produced using those parameters) are returned through the supplied **ccAcuSymbolTuneResult** object.

  Parameters

  findParams The search parameters to use to find the symbol.

  tuneParams The initial tuning parameters to use for tuning (supplied to your callback function).

  tuneResult A reference to a **ccAcuSymbolTuneResult** object into which the results of tuning are placed.

  Throws

  ccSecurityViolation

  Hardware security is not enabled for the specified operating mode; or hardware security is not enabled for any operating mode.

update

```
virtual bool update (
   const ccAcuSymbolTuneResult& currentTuneResult,
   const ccAcuSymbolTuneResult& bestTuneResult);
```

Provides a hook that lets you update intermediate **tune()** results. The tuning process continues as long as this function returns true. The default **update()** function always returns true.

Parameters

currentTuneResult

The result of the current tune cycle.
```

bestTuneResult The result of the tune cycle that has produced the best (highest scoring) result so far.

userPreProcessAcquiredImage

```
virtual bool userPreprocessAcquiredImage(
   ccPelBuffer<c_UInt8>& src,
   const ccPelRect& rect, ccPelBuffer<c_UInt8>& dst);
```

Provides a hook that lets perform your own preprocessing on images acquired by the tool for reading or tuning. If your override returns false, tuning is stopped.

The default **userPreprocessAcquiredImage()** function copies the pixels in *src* that lie within *rect* to *dst* and returns true.

Parameters

src The acquired image. This pel buffer must be bound.

rect The region of interest within *src*.

dst The destination pel buffer. This pel buffer must be unbound.

acquireImage

```
virtual ccPelBuffer<c_UInt8> acquireImage(
   const ccAcuSymbolTuneParams& tuneParams);
```

You must provide an override of this function if you use the second overload of the **tune()** function. Your implementation should acquire and return an image. The function is supplied with a **ccAcuSymbolTuneParams** you can use to control your acquisition.

Parameters

tuneParams The tuning parameters computed by the **tune()** function.

Throws

ccAcuSymbolDefs::BadImage
You did not provide an override of this function.

ccAcuSymbolTuneParams

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolTuneParams : public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class lets you specify the parameters used to tune the lighting, parameters for decoding symbols etched or scribed on reflective surfaces.

Constructors/Destructors

ccAcuSymbolTuneParams

```
ccAcuSymbolTuneParams (bool enableDark = true,
   double darkLow = 0.062745,
   double darkHigh = 1.0, double darkStep = 0.12157,
   bool enableBright = true, double brightLow = 0.062745,
   double brightHigh = 1.0, double brightStep = 0.12157,
   double nominalLightPower = 0.062745,
   double nominalBrightFieldPowerRatio = 1.0,
   double maxTime = 3000., c_Int32 validLimit = 255);
```

Constructs a **ccAcuSymbolTuneParams**.

Parameters

enableDark	True to enable darkfield tuning.
darkLow	The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkHigh	The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.
darkStep	The darkfield step value. Must be in the range 0.0 through 1.0.
enableBright	True to enable brightfield tuning.
brightLow	The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

brightHigh The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

brightStep The brightfield step value. Must be in the range 0.0 through 1.0.

nominalLightPower
The nominal light power value (used by the tune callback function).

nominalBrightFieldPowerRatio
The nominal brightfield power ratio (the portion of the light power allocated to brightfield lighting). Must be in the range 0.0 through 1.0. This value is used by the tune callback function.

maxTime The maximum number of seconds to allow for tuning.

validLimit The maximum number of successful decodes that can occur without producing a new best score.

Throws

ccAcuSymbolToolDefs::BadParams
A parameter value was out of range.

Operators

operator==

```
bool operator== (const ccAcuSymbolTuneParams& that) const;
```

Two **ccAcuSymbolTuneParams** objects are considered equal if all of their data members are equal to a numerical precision of 1.e-8.

Parameters

that The **ccAcuSymbolTuneParams** to compare to this one.

Public Member Functions

enableBright

```
bool enableBright() const;
void enableBright(bool val);
```

- `bool enableBright() const;`

  Returns true if brightfield tuning is enabled.

- `void enableBright(bool val);`

  Enables or disables brightfield tuning.

Parameters

val True to enable brightfield tuning, false to disable.

enableDark

```
bool enableDark() const;
void enableDark(bool val);
```

- `bool enableDark() const;`

  Returns true if darkfield tuning is enabled.

- `void enableDark(bool val);`

  Enables or disables darkfield tuning.

  Parameters

  val True to enable darkfield tuning, false to disable.

brightLow

```
double brightLow() const;
void brightLow(double val);
```

- `double brightLow() const;`

  Returns the minimum light power for brightfield tuning.

- `void brightLow(double val);`

  Sets the minimum light power for brightfield tuning.

  Parameters

  val The minimum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

ccAcuSymbolTuneParams

brightHigh

```
double brightHigh() const;
void brightHigh(double val);
```

- `double brightHigh() const;`

  Returns the maximum light power for brightfield tuning.

- `void brightHigh(double val);`

  Sets the maximum light power for brightfield tuning.

  Parameters

  val — The maximum light power for brightfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

brightStep

```
double brightStep() const;
void brightStep(double val);
```

- `double brightStep() const;`

  Returns the brightfield step for tuning.

- `void brightStep(double val);`

  Sets the brightfield step for tuning.

  Parameters

  val — The brightfield step value. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

darkLow

```
double darkLow() const;
void darkLow(double val);
```

- `double darkLow() const;`

  Returns the minimum light power for darkfield tuning.

- `void darkLow(double val);`

  Sets the minimum light power for darkfield tuning.

  Parameters

  val The minimum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

darkHigh

```
double darkHigh() const;
void darkHigh(double val);
```

- `double darkHigh() const;`

  Returns the maximum light power for darkfield tuning.

- `void darkHigh(double val);`

  Sets the maximum light power for darkfield tuning.

  Parameters

  val The maximum light power for darkfield tuning. Must be in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

darkStep

```
double darkStep() const;
void darkStep(double val);
```

- `double darkStep() const;`

  Returns the darkfield step for tuning.t

- `void darkStep(double val);`

  Sets the darkfield step for tuning.

  Parameters
  val The darkfield step value. Must be in the range 0.0 through 1.0.

  Throws
  ccAcuSymbolToolDefs::BadParams
  val was out of range.

nominalLightPower

```
double nominalLightPower() const;
void nominalLightPower(double val);
```

- `double nominalLightPower() const;`

  Returns the nominal light power value.

- `void nominalLightPower(double val);`

  Sets the nominal light power value. This value is used in conjunction with the **ccAcuSymbolTool::tune()** function. It specifies the light power setting for a remote fifo object used to acquire an image during tuning.

  Parameters
  val The light power value in the range 0.0 through 1.0.

  Throws
  ccAcuSymbolToolDefs::BadParams
  val was out of range.

nominalBrightFieldPowerRatio

```
double nominalBrightFieldPowerRatio() const;
void nominalBrightFieldPowerRatio(double val);
```

- `double nominalBrightFieldPowerRatio() const;`

  Returns the nominal brightfield power ratio (the portion, in the range 0.0 through 1.0, of light power allocated to brightfield illumination).

- `void nominalBrightFieldPowerRatio(double val);`

  Sets the nominal brightfield power ratio (the portion, in the range 0.0 through 1.0, of light power allocated to brightfield illumination). This value is used in conjunction with the **ccAcuSymbolTool::tune()** function. It specifies the brightfield power ratio for a remote fifo object used to acquire an image during tuning.

  Parameters

  val The brightfield power ratio in the range 0.0 through 1.0.

  Throws

  ccAcuSymbolToolDefs::BadParams
  val was out of range.

maxTime

```
double maxTime() const;
void maxTime(double maxTime);
```

- `double maxTime() const;`

  Returns the tuning timeout value (in seconds).

- `void maxTime(double maxTime);`

  Sets the tuning timeout value (in seconds). Tuning will be stopped after the specified number of seconds.

  Parameters

  maxTime The timeout value in seconds.

  Throws

  ccAcuSymbolDefs::BadParams if *maxTime* is less than 0.

validLimit

```
c_Int32 validLimit() const;
void validLimit(c_Int32 val);
```

- `c_Int32 validLimit() const;`

  Returns the maximum successful decode count. Tuning is stopped after the indicated number of decodes are performed with no score improvement.

- `void validLimit(c_Int32 val);`

  Sets the maximum successful decode count. Tuning is stopped after the indicated number of decodes are performed with no score improvement.

  Parameters

  val The maximum number of successful decodes in the range 0 through 255.

  Throws

  ccAcuSymbolDefs::BadParams
  val is out of range.

  Notes

  If you specify both a timeout and a valid limit, tuning stops when the first condition is met.

ccAcuSymbolTuneResult

```
#include <ch_cvl/acusymbl.h>

class ccAcuSymbolTuneResult : public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class contains the results of a tune operation performed by the Symbol tool.

Constructors/Destructors

ccAcuSymbolTuneResult

```
ccAcuSymbolTuneResult ();
```

Constructs a **ccAcuSymbolTuneResult** with the following values::

Parameter	Value
isTuned	false
tuneMethod	*ccAcuSymbolDefs::eLearn*
lightPower	0.0
brightFieldPowerRatio	0.12157
result	Default-constructed **ccAcuSymbolResult**
numSuccess	0
time	0
tuneExitCode	*ccAcuSymbolDefs::eNormal*

Operators

operator==

```
bool operator== (const ccAcuSymbolTuneResult& that) const;
```

Two **ccAcuSymbolTuneResult** objects are considered equal if all of their attributes are the same to a numerical precision of 1.e-8.

Parameters

that The **ccAcuSymbolTuneResult** to compare to this one.

Public Member Functions

isTuned

```
bool isTuned() const;
```

Returns true if this **ccAcuSymbolTuneResult** contains the results of a successful tune operation.

tuneMethod

```
ccAcuSymbolDefs::TuneMethod tuneMethod() const;
```

Returns the tuning method used during tuning (learn or decode). This function returns one of the following values:

ccAcuSymbolToolDefs::eLearn
ccAcuSymbolToolDefs::eDecode

lightPower

```
double lightPower() const;
```

Returns the tuned light power level value (in the range 0.0 through 1.0).

brightFieldPowerRatio

```
double brightFieldPowerRatio() const;
```

Returns the tuned bright field power ratio value (in the range 0.0 through 1.0).

result

```
const ccAcuSymbolResult& result() const;
```

Returns the **ccAcuSymbolResult** object containing the decode results produced using the tuned lighting values

numSuccesses

```
c_UInt32 numSuccesses() const;
```

Returns the number of successful learn or decode operations that were performed during tuning without improving the decode score.

time

```
double time() const;
```

Returns the amount of time (in seconds) required for tuning.

exitCode

```
ccAcuSymbolDefs::TuneExitCode exitCode() const;
```

Returns the reason that tuning terminated. This function returns one of the following values:

ccAcuSymbolDefs::eNormal
ccAcuSymbolDefs::eTime
ccAcuSymbolDefs::eNumSuccess

score

```
virtual double score() const;
```

Returns a score value for this **ccAcuSymbolTuneResult** object based on the values of the **ccAcuSymbolResult** object returned by **result()**. You can override this function to provide your own scoring function for use during tuning.

ccAcuSymbolTuneResult

ccAffineRectangle

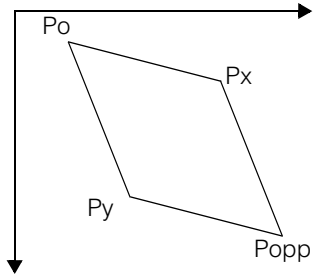
```
#include <ch_cvl/affrect.h>

class ccAffineRectangle : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class describes an affine rectangle (a quadrilateral where the opposite sides are parallel). A **ccAffineRectangle** can be defined by a unit square transformation, by the locations of three of its vertices, or by its location, width, height, and skew angle. Each of the vertices of an affine rectangle are labeled, as shown in the following figure:



Constructors/Destructors

ccAffineRectangle

```
ccAffineRectangle ();

ccAffineRectangle (const cc2Xform& affRectFromUS);

ccAffineRectangle (const cc2Vect& cornerPo,
  const cc2Vect& cornerPx, const cc2Vect& cornerPy);

ccAffineRectangle (const cc2Vect& center, double xLen,
  double yLen, const ccRadian& xRotation = ccRadian(0),
  const ccRadian& skew = ccRadian(0));
```

- `ccAffineRectangle ();`

  Constructs a **ccAffineRectangle** equal to the unit square in client coordinates (a rectangle whose vertices are the points (0,0), (1,0), (1,1), and (0,1)).

- `ccAffineRectangle (const cc2Xform& affRectFromUS);`

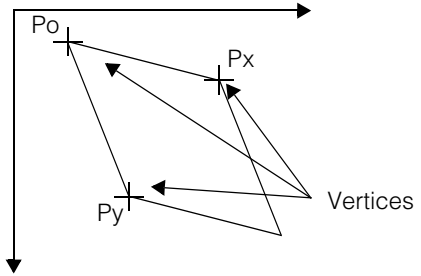
  Constructs the **ccAffineRectangle** defined by the application of the supplied **cc2Xform** to a unit square in client coordinates. A unit square is a rectangle whose vertices are the points (0,0), (1,0), (1,1), and (0,1).

  Parameters

  affRectFromUS A **cc2Xform** that defines this **ccAffineRectangle**.

- `ccAffineRectangle (const cc2Vect& cornerPo, const cc2Vect& cornerPx, const cc2Vect& cornerPy);`

  Constructs the **ccAffineRectangle** defined by the supplied vertices. The following figure shows the locations of these vertices.

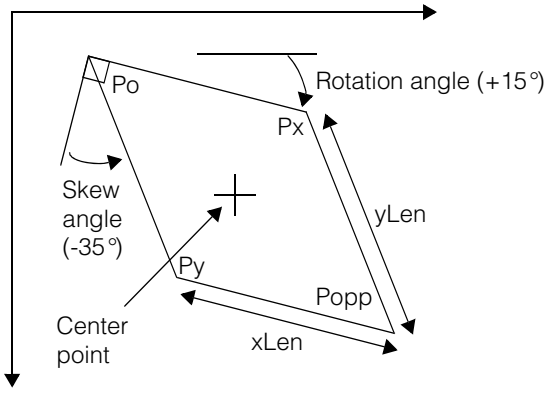


Parameters

cornerPo	The location of Po in client coordinates.
cornerPx	The location of Px in client coordinates.
cornerPy	The location of Py in client coordinates.

- `ccAffineRectangle (const cc2Vect& center, double xLen, double yLen, const ccRadian& xRotation = ccRadian(0), const ccRadian& skew = ccRadian(0));`

Constructs the **ccAffineRectangle** defined by the supplied center point location, width, height, angle of rotation, and angle of skew. The following figure shows how these values define the **ccAffineRectangle**.



Parameters

center	The center of the affine rectangle, in client coordinates
xLen	The length of the Po-Px side of the affine rectangle, in client coordinates
yLen	The length of the Po-Py side of the affine rectangle, in client coordinates
xRotation	The angle between the client coordinate system x-axis and the Po-Px side of the affine rectangle
skew	The angle between a line drawn perpendicular to the Po-Px side of the affine rectangle and the Po-Py side of the affine rectangle

Throws

ccAffineRectangle::BadLength
xLen or *yLen* is less than or equal to 0.

ccAffineRectangle::BadSkew
skew is π/2 radians or -π/2 radians (These two values are illegal; they produce a degenerate affine rectangle.) Note that this error is thrown if *skew* is within **ckAffineRectangleSkewAngleTol** of π/2 radians or -π/2 radians. You can determine if a given skew angle is valid by calling **ccAffineRectangle::isBadSkew()**.

Operators

operator==

```
bool operator== (const ccAffineRectangle& rhs) const;
```

Return true if this **ccAffineRectangle** is the same as the supplied **ccAffineRectangle**.

Two **ccAffineRectangle**s are considered equal if and only if they have the same Po, Px, and Py values.

Parameters
rhs The other **ccAffineRectangle** to compare.

operator!=

```
bool operator!= (const ccAffineRectangle& that) const;
```

Return true if this **ccAffineRectangle** is not the same as the supplied **ccAffineRectangle**.

Two **ccAffineRectangle**s are considered equal if and only if they have the same Po, Px, and Py values.

Parameters
that The other **ccAffineRectangle** to compare.

Public Member Functions

affRectFromUnitSq

```
const cc2Xform& affRectFromUnitSq () const;

void affRectFromUnitSq (const cc2Xform& affRectFromUS);
```

- `const cc2Xform& affRectFromUnitSq () const;`

Returns the **cc2Xform** that defines the transformation from a unit square to the affine rectangle described by this **ccAffineRectangle**.

- `void affRectFromUnitSq (const cc2Xform& affRectFromUS);`

  Sets the **cc2Xform** that defines the transformation from a unit square to the affine rectangle described by this **ccAffineRectangle**.

  Parameters

  affRectFromUS A **cc2Xform** that describes the transformation from the unit square to this **ccAffineRectangle**.

---

cornerPo

```
cc2Vect cornerPo () const;
void cornerPo (const cc2Vect& po);
```

- `cc2Vect cornerPo () const;`

  Returns the location of the Po vertex of this **ccAffineRectangle** in client coordinates.

- `void cornerPo (const cc2Vect& po);`

  Sets the Po vertex of this **ccAffineRectangle**. The remaining dimensions of the **ccAffineRectangle** are unchanged. Use this function to move a **ccAffineRectangle** without changing its size or shape.

  Parameters

  po The location of the Po vertex in client coordinates.

cornerPx

```
cc2Vect cornerPx () const;
```

Returns the location of the Px vertex of this **ccAffineRectangle** in client coordinates.

cornerPy

```
cc2Vect cornerPy () const;
```

Returns the location of the Py vertex of this **ccAffineRectangle** in client coordinates.

cornerPopp

```
cc2Vect cornerPopp () const;
```

Returns the location of the Popp vertex of this **ccAffineRectangle** in client coordinates.

center

```
cc2Vect center () const;
void center (const cc2Vect& ctr);
```

- `cc2Vect center () const;`

  Returns the location of the center of this **ccAffineRectangle** in client coordinates.

- `void center (const cc2Vect& ctr);`

  Sets the center point of this **ccAffineRectangle**. The remaining dimensions of the **ccAffineRectangle** are unchanged. Use this function to move a **ccAffineRectangle** without changing its size or shape.

  Parameters

  ctr The center point of this **ccAffineRectangle** in client coordinates.

xLength

```
double xLength () const;
void xLength (double xLen);
```

- `double xLength () const;`

  Returns the length of the Po-Px side of this **ccAffineRectangle** in client coordinates.

- `void xLength (double xLen);`

  Sets the length of the Po-Px side of this **ccAffineRectangle**. The center point, height, and angles of skew and rotation are unchanged.

  Parameters

  xLen The length of the Po-Px side in client coordinates.

  Throws

  ccAffineRectangle::BadLength
  xLen is less than or equal to 0.

yLength

```
double yLength () const;
void yLength (double yLen);
```

- `double yLength () const;`

  Returns the height of this **ccAffineRectangle** in client coordinates.

- `void yLength (double yLen);`

  Sets the height of this **ccAffineRectangle**. The center point, width, and angles of skew and rotation are unchanged.

  Parameters

  yLen The length of the Po-Py side in client coordinates.

  Throws

  ccAffineRectangle::BadLength
  yLen is less than or equal to 0.

xRotation

```
ccRadian xRotation () const;
void xRotation (const ccRadian& xRot);
```

- `ccRadian xRotation () const;`

  Returns the x rotation angle of this **ccAffineRectangle**. The x rotation angle is the angle between the Po-Px side of the affine rectangle and the client coordinate system x-axis.

  Notes

  The value returned by this function is between $-\pi$ and π radians.

- `void xRotation (const ccRadian& xRot);`

  Sets the x rotation angle of this **ccAffineRectangle**. The x rotation angle is the angle between the Po-Px side of the affine rectangle and the client coordinate system x-axis.

  The center point, height, and width of the **ccAffineRectangle** are not affected.

  Parameters

  xRot The angle to set.

yRotation

```
ccRadian yRotation () const;
```

Returns the y rotation angle of this **ccAffineRectangle**. The y rotation angle is the angle between the Po-Py side of affine rectangle and the client coordinate system y-axis.

Notes

The value returned by this function is between $-\pi$ and π radians.

skew

```
ccRadian skew () const;
void skew (const ccRadian& skew);
```

- `ccRadian skew () const;`

  Returns the skew angle of this **ccAffineRectangle**. The skew angle is the angle between a line drawn perpendicular to the Po-Px side of the affine rectangle and the Po-Py side of the rectangle. The skew angle is equal to the y rotation angle minus the x rotation angle.

  Notes

  The value returned by this function is between $-\pi/2$ and $\pi/2$ radians.

- `void skew (const ccRadian& skew);`

  Sets the skew angle of this **ccAffineRectangle**. The skew angle is the angle between a line drawn perpendicular to the Po-Px side of the affine rectangle and the Po-Py side of the rectangle. The skew angle is equal to the y rotation angle minus the x rotation angle.

  The center point, height, and width of the **ccAffineRectangle** are not affected.

  Parameters

  skew The skew angle

  Throws

  ccAffineRectangle::BadSkew

  skew is $\pi/2$ radians or $-\pi/2$ radians (These two values are illegal; they produce a degenerate affine rectangle.) Note that this error is thrown if *skew* is within **ckAffineRectangleSkewAngleTol** of $\pi/2$ radians or $-\pi/2$ radians. You can determine if a given skew angle is valid by calling **ccAffineRectangle::isBadSkew()**.

cornersPoPxPy

```
void cornersPoPxPy (const cc2Vect& cornerPo,
  const cc2Vect& cornerPx, const cc2Vect& cornerPy);
```

Sets the locations of the Po, Px, and Py vertices of this **ccAffineRectangle**.

Parameters

cornerPo The location of the Po vertex, in client coordinates.

cornerPx The location of the Px vertex, in client coordinates.

cornerPy The location of the Py vertex, in client coordinates.

Notes

This function fully defines an affine rectangle.

centerLengthsRotAndSkew

```
void centerLengthsRotAndSkew (const cc2Vect& center,
  double xLen, double yLen,
  const ccRadian& xRotation = ccRadian(0),
  const ccRadian& skew = ccRadian(0));
```

Sets the location, width, height, rotation angle, and skew angle of this **ccAffineRectangle**.

Parameters

center The center of the **ccAffineRectangle**, in client coordinates.

xLen The length of the Po-Px side of the **ccAffineRectangle**, in client coordinates.

yLen The length of the Po-Py side of the **ccAffineRectangle**, in client coordinates.

xRotation The rotation angle of the **ccAffineRectangle**.

skew The skew angle of the **ccAffineRectangle**.

Throws

ccAffineRectangle::BadLength
xLen or *yLen* is less than or equal to 0.

ccAffineRectangle::BadSkew
skew is $\pi/2$ radians or $-\pi/2$ radians (These two values are illegal; they produce a degenerate affine rectangle.) Note that this error is thrown if *skew* is within **ckAffineRectangleSkewAngleTol** of $\pi/2$ radians or $-\pi/2$ radians. You can determine if a given skew angle is valid by calling **ccAffineRectangle::isBadSkew()**.

Notes

This function fully defines an affine rectangle.

cornerPoLengthsRotAndSkew

```
void cornerPoLengthsRotAndSkew (const cc2Vect& cornerPo,
  double xLen, double yLen,
  const ccRadian& xRotation = ccRadian(0),
  const ccRadian& skew = ccRadian(0));
```

Sets the location of the Po vertex and the width, height, rotation angle, and skew angle of this **ccAffineRectangle**.

Parameters

cornerPo The location of the Po vertex, in client coordinates.

xLen The length of the Po-Px side of the **ccAffineRectangle**, in client coordinates.

yLen The length of the Po-Py side of the **ccAffineRectangle**, in client coordinates.

xRotation The rotation angle of the **ccAffineRectangle**.

skew The skew angle of the **ccAffineRectangle**.

Throws

ccAffineRectangle::BadLength
xLen or *yLen* is less than or equal to 0.

ccAffineRectangle::BadSkew
skew is π/2 radians or -π/2 radians (These two values are illegal; they produce a degenerate affine rectangle.) Note that this error is thrown if *skew* is within **ckAffineRectangleSkewAngleTol** of π/2 radians or -π/2 radians. You can determine if a given skew angle is valid by calling **ccAffineRectangle::isBadSkew()**.

Notes

This function fully defines an affine rectangle.

map

```
ccAffineRectangle map(const cc2Xform& c) const;
```

Maps this **ccAffineRectangle** by the supplied **cc2Xform** and returns the result. None of the dimensions of this **ccAffineRectangle** change. Useful for scaling.

Parameters

c The **cc2Xform** by which to map this **ccAffineRectangle**.

encloseImageRect

```
ccPelRect encloseImageRect(
  const cc2Xform& imageFromClientXform = cc2Xform::I)
  const;
```

Returns the smallest rectangle aligned to the supplied coordinate system that encloses this **ccAffineRectangle**. By default, this function returns the smallest enclosing rectangle in the image coordinate system.

Parameters

imageFromClientXform
A **cc2Xform** that specifies the transformation from the image coordinate system. A default parameter of the identity transformation is supplied.

degen

```
bool degen() const;
```

Returns true if this **ccAffineRectangle** is degenerate. A **ccAffineRectangle** is considered degenerate if either its width or height is 0.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this affine rectangle.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For affine rectangles, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

For affine rectangles, this function always returns true. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For affine rectangles, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For affine rectangles, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

Returns true for most affine rectangles. Returns false if all four vertices are coincident, in which case the affine rectangle collapses to a single point and there is no tangent. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For affine rectangles, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For affine rectangles, this function always returns true. See **ccShape::reverse()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this affine rectangle. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this affine rectangle. See **ccShape::boundingBox()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if this affine rectangle is right-handed. See **ccShape::isRightHanded()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this affine rectangle to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

sample

```
virtual void sample(const ccSampleParams &params,
  ccSampleResult &result);
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores affine rectangles for which **hasTangent()** is false.

Throws

ccShapesError::SampleOverflow
Supplied spacing and tolerance bounds require more than *maxPoint* samples to be generated. See **ccSampleParams** for details.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this affine rectangle mapped by *X*.

Parameters

X The transformation object.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccLineSeg**s. See **ccShape::decompose()** for additional information.

within

```
virtual bool within(const cc2Vect& v) const;
```

Returns true if the given point is within this affine rectangle.

Parameters

v The point.

See **ccShape::within()** for more information.

Static Functions

isBadSkew

```
static bool isBadSkew(const ccRadian& skew);
```

Returns true if the supplied value is within **ckAffineRectangleSkewAngleTol** radians of $\pi/2$ radians or $-\pi/2$ radians. The function returns false otherwise.

Parameters

skew The skew angle to test.

Deprecated Members

encloseRect `ccRect encloseRect() const;`

Use **boundingBox()** instead.

distToPoint `double distToPoint(const cc2Vect& v) const;`

Use **distanceToPoint()** (inherited from the **ccShape** base class) instead.

ccAffineSamplingParams

```
#include <ch_cvl/affsampl.h>

class ccAffineSamplingParams;
```

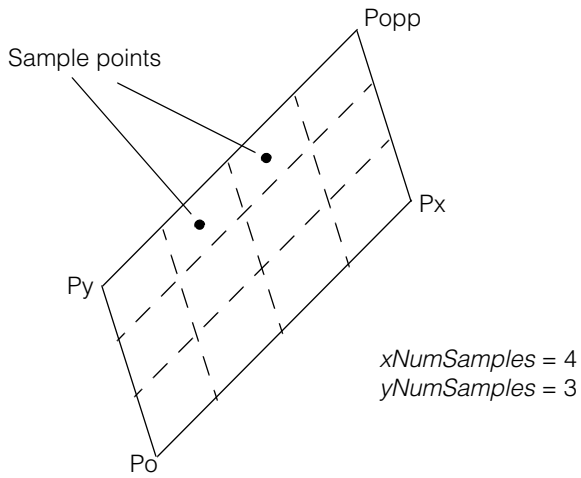
Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class describes affine sampling parameters. Affine sampling parameters control how the pixels within an affine rectangle in an image are sampled. The following are affine sampling parameters:

- The number of x-axis and y-axis divisions within an affine rectangle
- The sampling method
- An affine rectangle

See the following diagram.



Constructors/Destructors

ccAffineSamplingParams

```
ccAffineSamplingParams ();

ccAffineSamplingParams (
  const ccAffineRectangle& affRect,
  c_Int32 xNumSamples,
  c_Int32 yNumSamples,
  Interpolation method = kDefaultInterpolation);

ccAffineSamplingParams(const ccAffineSamplingParams&);
```

- `ccAffineSamplingParams ();`

  Default constructor.

- ```
  ccAffineSamplingParams (
    const ccAffineRectangle& affRect,
    c_Int32 xNumSamples,
    c_Int32 yNumSamples,
    Interpolation method = kDefaultInterpolation);
  ```

  Constructs a **ccAffineSamplingParams** using the supplied values.

  Parameters

  affRect — The **ccAffineRectangle** that defines the rectangle to sample

  xNumSamples — The number of divisions into which *affrect* is divided along the Po-Px side.

  yNumSamples — The number of divisions into which *affrect* is divided along the Po-Py side.

  method — The interpolation method to use to compute the sampled pixel values. *method* must be one of the following values:

  ccAffineSamplingParams::eNone
  ccAffineSamplingParams::eBilinear
  ccAffineSamplingParams::eHighPrecision

  Throws

  ccAffineSamplingParams::BadNumSamples
  xNumSamples or *yNumSamples* is less than 1.
  ```

- `ccAffineSamplingParams(const ccAffineSamplingParams&);`

  Copy constructor.

Enumerations

Interpolation `enum Interpolation`

This enumeration defines the sampling methods supported by the tool.

Value	Meaning
eNone = 1	Use nearest-neighbor interpolation.
eBilinear = 2 (Also called *eBilinearApprox*)	Use bilinear interpolation of four nearest pixels. This interpolation mode approximates true bilinear interpolation. While this is the default mode (for backward compatibility), Cognex recommends using *eBilinearAccurate*.
eHighPrecision = 3	Use high-precision interpolation to compute the interpolated value.
eBilinearAccurate = 4	Performs an accurate bilinear interpolation of the four nearest pixels. This method is the most accurate, and in most cases, the fastest method.
kDefaultInterpolation = *eBilinear*	The default interpolation.

Operators

operator=

```
ccAffineSamplingParams& operator=(
                          const ccAffineSamplingParams& rhs);
```

Assignment operator. Make this object a copy of *rhs*.

Parameters

rhs The copy source.

operator==

```
bool operator==(const ccAffineSamplingParams& that);
```

Returns true if this object is equal to *that*. Returns false otherwise.

Two **ccAffineSamplingParams** objects are equal if their affine rectangles are the same and the number of samples and interpolation methods are equal.

Parameters

that The other **ccAffineSamplingParams** object.

Public Member Functions

affineRectangle

```
const ccAffineRectangle& affineRectangle () const;
void affineRectangle (const ccAffineRectangle& affRect);
```

- ```
  const ccAffineRectangle& affineRectangle () const;
  ```

  Returns a reference to the **ccAffineRectangle** associated with this **ccAffineSamplingParams**.

- ```
  void affineRectangle (const ccAffineRectangle& affRect);
  ```

  Sets the **ccAffineRectangle** associated with this **ccAffineSamplingParams**.

  Parameters

  affRect The **ccAffineRectangle** to set.

xNumSamples

```
c_Int16 xNumSamples () const;
void xNumSamples (c_Int32 xNum);
```

- ```
  c_Int16 xNumSamples () const;
  ```

  This overload is deprecated. Use **xNumSamples32()** to obtain the current number of Po-Px divisions in this **ccAffineSamplingParams**.

  Throws

  ccAffineSamplingParams:BadNumSamples
  The number of samples (set using **xNumSamples32**) is greater than 32767.
  ```

- `void xNumSamples (c_Int32 xNum);`

  Sets the number of Po-Px divisions in this **ccAffineSamplingParams**. The **ccAffineRectangle** associated with this **ccAffineSamplingParams** is divided into the specified number of divisions along the Po-Px side.

  Parameters
  xNum The number of x-divisions

  Throws
  ccAffineSamplingParams:BadNumSamples
  xNum is less than 1.

yNumSamples

`c_Int16 yNumSamples () const;`

`void yNumSamples (c_Int32 yNum);`

- `c_Int16 yNumSamples () const;`

  This overload is deprecated. Use **yNumSamples32()** to obtain the current number of Po-Py divisions in this **ccAffineSamplingParams**.

  Throws
  ccAffineSamplingParams:BadNumSamples
  The number of samples (set using **yNumSamples32**) is greater than 32767.

- `void yNumSamples (c_Int32 yNum);`

  Sets the number of Po-Py divisions in this **ccAffineSamplingParams**. The **ccAffineRectangle** associated with this **ccAffineSamplingParams** is divided into the specified number of divisions along the Po-Py side.

  Parameters
  yNum The number of y-divisions

  Throws
  ccAffineSamplingParams:BadNumSamples
  yNum is less than 1.

xNumSamples32 `c_Int32 xNumSamples32 () const;`

Returns the number of Po-Px divisions in this **ccAffineSamplingParams**. The **ccAffineRectangle** associated with this **ccAffineSamplingParams** is divided into the returned number of divisions along the Po-Px side.

yNumSamples32 `c_Int32 yNumSamples32 () const;`

Returns the number of Po-Py divisions in this **ccAffineSamplingParams**. The **ccAffineRectangle** associated with this **ccAffineSamplingParams** is divided into the returned number of divisions along the Po-Py side.

interpolation

```
Interpolation interpolation () const;
void interpolation (Interpolation method);
```

- `Interpolation interpolation () const;`

  Returns the interpolation method of this **ccAffineSamplingParams**. The returned value is one of the following:

  ccAffineSamplingParams::eNone
  ccAffineSamplingParams::eBilinear
  ccAffineSamplingParams::eBilinearApprox
  ccAffineSamplingParams::eBilinearAccurate
  ccAffineSamplingParams::eHighPrecision

- `void interpolation (Interpolation method);`

  Sets the interpolation method of this **ccAffineSamplingParams**.

  Parameters

  method — The interpolation method to use. *method* must be one of the following values:

  ccAffineSamplingParams::eNone
  ccAffineSamplingParams::eBilinear
  ccAffineSamplingParams::eBilinearApprox
  ccAffineSamplingParams::eBilinearAccurate
  ccAffineSamplingParams::eHighPrecision

willClip `bool willClip(const cc_PelBuffer& srcImg) const;`

Returns true if the affine rectangle specified in this **ccAffineSamplingParams** would need to access pixels outside of the valid region of *srcImg*. The valid region within *srcImg* is defined as being all pixels in *srcImg* other than a two-pixel wide border around the edge of *srcImg*.

Parameters

srcImage — The image to test.

Throws

ccAffineSamplingParams::NotImplemented if the interpolation

ccAffProjImgDefs::NotImplemented

interpolation() is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImg.rowUpdate()* or *srcImg.height()* is greater than or equal to 32768.

ccAffineSamplingParams

ccAnalogAcqProps

```
#include <ch_cvl/prop.h>

class ccAnalogAcqProps : public ccAcqProps;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class is has been deprecated. Use the class **ccAcqProps** instead. See **ccAcqProps** on page 253.

ccAnalogAcqProps

ccAngle8

```
#include <ch_cvl/units.h>

class ccAngle8;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes an angle as an unsigned 8-bit integer with a value from 0 to 255. Each integer value represents a small range of angles:

Integer value	Angle in degrees	Range
0	0°	±0.703125
1	1.40625°	±0.703125
2	2.8125°	±0.703125
32	45.0°	±0.703125

Note that you can use the constructors to convert from one angle representation to another. For example, to specify 60° as a **ccAngle8**, you could write:

```
ccAngle8 ang8(ccDegree(60.0));
```

When converting angles, be aware that Cognex vision tools are not entirely consistent in their use of **ccAngle8** and **ccAngle16**. Some tools use a truncation model when converting between floating point angles and binary angles, and other tools use a rounding model. The following table shows an example of the different results produced when converting angles between floating point and **ccAngle8** representations using the truncation method as compared to the rounding method:

Convert From	Convert To	Truncation	Rounding
1.406°	**ccAngle8**	0	1
-0.001°	**ccAngle8**	255	0
0 **ccAngle8**	degrees	0°	0.703125°
1 **ccAngle8**	degrees	1.40625°	2.109375°

The rounding method is numerically more stable if multiple conversions will be made between floating point and binary angles. For example, using the truncation model a floating point computation that yields -0.0000000001° is represented as a 255 **ccAngle8**, which is then converted back to 358.59375°. If an iterative computation then added another -0.0000000001° and converted back to **ccAngle8**, you would get a steadily decreasing representation of 254, 253, 252, and so on.

Constructors/Destructors

ccAngle8

```
ccAngle8();
ccAngle8(ccRadian a);
ccAngle8(ccDegree a);
ccAngle8(ccAngle16 a);
explicit ccAngle8(c_UInt8 a);
```

- `ccAngle8();`

  Creates an uninitialized **ccAngle8** object.

- `ccAngle8(ccRadian a);`

  Creates a **ccAngle8** object from the given **ccRadian** object.

  Parameters

  a — The **ccRadian** object to convert to **ccAngle8** format.

- `ccAngle8(ccDegree a);`

  Creates a **ccAngle8** object from the given **ccDegree** object.

  Parameters

  a — The **ccDegree** object to convert.

- `ccAngle8(ccAngle16 a);`

  Creates a **ccAngle8** object from the given **ccAngle16** object.

  Parameters

  a — The **ccAngle16** object to convert.

- `explicit ccAngle8(c_UInt8 a);`

  Creates a **ccAngle8** object with the specified value.

  Parameters

  a The angle as an unsigned 8-bit integer.

Operators

operator+

```
ccAngle8 operator+(ccAngle8 a) const;
```

Returns the result of adding the angle *a* to this angle.

Parameters

a The angle to add to this angle.

---

operator-

```
ccAngle8 operator-(ccAngle8 a) const;
ccAngle8 operator-() const;
```

- `ccAngle8 operator-(ccAngle8 a) const;`

  Returns the result of subtracting the angle *a* from this angle.

  Parameters

  a The angle to subtract from this angle.

- `ccAngle8 operator-() const;`

  Returns the negative of this angle. The unary minus operator.

---

operator*

```
ccAngle8 operator*(c_UInt8 a) const;
c_UInt8 operator*(ccAngle8 a) const;
friend ccAngle8 operator*(c_UInt8 a, ccAngle8 b);
```

- `ccAngle8 operator*(c_UInt8 a) const;`

  Returns the result of multiplying this angle by *a*.

  Parameters

  a The amount to multiply by.

- `c_UInt8 operator*(ccAngle8 a) const;`

  Returns the result of multiplying this angle by the angle *a*.

  Parameters

a	The angle to multiply by.

- `friend ccAngle8 operator*(c_UInt8 a, ccAngle8 b);`

  Returns the result of multiplying the angle *b* by *a*.

  Parameters

a	The amount to multiply by.
b	The angle to multiply.

operator/

```
ccAngle8 operator/(c_UInt8 a) const;
c_UInt8 operator/(ccAngle8 a) const;
```

- `ccAngle8 operator/(c_UInt8 a) const;`

  Returns the result of dividing this angle by *a*.

  Parameters

a	The amount to divide by.

- `c_UInt8 operator/(ccAngle8 a) const;`

  Returns the result of dividing this angle by the angle *a*.

  Parameters

a	The angle to divide by.

operator= `ccAngle8& operator=(c_UInt8 a);`

Assigns the value *a* to this angle.

Parameters

a	The value to assign.

operator*=

```
ccAngle8& operator*=(c_UInt8 a);
ccAngle8& operator*=(ccAngle8 a);
```

- `ccAngle8& operator*=(c_UInt8 a);`

  Multiplies this angle by *a* and returns the result.

  Parameters

a	The value to multiply by.

- `ccAngle8& operator*=(ccAngle8 a);`

  Multiplies this angle by the angle *a* and returns the result.

  Parameters

a	The angle to multiply by.

operator/=

```
ccAngle8& operator/=(c_UInt8 a);
ccAngle8& operator/=(ccAngle8 a);
```

- `ccAngle8& operator/=(c_UInt8 a);`

  Divides this angle by the value *a* and returns the result.

  Parameters

a	The value to divide by.

- `ccAngle8& operator/=(ccAngle8 a);`

  Divides this angle by the angle *a* and returns the result.

  Parameters

a	The angle to divide by.

operator+=

```
ccAngle8& operator+=(ccAngle8 a);
```

Adds the angle *a* to this angle and returns the result.

Parameters

a	The angle to add.

operator-= `ccAngle8& operator-=(ccAngle8 a);`

Subtracts the angle *a* from this angle and returns the result.

Parameters

a The angle to subtract.

operator== `bool operator!=(ccAngle8 a) const;`

Returns true if this angle is exactly equal to the angle *a*.

Parameters

a The other angle.

operator!= `bool operator!=(ccAngle8 a) const;`

Returns true if this angle is not equal to the angle *a*.

Parameters

a The other angle.

operator< `bool operator<(ccAngle8 a) const;`

Returns true if this angle is less than angle *a*.

Parameters

a The other angle.

operator<= `bool operator<=(ccAngle8 a) const;`

Returns true if this angle is less than or equal to angle *a*.

Parameters

a The other angle.

operator> `bool operator>(ccAngle8 a) const;`

Returns true if this angle is greater than angle *a*.

Parameters

a The other angle.

operator>= `bool operator>=(ccAngle8 a) const;`

Returns true if this angle is greater than or equal to angle *a*.

Parameters

a	The other angle.

Public Member Functions

toDouble

```
double toDouble() const;
```

Returns this angle as a **double**.

plain

```
c_UInt8 plain() const;
```

Returns this angle as a **c_UInt8**.

ccAngle8

ccAngle16

```
#include <ch_cvl/units.h>

class ccAngle16;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes an angle as an unsigned 16-bit integer with a value from 0 to 65535. Each integer value represents a small range of angles:

Integer value	Angle in degrees	Range
0	0°	±0.00274658
1	0.00549316°	±0.00274658
2	0.010986°	±0.00274658
8192	45.0°	±0.00274658

Note that you can use the constructors to convert from one angle representation to another. For example, to specify 60° as a **ccAngle16**, you could write:

```
ccAngle16 ang16(ccDegree(60.0));
```

When converting angles, be aware that Cognex vision tools are not entirely consistent in their use of **ccAngle8** and **ccAngle16**. Some tools use a truncation model when converting between floating point angles and binary angles, and other tools use a rounding model. The following table shows an example of the different results produced when converting angles between floating point and **ccAngle16** representations using the truncation method as compared to the rounding method:

Convert From	Convert To	Truncation	Rounding
0.00549°	**ccAngle16**	0	1
-0.001°	**ccAngle16**	65535	0
0 **ccAngle16**	degrees	0°	0.00274658203125°
1 **ccAngle16**	degrees	0.0054931640625°	0.00823974609375°

The rounding method is numerically more stable if multiple conversions will be made between floating point and binary angles. For example, using the truncation model a floating point computation that yields -0.0000000001° is represented as a 65535 **ccAngle16**, which is then converted back to 359.9945068360375°. If an iterative computation then added another -0.0000000001° and converted back to **ccAngle16**, you would get a steadily decreasing representation of 65534, 65533, 65532, and so on.

Constructors/Destructors

ccAngle16

```
ccAngle16();
ccAngle16(ccRadian a);
ccAngle16(ccDegree a);
ccAngle16(ccAngle8 a);
explicit ccAngle16(c_UInt16 a);
```

- `ccAngle16();`

  Creates an uninitialized **ccAngle16** object.

- `ccAngle16(ccRadian a);`

  Creates a **ccAngle16** object from the given **ccRadian** object.

  Parameters

  a The **ccRadian** object to convert to degrees.

- `ccAngle16(ccDegree a);`

  Creates a **ccAngle16** object from the given **ccDegree** object.

  Parameters

  a The **ccDegree** object to convert.

- `ccAngle16(ccAngle8 a);`

  Creates a **ccAngle16** object from the given **ccAngle8** object.

  Parameters

  a The **ccAngle8** object to convert.

- `explicit ccAngle16(c_UInt16 a);`

  Creates a **ccAngle16** object with the specified value.

  Parameters

a	The angle as an unsigned 16-bit integer.

Operators

operator+

```
ccAngle16 operator+(ccAngle16 a) const;
```

Returns the result of adding the angle *a* to this angle.

Parameters

a	The angle to add to this angle.

operator-

```
ccAngle16 operator-(ccAngle16 a) const;
ccAngle16 operator-() const;
```

- `ccAngle16 operator-(ccAngle16 a) const;`

  Returns the result of subtracting the angle *a* from this angle.

  Parameters

a	The angle to subtract from this angle.

- `ccAngle16 operator-() const;`

  Returns the negative of this angle. The unary minus operator.

operator*

```
ccAngle16 operator*(c_UInt16 a) const;
c_UInt16 operator*(ccAngle16 a) const;
friend ccAngle16 operator*(c_UInt16 a, ccAngle16 b);
```

- `ccAngle16 operator*(c_UInt16 a) const;`

  Returns the result of multiplying this angle by *a*.

  Parameters

a	The amount to multiply by.

- `c_UInt16 operator*(ccAngle16 a) const;`

  Returns the result of multiplying this angle by the angle *a*.

  Parameters

a	The angle to multiply by.

- `friend ccAngle16 operator*(c_UInt16 a, ccAngle16 b);`

  Returns the result of multiplying the angle *b* by *a*.

  Parameters

a	The amount to multiply by.
b	The angle to multiply.

operator/

```
ccAngle16 operator/(c_UInt16 a) const;
c_UInt16 operator/(ccAngle16 a) const;
```

- `ccAngle16 operator/(c_UInt16 a) const;`

  Returns the result of dividing this angle by *a*.

  Parameters

a	The amount to divide by.

- `c_UInt16 operator/(ccAngle16 a) const;`

  Returns the result of dividing this angle by the angle *a*.

  Parameters

a	The angle to divide by.

operator= `ccAngle16& operator=(c_UInt16 a);`

Assigns the value *a* to this angle.

Parameters

a	The value to assign.

operator*=

```
ccAngle16& operator*=(c_UInt16 a);
ccAngle16& operator*=(ccAngle16 a);
```

- `ccAngle16& operator*=(c_UInt16 a);`

  Multiplies this angle by *a* and returns the result.

  Parameters

a	The value to multiply by.

- `ccAngle16& operator*=(ccAngle16 a);`

  Multiplies this angle by the angle *a* and returns the result.

  Parameters

a	The angle to multiply by.

operator/=

```
ccAngle16& operator/=(c_UInt16 a);
ccAngle16& operator/=(ccAngle16 a);
```

- `ccAngle16& operator/=(c_UInt16 a);`

  Divides this angle by the value *a* and returns the result.

  Parameters

a	The value to divide by.

- `ccAngle16& operator/=(ccAngle16 a);`

  Divides this angle by the angle *a* and returns the result.

  Parameters

a	The angle to divide by.

operator+=

```
ccAngle16& operator+=(ccAngle16 a);
```

Adds the angle *a* to this angle and returns the result.

Parameters

a	The angle to add.

operator-= `ccAngle16& operator-=(ccAngle16 a);`

Subtracts the angle *a* from this angle and returns the result.

Parameters

a The angle to subtract.

operator== `bool operator!=(ccAngle16 a) const;`

Returns true if this angle is exactly equal to the angle *a*.

Parameters

a The other angle.

operator!= `bool operator!=(ccAngle16 a) const;`

Returns true if this angle is not equal to the angle *a*.

Parameters

a The other angle.

operator< `bool operator<(ccAngle16 a) const;`

Returns true if this angle is less than angle *a*.

Parameters

a The other angle.

operator<= `bool operator<=(ccAngle16 a) const;`

Returns true if this angle is less than or equal to angle *a*.

Parameters

a The other angle.

operator> `bool operator>(ccAngle16 a) const;`

Returns true if this angle is greater than angle *a*.

Parameters

a The other angle.

operator>= `bool operator>=(ccAngle16 a) const;`

Returns true if this angle is greater than or equal to angle *a*.

Parameters

a	The other angle.

Public Member Functions

toDouble

```
double toDouble() const;
```

Returns this angle as a **double** value.

plain

```
c_UInt16 plain() const;
```

Returns this angle as a **c_UInt16**.

ccAngle16

ccAngleRange

```
#include <ch_cvl/range.h>

class ccAngleRange;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

The class **ccAngleRange** specifies a range of orientations and provides methods for performing the following operations:

- Check whether a value is within a range of angles.
- Check whether a range of angles is full, partly full, or empty.
- Dilate ranges of angles (Minkowski sum operation).

This class is can specify a range that contains an angle whose measure is 2 * π radians. For example, an angle range from 6.0 to 7.0 radians would contain the angle of 0.0 degrees (since 6.28 is within the range [6.0 through 7.0] and 0 ~= 6.28 (2 * π).

Constructors/Destructors

ccAngleRange

```
ccAngleRange ();

ccAngleRange (const ccRadian &start, const ccRadian &end);
```

- `ccAngleRange ();`

  Returns a default constructed empty angle range.

- `ccAngleRange (const ccRadian &start, const ccRadian &end);`

  Returns an **ccAngleRange** object characterized by the specified start and end values. If (**end.toDouble()** - **start.toDouble()**) > 2 * π, then the function constructs a full range. Otherwise, it constructs a partial range.

  Parameters

start	The start position of the angle range.
end	The end position of the angle range.

Operators

operator==

```
bool operator== (const ccAngleRange& that) const;
```

True if this range equals the other range; false otherwise.

Parameters

that The other range.

Notes

Two **ccAngleRange** objects are considered equal if their ranges, start angles, and end angles are equal.

operator!=

```
bool operator!= (const ccAngleRange& that) const;
```

True if this range does not equal that range; false if this range equals that range.

Parameters

that The other range.

Notes

Two **ccAngleRange** objects are considered equal if their ranges, start angles, and end angles are equal or if they are both full or both empty.

Public Member Functions

dilate

```
ccAngleRange dilate(const ccAngleRange &x) const;
```

Returns a new **ccAngleRange** object that is created by dilating this range with another range specified by *x*. Dilation is accomplished by using the Minkowski sum of two sets A and B. The resulting range is the set of all points which can be generated by adding an element of A to an element of B.

Parameters

x The range used to dilate this angle range.

end

```
ccRadian end() const;
```

Returns the end position of a partial range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial angle range.

isWithin

```
bool isWithin(const ccRadian &x) const;
```

Returns a bool that indicates whether or not the value *x* is inside this angle range.

Parameters

x The value that may or may not be inside this angle range.

length

```
ccRadian length() const;
```

Returns the length of the angle range which is defined as one of the following:

ck2Pi if the angle range is full (range_ == *eFull*)

0 if the angle range is empty (range_ == *eEmpty*)

*end_-start_* if the angle range contains some members (range_ == ePartial).

middle

```
ccRadian middle() const;
```

Returns the middle of the given angle range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial angle range.

start

```
ccRadian start() const;
```

Returns the start position of a partial angle range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial angle range.

Static Functions

EmptyAngleRange

```
static ccAngleRange EmptyAngleRange();
```

Returns the default constructed empty angle range.

FullAngleRange

```
static ccAngleRange FullAngleRange();
```

Returns the default constructed full angle range.

ccAngleRange

ccAnnulus

```
#include <ch_cvl/shapes.h>

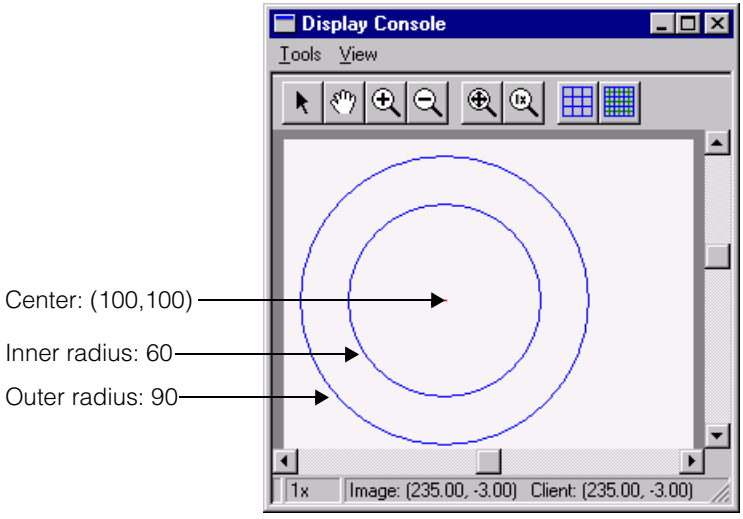
class ccAnnulus : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccAnnulus** class describes an annulus, a ring shape made up of two concentric circles. You specify a center and the inner and outer radii to describe an annulus. The following figure shows an annulus.

```
ccAnnulus(cc2Vect(100,100), 60, 90)
```



Constructors/Destructors

ccAnnulus

```
ccAnnulus();
ccAnnulus(const cc2Vect& c, double r1, double r2);
ccAnnulus(const ccCircle& c1, const ccCircle& c2);
```

- `ccAnnulus();`

  The default constructor creates a degenerate annulus with its center at (0,0) and inner and outer radii set to zero.

- `ccAnnulus(const cc2Vect& c, double r1, double r2);`

  Creates an annulus with the specified center and radii.

  Parameters

  c The center of the annulus.

  r1 The inner radius. The radius must be non-negative.

  r2 The outer radius. The radius must be non-negative.

  Throws

  ccShapesError::BadRadius
  Either radius is negative.

- `ccAnnulus(const ccCircle& c1, const ccCircle& c2);`

  Creates an annulus from two concentric circles.

  Parameters

  c1 The inner circle.

  c2 The outer circle.

  Throws

  ccShapesError::NotConcentric
  Circles c1 and c2 are not concentric.

Operators

operator==

```
bool operator==(const ccAnnulus& other) const;
```

Returns true if this annulus is equal to another annulus: it has the same center, inner radius, and outer radius as the other annulus.

Parameters

other	The other annulus.

operator!=

```
bool operator!=(const ccAnnulus&) const;
```

Returns true if this annulus is not equal to another annulus.

Parameters

other	The other annulus.

Public Member Functions

center

```
const ccPoint& center() const;
```

Returns the center of the annulus.

innerRadius

```
double innerRadius() const;
```

Returns the inner radius of the annulus.

outerRadius

```
double outerRadius() const;
```

Returns the outer radius of the annulus.

innerCircle

```
ccCircle innerCircle() const;
```

Returns the inner circle of the annulus.

outerCircle

```
ccCircle outerCircle() const;
```

Returns the outer circle of the annulus.

map

```
ccGenAnnulus map(const cc2Xform& c) const;
```

Returns an annulus that is the result of mapping this annulus with the transformation object *c*.

Parameters

c The transformation object.

Notes

Both of the radii of this annulus must be strictly positive, and the transform *c* must be nonsingular. If both of these conditions are false, use **mapshape()** instead.

degen

```
bool degen() const;
```

Returns true if this annulus is *degenerate*. An annulus is degenerate if either both radii are equal, or one of the radii is less than or equal to zero.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this annulus.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For annuli, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

For annuli, this function always returns true, even for annuli that are degenerate. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For annuli, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For annuli, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

This function returns true if at least one of the radii of this annulus is positive. It returns false if neither radius is positive. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For annuli, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For annuli, this function always returns false. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this annulus. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this annulus to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this annulus to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this annulus.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

For annuli, this function always returns true. Annuli are always right-handed. See **ccShape::isRightHanded()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params Specifies details of how the sampling should be done.

result Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores annuli for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this annulus mapped by *X*.

Parameters

X The transformation object.

Notes

If *X* is the identity transform, this function returns a **ccAnnulus**. Otherwise, if *X* is singular this function returns a **ccRegionTree**, or if *X* is nonsingular and either radius is zero, this function returns a **ccEllipseAnnulus**. In all other cases, it returns a **ccGenAnnulus**.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccEllipseArc2**s. See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect& v) const;
```

Returns true if the given point is within this annulus.

Parameters

v The point.

Notes

A point is within an annulus if it is between the inner and outer circles of the annulus.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this annulus over the given perimeter range. The perimeter of the final returned shape is equal to the absolute value of the distance component of *range*, assuming the distance is not clipped.

Parameters

info Shape information for this annulus.

range The perimeter range.

See **ccShape::subShape()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

ccAnnulus

ccArchive

```
#include <ch_cvl/archive.h>

class ccArchive;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	Not applicable

The **ccArchive** class is an abstract base class from which the concrete archive classes **ccFileArchive** and **ccMemoryArchive** are derived. This class implements the **||**, **<<**, and **>>** operators for the built-in C++ types.

Constructors/Destructors

ccArchive

```
virtual ~ccArchive();
```

Enumerations

Direction

```
enum Direction;
```

This enumeration defines the mode for a **ccArchive**.

Value	Meaning
eLoading	This archive is used to load objects.
eStoring	This archive is used to store objects.

Ordering

```
enum Ordering;
```

This enumeration defines the endianness of a **ccArchive**.

The endianness of an archive is the endianness with which data are stored in the archive. Whenever an archive is loaded, if the endianness of the machine onto which it is being loaded does not match the endianness of the archive, byte swapping is performed as the objects are loaded.

When you instantiate a **ccArchive**-derived concrete class for storing, you must specify the endianness of the archive. If the endianness of the archive does not match the endianness of the machine from which the objects are being stored, then byte swapping is performed as the objects are stored.

The constructors for all **ccArchive**-derived concrete classes provide a default value of *ccArchive::eLittleEndian* for the endianness of the archive.

Value	Meaning
eBigEndian	Big-endian.
eLittleEndian	Little-endian.

Operators

operatorII

```
ccArchive& operator|| (c_UInt8& val);
ccArchive& operator|| (c_Int8& val);
ccArchive& operator|| (char& val);
ccArchive& operator|| (c_UInt16& val);
ccArchive& operator|| (c_Int16& val);
ccArchive& operator|| (c_UInt32& val);
ccArchive& operator|| (c_Int32& val);
ccArchive& operator|| (c_UInt64& val);
ccArchive& operator|| (c_Int64& val);
ccArchive& operator|| (unsigned int& val);
ccArchive& operator|| (int& val);
ccArchive& operator|| (float& val);
ccArchive& operator|| (double& val);
ccArchive& operator|| (cmStd string& val);
ccArchive& operator|| (cmStd wstring& val);
ccArchive& operator|| (wchar_t& val);
ccArchive& operator|| (ccCvlString32& val);
ccArchive& operator|| (bool& val);
```

Notes

All of the overloads of `operator||` may throw the following errors:

ccArchive::BadType
: The stream data do not match the expected type while loading (the stream position after this error is unspecified).

ccArchive::Eof
: There is no more input data (loading only).

ccArchive::BadBuffer
: The archive is broken and unusable. If this error occurs during storing, it may indicate that the output device (disk) is full.

- `ccArchive& operator|| (c_UInt8& val);`

  Serializes the supplied **c_UInt8** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters
  val The value to serialize.

- `ccArchive& operator|| (c_Int8& val);`

  Serializes the supplied **c_Int8** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters
  val The value to serialize.

- `ccArchive& operator|| (char& val);`

  Serializes the supplied **char** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters
  val The value to serialize.

- `ccArchive& operator|| (c_UInt16& val);`

  Serializes the supplied **c_UInt16** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters
  val The value to serialize.

- `ccArchive& operator|| (c_Int16& val);`

  Serializes the supplied **c_Int16** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters
  val The value to serialize.

- `ccArchive& operator|| (c_UInt32& val);`

  Serializes the supplied **c_UInt32** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val The value to serialize.

- `ccArchive& operator|| (c_Int32& val);`

  Serializes the supplied **c_Int32** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val The value to serialize.

- `ccArchive& operator|| (c_UInt64& val);`

  Serializes the supplied **c_UInt64** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val The value to serialize.

- `ccArchive& operator|| (c_Int64& val);`

  Serializes the supplied **c_Int64** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val The value to serialize.

- `ccArchive& operator|| (unsigned int& val);`

  Serializes the supplied **unsigned int** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val The value to serialize. The value is always serialized as an unsigned 32-bit integer.

- `ccArchive& operator|| (int& val);`

  Serializes the supplied **int** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val — The value to serialize. The value is always serialized as a 32-bit integer.

- `ccArchive& operator|| (float& val);`

  Serializes the supplied **float** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val — The value to serialize. The value is serialized using the IEEE 754 format.

- `ccArchive& operator|| (double& val);`

  Serializes the supplied **double** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Parameters

  val — The value to serialize. The value is serialized using the IEEE 754 format.

- `ccArchive& operator|| (cmStd string& val);`

  Serializes the supplied **string** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

  Upon storing, the supplied **string** is converted to Unicode using the application's current C-runtime locale setting before being archived. Upon loading, if the data being read from the archive is Unicode, then the string is converted to an 8-bit representation using the application's current C-runtime locale setting.

  Parameters

  val — The value to serialize. The maximum length of a string that can be serialized using this operator is 32,767 bytes.

Throws

ccBadUnicodeChar

A character in *val* cannot be converted to Unicode using the current C-runtime locale setting (storing) or a Unicode character in the archive cannot be converted to an 8-bit representation using the current C-runtime locale setting (loading).

- `ccArchive& operator|| (cmStd wstring& val);`

Serializes the supplied **wstring** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

Parameters

val The value to serialize. The maximum length cmStd wstring that may be serialized is 32767 wchars.

- `ccArchive& operator|| (wchar_t& val);`

Serializes the supplied **wchar_t** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

Parameters

val The value to serialize.

- `ccArchive& operator|| (ccCvlString32& val);`

Serializes the supplied **ccCvlString32** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

Parameters

val The value to serialize.

- `ccArchive& operator|| (bool& val);`

Serializes the supplied **bool** value to or from this **ccArchive**. The value is serialized to the archive if the **ccArchive** is storing; the value is serialized from the **ccArchive** if the **ccArchive** is loading.

Parameters

val The value to serialize.

operator<<

```
ccArchive& operator<< (c_UInt8 val);
ccArchive& operator<< (c_Int8 val);
ccArchive& operator<< (char val);
ccArchive& operator<< (c_UInt16 val);
ccArchive& operator<< (c_Int16 val);
ccArchive& operator<< (c_UInt32 val);
ccArchive& operator<< (c_Int32 v) val);
ccArchive& operator<< (c_UInt64 val);
ccArchive& operator<< (c_Int64 val);
ccArchive& operator<< (unsigned int val);
ccArchive& operator<< (int val);
ccArchive& operator<< (float val);
ccArchive& operator<< (double val);
ccArchive& operator<< (cmStd string& val);
ccArchive& operator<< (const cmStd wstring& val);
ccArchive& operator<< (wchar_t& val);
ccArchive& operator<< (const ccCvlString32& val);
ccArchive& operator<< (bool& val);
```

Each of the overloads of the **operator<<** function is identical to the corresponding **operatorII** function except that the **ccArchive** must be storing.

operator>>

```
ccArchive& operator>> (c_UInt8& val);
ccArchive& operator>> (c_Int8& val);
ccArchive& operator>> (char& val);
ccArchive& operator>> (c_UInt16& val);
ccArchive& operator>> (c_Int16& val);
ccArchive& operator>> (c_UInt32& val);
ccArchive& operator>> (c_Int32& val);
ccArchive& operator>> (c_UInt64& val);
ccArchive& operator>> (c_Int64& val);
ccArchive& operator>> (unsigned int& val);
ccArchive& operator>> (int& val);
ccArchive& operator>> (float& val);
ccArchive& operator>> (double& val);
ccArchive& operator>> (cmStd string& val);
ccArchive& operator>> (cmStd wstring& val);
ccArchive& operator>> (wchar_t& val);
ccArchive& operator>> (ccCvlString32& val);
ccArchive& operator>> (bool& val);
```

Each of the overloads of the **operator>>** function is identical to the corresponding **operatorII** function except that the **ccArchive** must be loading.

Public Member Functions

raw

```
void raw(char* data, c_Int32 count);
```

Stores or loads raw data to or from the **ccArchive** without any format modification. The data is loaded or stored according to this **ccArchive**'s mode.

Parameters

data	The data to store or load. *data* must not be null.

count The number of bytes to store or load. *count* must not be less than 0.

Throws

ccArchive::Eof No more input data (loading only). The archive is left positioned at the end of the input stream.

ccArchive::BadBuffer
This **ccArchive** is broken and is unusable (loading or storing). If you are storing data, the disk may be full.

mode

```
Direction mode() const;

void mode(Direction mode);
```

- `Direction mode() const;`

  Returns a value indicating whether this **ccArchive** is loading or storing. This function returns one of the following values:

  ccArchive::eLoading
  ccArchive::eStoring

  Throws

  ccArchive::NotSeekable
  The ccArchive is not seekable.

- Sets this **ccArchive** to the specified mode (loading or storing). Cognex recommends that you do not call this function. Instead, specify the mode when you instantiate the **ccArchive**-derived concrete class.

  Parameters

  mode The mode to set. *mode* must be one of the following values:

  ccArchive::eLoading
  ccArchive::eStoring

  Notes

  In order to call this function, **ccArchive::isSeekable()** must return true. If **ccArchive::isReadOnly()** returns true, you cannot set this archive to storing.

  Throws

  ccArchive::NotSeekable
  The ccArchive is not seekable.

isLoading

```
bool isLoading() const;
```

Returns true if this **ccArchive** is loading, false otherwise.

isStoring

```
bool isStoring() const;
```

Returns true if this **ccArchive** is storing, false otherwise.

isReadOnly

```
bool isReadOnly() const;
```

Returns true if this **ccArchive** is read-only, false otherwise.

getByteOrder

```
Ordering getByteOrder() const;
```

Returns the endianness of this **ccArchive**. This function returns one of the following values:

ccArchive::eBigEndian
ccArchive::eLittleEndian

append

```
void append();
```

Sets this **ccArchive** to storing, seeks to the end, and prepares to accept additional stored objects. You must call **append()** when switching an archive constructed for loading to storing mode. Use this function to store objects to an archive that was constructed for loading.

Notes

This operation does not store anything into the **ccArchive**. In order to call this function, **ccArchive::isSeekable()** must return true. If **ccArchive::isReadOnly()** returns true, you cannot set this archive to storing.

Throws

ccArchive::NotSeekable
The ccArchive is not seekable.

sync

```
void sync();
```

Ensures that all of this **ccArchive**'s input or output data is flushed.

isSeekable

```
bool isSeekable() const;
```

Returns true if this **ccArchive** was constructed as a seekable archive.

version

```
c_Int32 version() const;
```

Returns the archive format version number of this archive.

Notes

It may not be possible to append to an archive with an old version number. Attempting an unsupported operation will throw *CannotWriteToOldArchive*.

tell

```
cmStd streampos tell() const;
```

Returns the **ccArchive**'s current offset from its beginning.

Throws

ccArchive::BadBuffer
The **ccArchive** is broken and is unusable.

---

seek

```
ccArchive& seek(cmStd streampos pos);

ccArchive& seek(cmStd streamoff offset,
  cmStd ios::seek_dir dir);
```

- `ccArchive& seek(cmStd streampos pos);`

Seeks to the specified location within this **ccArchive**. Cognex recommends that you do not use this function.

Parameters

pos The position to which to seek.

Throws

ccArchive::NotSeekable
The ccArchive is not seekable.

-
```
ccArchive& seek(cmStd streamoff offset,
  cmStd ios::seek_dir dir);
```

Seeks to the specified offset and direction from the current seek position within this **ccArchive**. Cognex recommends that you do not use this function.

Parameters

offset The offset from the current seek position.

dir The direction in which to seek.

Notes

You can only seek to an offset that lies within the extent of this **ccArchive**. A storing archive should be written sequentially. Previously written complex-persistent objects and pointers must not be overwritten.

Throws

ccArchive::BadBuffer
The **ccArchive** is broken and is unusable.

ccArchive::NotSeekable
The ccArchive is not seekable.

archiveAsData

```
ccArchive& archiveAsData (cmStd string&);
```

Archives the supplied string as 8-bit data. Unlike **operator ll()**, this function does not attempt to convert the supplied string to or from Unicode.

Parameters

string The data to archive.

Static Functions

archive8BitStringsAsLegacy

```
static void archive8BitStringsAsLegacy8BitData(
   bool useLegacy);

static bool archive8BitStringsAsLegacy8BitData();
```

- ```
  static void archive8BitStringsAsLegacy8BitData(
     bool useLegacy);
  ```

  Sets legacy archive mode for the current application. If *useLegacy* is true, all instances of **cmStd string** are archived as 8-bit data, for all instances of **ccArchive**. No attempt is made to interpret the bytes as characters using the current locale. Embedded NULLs are accepted and archived properly.

  Setting legacy mode to true overrides the normal behavior of **ccArchive::operatorll(cmStd string& val)**.

  Notice that the use of legacy mode is discouraged. Legacy behavior makes the interpretation of stored non-ASCII characters (outside of the range 0x00 to 0x7F) impossible unless you also know the locale in which they were encoded. The encoding of the bytes is not stored in the archive.
  ```

Parameters

useLegacy *true* to enable legacy mode, *false* to disable legacy mode.

- `static bool archive8BitStringsAsLegacy8BitData();`

  Returns *true* if legacy archive mode is set for the current application, false otherwise.

ccAutoSelectDefs

```
#include <ch_cvl/autoslct.h> // If not calling cfAutoSelect()
#include <ch_cvl/atslptmx.h> // If calling cfAutoSelect() with
                             // PatMax
#include <ch_cvl/atslcnls.h> // If calling cfAutoSelect() with
                             // CNLSearch

class ccAutoSelectDefs;
```

This class is a name space that holds enumerations and constants that are used with the Auto-select tool, and errors that the tool can throw.

cfAutoSelect<>() is a template function declared in *<ch_cvl/autoslct.h>*. As the definition does not provide any specialization for using this function with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>* to use this function with either of these tools.

ccAutoSelectDefs, **ccAutoSelectParams**, and **ccAutoSelectResult**, which are not templates, are also declared in *<ch_cvl/autoslct.h>*. If you want to use these classes in a compilation unit (for example, source code or header) that does not make a call to **cfAutoSelect()**, you can safely include only *<ch_cvl/autoslct.h>*. However, if you want to derive objects from these classes for use with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>*, respectively.

For example, if your program uses these source files:

- *a.cpp* --- which implements the base class, references defs, params, and results
- *b.cpp* --- which implements a derived class that runs Auto-select for PatMax
- *c.cpp* --- which implements a derived class that runs Auto-select for CNLSearch

then *a.cpp* can safely include *<ch_cvl/autoslct.h>*, but *b.cpp* must include *<ch_cvl/atslptmx.h>* for PatMax support, and *c.cpp* must include *<ch_cvl/atslcnls.cpp>* for CNLSearch support.

Enumerations

Direction

`enum Direction`

This enumeration defines the orientation of the axes about which model symmetry and orthogonality are measured.

Value	Meaning
eImageNormal	The axes are the image coordinate system x-axis and y-axis.
kDefaultDirection	The default direction (the default is *eImageNormal*).

ScoreCombineMethod

`enum ScoreCombineMethod`

This enumeration defines how the individual symmetry, orthogonality, and uniqueness scores are combined.

Value	Meaning
eGeometricMean	The geometric mean is computed.
eArithmeticMean	The arithmetic mean is computed.
kDefaultScoreCombineMethod	The default combination method (the default is *eGeometricMean*).

ccAutoSelectParams

```
#include <ch_cvl/autoslct.h> // If not calling cfAutoSelect()
#include <ch_cvl/atslptmx.h> // If calling cfAutoSelect() with
                             // PatMax
#include <ch_cvl/atslcnls.h> // If calling cfAutoSelect() with
                             // CNLSearch

class ccAutoSelectParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the run-time parameters for the Auto-select tool.

cfAutoSelect<>() is a template function declared in *<ch_cvl/autoslct.h>*. As the definition does not provide any specialization for using this function with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>* to use this function with either of these tools.

ccAutoSelectDefs, **ccAutoSelectParams**, and **ccAutoSelectResult**, which are not templates, are also declared in *<ch_cvl/autoslct.h>*. If you want to use these classes in a compilation unit (for example, source code or header) that does not make a call to **cfAutoSelect()**, you can safely include only *<ch_cvl/autoslct.h>*. However, if you want to derive objects from these classes for use with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>*, respectively.

For example, if your program uses these source files:

- *a.cpp* --- which implements the base class, references defs, params, and results
- *b.cpp* --- which implements a derived class that runs Auto-select for PatMax
- *c.cpp* --- which implements a derived class that runs Auto-select for CNLSearch

then *a.cpp* can safely include *<ch_cvl/autoslct.h>*, but *b.cpp* must include *<ch_cvl/atslptmx.h>* for PatMax support, and *c.cpp* must include *<ch_cvl/atslcnls.cpp>* for CNLSearch support.

Constructors/Destructors

ccAutoSelectParams

```
ccAutoSelectParams(bool enhancedMode = false);
```

Constructs a **ccAutoSelectParams** object that specifies whether the Auto-select tool should run in enhanced mode or non-enhanced mode. All other parameters are set to the following default values.

Parameter	Default Value
Direction	*ccAutoSelectDefs::kDefaultDirection* (currently *eImageNormal*)
Model size	64x64 pixels
Sampling rate	2
Score combination method	*ccAutoSelectDefs::kDefaultScoreCombineMethod* (currently *eGeometricMean*)
Score combination weights	Relative weight of symmetry score = 1 Relative weight of orthogonality score = 1 Relative weight of uniqueness score = 1
Maximum number of results	1
Window mask	Unbound 8-bit pel buffer
XY overlap	0.8

Parameters

enhancedMode If true, the Auto-select tool will run in enhanced mode; if false , the tool will run in non-enhanced mode (the default). There is no setter that will allow you to change this parameter later on.

Notes

Enhanced mode supports masking, overlap constraints, query operations on selected locations, and blanket search operations. When run in enhanced mode, the tool may return different results than in would be returned non-enhanced mode. You can enable enhanced mode only at the time the **ccAutoSelectParams** object is constructed.

Operators

operator==

```
bool operator==(const ccAutoSelectParams &rhs) const;
```

Compares two **ccAutoSelectParams** objects for equality. Returns true if all parameters in both objects are equal, false otherwise.

Parameters

rhs The **ccAutoSelectParams** object to be compared to this one.

Public Member Functions

direction

```
ccAutoSelectDefs::Direction direction() const;
```

```
void direction(ccAutoSelectDefs::Direction direction);
```

- `ccAutoSelectDefs::Direction direction() const;`

Returns the orientation of the axes about which pattern symmetry and orthogonality are computed. The returned direction is one of the following values:

ccAutoSelectDefs::eImageNormal

- `void direction(ccAutoSelectDefs::Direction direction);`

Sets the orientation of the axes about which pattern symmetry and orthogonality are computed.

Parameters

direction The axis orientation to set. Must be one of the following values:

ccAutoSelectDefs::eImageNormal
ccAutoSelectDefs::kDefaultDirection

Notes

In the current release, only the direction *ccAutoSelectDefs::eImageNormal* works.

modelSize

```
ccIPair modelSize() const;
```

```
void modelSize(const ccIPair &modelSize);
```

- `ccIPair modelSize() const;`

Returns the dimensions of the model training window in image coordinates.

- `void modelSize(const ccIPair &modelSize);`

  Sets the dimensions of the model training window in image coordinates.

  Parameters

  modelSize The model dimensions to set.

  Notes

  Invocations of **cfAutoSelect()** will throw *ccAutoSelectDefs::BadModel* if at least one of the components of the run parameter's model size either too small or too large to be able to obtain reliable data.

sample

```
c_Int16 sample() const;

void sample(c_Int16 sample);
```

- `c_Int16 sample() const;`

  Returns the sampling rate. The input image is sub-sampled by this factor before it is evaluated. The larger the sampling rate, the quicker the Auto-select tool will run, and the worse the quality of the result will be.

- `void sample(c_Int16 sample);`

  Sets the sampling rate. The input image is sub-sampled by this factor before it is evaluated. The larger the sampling rate, the quicker the Auto-select tool will run, and the worse the quality of the result will be.

  Parameters

  sample The sampling rate set. Do not specify a sampling rate larger than 8.

  Notes

  Invocations of **cfAutoSelect()** will throw *ccAutoSelectDefs::BadSample* if the sampling rate is less than or equal to 0.

scoreCombineMethod

```
ccAutoSelectDefs::ScoreCombineMethod scoreCombineMethod()
  const;

void scoreCombineMethod(
  ccAutoSelectDefs::ScoreCombineMethod method);
```

- `ccAutoSelectDefs::ScoreCombineMethod scoreCombineMethod() const;`

  Returns the score combination method configured for this **ccAutoSelectParams**. The returned value is one of the following values:

  ccAutoSelectDefs::eGeometricMean
  ccAutoSelectDefs::eArithmeticMean

- `void scoreCombineMethod( ccAutoSelectDefs::ScoreCombineMethod method);`

  Sets the score combination method for this **ccAutoSelectParams**. Specify the geometric mean if you only want a high overall score if all component scores are high; specify the arithmetic mean if you want a high overall score if *any* component score is high.

  Parameters

  method — The score combination method to set. Must be one of:

  ccAutoSelectDefs::eGeometricMean
  ccAutoSelectDefs::eArithmeticMean

scoreCombineWeights

```
cc3Vect scoreCombineWeights() const;

void scoreCombineWeights(const cc3Vect &weights);
```

- `cc3Vect scoreCombineWeights() const;`

  Returns a vector containing the weights to apply to the component scores when computing the overall score. The first element of the returned vector is the weight for the symmetry score, the second element is the weight for the orthogonality score, and the third element is the weight for the uniqueness score.

  The weights vector is normalized to a unit sum.

- `void scoreCombineWeights(const cc3Vect &weights);`

  Sets the weights to apply to the component scores when computing the overall score. Set the first element of *weights* to be the weight for the symmetry score, the second element to be the weight for the orthogonality score, and the third element to be the weight for the uniqueness score.

  scoreCombineWeights() normalizes the values you supply to a unit sum; only the relative values of the weights is considered.

  Parameters

  weights The weights to set. All of the elements of *weights* must be greater than or equal to 0, and at least one of the elements must be greater than 0.

  Notes

  Invocations of **cfAutoSelect()** will throw *ccAutoSelectDefs::BadWeights* if any of the run parameter object's weights is negative, or if all are 0.

maxNumResult

```
c_Int16 maxNumResult() const;

void maxNumResult(c_Int16 maxNumResult);
```

- `c_Int16 maxNumResult() const;`

  Returns the maximum number of results this **ccAutoSelectParams** is configured to return. The tool might return fewer than the specified number of results; it will never return more results than you specify.

- `void maxNumResult(c_Int16 maxNumResult);`

  Sets the maximum number of results that this **ccAutoSelectParams** returns. The tool will never return more results than you specify, but it may return fewer.

  Parameters

  maxNumResult The maximum number of results to return

  Notes

  Invocations of **cfAutoSelect()** will throw *ccAutoSelectDefs::BadResult* if *maxNumResult* is not positive.

  Only the 2***maxNumResult()** results with the best symmetry scores are used to compute overall scores. This means that if you set a low value for the maximum number of results, you might exclude results with low symmetry scores but high orthogonality and uniqueness scores.

windowMask

```
const ccPelBuffer_const<c_UInt8> &windowMask() const;

void windowMask(
  const ccPelBuffer_const<c_UInt8> &windowMask);
```

- `const ccPelBuffer_const<c_UInt8> &windowMask() const;`

  Retrieves the window mask, an 8-bit pel buffer that is the size of the model window.

  Throws

  ccAutoSelectDefs::NotEnhancedMode
  Enhanced mode is not enabled.

- `void windowMask(`
  `  const ccPelBuffer_const<c_UInt8> &windowMask);`

  Sets the window mask.

  Parameters

  windowMask An 8-bit pel buffer. The window mask should either be unbound or have the same size as the model window, as returned by **ccAutoSelectParams::modelSize()**.

  Notes

  Invocations of **cfAutoSelect()** will throw *ccAutoSelectDefs::BadMask* if the window mask is a bound pel buffer of any size other the model size.

  Throws

  ccAutoSelectDefs::NotEnhancedMode
  Enhanced mode is not enabled.

xyOverlap

```
double xyOverlap() const;

void xyOverlap(double xyOverlap);
```

- `double xyOverlap() const;`

  Retrieves the XY overlap value. The overlap value is approximately the ratio of the overlapping area to the total area of the pattern. Two pattern instances are considered to overlap if their overlap value is greater than the XY overlap, and only one of them will be returned as a result from a search operation.

  Notes

  Meaningful XY overlap values range from 0.0 to 1.0. A value of 0.0 specifies that no overlap is allowed. A value of 1.0 specifies that any amount of overlap is allowed (overlap checking is disabled).

Throws

ccAutoSelectDefs::NotEnhancedMode
Enhanced mode is not enabled.

- `void xyOverlap(double xyOverlap);`

Sets the XY overlap value that determines whether two pattern instances are considered the same result, and only one of them will be returned from a search operation.

Parameters

xyOverlap The XY overlap value to set. Must be in the range of 0.0 to 1.0.

Value	Meaning
0.0	No overlap is allowed.
1.0	Any amount of overlap is allowed (overlap checking is disabled).

Throws

ccAutoSelectDefs::NotEnhancedMode
Enhanced mode is not enabled.

ccAutoSelectDefs::BadParams
xyOverlap is outside the range of 0.0 through 1.0, inclusive.

isEnhancedMode

```
bool isEnhancedMode() const;
```

Returns true if the enhanced mode is enabled, false otherwise.

Notes

Enhanced mode can be enabled only at the time the **ccAutoSelectParams** object is constructed.

ccAutoSelectResult

```
#include <ch_cvl/autoslct.h> // If not calling cfAutoSelect()
#include <ch_cvl/atslptmx.h> // If calling cfAutoSelect() with
                             // PatMax
#include <ch_cvl/atslcnls.h> // If calling cfAutoSelect() with
                             // CNLSearch

class ccAutoSelectResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the result of running the Auto-select tool on the input image. The global function **cfAutoSelect()** returns a vector of **ccAutoSelectResult** objects.

cfAutoSelect<>() is a template function declared in *<ch_cvl/autoslct.h>*. As the definition does not provide any specialization for using this function with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>* to use this function with either of these tools.

ccAutoSelectDefs, **ccAutoSelectParams**, and **ccAutoSelectResult**, which are not templates, are also declared in *<ch_cvl/autoslct.h>*. If you want to use these classes in a compilation unit (for example, source code or header) that does not make a call to **cfAutoSelect()**, you can safely include only *<ch_cvl/autoslct.h>*. However, if you want to derive objects from these classes for use with PatMax or CNLSearch, you must include either *<ch_cvl/atslptmx.h>* or *<ch_cvl/atslcnls.h>*, respectively.

For example, if your program uses these source files:

- *a.cpp* --- which implements the base class, references defs, params, and results
- *b.cpp* --- which implements a derived class that runs Auto-select for PatMax
- *c.cpp* --- which implements a derived class that runs Auto-select for CNLSearch

then *a.cpp* can safely include *<ch_cvl/autoslct.h>*, but *b.cpp* must include *<ch_cvl/atslptmx.h>* for PatMax support, and *c.cpp* must include *<ch_cvl/atslcnls.cpp>* for CNLSearch support.

Constructors/Destructors

ccAutoSelectResult

```
ccAutoSelectResult();
```

Constructs a default **ccAutoSelectResult** object with its location set to (0,0) and all scores set to 0.0.

Notes

You should not attempt to create **ccAutoSelectResult** objects yourself.

Public Member Functions

location

```
ccIPair location() const;
```

Returns the upper-left corner of the returned model location window for this **ccAutoSelectResult**, in image coordinates.

score

```
double score() const;
```

Returns the overall score for this **ccAutoSelectResult**. The overall score is computed from the three component scores according to the weighting and combination method parameters you specified.

symmetryScore

```
double symmetryScore() const;
```

The symmetry score for this **ccAutoSelectResult**. This score is a whether or not this window is more symmetrical than nearby locations in the image.

orthoScore

```
double orthoScore() const;
```

The orthogonality score for this **ccAutoSelectResult**. This score is a measure of the degree to which the model window contains a balance of strong horizontal and vertical features. A low orthogonality score can indicate few horizontal and vertical features or an imbalance between horizontal and vertical features.

uniqueScore

```
double uniqueScore() const;
```

The uniqueness score for this **ccAutoSelectResult**. The uniqueness score is a measure of how unique the model window is when compared to the rest of the input image, using the pattern-location tool run-time parameters you specified when you called **cfAutoSelect()**.

ccBallPatternAlignBallResult

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignBallResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class holds the result of ball inspection. Instances of this class are created only by the tool. The **ccBallPatternAlignBallResult** class has const getters for all of the available data.

Constructors/Destructors

ccBallPatternAlignBallResult

```
ccBallPatternAlignBallResult();
```

Default constructor.

Notes

Compiler generated copy constructor, assignment operator, and destructor are used.

Operators

operator==

```
bool operator==(const ccBallPatternAlignBallResult &rhs)
const;
```

Equality test operator. Returns true if this object is exactly equal to *rhs*. Returns false otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

found

```
bool found() const;
```

Returns true if the ball is found; otherwise, returns false.

ccBallPatternAlignBallResult

position

```
const cc2Vect & position() const;
```

If **found()** returned true, returns the found ball position in client space.

size

```
double size() const;
```

If **found()** returned true, returns the found ball size in physical units.

ccBallPatternAlignDefs

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignDefs;
```

A name space that holds enumerations used with the Ball Pattern Align tool classes.

Enumerations

DOF

```
enum DOF;
```

Degrees of freedom.

Value	Meaning
eAngle =1	Whether rotation is enabled.
eUniformScale = 2	Whether uniform scale is enabled.
eXScale = 4	Whether X scale is enabled.
eYScale = 8	Whether Y scale is enabled.

Polarity

```
enum Polarity;
```

Supported polarities.

Value	Meaning
eLightOnDark = 0x0001	Light on dark polarity.
eDarkOnLight = 0x0002	Dark on light polarity.
eUnknown = *eDarkOnLight* | *eLightOnDark*	Unknown polarity.
kDefaultPolarity = *eLightOnDark*	The default is light on dark.

ccBallPatternAlignDefs

RefineMode `enum RefineMode;`

The refine mode.

Value	Meaning
eRefineByImageFeatures = 1	Refine by image features.
eRefineByTrainedBlobs = 2	Refine by trained blobs.
kRefineDefault = *eRefineByImageFeatures*	The default is refining by image features.

DrawMode `enum DrawMode;`

The drawing mode.

Value	Meaning
eDrawOrigin = 0x001	Whether to draw the origin.
eDrawLabel = 0x002	Whether to draw the label.
eDrawBoundingBox = 0x004	Whether to draw the bounding box.
eDrawBlobs = 0x008	Whether to draw the blobs.
eDrawEdgelets = 0x010	Whether to draw the edgelets.
eDrawCircles = 0x020	Whether to draw the circles.
eDrawStandard = *eDrawOrigin* | *eDrawBoundingBox* | *eDrawEdgelets*	The standard is drawing the origin, the bounding box, and the edgelets.

ccBallPatternAlignModel

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignModel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is the central object for the Ball Pattern Align tool. It contains the trained representation of the model, and the functions to do the training. This class also features a function that runs the model on an image and produces results.

Constructors/Destructors

ccBallPatternAlignModel

```
ccBallPatternAlignModel();

~ccBallPatternAlignModel();

ccBallPatternAlignModel(
  const ccBallPatternAlignModel& rhs);
```

- `ccBallPatternAlignModel();`

  Construct an untrained alignment model with default values.

- `~ccBallPatternAlignModel();`

  Destructor.

- ```
  ccBallPatternAlignModel(
    const ccBallPatternAlignModel& rhs);
  ```

  Copy constructor.

  Parameters

rhs	The source of the copy.
  ```

Operators

operator=

```
const ccBallPatternAlignModel& operator=(
  const ccBallPatternAlignModel& rhs);
```

Assignment operator.

Parameters

rhs The object to assign.

Public Member Functions

origin

```
cc2Vect origin() const;

void origin(const cc2Vect &origin);
```

- `cc2Vect origin() const;`

Returns the model's origin.

- `void origin(const cc2Vect &origin);`

Sets the model's origin.

Parameters

origin The origin to be set.

Notes

The origin is the translation component of the model coordinate system (see above). The origin is specified in the client coordinate system of the training image. The origin is a point attached to the model, but it may reside outside of the model. When an instance of the model is found, the result location is defined by the position of the origin in the search image.

The location of the origin in the image is trained as the origin. Found poses will transform this origin into the runtime image.

Setting **trainClientFromModel()** changes the origin and setting the origin changes the translation component of **trainClientFromModel()**, but does not affect the matrix portion of the transform.

The origin can be read or written for either a trained or an untrained model. Changing the origin does not require that the model be retrained.

Setting the origin affects not only the **location()** of the result, but also the **pose()**.

The default is cc2Vect(0, 0)

trainClientFromModel

```
cc2Xform trainClientFromModel();

void trainClientFromModel(const cc2Xform&);
```

- `cc2Xform trainClientFromModel();`

  Returns the mapping from model coordinates to training image client coordinates.

- `void trainClientFromModel(const cc2Xform&);`

  Sets the mapping from model coordinates to training image client coordinates.

  Notes

  Model coordinates are a client-controlled coordinate system that specifies how to match the model to an image and report result poses.
  A result pose is a mapping from model coordinates to run-time client coordinates, and likewise the generalized DOFs define the search range as a mapping from model coordinates to run-time client coordinates. Model coordinates may be set in all 6 DOFs. Note that model coordinates includes the model's origin as its translation component, and that setting the model coordinates with this member always sets the origin. Model coordinates are never modified by the act of training; they are relative to the client coordinates established by the most recent training, if any.

  trainClientFromModel() cannot be used after training, although the translation component can be changed using **origin()**

  Throws

  AlreadyTrained The model is already trained.

  BadParams The new xform is singular.

  The default is identity **cc2Xform**.

train

```
void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccBallPatternAlignTrainParams& trainParams,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccBallPatternAlignTrainParams &trainParams,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const cmStd vector<ccCircle>& blobs,
  const ccBallPatternAlignTrainParams& trainParams,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const cmStd vector<ccCircle>& blobs,
  const ccBallPatternAlignTrainParams& trainParams,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);
```

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccBallPatternAlignTrainParams& trainParams,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

  Image-based training. Extracts the grey-scale blobs from the given image, and trains this model from the extracted blobs.

  Parameters

image	The image.
trainParams	The training parameters.
diagobj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values:
  ```

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

InsufficientFeatures
Not enough blobs are found for successful training.

BadImage
The image is unbound or has a Null window (that is, height==0 OR width==0)

BadImageSize
The image is too small.

Notes

If this model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccBallPatternAlignTrainParams &trainParams,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

Image-based training. Extracts the grey-scale blobs from the given image and mask, and trains this model from the extracted blobs.

Parameters

image The image.

mask The mask.

trainParams The training parameters.

diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:
  ```

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

InsufficientFeatures
Not enough blobs are found for successful training.

BadImage The image is or unbound or has a Null window (that is, height==0 OR width==0)
OR
the mask is unbound
OR
the mask does not have the same window as the image
OR
any of the mask pels are values which are not 0 or 255

BadImageSize The image is too small.

Notes

If this model is already trained, it is automatically untrained and retrained.

In the mask, pixels whose grey level is 0 indicate “don't care” pixels in the training image. Mask pixels whose grey level is 255 denote “care” pixels in the training image.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const cmStd vector<ccCircle>& blobs,
    const ccBallPatternAlignTrainParams& trainParams,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

Geometric training. Trains this model from the given circular blobs, together with the given image.

Parameters

image The image.

blobs The blobs.

trainParams The training parameters.

diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
  ```

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

InsufficientFeatures
Not enough blobs are supplied for successful training.

BadImage The image is unbound or has a Null window (that is, height==0 OR width==0).

BadImageSize The image is too small.

Notes

This training is the same as the image-based training, except that it does not extract the grey-scale blobs from the image; instead, it uses the user-provided circular blobs. It is useful in the case that the user has obtained the blobs elsewhere before training this model. Note that both the input image and user-provided blobs are used in training; it is required that the user-provided blobs match with the actual blobs in the image.

If this model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
   const ccPelBuffer_const<c_UInt8>& mask,
   const cmStd vector<ccCircle>& blobs,
   const ccBallPatternAlignTrainParams& trainParams,
   ccDiagObject* diagobj=0,
   c_UInt32 diagFlags=0);
  ```

Geometric training. Trains this model from the given circular blobs, together with the given image and mask.

Parameters

image The image.

mask The mask.
  ```

blobs The blobs.

trainParams The training parameters.

diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

InsufficientFeatures
Not enough blobs are supplied for successful training.

BadImage The image is unbound or has a Null window (that is, height==0 OR width==0)
OR
the mask is unbound
OR
the mask does not have the same window as the image
OR
any of the mask pels are values which are not 0 or 255

BadImageSize The image is too small.

Notes

This training is the same as the image-based training, except that it does not extract the grey-scale blobs from the image; instead, it uses the user-provided circular blobs. It is useful in the case that the user has obtained the blobs elsewhere before training this model. Note that both the input image and user-provided blobs are used in training; it is required that the user-provided blobs match with the actual blobs in the image.

If this model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

untrain

```
void untrain();
```

Untrains this model. Releases any saved training data. It has no effect if this model is currently not trained.

trainParams

```
const ccBallPatternAlignTrainParams& trainParams() const;
```

Returns the *trainParams* used to train this model.

Throws

NotTrained This model is not trained.

trainImage

```
ccPelBuffer_const<c_UInt8> trainImage() const;
```

Returns the *image* used to train this model.

Throws

NotTrained This model is not trained.

trainMask

```
ccPelBuffer_const<c_UInt8> trainMask() const;
```

Returns the *mask* image used when this model was trained.

Throws

NotTrained This model is not trained.

Notes

Returns an unbound pel buffer if the model was trained without a mask.

isGeometricTraining

```
bool isGeometricTraining() const;
```

Returns whether a Geometric Training was performed.

Throws

NotTrained This model is not trained.

trainedBlobs

```
std::vector<ccCircle> trainedBlobs() const;
```

Returns the trained blobs if image-based training was performed; returns the user-supplied blobs if the geometric training was performed. The blobs are returned in client coordinates.

Throws

NotTrained This model is not trained.

Notes

It is usually fine if image-based training did not return all possible blobs in the image. Not all but enough blobs need to be found for successful training.

trainedBlobCount

```
c_Int32 trainedBlobCount() const;
```

Returns the count of the blobs returned by **trainedBlobs()**.

Throws

NotTrained This model is not trained.

trainedBlobMeanDiameter

```
double trainedBlobMeanDiameter() const;
```

Returns the mean diameter, in client units, of the blobs returned by **trainedBlobs()**.

Throws

NotTrained This model is not trained.

Notes

Diameters of trained blobs by image-based training should not be considered a high-accuracy measurement.

trainedPatternBoundingBox

```
ccAffineRectangle trainedPatternBoundingBox() const;
```

Returns client-coordinates-aligned bounding box, in client coordinates, of the blobs returned by **trainedBlobs()**.

Throws

NotTrained This model is not trained.

Notes

This includes sufficient padding to locate the model using this trained tool.

trainedPolarity

```
ccBallPatternAlignDefs::Polarity trainedPolarity() const;
```

Returns polarity chosen by image-based training.

Throws

NotTrained This model is not trained or Geometric Training was performed.

Notes

This will always be a unique polarity. Training can choose a polarity, but never trains multiple polarities.

trainedCoarseAlignGrainLimit

```
double trainedCoarseAlignGrainLimit() const;
```

Returns the trained coarse grain limit for alignment.

Throws

NotTrained This model is not trained.

trainedFineAlignGrainLimit

```
double trainedFineAlignGrainLimit() const;
```

Returns the trained fine grain limit for alignment.

Throws

NotTrained This model is not trained.

trainedRefineGrainLimit

```
double trainedRefineGrainLimit() const;
```

Returns the trained refine grain limit.

Throws

NotTrained This model is not trained.

isTrained

```
bool isTrained() const;
```

Returns true if model is currently trained, false otherwise.

---

run

```
void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccBallPatternAlignRunParams &runParams,
  ccBallPatternAlignResultSet &resultSet,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccBallPatternAlignRunParams &runParams,
```

```
  ccBallPatternAlignResultSet &resultSet,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0) const;
```

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccBallPatternAlignRunParams &runParams,
    ccBallPatternAlignResultSet &resultSet,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0) const;
  ```

  Run this model on the given image with the given runtime parameters. The supplied *resultSet* will be cleared and then filled with new results, in order of decreasing score.

  Parameters

image	The image.
runParams	The runtime parameters.
resultSet	The result set.
diagobj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

  Notes

  This function respects CVL timeouts. If a timeout occurs, no valid results are produced by the tool.

  This **run()** function can be called for models which were trained using masks, as well as by models that were trained without masks.

  Throws

NotTrained	This model is currently not trained.
BadImage	The *inputImage* is unbound.
  ```

BadParams One of the dof ranges in the *runParams* (composed by the *startPose*) exceeds the corresponding dof range in the *trainParams*.

ccTimeout::Expired
This function executes longer than the timeout specified by the user. If this occurs, no valid results are produced by the tool.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccBallPatternAlignRunParams &runParams,
    ccBallPatternAlignResultSet &resultSet,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0) const;
  ```

  Run this model on the given image with the given runtime parameters. The supplied *resultSet* will be cleared and then filled with new results, in order of decreasing score.

  Parameters

  image The image.

  mask The mask.

  runParams The runtime parameters.

  resultSet The result set.

  diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff
  ```

Notes

This function respects CVL timeouts. If a timeout occurs, no valid results are produced by the tool.

This **run()** function can be called for models which were trained using masks, as well as by models which were trained without masks.

Throws

NotTrained	This model is currently not trained.
BadImage	The image is unbound OR the mask is unbound OR the mask does not have the same window as the image OR any of the mask pels are values which are not 0 or 255.
BadParams	One of the dof ranges in the *runParams* (composed by the *startPose*) exceeds the corresponding dof range in the *trainParams*.
ccTimeout::Expired	This function executes longer than the timeout specified by the user. If this occurs, no valid results are produced by the tool.

drawFeatures

```
void drawFeatures(ccGraphicList& graphicList,
 const cc2XformLinear& pose,
 const ccColor& color) const;
```

Draws the trained blobs into *graphicList*.

Parameters

graphicList	The graphic list.
pose	The pose.
color	The color.

drawAlignFeatures

```
void drawAlignFeatures(ccGraphicList& graphicList,
 const cc2XformLinear& pose,
 const ccColor& color) const;
```

Draws the edgelets used for refinement into *graphicList*.

Parameters

graphicList	The graphic list.

pose	The pose.
color	The color.

ccBallPatternAlignModel

ccBallPatternAlignResult

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single Ball Pattern Align tool result. Instances of this class are created only by the tool. The **ccBallPatternAlignResult** class has const getters for all of the available data.

Constructors/Destructors

ccBallPatternAlignResult

```
ccBallPatternAlignResult();
```

Constructs this object with no useful data.

Notes

Compiler generated copy constructor, assignment operator, and destructor are used.

Operators

operator==

```
bool operator==(const ccBallPatternAlignResult &rhs) const;
```

Equality test operator. Returns true if this object is exactly equal to *rhs*. Returns false otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

location

```
cc2Vect location() const;
```

Returns the location of the model origin in the client coordinate system of the runtime image.

The default is (0,0).

pose

```
const cc2Xform& pose() const;
```

Returns a transform from the training time client coordinates (translated to the model origin) to runtime client coordinates. Map **cc2Vect(**0,0**)** through this to get the location of the model origin in runtime client coordinates.

The default is *cc2Xform::I*

angle

```
ccDegree angle() const;
```

Returns the angle of the located model in the client coordinate system of the runtime image.

The default is 0.

xScale

```
double xScale() const;
```

Returns the X scale of the located model.

yScale

```
double yScale() const;
```

Returns the Y scale of the located model.

scale

```
double scale() const;
```

Returns the scale of the located model.

The default is 1.

score

```
double score() const;
```

Returns the score, a number between 0.0 and 1.0.

The default is 0.

accepted

```
bool accepted() const;
```

Returns true if the score was >= the runtime parameter accept threshold, otherwise returns false.

The default is false.

matchRegion

```
const ccAffineRectangle& matchRegion() const;
```

Returns an affine rectangle which describes the location of the matched model in the runtime image's client coordinates.

The default is **ccAffineRectangle()**

balls

```
const cmStd vector<ccBallPatternAlignBallResult> & balls()
const;
```

Return a vector of results for balls that are specified by **ccBallPatternAlignModel::trainedBlobs()**.

Notes

Only balls that are specified by **ccBallPatternAlignModel::trainedBlobs()** are included in the returned vector.

draw

```
void draw(ccGraphicList& graphicList,
  c_UInt32 drawMode =
  ccBallPatternAlignDefs::eDrawStandard,
  const ccCvlString& label = ccCvlString(),
  const ccBallPatternAlignModel* model = 0) const;
```

Appends graphics to *graphicList* in client coordinate system for this result.

Parameters

graphicList	The graphic list.
drawMode	The draw mode.
label	The label.
model	The model.

drawMode is used to select which graphics are drawn and must be a bitwise combination of the following flags (defined in **ccBallPatternAlignDefs**):

eDrawOrigin: Draw a cross at this result's location. The cross is rotated as the angle of this result.

eDrawLabel: Label the origin of this result with the provided label string.

eDrawBoundingBox: Draw a bounding box around this result representing matched region.

eDrawBlobs: Draw the trained blobs. Ignored if *model* == 0. Graphics will only be meaningful if model points to the model that generated this result and it has not been since modified.

eDrawEdgelets: Draw the edgelets used for refinement. The colors of the edgelets are dependent on whether *saveMatchInfo* was set in runtime params when running the tool to generate this result.

- If *saveMatchInfo* was set, the colors of the edgelets show the match info.
- If *saveMatchInfo* was not set, the edgelets are shown in a single color (either green or red, depending on whether this result was accepted). Additionally, if saveMatchInfo was not set, graphics will only be meaningful if model points to the model that generated this result and it has not been since modified.

eDrawCircles: Draw the balls. Draw found balls in green and not-found balls in red.

If **accepted()** is true for this result, all graphics, except *eDrawEdgelets*, are drawn in green; otherwise, they are drawn in red.

Notes

model is required for *eDrawBlobs* and for *eDrawEdgelets*; otherwise, it can be 0.

ccBallPatternAlignResultSet

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all of the results from a single invocation of the **ccBallPatternAlignModel::run()** function.

Constructors/Destructors

ccBallPatternAlignResultSet

```
ccBallPatternAlignResultSet();
```

Creates a result set with no results.

Notes

Compiler generated copy constructor, assignment operator, and destructor are used.

Operators

operator==

```
bool operator==(const ccBallPatternAlignResultSet &rhs)
const;
```

Equality test operator. Returns true if this object is exactly equal to *rhs*. Returns false otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

numFound

```
c_Int32 numFound() const;
```

Returns the number of results in this result set.

ccBallPatternAlignResultSet

results

```
const cmStd vector<ccBallPatternAlignResult>& results()
const;
```

Returns all results. The returned vector is of size **numFound()**.

ccBallPatternAlignRunParams

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class holds the runtime parameters used by the Ball Pattern Align tool. The parameters are defaulted at construction, and may be read/written via getters/setters.

Constructors/Destructors

ccBallPatternAlignRunParams

```
ccBallPatternAlignRunParams();
```

Constructs a ccBallPatternAlignRunParams object using the default values.

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Operators

operator==

```
bool operator==(
  const ccBallPatternAlignRunParams &rhs) const;
```

Equality test operator. Returns true if this object is exactly equal to *rhs*. Returns false otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

acceptThreshold

```
double acceptThreshold() const;
void acceptThreshold(double a);
```

- `double acceptThreshold() const;`

  Returns the threshold on the score of results.

- `void acceptThreshold(double a);`

  Sets the threshold on the score of results.

  This is used to set the “accepted” field of each result as follows:

  accepted = (score >= acceptThreshold);

  Parameters

  a The threshold.

  Throws

  BadParams

  A threshold value is supplied that is less than zero or greater than one.

  The default is 0.5.

numToFind

```
c_Int32 numToFind() const;
void numToFind(c_Int32 n);
```

- `c_Int32 numToFind() const;`

  Returns the number of results to look for.

- `void numToFind(c_Int32 n);`

  Sets the number of results to look for.

  The **ccBallPatternAlignModel::run()** functions may not return exactly **numToFind()** results. Fewer results will be returned if less than *numToFind* were found.

Parameters

n The number of results to look for.

Throws

BadParams

n <= 0

The default is 1.

startPose

```
cc2XformLinear startPose() const;
void startPose(const cc2XformLinear &startPose);
```

- `cc2XformLinear startPose() const;`

  Returns the start pose.

- `void startPose(const cc2XformLinear &startPose);`

  Sets the start pose.

  Parameters

  startPose The start pose.

  Throws

  BadParams

  The given start pose is singular.

  Notes

  This start pose maps the model from training-time coordinates into run-time coordinates. If the start pose is exactly correct, then the found result will have exactly the same pose.

  The default is **cc2XformLinear()**.

saveMatchInfo

```
bool saveMatchInfo() const;
void saveMatchInfo (bool x);
```

- `bool saveMatchInfo() const;`

  Returns the flag indicating whether to save information necessary to generate a match display.

- `void saveMatchInfo (bool x);`

  Sets the flag indicating whether to save information necessary to generate a match display.

  Parameters

  x The flag.

  Notes

  If this flag is set, some extra time and extra memory is used for each result returned.

  The default is false.

translationUncertainty

```
ccRect translationUncertainty() const;

void translationUncertainty(
  const ccRect& translationUncertainty);
```

- `ccRect translationUncertainty() const;`

  Returns the translation uncertainty.

- `void translationUncertainty(`
  `const ccRect& translationUncertainty);`

  Sets the translation uncertainty.

  Parameters

  translationUncertainty

  The translation uncertainty.

  Throws

  ccBallPatternAlignDefs::BadParams

  A rect is given that does not contain the point (0, 0) and is not the rect (0, 0, 0, 0)
  or
  a rect is given that has HUGE_VAL or -HUGE_VAL for any corner or size except for the fully infinite rect (-HUGE_VAL,-HUGE_VAL,HUGE_VAL,HUGE_VAL).

  Notes

  The translation uncertainty is in client coordinate units and is aligned to the client coordinate axes. The rect may be (0, 0, 0, 0) to indicate a point search. Otherwise, the rect must contain the point (0, 0).

The default is **ccRect(**-*HUGE_VAL*,-*HUGE_VAL*,*HUGE_VAL*,*HUGE_VAL***)**;

xyOverlap

```
double xyOverlap() const;
void xyOverlap(double overlapThresh);
```

- `double xyOverlap() const;`

Returns the required xy overlap to consider two instances to be the same result.

- `void xyOverlap(double overlapThresh);`

Sets the required xy overlap to consider two instances to be the same result.

Two results are considered overlapping if the Overlap value is > *overlapThresh*.

Parameters

overlapThresh The overlap threshold.

Throws

BadParams

The argument is outside the range 0.0 to 1.0.

Notes

Overlap is (approximately) the ratio of overlap area to total area of the model.

Meaningful values range from 0.0 to 1.0.

overlapThresh	Effect
0	Results with non-null intersection overlap
1	No results overlap (overlap disabled)

The default is 0.8.

zoneEnable

```
c_UInt32 zoneEnable() const;
void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

Returns the zone enable for each degree of freedom. Non-zero bits in *enable* indicate degrees of freedom to be searched.

- `void zoneEnable(c_UInt32 enable);`

  Sets the zone enable for each degree of freedom. Non-zero bits in *enable* indicate degrees of freedom to be searched.

  If *zoneEnable* is set for a given DOF, **ccBallPatternAlignModel::run()** will search between zoneLow and zoneHigh. Otherwise, **ccBallPatternAlignModel::run()** will use the start pose value.

  Parameters

  enable The zone enable for each degree of freedom.

  Throws

  BadParams

  The given *enable* value is not:
  1) zero or
  2) created by a bitwise-OR of the values from *ccBallPatternAlignDefs::DOF*.

  Notes

  If *zoneEnable* is set for a given DOF, results produced by **ccBallPatternAlignModel::run()** may fall outside zoneLow and zoneHigh. If the DOF is not enalbed, results produced by **ccBallPatternAlignModel::run()** will always be at exactly the start pose for that DOF.

  The runtime zones are relative to the start pose. For example, if the start pose is rotated by 30 degrees, then enabling the rotation DOF by -10 degrees to +10 degrees would mean that the tool would search from +20 degrees to +40 degrees.

  The default is 0 (no DOFs are enabled).

zoneLow `double zoneLow (ccBallPatternAlignDefs::DOF dof) const;`

Returns the low zone parameter for the given DOF.

Parameters

dof The given DOF.

Throws

BadParams

The given DOF value is illegal. See the following table regarding what is legal.

For the defaults, see the table hereinafter.

zoneHigh `double zoneHigh (ccBallPatternAlignDefs::DOF dof) const;`

Returns the high zone parameter for the given DOF.

Parameters

dof The given DOF.

Throws

BadParams

The given DOF value is illegal. See the following table regarding what is legal.

For the defaults, see the table hereinafter.

zone

```
void  zone(ccBallPatternAlignDefs::DOF dof, double low,
  double high);
```

Sets the low and high zone parameters for the given DOF.

Parameters

dof The given DOF.

low The low zone.

high The high zone.

Throws

BadParams

Illegal low zone or high zone values are given for the given DOF. See the following table regarding what is legal.

Notes

The span of each DOF's runtime zone must be smaller than or equal to the span of the associated DOF's training zone; otherwise, a runtime exception will be thrown.

The runtime zones are relative to the start pose. For example, if the start pose is rotation by 30 degrees, then enabling the rotation DOF by -10 degrees to +10 degrees would mean that the tool would search from +20 degrees to +40 degrees.

For the defaults, see the table hereinafter.

DOF Summary Table

This table summarizes the degrees of freedom values for this tool.

DOF	Unit	Default low	Default high	Range	Restrictions
Angle	degrees	-45	+45	any	none
Uniform scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh

DOF	Unit	Default low	Default high	Range	Restrictions
X scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh
Y scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh

Notes

- Uniform scale is equal scale in both the x and y dimensions.
- X scale and Y scale only scale in the given dimension.
- Scale is specified as a multiplier of the trained model size. For example, a uniform scale of 1.25 implies that the runtime (client coordinate) size of the model will be 25% larger in that dimension than the trained model.
- The angle zone is always searched from the zoneLow to the zoneHigh. So, setting zoneLow to 0 and zoneHigh to 180 searches one half of the 360 degree angle range – setting zoneHigh to 0 and zoneLow to 180 searches the other half.

zoneOverlap

```
double zoneOverlap(ccBallPatternAlignDefs::DOF dof) const;

void zoneOverlap(ccBallPatternAlignDefs::DOF dof,
  double overlapThresh);
```

- `double zoneOverlap(ccBallPatternAlignDefs::DOF dof) const;`

Returns the zone overlap parameter for the given DOF. Angle and Scale overlap values are specified in different units.

Parameters

dof The DOF.

- `void zoneOverlap(ccBallPatternAlignDefs::DOF dof, double overlapThresh);`

  Sets the zone overlap parameter for the given DOF. Angle and Scale overlap values are specified in different units.

  For *ccBallPatternAlignDefs::kAngle*, two results are considered overlapping if the absolute difference between their angles is <= *overlapThresh*. Therefore, if dof is *kAngle*, *overlapThresh* must be >= 0.

  For any scale DOF, *overlapThresh* is a ratio which is compared to the ratio of the result with greater scale to the one with smaller scale. If the ratio of the two results is <= the *overlapThresh* ratio, the results are considered overlapping. Since the ratio is compared to the greater scale over the smaller scale, the *overlapThresh* must be >= 1.0. For example, if dof is one of the scale degrees of freedom, and *overlapThresh* = 1.2, then two results, one with a scale of 1.25 and one with a scale of 2.5, would not overlap in scale since 2.5/1.25 is greater than 1.2.

  Parameters

dof	The DOF.
overlapThresh	The zone overlap parameter to be set for the given DOF.

  Throws

BadParams	An illegal *dof* value is supplied to this setter or the *dof* value is out of range as specified above.

  The default is:

  Angle: 360.0.
  Uniform, X, and Y scales: 1.4.

ccBallPatternAlignRunParams

ccBallPatternAlignTrainParams

```
#include <ch_cvl/bpalign.h>

class ccBallPatternAlignTrainParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class holds the traintime parameters used by the Ball Pattern Align tool. The parameters are defaulted at construction, and may be read/written via getters/setters.

Constructors/Destructors

ccBallPatternAlignTrainParams

```
ccBallPatternAlignTrainParams();
```

Constructs the object using the default values.

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Operators

operator==

```
bool operator==(
  const ccBallPatternAlignTrainParams &rhs) const;
```

Equality test operator. Returns true if this object is exactly equal to *rhs*. Returns false otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

diameterRange

```
ccRange diameterRange() const;
void diameterRange(const ccRange& diameterRange);
```

- `ccRange diameterRange() const;`

  Returns the diameter range, in client units.

- `void diameterRange(const ccRange& diameterRange);`

  Sets the diameter range, in client units.

  At train time, all balls whose diameter lies within this range are identified. Some or all of these blobs are then trained as the model, depending on *diameterUncertainty*.

  Parameters

  diameterRange The diameter range.

  Throws

  BadParams

  The range is empty or invalid.

  The default is 0 to HUGE_VAL. It is not recommended to use this setting, as train time may be overly long and robustness is better when a more realistic range is specified.

  Notes

  Extraction diameter is somewhat approximate, so it may be necessary to pad this range slightly to extract all desired candidates.

  This parameter is ignored when using Geometric Training overloads of train.

diameterUncertainty

```
double diameterUncertainty() const;
void diameterUncertainty(double diameterUnc);
```

- `double diameterUncertainty() const;`

  Returns the diameter uncertainty, in client units.

- `void diameterUncertainty(double diameterUnc);`

  Sets the diameter uncertainty, in client units.

  This uncertainty is used to facilitate Image-based training, by picking the "most popular" blob size and training only those. The exact effect is to select the largest subset of found blobs that lie within this uncertainty of their mean diameter.

  If there is a tie on that metric, the group with the smallest spread (difference from smallest to largest) is selected from among the tied groups.

  Parameters

  diameterUnc The diameter uncertainty.

  Throws

  BadParams

  diameterUncertainty < 0

  The default is HUGE_VAL. This value is appopriate when not doing "autotrain" of blob size. This means to use all of the blobs in the *diameterRange* for training.

  Notes

  This parameter is ignored when using Geometric Training overloads of train.

polarity

```
ccBallPatternAlignDefs::Polarity polarity() const;
void polarity(ccBallPatternAlignDefs::Polarity pol);
```

- `ccBallPatternAlignDefs::Polarity polarity() const;`

  Returns the target blob polarity.

- `void polarity(ccBallPatternAlignDefs::Polarity pol);`

  Sets the target blob polarity.

  Parameters

  pol The target blob polarity.

  Throws

  BadParams

  Polarity setting is invalid.

Notes

This parameter is ignored when using Geometric Training overloads of train.

When *eUnknown* polarity is set, blobs of each polarity are extracted, and then the polarity that trains the most blobs, subject to *diameterRange* and *diameterUncertainty*, is chosen. Only one polarity is actually trained.

eUnknown polarity will generally double the train time.

refineMode

```
ccBallPatternAlignDefs::RefineMode refineMode() const;

void refineMode(
  ccBallPatternAlignDefs::RefineMode aRefineMode);
```

- `ccBallPatternAlignDefs::RefineMode refineMode() const;`

Returns the refinement mode.

- `void refineMode(`
  `ccBallPatternAlignDefs::RefineMode aRefineMode);`

Sets the refinement mode.

Refine mode guides the tool how to refine the pose and score at runtime in the following manner:

ccBallPatternAlignDefs::eRefineByImageFeatures:

Use features collected from the training image to refine (even if the tool is trained by geometric training).

ccBallPatternAlignDefs::eRefineByTrainedBlobs:

Use trained blobs (that is, what is returned by **ccBallPatternAlignModel::trainedBlobs()**) to refine.

Parameters

aRefineMode The refine mode.

Throws

BadParams

Refine mode setting is invalid.

The default is *ccBallPatternAlignDefs::kRefineDefault*

zoneEnable

```
c_UInt32 zoneEnable() const;
void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

  Returns the zone enable for each degree of freedom.

- `void zoneEnable(c_UInt32 enable);`

  Sets the zone enable for each degree of freedom.

  Non-zero bits in *enable* indicate degrees of freedom to be searched.

  If *zoneEnable* is set for a given DOF, **ccBallPatternAlignModel::train()** will train between *zoneLow* and *zoneHigh*. Otherwise, **ccBallPatternAlignModel::train()** will use the nominal value. “nominal” and “zone” are two separate train modes.

  Parameters

  enable The zone enable for each degree of freedom.

  Throws

  BadParams
  The given *enable* value was not:
  1) zero or
  2) created by a bitwise-OR of the values from *ccBallPatternAlignDefs::DOF*

  The default is 0 (no DOFs are enabled).

  Notes

  If *zoneEnable* is set for a given DOF, then the **nominal()** value is ignored.

nominal

```
double nominal(ccBallPatternAlignDefs::DOF dof) const;
void  nominal(ccBallPatternAlignDefs::DOF dof, double val);
```

- `double nominal(ccBallPatternAlignDefs::DOF dof) const;`

  Returns the nominal value for the given DOF.

  Parameters

  dof The given DOF.

- `void nominal(ccBallPatternAlignDefs::DOF dof, double val);`

Sets the nominal value for the given DOF.

The nominal value is only used if the given DOF is not enabled by **zoneEnable()**. The nominal value need not be related in any way to the values of **zoneLow()** and **zoneHigh()**.

Parameters

dof The given DOF.

val The nominal value to be set.

Throws

BadParams

The given nominal value for the given DOF is illegal. See the following table regarding what is legal.

The defaults:

Angle: 0.0.

Uniform, X, and Y scales: 1.0.

Notes

If a zone is enabled, then the nominal value is ignored.

zoneLow `double zoneLow (ccBallPatternAlignDefs::DOF dof) const;`

Returns the low zone parameter for the given DOF.

Parameters

dof The given DOF.

Throws

BadParams

The given DOF value is illegal. See the following table regarding what is legal.

For the defaults, see the table hereinafter.

zoneHigh `double zoneHigh (ccBallPatternAlignDefs::DOF dof) const;`

Returns the high zone parameter for the given DOF.

Parameters

dof The given DOF.

Throws

BadParams

The given DOF value is illegal. See the following table regarding what is legal.

For the defaults, see the table hereinafter.

zone

```
void  zone(ccBallPatternAlignDefs::DOF dof, double low,
 double high);
```

Sets the low and high zone parameters for the given DOF.

Parameters

dof The given DOF.

low The low zone.

high The high zone.

Throws

BadParams

Illegal low zone or high zone values are given for the given DOF. See the following table regarding what is legal.

For the defaults, see the table hereinafter.

DOF Summary Table

This table summarizes the degrees of freedom values for this tool.

DOF	Unit	Default low	Default high	Range	Restrictions
Angle	degrees	-45	+45	any	none
Uniform scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh
X scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh
Y scale	multiplier	0.8	1.2	> 0	zoneLow is less than or equal to zoneHigh

Notes

- Uniform scale is equal scale in both the x and y dimensions.
- X scale and Y scale only scale in the given dimension.

- Uniform scale is specified as a multiplier of the trained model size. For example, a uniform scale of 1.25 implies that the runtime (client coordinate) size of the model will be 25% larger in both dimensions than the trained model.
- The angle zone is always searched from the zoneLow to the zoneHigh. So, setting zoneLow to 0 and zoneHigh to 180 searches one half of the 360 degree angle range – setting zoneHigh to 0 and zoneLow to 180 searches the other half.

maxCoarseAlignGrainLimit

```
double maxCoarseAlignGrainLimit() const;
```

Returns the maximum coarse granularity limit for alignment.

maxFineAlignGrainLimit

```
double maxFineAlignGrainLimit() const;
```

Returns the maximum fine granularity limit for alignment.

maxRefineGrainLimit

```
double maxRefineGrainLimit() const;
```

Returns the maximum granularity limit for refinement.

maxGrainLimits

```
void maxGrainLimits(double maxCoarseAlignGrainLimit,
  double maxFineAlignGrainLimit,
  double maxRefineGrainLimit);
```

Sets the maximum granularity limits for alignment and refinement. At training time, the tool automatically determines the granularity limits, which are bounded by these maximum values.

Parameters

maxCoarseAlignGrainLimit
The maximum coarse granularity limit for alignment to be set.

maxFineAlignGrainLimit
The maximum fine granularity limit for alignment to be set.

maxRefineGrainLimit
The maximum granularity limit for refinement to be set.

Throws

BadParams

If the following condition is not met:
1 <= *maxRefineGrainLimit*
<= *maxFineAlignGrainLimit*
<= *maxCoarseAlignGrainLimit*

The defaults are as follows:

maxCoarseAlignGrainLimit: 40

maxFineAlignGrainLimit: 8

maxRefineGrainLimit: 2

ccBallPatternAlignTrainParams

ccBezierCurve

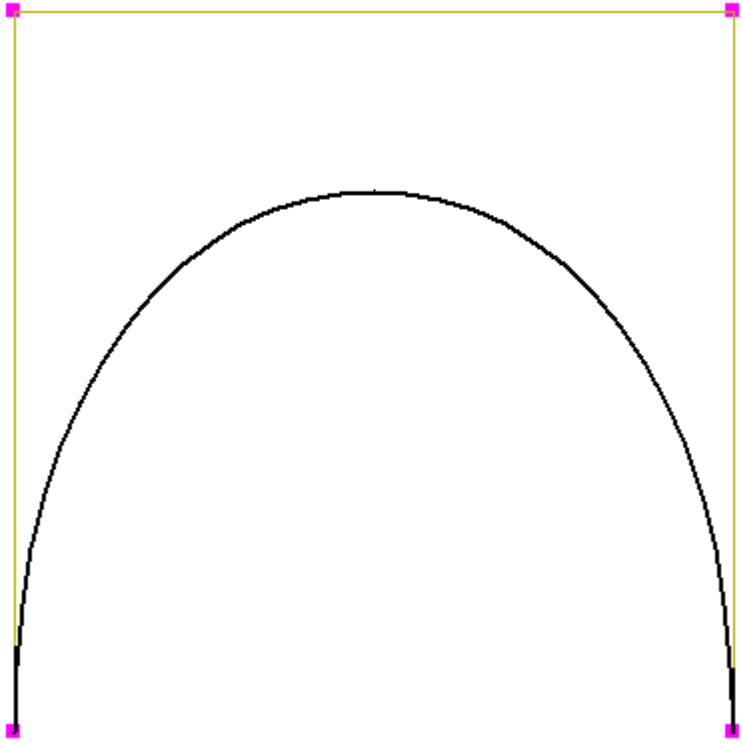
```
#include <ch_cvl/spline.h>

class ccBezierCurve : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccBezierCurve** class is an implementation of 2D cubic Bezier curves with optional control point weights.



The above figure shows an example of a Bezier curve with four control points.

Bezier Curves

A 2D cubic Bezier curve is a finite, continuous, and infinitely differentiable curve specified by four 2D Bezier control points. Bezier curves interpolate the first and last control points. It generally does not interpolate the inner two control points, although these affect the shape of the curve.

You can assign optional positive scalar weights to the control points to produce a *rational* Bezier curve. Coordinate functions along a rational Bezier curve are of the form:

$$x(t) = (f(t))/(h(t))$$

$$y(t) = (g(t))/(h(t))$$

where *f*, *g*, and *h* are cubic polynomials determined by the control points and weights. If all weights are equal, the function h(*t*) is a constant, and therefore x(*t*) and y(*t*) are themselves cubic polynomials. Weights are relative quantities, and multiplying all control point weights by a common factor thus would have no effect on the curve.

Parameter Range

Mathematically, the range of the parameter *t* is arbitrary, but all **ccBezierCurve** class methods that take or return parameter values assume a parameter range of 0 through 1, where 0 corresponds to the start point of the Bezier curve, and 1 corresponds to the endpoint. Note that the parameter *t* does not correspond to arc length. Sampling at uniformly spaced values of *t* does not in general produce points that are equally spaced with respect to arc length along the curve.

Tangent Vectors

Some methods of the Bezier curve and spline classes refer to tangent vectors. Unless otherwise noted, the implied meaning is the *parametric* tangent, given by [x'(*t*), y'(*t*)], where ' denotes differentiation with respect to *t*. The parametric tangent is subtly different from the geometric tangent to the curve at *t*. For example, if the first two control points of a Bezier curve are coincident, [x'(0), y'(0)], and so the parametric tangent vanishes. Yet the curve still has a geometric tangent at *t = 0* if the second or third derivatives of x(*t*) and y(*t*) do not all vanish. Also, the magnitude of the parametric tangent is not generally constant along a Bezier or spline curve. What is always true is that the parametric tangent at a given point on the curve is either zero or lies along the geometric tangent line to the curve at that point.

Note For in-depth information on the theory and use of 2D cubic Bezier curves and splines, see any textbook on the subject, such as *Curves and Surfaces for Computer Aided Geometric Design* by Gerald Farin, Second Edition, Academic Press, 1990, ISBN 0-12-249051-7.

Note All methods defined for this class leave a **ccBezierCurve** object unchanged when they throw an error.

Constructors/Destructors

```
ccBezierCurve();

explicit
ccBezierCurve(const cmStd vector<cc2Vect> &points);

explicit
ccBezierCurve(const cmStd vector<cc2Vect> &points,
  const cmStd vector<double> &weights);

explicit
ccBezierCurve(const cmStd vector<cc3Vect>
  &weightedControlPoints);
```

- `ccBezierCurve();`

  Default constructor. Constructs a default Bezier curve with all four control points coincident, equal to the origin, and with unit weights (that is, all weights equal to 1.0).

- ```
  explicit
  ccBezierCurve(const cmStd vector<cc2Vect> &points);
  ```

  Constructs a **ccBezierCurve** with the given control points and unit weights. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  points The vector of control points.

  Notes

  The control points correspond to the Bezier curve's start point, middle two handle points, and end point, in that order.

  Throws

  ccShapesError::BadParams

  points does not have a size of four.

- ```
  explicit
  ccBezierCurve(const cmStd vector<cc2Vect> &points,
    const cmStd vector<double> &weights);
  ```

  Constructs a Bezier curve with the given control points and weights. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  points The four 2D Bezier control points that specify the curve.

weights Positive scalar weights assigned to the control points to produce a *rational* Bezier curve (the default weight is 1.0 for all four points).

Notes

The elements of the vectors passed in correspond to the Bezier curve's start point, middle two handle points, and end point, in that order.

Throws

ccShapesError::BadParams
The *points* and *weights* vectors do not both have a size of 4.

ccShapesError::NonpositiveWeight
Any element of *weights* is non-positive.

- ```
  explicit
  ccBezierCurve(
    const cmStd vector<cc3Vect> &weightedControlPoints);
  ```

Constructs a Bezier curve with the given weighted control points. A control point (*x*, *y*) with weight *w* is represented as the **cc3Vect (w*x, w*y, w)**. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

weightedControlPoints
Vector of weighted control points.

Notes

The elements of the vector passed in correspond to the Bezier curve's start point, middle two handle points, and end point, in that order.

Throws

ccShapesError::BadParams
The *weightedControlPoints* vector does not have a size of 4.

ccShapesError::NonpositiveWeight
Any weight is non-positive.

Operators

operator== `bool operator==(const ccBezierCurve &rhs) const;`

Returns true if and only if this ccBezierCurve is equal to *rhs*. Two **ccBezierCurve**s are equal if their control points and weights are all identical (no tolerance is used).
  ```

Parameters

rhs — The other **ccBezierCurve**.

Notes

ccBezierCurves that describe identical curves are not necessarily equal. For example, the curve itself is invariant with respect to uniform scaling of weights, but **operator==()** is not.

operator!=

```
bool operator!=(const ccBezierCurve &rhs) const;
```

Returns the opposite truth value to **operator==()**.

Parameters

rhs — The other **ccBezierCurve**.

Public Member Functions

isWeighted

```
bool isWeighted() const;
```

Returns true if and only if this Bezier curve is weighted; that is, not all of the weights are equal.

controlPoint

```
cc2Vect controlPoint(c_Int32 idx) const;
void controlPoint(c_Int32 idx, const cc2Vect &ctrlPt);
```

- `cc2Vect controlPoint(c_Int32 idx) const;`

  Gets the control point with the given index.

  Parameters

  idx — The index.

- `void controlPoint(c_Int32 idx, const cc2Vect &ctrlPt);`

  Sets the control point with the given index.

  Parameters

  idx — The index.

  ctrlPt — The control point.

  Throws

  ccShapesError::BadIndex

  idx is either less than 0 or greater than or equal to 4.

controlPoints

```
cmStd vector<cc2Vect> controlPoints() const;
void controlPoints(const cmStd vector<cc2Vect> &points);
```

- `cmStd vector<cc2Vect> controlPoints() const;`

  Gets the vector of Bezier control points.

- `void controlPoints(const cmStd vector<cc2Vect> &points);`

  Sets the vector of Bezier control points.

  Parameters

  points The vector of four Bezier control points.

  Throws

  ccShapesError::BadParams
  The control points vector does not have a size of 4.

weight

```
double weight(c_Int32 idx) const;
void weight(c_Int32 idx, double newWeight);
```

- `double weight(c_Int32 idx) const;`

  Gets the weight of the control point with the given index.

  Parameters

  idx The index.

- `void weight(c_Int32 idx, double newWeight);`

  Sets the weight of the control point with given index.

  Parameters

  idx The index.

  newWeight The weight.

  Throws

  ccShapesError::BadIndex
  idx is either less than 0 or greater than or equal to 4.

  ccShapesError::NonpositiveWeight
  newWeight is non-positive.

weights

```
cmStd vector<double> weights() const;
void weights(const cmStd vector<double> &wghts);
```

- `cmStd vector<double> weights() const;`

  Gets the vector of control point weights.

- `void weights(const cmStd vector<double> &wghts);`

  Sets the vector of control point weights.

  Parameters

  wghts The vector of four control point weights.

  Throws

  ccShapesError::BadParams
  wghts vector does not have a size of 4.

  ccShapesError::NonpositiveWeight
  Any of the new weights are non-positive.

map

```
ccBezierCurve map(const cc2Xform& X) const;
```

Returns this Bezier curve mapped by *X*.

Parameters

X The 2D transform used to modify this Bezier curve.

Notes

This function maps each of the four control points by *X* while leaving the weights unchanged. The locus of points of the resulting mapped Bezier curve is exactly the locus of points of the original Bezier curve mapped by X.

point

```
cc2Vect point(double t) const;
```

Returns the point at parameter value *t* along the Bezier curve. Values of *t* outside of the range 0 through 1 are legal, but correspond to points on the extrapolation of the curve, not on the curve itself. The value returned is an exact value, not an approximation.

Parameters

t The parameter value.

tangent

```
cc2Vect tangent(double t) const;
```

Returns the tangent vector at parameter value *t* along the Bezier curve. Values of *t* outside of the range 0 through 1 are legal, but correspond to points on the extrapolation of the curve, not on the curve itself. The value returned is an exact value, not an approximation.

Parameters

t	The parameter value.

pointAndTangent

```
void pointAndTangent(double t, cc2Vect &point,
  cc2Vect &tangent) const;
```

Returns the point and tangent vector at parameter value *t* along the Bezier curve. Values of *t* outside of the range 0 through 1 are legal, but correspond to points on the extrapolation of the curve, not on the curve itself. The value returned is an exact value, not an approximation.

Parameters

t	The parameter value.

Notes

Calling this routine is more efficient than calling **point()** and **tangent()** separately.

nearestPoint

```
cc2Vect nearestPoint(const cc2Vect &p, double &t) const;

virtual cc2Vect nearestPoint(const cc2Vect& p) const;
```

- `cc2Vect nearestPoint(const cc2Vect &p, double &t) const;`

  Returns the nearest point on this Bezier curve to the given point as well as the nearest point's parameter value. If the nearest point is not unique, one of the nearest points is returned.

  Parameters

p	The point.
t	The nearest point's parameter value.

- `virtual cc2Vect nearestPoint(const c2Vect& p) const;`

  Returns the nearest point on this Bezier curve to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p The point.

See **ccShape::nearestPoint()** for more information.

intersections

```
cmStd vector<double> intersections(const ccLineSeg &seg)
 const;
```

Returns the parameter values at which this Bezier curve intersects the given line segment.

Parameters

seg The line segment.

Notes

Returns an empty vector if there are no intersections.

There are infinite intersections if a portion of the spline lies exactly on the line segment. In this case, only a single intersection from this infinite set is returned.

subCurve

```
ccBezierCurve subCurve(double s, double t) const;
```

Returns the subcurve of this Bezier curve lying between the parameter values *s* and *t*.

Parameters

s The first parameter value.

t The second parameter value.

Notes

The cases $s == t$, $s > t$, and $s < t$ are all legal.

Passing $s = 1.0$ and $t = 0.0$ returns the same curve as **reverse()**.

The values of *s* and *t* are internally clipped if they fall outside the range 0 through 1.

cubicCoeffs

```
void cubicCoeffs(cmStd vector<double> &fCoeffs,
  cmStd vector<double> &gCoeffs,
  cmStd vector<double> &hCoeffs) const;
```

This Bezier curve is parameterized by

$$x(t) = (f(t))/(h(t))$$

$$y(t) = (g(t))/(h(t))$$

where *f*, *g*, and *h* are cubic polynomials. This method computes and returns these cubics. Each of the returned vectors has four elements, corresponding to the cubic coefficients, leading coefficient first.

Parameters

fCoeffs	Cubic coefficient of the polynomial f(*t*).
gCoeffs	Cubic coefficient of the polynomial g(*t*).
hCoeffs	Cubic coefficient of the polynomial h(*t*).

Notes

If **isWeighted()** is false, the polynomial h(*t*) is a constant.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this Bezier curve.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For Bezier curves, this function always returns true.

See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For Bezier curves, this function always returns false.

See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

Returns true if this shape has finite extent. For Bezier curves, this function always returns true.

See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For Bezier curves, this function always returns false.

See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

Returns true if the set of points that lie on the boundary of this shape is infinite, and there is a well-defined tangent at all but a finite number of these points. This function returns true for most Bezier curves. It returns false if all four control points are coincident, in which case the curve collapses to a single point and there is no tangent.

See **ccShape::hasTangent()** for more information.

isReversible

```
virtual bool isReversible() const;
```

Returns true if this shape can be reversed. For Bezier curves, this function always returns true.

See **ccShape::reverse()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

Returns true if this shape is already decomposed. For Bezier curves, this function always returns true.

See **ccShape::isDecomposed()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this Bezier curve.

Notes

The returned shape is a tight rectangle based on the curve itself, not the control points.

See **ccShape::boundingBox()** for more information.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this Bezier curve.

See **ccShape::perimeter()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this Bezier curve to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this shape.

point The point.

See **ccShape::nearestPerimPos()** for more information.

startPoint

```
virtual cc2Vect startPoint() const;
```

Returns the starting point of this Bezier curve.

See **ccShape::startPoint()** for more information.

endPoint

```
virtual cc2Vect endPoint() const;
```

Returns the ending point of this Bezier curve.

See **ccShape::endPoint()** for more information.

startAngle

```
virtual ccRadian startAngle() const;
```

Returns the starting angle of this Bezier curve.

Throws

ccShapesError::NoTangent
hasTangent() is false for this Bezier curve.

See **ccShape::startAngle()** for more information.

endAngle

```
ccRadian endAngle() const;
```

Returns the ending angle for this Bezier curve.

Throws

ccShapesError::NoTangent
hasTangent() is false for this Bezier curve.

See **ccShape::endAngle()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this Bezier curve.

See **ccShape::reverse()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this Bezier curve mapped by *X*.

Parameters

X The transformation object.

See **ccShape::mapShape()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns the net signed angle through which the tangent vector rotates along this open contour shape from the start point to the end point.

Throws

ccShapesError::NoTangent
hasTangent() is false.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

Parameters

p The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

See **ccShape::windingAngle()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
 ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this **ccBezierCurve**. Returned sample points are generally not equally spaced along the curve.

Parameters

params	Parameters object specifying details of how the sampling should be done.
result	Result object to which position and tangent chains are stored.

Notes

If **params.computeTangents()** is true, this function ignores Bezier curves for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a clone of this Bezier curve. As a Bezier curve is already a decomposed shape, this method is equivalent to **clone()** for Bezier curves.

See **ccShape::decompose()** for more information.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this Bezier curve over the given perimeter range.

Parameters

info	Shape information for this Bezier curve.
range	The perimeter range.

See **ccShape::subShape()** for more information.

ccBlob

```
#include <ch_cvl/blobdesc.h>

class ccBlob: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains a single feature produced by performing blob analysis on an image.

ccBlob

```
ccBlob();

ccBlob(const ccBlob& rhs);
```

- `ccBlob();`

  You should not create **ccBlob**s.

Enumerations

Direction

`enum Direction`

This enumeration defines the direction codes that can appear in the chain code that describes the perimeter of a feature.

Value	Meaning
ePlusX	Increase in x-direction
eMinusX	Decrease in x-direction
ePlusY	Increase in y-direction
eMinusY	Decrease in y-direction
eEnd	End of chain

Measure `enum Measure`

This enumeration defines all the measures that can be computed for a feature.

Value	Meaning
eLabel	The feature label. For grey-scale connectivity this is 1 for blobs, 0 for holes. For labeled connectivity this is the feature's label.
eArea	The area of the feature in client coordinate system units. For grey-scale connectivity, this is the sum of the weights of the pixels. For other types of connectivity, it is the number of pixels.
eNumSteps	The number of steps in the chain code that describes this feature's perimeter
ePerimeter	The perimeter of the feature in client coordinate system units. This value is based on *eNumSteps* but is corrected to approximate the true perimeter of the feature. The correction formula is described as part of the **perimeter()** function on page 583.
eNumChildren	The number of features contained within this feature
eCenterMassX	The x-coordinate of the center of mass of the feature
eCenterMassY	The y-coordinate of the center of mass of the feature
eInertiaX	The second moment of inertia of this feature about an axis drawn through the feature's center of mass and parallel to the image coordinate system x-axis
eInertiaY	The second moment of inertia of this feature about an axis drawn through the feature's center of mass and parallel to the image coordinate system y-axis

Value	Meaning
eInertiaMin	The second moment of inertia of this feature about its major axis
eInertiaMax	The second moment of inertia of this feature about its minor axis
eElongation	The ratio of *eInertiaMax* to *eInertiaMin*
eAngle	The angle of the major axis of the feature with respect to the client coordinate system x-axis. If *eElongation* is 1.0 *eAngle* is reported as 0, although it is actually undefined.
eAcircularity	The acircularity of the feature as measured by dividing the square of the feature's perimeter by 4 times the feature's area times pi. The value of *eAcircularity* is 1 for a perfectly circular feature; the less circular the feature, the greater the value of *eAcircularity.*
eAcircularityRms	The acircularity of the feature as measured by the normalized rms deviation of the boundary point radius values from r0, where r0 is the square root of the feature's area divided by pi. The value of *eAcircularityRms* is 1 for a perfectly circular feature; the less circular the feature, the greater the value of *eAcircularityRms*.
eIsInterior	The blob is interior to the image.
eImageBoundCenterX	The x-coordinate of the center of the rectangle defining the image coordinate extents of the feature.
eImageBoundCenterY	The y-coordinate of the center of the rectangle defining the image coordinate extents of the feature

Value	Meaning
eImageBoundMinX	The x-coordinate of the left edge of the rectangle defining the image coordinate extents of this feature
eImageBoundMaxX	The x-coordinate of the right edge of the rectangle defining the image coordinate extents of this feature
eImageBoundMinY	The y-coordinate of the top edge of the rectangle defining the image coordinate extents of this feature
eImageBoundMaxY	The y-coordinate of the bottom edge of the rectangle defining the image coordinate extents of this feature
eImageBoundWidth	The width of the rectangle defining the image coordinate extents of this feature
eImageBoundHeight	The height of the rectangle defining the image coordinate extents of this feature
eImageBoundAspect	The ratio of *eImageBoundHeight* to *eImageBoundWidth*
eMedianX	The point on the client coordinate system x-axis through which a vertical line which divides the feature's area in half passes
eMedianY	The point on the client coordinate system y-axis through which a horizontal line which divides the feature's area in half passes
eBoundCenterX	The x-coordinate of the center of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription::extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription::extremaExcludeArea()**.

Value	Meaning
eBoundCenterY	The y-coordinate of the center of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription:: extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription:: extremaExcludeArea()**.
eBoundMinX	The x-coordinate of the left edge of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription:: extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription:: extremaExcludeArea()**.
eBoundMaxX	The x-coordinate of the right edge of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription:: extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription:: extremaExcludeArea()**.
eBoundMinY	The y-coordinate of the top edge of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription:: extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription:: extremaExcludeArea()**.

Value	Meaning
eBoundMaxY	The y-coordinate of the bottom edge of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription::extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription::extremaExcludeArea()**.
eBoundWidth	The width of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription::extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription::extremaExcludeArea()**.
eBoundHeight	The height of a bounding box aligned to the client coordinate system angle specified by the most recent call to **ccBlobSceneDescription::extremaAngle()** and respecting the amount of area to exclude specified by the most recent call to **ccBlobSceneDescription::extremaExcludeArea()**.
eBoundAspect	The ratio of *eBoundHeight* to *eBoundWidth*
eBoundPrincipalMinX	The distance, in client coordinates, along the first principal axis of the feature from the feature's center of mass in the negative X-direction to the edge of a bounding box aligned to the feature's principal axes. The distance is expressed in the modified client coordinate system returned by **ccBlob::boundingBoxPrincipal()**; the value of this measure is negative.

Value	Meaning
eBoundPrincipalMaxX	The distance, in client coordinates, along the first principal axis of the feature from the feature's center of mass in the positive X-direction to the edge of a bounding box aligned to the feature's principal axes. The distance is expressed in the modified client coordinate system returned by **ccBlob::boundingBoxPrincipal()**.
eBoundPrincipalMinY	The distance, in client coordinates, along the second principal axis of the feature from the feature's center of mass in the negative Y-direction to the edge of a bounding box aligned to the feature's principal axes. The distance is expressed in the modified client coordinate system returned by **ccBlob::boundingBoxPrincipal()**; the value of this measure is negative.
eBoundPrincipalMaxY	The distance, in client coordinates, along the second principal axis of the feature from the feature's center of mass in the positive Y-direction to the edge of a bounding box aligned to the feature's principal axes. The distance is expressed in the modified client coordinate system returned by **ccBlob::boundingBoxPrincipal()**.
eBoundPrincipalWidth	The distance, in client coordinates, along the first principal axis of the feature between the sides of the bounding rectangle aligned to the feature's first principal axis.

Value	Meaning
eBoundPrincipalHeight	The distance, in client coordinates, along the second principal axis of the feature between the sides of the bounding rectangle aligned to the feature's first principal axis.
eBoundPrincipalAspect	The ratio of *eBoundPrincipalHeight* to *eBoundPrincipalWidth*

scene

```
const ccBlobSceneDescription* scene() const;
```

Returns a pointer to the **ccBlobSceneDescription** of which this feature is a component.

id

```
c_Int32 id() const;
```

Returns the ID value of this feature. You can use this ID to refer to the feature.

label

```
c_UInt8 label() const;
```

Returns the type of feature that this **ccBlob** is. For grey-scale connectivity, this function returns 1 if the feature is a blob and 0 if it is a hole. For labelled connectivity, this function returns the feature's label value.

imageBoundingBox

```
ccPelRect imageBoundingBox() const;
```

Returns the smallest image-coordinate-aligned **ccPelRect** that encloses all of the pixels of this feature. The origin of the rectangle is the location of this blob in the original scene.

Notes

This function requires much less time to execute than functions that compute a feature's area or size with respect to its principal axes.

imageBoundingBoxCenter

```
cc2Vect imageBoundingBoxCenter() const;
```

Returns the location of the center of the **ccPelRect** returned by **imageBoundingBox()** in image coordinates.

Notes

This function requires much less time to execute than functions that compute a feature's area or size with respect to its principal axes.

imageBoundingBoxAspect

```
double imageBoundingBoxAspect() const;
```

Returns the ratio of the height of the **ccPelRect** returned by **imageBoundingBox()** to its width.

Notes

This function requires much less time to execute than functions that compute a feature's area or size with respect to its principal axes.

region

```
const ccRLEBuffer& region() const;
```

Returns a reference to a **ccRLEBuffer** that contains the feature described by this **ccBlob**.

If this **ccBlob** refers to a blob produced by grey-scale connectivity, runs in the returned **ccRLEBuffer** with nonzero values are part of the blob, while runs with a value of 0 are parts of holes or the background. If this **ccBlob** refers to a hole produced by grey-scale connectivity, runs in the returned **ccRLEBuffer** with a value of 1 are part of the hole, while runs with a value of 0 are parts of the background (either parts of the blob surrounding this hole or blobs within this hole). If this **ccBlob** refers to a feature produced by labelled connectivity, runs in the returned **ccRLEBuffer** with a value of 1 are part of the feature, while runs with a value of 0 are part of features with other labels.

boundaryChainCode

```
ccIPair boundaryChainCode(
  cmStd vector<ceBlobDirection>& chain) const;
```

Returns the location, in image coordinates, of the start (and end) of a chain code that describes this feature's outer boundary. The chain code itself is returned in the supplied reference to a vector of **ceBlobDirection**.

The chain code is defined as the path along the outside edges of the outermost pixels of the feature, moving in a clockwise direction. Each element of the chain code can indicate one of four directions. The end of the chain code is marked with an *eEnd* code.

Parameters

chain — The chain code. Each element of *chain* is one of the following values:

ePlusX
eMinusX
ePlusY
eMinusY
eEnd

Throws

ccBlob::BadMeasure
No chain code is available. This feature was produced using whole-image connectivity analysis.

numSteps

```
c_Int32 numSteps() const;
```

Returns the number of elements in the chain code that describes this feature's outer boundary.

Throws

ccBlob::BadMeasure
No chain code is available: this feature was produced using whole-image connectivity analysis.

area

```
double area() const;
```

Returns the area of the feature described by this **ccBlob** measured in client coordinate units. The area is computed in image coordinates, then converted to the units of the client coordinate system.

The initial area computation is performed as follows. If the feature is a blob that was produced by grey-scale connectivity, the area is the weighted sum of the nonzero pixels of the blob, normalized by any scaling value that you specified. If the feature is a hole produced by grey-scale connectivity, the area is the number of pixels in the hole. If the feature was produced by labelled connectivity, the area is the number of pixels in the feature.

Notes

The area is converted to client coordinate system units by calling the following functions:

```
region().clientFromImageXform().mapArea()
```

perimeter `double perimeter() const;`

Returns the perimeter of the feature. The perimeter is computed using the following formula:

$$P = 0.94806(Sx \times Nx + Sy \times Ny - Sc \times C)$$

Where:

Sx is the value returned by **cc2Xform::xScale()** when called on the **cc2Xform** associated with this feature.

Nx is the number of *ePlusX* and *eMinusX* codes in this feature's chain code.

Sy is the value returned by **cc2Xform::yScale()** when called on the **cc2Xform** associated with this feature.

Ny is the number of *ePlusY* and *eMinusY* codes in this feature's chain code.

Sc is equal to:

$$Sx + Sy - \sqrt{Sx^2 + Sy^2}$$

C is the number of convex corners in this feature's chain code. A convex corner is any of the following pairs of chain codes:

ePlusX followed by *eMinusY*
eMinusY followed by *eMinusX*
eMinusX followed by *ePlusY*
ePlusY followed by *ePlusX*

This formula corrects for the tendency of the raw chain code count to overstate the true blob perimeter.

The perimeter is returned in the units of the client coordinate system associated with the image being analyzed.

Throws

ccBlob::BadMeasure
No chain code is available: this feature was produced using whole-image connectivity analysis.

centerOfMass `cc2Vect centerOfMass() const;`

Returns the position of the center of mass of this feature in the client coordinate system.

inertia `ccDPair inertia() const;`

Returns the feature's second moments of inertia about the horizontal and vertical axes within the client coordinate system through the feature's center of mass.

inertia().x() contains the moment about the vertical axis, **inertia().y()** contains the moment about the horizontal axis.

inertiaPrincipal `ccDPair inertiaPrincipal() const;`

Returns the feature's second moments of inertia about its first and second principal axes.

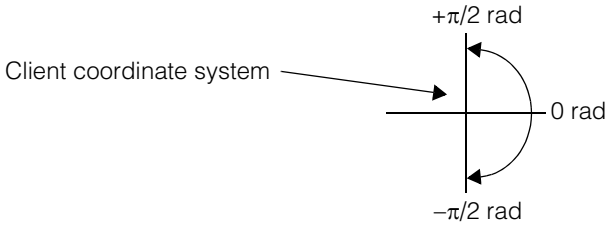
inertiaPrincipal().x() contains the moment about the first principal axis, **inertiaPrincipal().y()** contains the moment about the second principal axis.

elongation `double elongation() const;`

Returns the ratio of the feature's second moment of inertia about its second principal axis to the feature's second moment of inertia about its first principal axis.

angle `ccRadian angle() const;`

Returns the orientation of the feature's first principal axis with respect to the x-axis of the client coordinate system, in radians. The following figure shows how the angle is reported:



Notes

If the value returned by **elongation()** is exactly 1, then this function returns 0, although the actual value for the angle is undefined. If the value returned by **elongation()** is very close 1, the value for the angle may be meaningless.

acircularity

```
double acircularity() const;
```

Returns a measure of the acircularity of this feature. The return value is computed using the following formula:

$$p^2 / (4 \times \pi \times A)$$

Where:

p is the value returned by **perimeter()**

A is the value returned by **area()**

Throws

ccBlob::BadMeasure

No perimeter information is available: this feature was produced using whole-image connectivity analysis.

acircularityRms

```
double acircularityRms() const;
```

Returns a measure of the acircularity of this feature. The return value is the normalized RMS deviation of boundary point radius values from r0, where r0 computed using the following formula:

$$\sqrt{\frac{A}{\pi}}$$

Where:

A is the value returned by **area()**

Throws

ccBlob::BadMeasure

No perimeter information is available: this feature was produced using whole-image connectivity analysis.

median

```
cc2Vect median(const ccRadian& angle = ccRadian(0)) const;
```

Returns the median point for this feature. The median point is defined as the point through which a pair of perpendicular lines will divide the feature in half, vertically and horizontally. By default, the lines are aligned to the x- and y-axes of the client coordinate system. You can specify an optional angle at which to draw the horizontal line.

Parameters

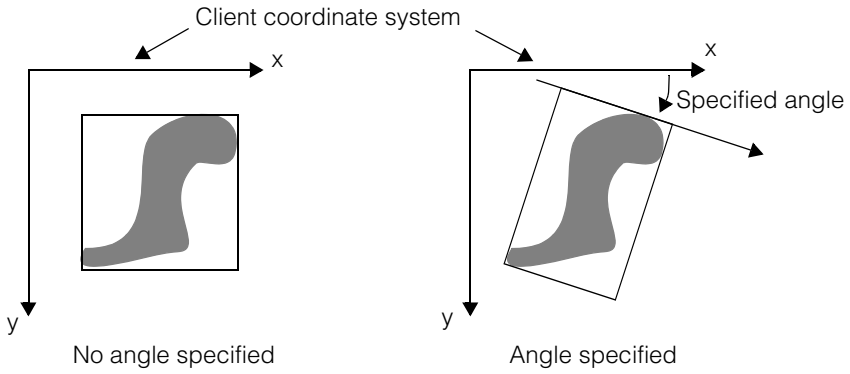
angle The angle (in the client coordinate system) at which to draw the horizontal median line. An angle of 0 is the same as the client coordinate system x-axis.

boundingBox

```
ccDRect boundingBox(bool excludeExtrema = true,
  const ccRadian& angle = ccRadian(0)) const;
```

Returns the smallest rectangle that completely encloses the feature described by this **ccBlob**. The bounding box is computed in a new coordinate system which is a rotated and translated version of the client coordinate system. The origin of the new coordinate system is the blob's center of mass, and the coordinate system is rotated by the specified angle, positive angles indicating that the new x-axis is rotated towards the +y-axis relative to the old x-axis.

The following diagram illustrates the effect of specifying a rotation angle:



You can specify the angle of the first principal axis of the feature to obtain the bounding box aligned to the blob's principal axis.

Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

angle The angle at which to align the bounding box, relative to the x-axis of client coordinate system.

Notes

Cognex recommends that you use the **boundingBox().origin()**, **boundingBox().width()**, and **boundingBox().height()** functions to obtain the bounding box dimensions.

The **boundingBox().origin()** function returns the location of the lower-left corner of the returned rectangle, in a coordinate system whose origin is at the center of the feature. Accordingly, the returned location will have negative values for both x and y.

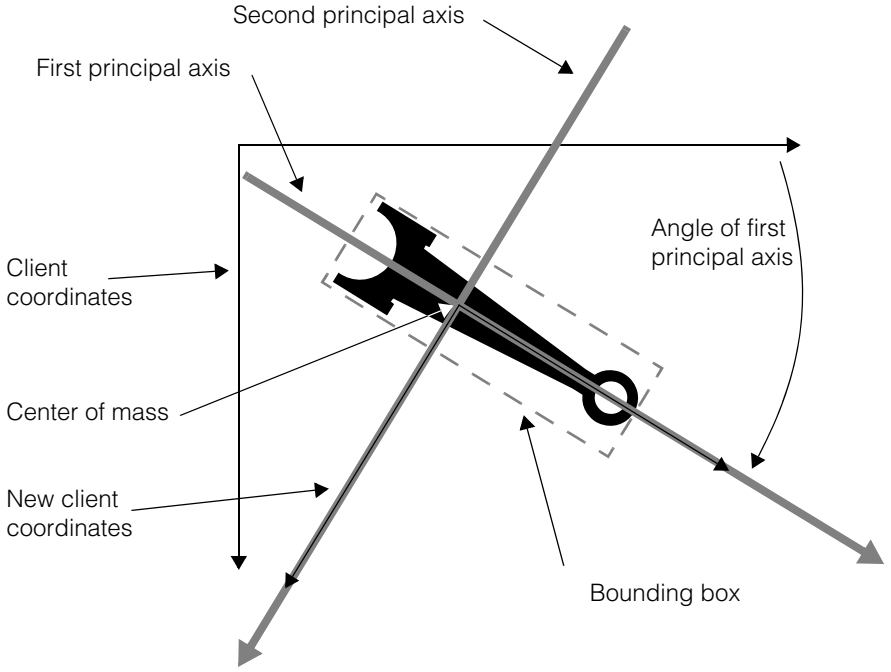
boundingBoxPrincipal

```
ccDRect boundingBoxPrincipal(bool excludeExtrema = true)
  const;
```

Returns the smallest rectangle that completely encloses the feature described by this **ccBlob** aligned to the feature's first principal axis. The returned **ccDRect** has its origin set to the center of mass of the feature.

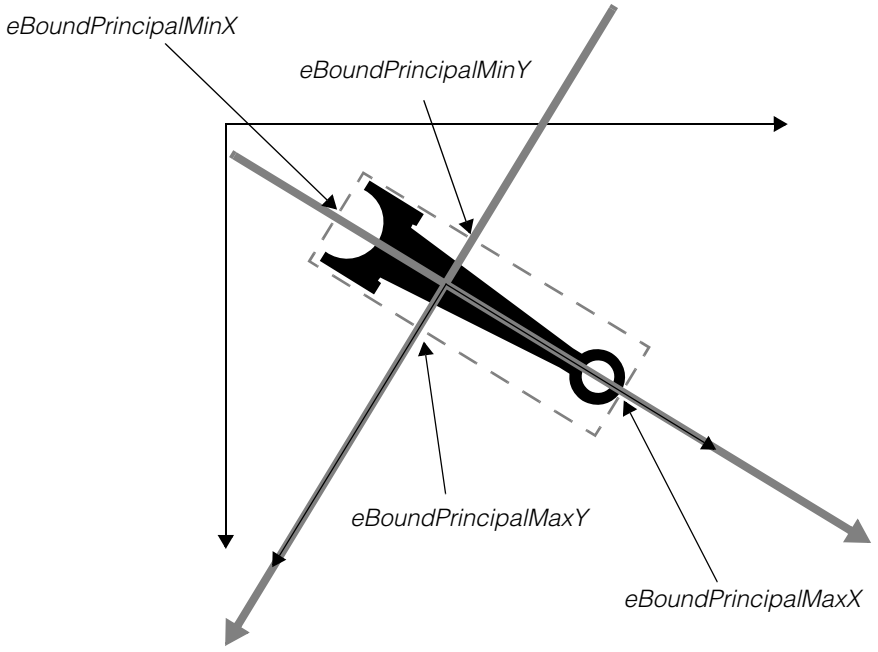
Unlike **imageBoundingBox()**, this function returns a measure of the blob that does not vary with the angle of the blob.

The location of the rectangle returned by this function is given in terms of a new client coordinate system. This new client coordinate system is a copy of the current client coordinates translated and rotated such that the origin of the new coordinate system is at the feature's center of mass and the positive x-axis is aligned to the first principal axis of the feature. The following figure shows how this new coordinate system is created:



The blob measures *eBoundPrincipalMinX*, *eBoundPrincipalMaxX*, *eBoundPrincipalMinY*, and *eBoundPrincipalMaxY* are all expressed using this same

client coordinate system, as shown in the following figure:



Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

Notes

This function is equivalent to calling **boundingBox()** and specifying **angle()** for the *angle* argument.

Cognex recommends that you use the **boundingBoxPrincipal().origin()**, **boundingBoxPrincipal().width()**, and **boundingBoxPrincipal().height()** functions to obtain the bounding box dimensions.

center

```
cc2Vect center(bool excludeExtrema = true,
  const ccRadian& angle = ccRadian(0)) const;
```

Returns the position of the center of the bounding box computed by **boundingBox()**. The position is returned in terms of the client coordinate system for the image which contained this feature.

Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

angle The angle at which to align the bounding box, relative to the x-axis of client coordinate system.

centerPrincipal

```
cc2Vect centerPrincipal(bool excludeExtrema = true) const;
```

Returns the position of the center of the bounding box computed by **boundingBoxPrincipal()**. The position is returned in terms of the client coordinate system for the image which contained this feature.

Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

aspect

```
double aspect(bool excludeExtrema = true,
  const ccRadian& angle = ccRadian(0)) const;
```

Returns the aspect ratio of the bounding box computed by **boundingBox()**. This is equal to the ratio of the value returned by **ccDRect::height()** to the value returned by **ccDRect::width()** when called on the **ccDRect** returned by **boundingBox()**.

Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

angle The angle at which to align the bounding box, relative to the x-axis of client coordinate system.

isInterior

```
bool isInterior() const;
```

This function tests whether the blob is interior to the image. The function may, or may not use the mask **ccBlobParams::mask()**.

If **ccBlobParams::useMaskForInterior()** is true and the mask is not degenerate, the mask is used. Otherwise the mask is not used.

When the mask is not used, the function returns false if some blob pixel is a boundary pixel of the input image. When the mask is used the function returns false if some blob pixel is 8-connected to some don't care pixel of the mask. In all other cases the function returns true.

aspectPrincipal

```
double aspectPrincipal(bool excludeExtrema = true) const;
```

Returns the aspect ratio of the bounding box computed by **boundingBoxPrincipal()**. This is equal to the ratio of the value returned by **ccDRect::height()** to the value returned by **ccDRect::width()** when called on the **ccDRect** returned by **boundingBoxPrincipal()**.

Parameters

excludeExtrema If *excludeExtrema* is *true*, the amount of the feature's extrema that you specified when you called **ccBlobSceneDescription::extremaExclude()**, **ccBlobSceneDescription::extremaExcludePels()**, or **ccBlobSceneDescription::extremaExcludePercent()** is excluded before the bounding box is computed.

If *excludeExtrema* is *false*, the bounding box is computed to enclose the entire feature.

Notes

The value returned by this function is typically less than or equal to 1 while the value returned by **elongation()** is always greater than or equal to 1.

measure

```
double measure(theMeasure) const;
```

Returns the specified measure for this feature. Measures are always computed and returned in terms of the client coordinate system.

Parameters

theMeasure The measure to obtain. *theMeasure* must be one of the following values:

ccBlob::eLabel
ccBlob::eArea
ccBlob::eNumSteps
ccBlob::ePerimeter
ccBlob::eNumChildren
ccBlob::eCenterMassX
ccBlob::eCenterMassY
ccBlob::eInertiaX
ccBlob::eInertiaY
ccBlob::eInertiaMin
ccBlob::eInertiaMax
ccBlob::eElongation
ccBlob::eAngle
ccBlob::eAcircularity
ccBlob::eAcircularityRms
ccBlob::eIsInterior
ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY

ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY
ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

Notes

This function is called internally by the Blob tool if you have defined sorting or filtering criteria in the **ccBlobSceneDescription** that contains this feature.

Throws

ccBlob::BadMeasure
The requested measure is not available: this feature was produced using whole-image connectivity analysis.

parent

```
const ccBlob* parent() const;
```

Returns a pointer to the feature that encloses this feature. If no feature encloses this one, this function returns *NULL*.

nextSibling

```
const ccBlob* nextSibling(bool filtered = true) const;
```

Returns a pointer to the next feature that is contained within this feature's parent. The order in which features are returned by this function is determined by the current sort order, which you can set by calling **scene().setSort()**. If this feature has no siblings, this function returns *NULL*.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

prevSibling

```
const ccBlob* prevSibling(bool filtered = true) const;
```

Returns a pointer to the previous feature that is contained within this feature's parent. The order in which features are returned by this function is determined by the current sort order, which you can set by calling **scene().setSort()**. If this feature has no siblings, this function returns *NULL*.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

numChildren

```
c_Int32 numChildren(bool filtered=true) const;
```

Returns the number of features that are enclosed within this feature.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

firstChild

```
const ccBlob* firstChild(bool filtered = true) const;
```

Returns a pointer to the first feature that is contained within this feature. The order in which features are returned by this function is determined by the current sort order, which you can set by calling **scene().setSort()**. If this feature does not contain any features, this function returns *NULL*.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

lastChild

```
const ccBlob* lastChild(bool filtered = true) const;
```

Returns a pointer to the last feature that is contained within this feature. The order in which features are returned by this function is determined by the current sort order, which you can set by calling **scene().setSort()**. If this feature does not contain any features, this function returns *NULL*.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

draw

```
void draw(ccGraphicList& graphList,
  c_UInt32 drawMode=ccBlobDefs::eDrawStandard,
  const ccCvlString& label=ccCvlString()) const;
```

Appends result graphics for this blob to the supplied **ccGraphicList**.

The graphics are drawn in client coordinates.

Parameters

graphList	The graphics list to append the graphics to.
drawMode	The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values: *ccBlobDefs::eDrawImageCenterOfMass* *ccBlobDefs::eDrawCenterOfMass* *ccBlobDefs::eDrawLabel* *ccBlobDefs::eDrawImageBoundingBox* *ccBlobDefs::eDrawBoundingBox* *ccBlobDefs::eDrawBoundingTrace* *ccBlobDefs::eDrawStandard*
label	If you include *ccBlobDefs::eDrawLabel* in *drawMode*, then the contents of *label* are used to label the center of mass.

ccBlobDefs

```
#include <blobdesc.h>

class ccBlobDefs;
```

A name space that holds enumerations and constants used with the Blob tool.

Enumerations

DrawMode

```
enum DrawMode
```

This enumeration defines the types of result graphics you can draw for blobs and blob scene descriptions.

Value	Meaning
eDrawImageCenterOfMass	Draws a cross at the center of mass.
eDrawCenterOfMass	Draws a cross at the center of mass aligned to the angle of the principal axis. (Used with *eDrawBoundingBox*.)
eDrawLabel	Draws a text label at the center of mass.
eDrawImageBoundingBox	Draws a box that encloses all of the feature's pixels. The box is image-aligned.
eDrawBoundingBox	Draws a box that encloses all of the feature's pixels. The box is aligned to the angle of the principal axis.
eDrawBoundingTrace	Draws the bounding trace (feature perimeter) that describes this feature.
eDrawStandard	Draws an image-aligned bounding box, image-aligned cross at the center of mass, and a text label at the center of mass.

Notes

All graphics are drawn in **ccColor::greenColor()** by default, except for *eDrawBoundingTrace*, which is drawn in **ccColor::cyanColor()**.

ccBlobDefs

ccBlobParams

```
#include <ch_cvl/blobtool.h>

class ccBlobParams: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains all of the parameters required to perform blob analysis on an image.

Constructors/Destructors

ccBlobParams `ccBlobParams();`

Constructs a **ccBlobParams** with the following default values:

Parameter	Default value
segmentationType	*eNone* Assumes a binary segmented image
scaleVal	1 Assumes a binary segmented image
keepRLE	False
mask	Degenerate (none)
keepMasked	False
morph	0-sized (none)
connectivityType	eGreyScale
connectivityCleanup	*eNone*
connectivityMinPels	0
useMaskForInterior	False

Each of these parameters may be examined and changed using **ccBlobParams** member functions.

Enumerations

MorphOp `enum MorphOp`

This enumeration defines the grey-scale morphological operations that are supported as part of the image segmentation process.

Value	Meaning
eMinH	Replace the target pixel with the minimum value of the 3 horizontal pixels centered on the target pixel.
eMinV	Replace the target pixel with the minimum value of the 3 vertical pixels centered on the target pixel.

Value	Meaning
eMinS	Replace the target pixel with the minimum value of the 9 square pixel area centered on the target pixel.
eMaxH	Replace the target pixel with the maximum value of the 3 horizontal pixels centered on the target pixel.
eMaxV	Replace the target pixel with the maximum value of the 3 vertical pixels centered on the target pixel.
eMaxS	Replace the target pixel with the maximum value of the 9 square pixel area centered on the target pixel.
eMinMaxH	Perform an *eMaxH* followed by an *eMinH*; also called closing.
eMinMaxV	Perform an *eMaxV* followed by an *eMinV*; also called closing.
eMinMaxS	Perform an *eMaxS* followed by an *eMinS* also called closing.
eMaxMinH	Perform an *eMinH* followed by an *eMaxH*; also called opening.
eMaxMinV	Perform an *eMinV* followed by an *eMaxV*; also called opening.
eMaxMinS	Perform an *eMinS* followed by an *eMaxS*; also called opening.

Segmentation `enum Segmentation`

This enumeration defines the segmentation types supported in **ccBlobParams**. You can only set the segmentation type by calling a member function that includes all of the parameters required for that segmentation type.

Value	Meaning
eNone	No segmentation is performed; the input image is already segmented.
eMap	Segment using a pixel map.
eHardThresh	Segment using a hard binary threshold; you can specify an absolute or relative threshold value.
eSoftThresh	Segment using a soft binary threshold; you can specify an absolute or relative threshold value.
eThreshImage	Segment using a threshold image.

Public Member Functions

setSegmentationNone

```
void setSegmentationNone(c_UInt8 scaleVal);
```

Sets this **ccBlobParams** to perform no segmentation on the input image. Use this function if the input image is already segmented.

You specify a scaling value to indicate the pixel value in the input image that represents a weight of 1.0. All pixels in the input image are interpreted on a linear scale relative to the scaling value. No pixel in the input image should have a value greater than *scaleVal*.

Parameters

scaleVal The scaling value.

Throws

ccBlobDefs::BadParams
scaleVal is equal to zero.

setSegmentationMap

```
void setSegmentationMap(const cmStd vector<c_UInt8>& map,
 c_UInt8 scaleVal);
```

Sets this **ccBlobParams** to segment the input image using the supplied pixel map. Each pixel in the input image is assigned a weight equal to the value within the pixel map at the index equal to the input image pixel value.

You specify a scaling value to indicate the pixel value in the resulting mapped image that represents a weight of 1.0. All pixels in the mapped image are interpreted on a linear scale relative to the scaling value; no pixel in the input image should have a value greater than *scaleVal*.

Parameters

map The pixel map. *map* must have at least as many elements as the largest pixel value in the input image.

scaleVal The scaling value.

Notes

This function creates an internal copy of the supplied pixel map.

Throws

ccBlobDefs::BadParams
scaleVal is equal to zero.
map size is equal to zero.

setSegmentationHardThresh

```
void setSegmentationHardThresh(c_UInt8 thresh,
  bool invert=false);

void setSegmentationHardThresh(c_Int32 lowTailPercent,
  c_Int32 highTailPercent, c_Int32 threshPercent,
  bool invert = false);
```

- ```
  void setSegmentationHardThresh(c_UInt8 thresh,
    bool invert=false);
  ```

  Sets this **ccBlobParams** to segment the input image using the supplied hard threshold. Each pixel in the input image with a value below the threshold is assigned a weight of 0; each pixel in the input image with a value greater than or equal to the threshold is assigned a weight of 1.

  You can specify an invert flag to specify that pixels below the threshold are assigned a weight of 1 and pixels at or above the threshold are assigned a weight of 0.

  Parameters

thresh	The threshold value.
invert	If *invert* is *true*, then all pixels in *image* with values greater than or equal to the supplied threshold are set to 0; pixels with values less than the threshold are set to 1. If *invert* is *false*, then all pixels in *image* with values greater than or equal to the supplied threshold are set to 1; pixels with values less than the threshold are set to 0.

- ```
  void setSegmentationHardThresh(c_Int32 lowTailPercent,
    c_Int32 highTailPercent, c_Int32 threshPercent,
    bool invert = false);
  ```

  Sets this **ccBlobParams** to segment the input image using the supplied relative threshold value. The specified percentage of low tail and high tail pixels are discarded, then the threshold pixel value is computed by determining the pixel value which lies at the specified percentage of the distance between the low tail pixel value and the high tail pixel value.

  Each pixel in the input image with a value below the computed threshold is assigned a weight of 0; each pixel in the input image with a value greater than or equal to the computed threshold is assigned a weight of 1.

  You can specify an invert flag to specify that pixels below the computed threshold are assigned a weight of 1 and pixels at or above the threshold are assigned a weight of 0.

Parameters

lowTailPercent The percentage of low tail pixels to discard before computing the threshold.

highTailPercent The percentage of pixels above which to discard high tail pixels before computing the threshold.

threshPercent The pixel value that lies *threshPercent* of the distance between the low tail pixel value and the high tail pixel value is used as the threshold value.

invert If *invert* is *true*, then all pixels in *image* with values greater than or equal to the computed threshold are set to 0; pixels with values less than the threshold are set to 1. If *invert* is *false*, then all pixels in *image* with values greater than or equal to the computed threshold are set to 1; pixels with values less than the threshold are set to 0.

Throws

ccBlobDefs::BadParams
Any percentage is not in the range 0 through 100, inclusive.

setSegmentationSoftThresh

```
void setSegmentationSoftThresh(c_UInt8 loThresh,
  c_UInt8 hiThresh, c_UInt8 softness, bool invert=false);

void setSegmentationSoftThresh(c_Int32 lowTailPercent,
  c_Int32 highTailPercent, c_Int32 lowThreshPercent,
  c_Int32 highThreshPercent, c_UInt8 softness,
  bool invert = false);
```

- ```
  void setSegmentationSoftThresh(c_UInt8 loThresh,
    c_UInt8 hiThresh, c_UInt8 softness, bool invert=false);
  ```

  Sets this **ccBlobParams** to segment the input image using the supplied soft threshold values.

  Each pixel in the input image with a value below the low threshold is assigned a weight of 0; each pixel in the input image with a value greater than or equal to the high threshold is assigned a weight of *softness*+1. The range of pixel values between the low and high threshold is divided into *softness* equally sized ranges. Pixels with values in each of these ranges are assigned values between 1 and *softness*.

  You can specify an invert flag to specify that pixels below the computed low threshold are assigned a weight of *softness*+1 and pixels at or above the computed high threshold are assigned a weight of 0.
  ```

Parameters

loThresh The low threshold. Pixels with values below *loThresh* are assigned a value of 0.

hiThresh The high threshold. Pixels with values greater than or equal to *hiThresh* are assigned a value of *softness*+1.

softness The number of intermediate pixel weights. The range of *loThresh* to *hiThresh* is divided into *softness* ranges. Pixels in each range receive a value equal to the number of the range in which they are.

softness should be in the range [1, *hiThresh* - *loThresh*]. Zero can be used, and is equivalent to hard thresholding with *hiThresh*. Higher *softness* values provide more accurate results, but processing may be slower than with a lower *softness* value.

invert If *invert* is *true*, then pixels with values greater than or equal to the high threshold are set to 0; pixels with values less than the low threshold are set to *softness*+1. If *invert* is *false*, then pixels with values greater than or equal to the high threshold are set to *softness*+1; pixels with values less than the low threshold are set to 0.

Throws

ccBlobDefs::BadParams

softness is equal to 255.
loThresh is greater than or equal to *hiThresh*.
softness is greater than (*hiThresh* minus *loThresh*).

- ```
  void setSegmentationSoftThresh(c_Int32 lowTailPercent,
    c_Int32 highTailPercent, c_Int32 lowThreshPercent,
    c_Int32 highThreshPercent, c_UInt8 softness,
    bool invert = false);
  ```

  Sets this **ccBlobParams** to segment the input image using the supplied soft threshold parameters. The specified percentage of low tail and high tail pixels are discarded, then two threshold pixel values are computed by determining the pixel values which lie at the specified percentages of the distance between the low tail pixel value and the high tail pixel value.

  Each pixel in the input image with a value below the computed low threshold is assigned a weight of 0; each pixel in the input image with a value greater than or equal to the computed high threshold is assigned a weight of *softness*+1. The range of pixel values
  ```

between the computed low and computed high threshold is divided into *softness* equally sized ranges. Pixels with values in each of these ranges are assigned values between 1 and *softness*.

You can specify an invert flag to specify that pixels below the computed low threshold are assigned a weight of *softness*+1 and pixels at or above the computed high threshold are assigned a weight of 0.

Parameters

lowTailPercent The percentage of low tail pixels to discard before computing the threshold.

highTailPercent The percentage of pixels above which to discard high tail pixels before computing the threshold.

lowThreshPercent

The pixel value that lies *lowThreshPercent* of the distance between the low tail pixel value and the high tail pixel value is used as the computed low threshold value.

highThreshPercent

The pixel value that lies *highThreshPercent* of the distance between the low tail pixel value and the high tail pixel value is used as the computed high threshold value.

softness The number of intermediate pixel weights. The range between the computed low and high thresholds is divided into *softness* ranges. Pixels in each range receive a value equal to the number of the range in which they are.

softness should be in the range [1, *hiThresh* - *loThresh*], where *hiThresh* and *loThresh* are the pixel values calculated from *lowThreshPercent* and *highThreshPercent*. If you believe you have images where these computed thresholds may lie close together, use a small *softness* value such as 1, 2, or 3.

invert If *invert* is *true*, then pixels with values greater than or equal to the computed high threshold are set to 0; pixels with values less than the computed low threshold are set to *softness*+1. If *invert* is *false*, then pixels with values greater than or equal to the computed high threshold are set to *softness*+1; pixels with values less than the computed low threshold are set to 0.

Notes

lowTailPercent must be less than *highTailPercent*, *lowThreshPercent* must be less than *highTailPercent*, and *softness* must be greater than or equal to 0.

Throws

ccBlobDefs::BadParams

softness is equal to 255.
Any percentage is not in the range of 0 through 100 inclusive.
lowTailPercent plus *highTailPercent* is greater than 100.
lowThreshPercent is greater than *highThreshPercent*.

setSegmentationThreshImage

```
void setSegmentationThreshImage(
  const cmStd vector<c_UInt8>& preMap,
  const ccPelBuffer_const<c_UInt8>& threshImg,
  const cmStd vector<c_UInt8>& postMap, c_UInt8 scaleVal);
```

Sets this **ccBlobParams** to segment the input image using the supplied threshold image and threshold image parameters.

The supplied pixel map is applied to the input image, then each pixel in the threshold image is subtracted from the corresponding pixel in the input image. A second pixel map is applied to the results of this subtraction.

You specify a scaling value to indicate the pixel value in the resulting image that represents a weight of 1.0. All pixels in the resulting image are interpreted on a linear scale relative to the scaling value; no pixel in the image should have a value greater than *scaleVal*.

Parameters

preMap — The pixel map to apply to the input image. Each pixel in the input image is used as an index into *preMap*. The input pixel value is replaced with the value from *preMap*.

preMap must be at least as large as the largest pixel value in the input image.

threshImg — The threshold image. *threshImg* must have the same dimensions as the input image. The value of each pixel in *threshImg* is subtracted from the corresponding pixel in the input image with the result clamped to 0. The image that results from this operation is mapped using *postMap*.

postMap — The pixel map to apply to the result of the image subtraction. Each pixel value that results from the subtraction of the *threshImg* from the input image is used as an index into *postMap*. The pixel value in the encoded image is the value found at that pixel value index in *postMap*.

postMap must be at least as large as the largest difference in pixel values between the input image and *threshImg*.

scaleVal The pixel value in the resulting image that represents a weight of 1.0. All pixels in the resulting image are interpreted on a linear scale relative to *scaleVal*; no pixel in *postMap* should have a value greater than *scaleVal*.

Notes

This function makes copies of *preMap*, *thresh*, and *postMap*. *threshImg* must be bound and located and is not copied. Any change to the pixels in *threshImg*'s root image will affect the segmentation.

Throws

ccBlobDefs::BadParams

scaleVal is equal to zero.
threshImg is unbound.

segmentationType

```
Segmentation segmentationType() const;
```

Returns the segmentation type of this **ccBlobParams**, one of the following values:

ccBlobParams::eNone
ccBlobParams::eMap
ccBlobParams::eHardThresh
ccBlobParams::eSoftThresh
ccBlobParams::eThreshImage

map

```
const cmStd vector<c_UInt8>& map() const;
```

If you called **setSegmentationMap()** to configure this **ccBlobParams**, this function returns the pixel map you specified.

If you called **setSegmentationThreshImage()** to configure this **ccBlobParams**, this function returns the pixel pre-map you specified.

Throws

ccBlobDefs::BadParams

Segmentation type is neither *ccBlobParams::eMap* nor *ccBlobParams::eThreshImage*.

postMap

```
const cmStd vector<c_UInt8>& postMap() const;
```

If you called **setSegmentationThreshImage()** to configure this **ccBlobParams**, this function returns the pixel post-map you specified.

Throws

ccBlobDefs::BadParams

Segmentation type is not *ccBlobParams::eThreshImage*.

thresh

```
c_UInt8 thresh() const;
```

If you called **setSegmentationHardThresh()** to configure this **ccBlobParams**, this function returns the threshold value.

If you called **setSegmentationSoftThresh()** to configure this **ccBlobParams**, this function returns the low threshold value.

Throws

ccBlobDefs::BadParams

Segmentation type is neither *ccBlobParams::eHardThresh* nor *ccBlobParams::eSoftThresh*.

hiThresh

```
c_UInt8 hiThresh() const;
```

If you called **setSegmentationSoftThresh()** to configure this **ccBlobParams**, this function returns the high threshold value.

Throws

ccBlobDefs::BadParams

Segmentation type is not *ccBlobParams::eSoftThresh*.

invert

```
bool invert() const;
```

If you called **setSegmentationSoftThresh()** or **setSegmentationHardThresh()** to configure this **ccBlobParams**, this function returns the value of the invert flag.

Throws

ccBlobDefs::BadParams

Segmentation type is neither *ccBlobParams::eHardThresh* nor *ccBlobParams::eSoftThresh*.

softness

```
c_UInt8 softness() const;
```

If you called **setSegmentationSoftThresh()** to configure this **ccBlobParams**, this function returns the softness value.

Throws

ccBlobDefs::BadParams

Segmentation type is not *ccBlobParams::eSoftThresh*.

isThreshPercent `bool isThreshPercent() const;`

If you called **setSegmentationSoftThresh()** or **setSegmentationHardThresh()** to configure this **ccBlobParams**, this function returns *true* if you specified relative (percentage) thresholds, *false* if you specified absolute (pixel value) thresholds.

Throws

ccBlobDefs::BadParams
Segmentation type is neither *ccBlobParams::eHardThresh* nor *ccBlobParams::eSoftThresh*.

lowTailPercent `c_Int32 lowTailPercent() const;`

If you called **setSegmentationSoftThresh()** or **setSegmentationHardThresh()** to configure this **ccBlobParams** and specified relative (percentage) thresholds, this function returns the low tail percentage value you specified.

Throws

ccBlobDefs::BadParams
Segmentation type is neither *ccBlobParams::eHardThresh* nor *ccBlobParams::eSoftThresh*.
Segmentation was not done with percentages.

hiTailPercent `c_Int32 hiTailPercent() const;`

If you called **setSegmentationSoftThresh()** or **setSegmentationHardThresh()** to configure this **ccBlobParams** and you specified relative (percentage) thresholds, this function returns the high tail percentage value you specified.

Throws

ccBlobDefs::BadParams
Segmentation type is neither *ccBlobParams::eHardThresh* nor *ccBlobParams::eSoftThresh*.
Segmentation was not done with percentages.

threshImage `const ccPelBuffer_const<c_UInt8>& threshImage() const;`

If you called **setSegmentationThreshImage()** to configure this **ccBlobParams**, this function returns the threshold image you specified.

Throws

ccBlobDefs::BadParams
Segmentation type is not *ccBlobParams::eThreshImage*.

scaleVal

```
c_UInt8 scaleVal() const;
```

If you called **setSegmentationNone()**, **setSegmentationMap** or **setSegmentationThreshImage()** to configure this **ccBlobParams**, this function returns the scaling value.

keepRLE

```
bool keepRLE() const;
void keepRLE(bool keep);
```

- `bool keepRLE() const;`

  Returns *true* if this **ccBlobParams** is configured to retain the **ccRLEBuffer** created when the input image is segmented.

- `void keepRLE(bool keep);`

  Configures this **ccBlobParams** to either retain or discard the **ccRLEBuffer** created when the input image is segmented.

  Parameters

keep	If *true*, this **ccBlobParams** will retain a copy of the **ccRLEBuffer**, if *false* the **ccRLEBuffer** will be discarded.

mask

```
const ccRLEBuffer& mask() const;
void mask(const ccRLEBuffer& m);
```

- `const ccRLEBuffer& mask() const;`

  Returns a reference to a **ccRLEBuffer** that contains the mask image that will be applied to the input image during segmentation.

  If no mask image has been specified for this **ccBlobParams**, calling **mask().isDegenerate()** returns *true*.

- `void mask(const ccRLEBuffer& theMask);`

  Specifies the mask to be applied to the input image before the image is segmented. Only pixels in the input image that correspond to nonzero pixels in *theMask* are included in the image to be segmented.

  Parameters

theMask	The mask image. *theMask* must have the same dimensions as the input image.

keepMasked

```
bool keepMasked() const;

void keepMasked(bool keep);
```

- `bool keepMasked() const;`

  Returns *true* if this **ccBlobParams** is configured to retain the **ccRLEBuffer** created by applying a mask image before the input image is segmented.

- `void keepMasked(bool keep);`

  Configures this **ccBlobParams** to either retain or discard the **ccRLEBuffer** image created by applying a mask image before the input image is segmented.

  Parameters

keep	If *true*, this **ccBlobParams** will retain a copy of the masked image, if *false* the masked image will be discarded.

morph

```
const cmStd vector<ceBlobParamsMorphOp>& morph() const;

void morph(const cmStd vector<ceBlobParamsMorphOp>& mOps);
```

- `const cmStd vector<ceBlobParamsMorphOp>& morph() const;`

  Returns a vector of **ccBlobParams::ceBlobParamsMophOp** that specifies the morphological operations that will be applied to the input image. Each element of the vector will have one of the following values:

  ccBlobParams::eMinH
  ccBlobParams::eMinV
  ccBlobParams::eMinS
  ccBlobParams::eMaxH
  ccBlobParams::eMaxV
  ccBlobParams::eMaxS
  ccBlobParams::eMinMaxH
  ccBlobParams::eMinMaxV
  ccBlobParams::eMinMaxS
  ccBlobParams::eMaxMinH
  ccBlobParams::eMaxMinV
  ccBlobParams::eMaxMinS

  If no morphological operations are specified, the returned vector has a length of 0. For more information, see the description of **ccBlobParams::ceBlobParamsMophOp**.

- `void morph(const cmStd vector<ceBlobParamsMorphOp>& mOps);`

  Specifies the morphological operations to be applied to the input image. You specify the morphological operations by supplying a vector of **ccBlobParams::ceBlobParamsMophOp**. Each element of the vector must have one of the following values:

  ccBlobParams::eMinH
  ccBlobParams::eMinV
  ccBlobParams::eMinS
  ccBlobParams::eMaxH
  ccBlobParams::eMaxV
  ccBlobParams::eMaxS
  ccBlobParams::eMinMaxH
  ccBlobParams::eMinMaxV
  ccBlobParams::eMinMaxS
  ccBlobParams::eMaxMinH
  ccBlobParams::eMaxMinV
  ccBlobParams::eMaxMinS

  To specify no morphological operations, supply a vector with a length of 0.

  Parameters

mOps	The morphological operations to perform.

keepMorphed

```
bool keepMorphed() const;
void keepMorphed(bool keep);
```

- `bool keepMorphed() const;`

  Returns *true* if this **ccBlobParams** is configured to retain the **ccRLEBuffer** created when the specified morphological operations are applied to the input image.

- `void keepMorphed(bool keep);`

  Configures this **ccBlobParams** to either retain or discard the **ccRLEBuffer** created when the specified morphological operations are applied to the input image.

  Parameters

keep	If *true*, this **ccBlobParams** will retain a copy of the image produced by the morphological operations, if *false* the image will be discarded.

connectivityType

```
ccBlobSceneDescription::Analysis connectivityType() const;

void connectivityType(
  ccBlobSceneDescription::Analysis cType);
```

- `ccBlobSceneDescription::Analysis connectivityType() const;`

  Returns the connectivity type configured for this **ccBlobParams**. The connectivity type is one of the following values:

  ccBlobSceneDescription::eGreyScale
  ccBlobSceneDescription::eLabelled
  ccBlobSceneDescription::eWholeImageGreyScale

- `void connectivityType(`
  `ccBlobSceneDescription::Analysis cType);`

  Sets the connectivity type for this **ccBlobParams**. The connectivity type must be one of the following values:

  ccBlobSceneDescription::eGreyScale
  ccBlobSceneDescription::eLabelled
  ccBlobSceneDescription::eWholeImageGreyScale

  Parameters

cType	The connectivity type to set.

connectivityCleanup

```
ccBlobSceneDescription::ConnectCleanup
  connectivityCleanup() const;

void connectivityCleanup(
  ccBlobSceneDescription::ConnectCleanup cType);
```

- `ccBlobSceneDescription::ConnectCleanup`
  `connectivityCleanup() const;`

  Returns the connectivity cleanup type configured for this **ccBlobParams**. The connectivity cleanup type is one of the following values:

  ccBlobSceneDescription::eNone
  ccBlobSceneDescription::ePrune
  ccBlobSceneDescription::eFill

- ```
  void connectivityCleanup(
    ccBlobSceneDescription::ConnectCleanup cType);
  ```

  Sets the connectivity cleanup type for this **ccBlobParams**. The connectivity cleanup type must be one of the following values:

  ccBlobSceneDescription::eNone
  ccBlobSceneDescription::ePrune
  ccBlobSceneDescription::eFill

  Parameters
  cType The connectivity cleanup type to set.

connectivityMinPels

```
c_Int32 connectivityMinPels() const;

void connectivityMinPels(c_Int32 min);
```

Specifies the minimum size, in pixels, of features returned by **cfBlobAnalysis()** when the **ccBlobSceneDescription::ConnectCleanup** value in effect is not *eNone.*

- ```
  c_Int32 connectivityMinPels() const;
  ```

  Returns the minimum feature size configured for this **ccBlobParams**.

- ```
  void connectivityMinPels(c_Int32 min);
  ```

  Sets the minimum feature size for this **ccBlobParams**.

  Parameters
  min The minimum feature size, in pixels.

  Throws
  ccBlobDefs::BadParams
  min is less than zero.

useMaskForInterior

```
bool useMaskForInterior() const;

void useMaskForInterior(bool useMaskForInterior);
```

This flag determines whether the image mask contained in this object will be used during the computation of **ccBlob::isInterior()**. If this flag is true and the mask is not degenerate, the mask is used. Otherwise, the mask is not used.
```

- `bool useMaskForInterior() const;`

  Returns the current *useMaskForInterior* flag, true or false.

- `void useMaskForInterior(bool useMaskForInterior);`

  Sets the *useMaskForInterior* flag, true or false.

  Parameters

  useMaskForInterior
  The new flag.

ccBlobResults

```
#include <ch_cvl/blobtool.h>

class ccBlobResults: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the results from a blob analysis.

Constructors/Destructors

ccBlobResults

```
ccBlobResults();

~ccBlobResults();
```

- `ccBlobResults();`

  Constructs a **ccBlobResults** with the following default values:

  - All timing information set to 0.
  - All intermediate images (RLE image, masked image, morphology output image) set to degenerate images.
  - Blob scene description set to *NULL*.

Operators

operator=

```
ccBlobResults& operator= (const ccBlobResults& rhs);
```

Assignment.

Public Member Functions

connectedBlobs

```
ccBlobSceneDescription * connectedBlobs() const;
```

Returns a pointer to the **ccBlobSceneDescription** produced by blob analysis.

Notes

The result structure retains ownership of the BSD object.

relinquishBSDOwnership

```
void relinquishBSDOwnership();
```

Sets this **ccBlobResults**'s internal **ccBlobSceneDescription** pointer to *NULL*. If you call this function, you *must* have already called **ccBlobSceneDescription::connectedBlobs()**, and you are responsible for deleting the **ccBlobSceneDescription** created by the call.

If you call this function without having called **ccBlobSceneDescription::connectedBlobs()**, you will not be able to obtain the results of the blob analysis, and your application will be unable to recover the memory allocated for the **ccBlobSceneDescription**.

RLETime

```
double RLETime() const;
```

Returns the amount of time, in seconds, required to encode the input image as a **ccRLEBuffer**.

rle

```
const ccRLEBuffer& rle() const;
```

Returns a **ccRLEBuffer** that contains the image produced during the segmentation step of this blob analysis.

maskTime

```
double maskTime() const;
```

Returns the amount of time, in seconds, required to apply the mask image to the input image.

masked

```
const ccRLEBuffer& masked() const;
```

Returns a **ccRLEBuffer** that contains the image produced by applying the mask image.

morphTime

```
double morphTime() const;
```

Returns the amount of time, in seconds, required to apply the specified morphological operations to the input image.

morphed

```
const ccRLEBuffer& morphed() const;
```

Returns a **ccRLEBuffer** that contains the image produced by applying the morphological operations.

connectTime `double connectTime() const;`

Returns the amount of time, in seconds, required to perform the connectivity analysis.

ccBlobResults

ccBlobSceneDescription

```
#include <ch_cvl/blobdesc.h>

class ccBlobSceneDescription: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains a **ccBlob** for each feature that was identified by the blob analysis.

Information about individual **ccBlob**s within a **ccBlobSceneDescription** can be obtained using the **ccBlob** member functions.

Constructors/Destructors

ccBlobSceneDescription

```
ccBlobSceneDescription();

~ccBlobSceneDescription();

ccBlobSceneDescription(const ccBlobSceneDescription& rhs);
```

- `ccBlobSceneDescription();`

  Constructs an empty **ccBlobSceneDescription**.

- `~ccBlobSceneDescription();`

  Destroys this **ccBlobSceneDescription** and all of its contained **ccBlob** objects.

Enumerations

Analysis

```
enum Analysis;
```

This enumeration defines the types of connectivity analysis that can be performed on an image.

Value	Meaning
eGreyScale	Connected object pixels are grouped and analyzed as individual features (blobs and holes). Blobs (made up of object pixels) are 8-connected. Holes (made up of background pixels) are 4-connected.
eLabelled	All pixels with the same label value are connected into individual features. No concept of object and background. All features are 6-connected.
eWholeImageGreyScale	All of the object pixels in the image are analyzed as a single object, regardless of whether or how they are connected to each other. No connectivity is performed.

ConnectCleanup

```
enum ConnectCleanup;
```

This enumeration defines the types of connectivity cleanup that can be performed during blob analysis.

Value	Meaning
eNone	No connectivity cleanup.

Value	Meaning
ePrune	Features below a specified size threshold are not counted as part of the topology of the blob scene. The size and shape measures of features that contain pruned features are reported taking into account the area of the pruned features.
eFill	Features below a specified size threshold are filled in with the pixel value of the surrounding feature.

SortOrder

```
enum SortOrder;
```

This enumeration defines the available sort orders. You can specify the sort order and measure that determines the order in which features are returned to you.

Value	Meaning
eDescending	Features are returned from largest to smallest value.
eAscending	Features are returned from smallest to largest value.

Public Member Functions

isDegenerate

```
bool isDegenerate() const;
```

Returns true if this **ccBlobSceneDescription** was default constructed.

connectivityKind

```
Analysis connectivityKind() const;
```

Returns the type of connectivity analysis used to generate the information in this **ccBlobSceneDescription**. Returns one of the following values:

ccBlobSceneDescription::eGreyScale
ccBlobSceneDescription::eLabelled
ccBlobSceneDescription::eWholeImageGreyScale

scaleVal

```
c_UInt8 scaleVal() const;
```

Returns the scaling value used to perform the grey-scale connectivity analysis that produced this **ccBlobSceneDescription**.

cleanupKind

```
ConnectCleanup cleanupKind() const;
```

Returns the type of connectivity cleanup performed to generate the information in this **ccBlobSceneDescription**. Returns one of the following values:

ccBlobSceneDescription::eNone
ccBlobSceneDescription::ePrune
ccBlobSceneDescription::eFill

minPels

```
c_Int32 minPels() const;
```

Returns the minimum feature size applied during the connectivity cleanup operation performed to generate the information in this **ccBlobSceneDescription**.

sceneWindow

```
ccPelRect sceneWindow() const;
```

Returns the dimensions of the **ccRLEBuffer** upon which connectivity analysis was performed.

clientFromImageXformBase

```
cc2XformBasePtrh_const clientFromImageXformBase() const;

void clientFromImageXformBase(
  const cc2XformBasePtrh_const& xform, bool copy = true);

void clientFromImageXformBase(const cc2XformBase& xform);
```

- `cc2XformBasePtrh_const clientFromImageXformBase() const;`

  Returns the transformation object that it is suitable for transforming the **ccRLEBuffer** coordinates to the client's reference coordinates.

- ```
  void clientFromImageXformBase(
    const cc2XformBasePtrh_const& xform, bool copy = true);
  ```

  Sets this **ccBlobSceneDescription**'s transformation object suitable for transforming the **ccRLEBuffer** coordinates to the client's reference coordinates.
  ```

Parameters

xform	A pointer handle to the transformation object.
copy	If true, this window is assigned a copy of *xform*. If false, this window is assigned a reference to *xform*.

Notes

If *copy* is false, you must ensure that *xform* will not change during this **ccBlobSceneDescription**'s lifetime.

- `void clientFromImageXformBase(const cc2XformBase& xform);`

Sets this window's transformation object suitable for transforming the **ccRLEBuffer** coordinates to the client's reference coordinates.

Parameters

xform	A transformation object.

Notes

This setter always makes a copy of *xform*.

Both **imageFromClientXformBase()** and **clientFromImageXformBase()** setters set the same object. Use one or the other, but not both. The deprecated functions **imageFromClientXform()** and **clientFromImageXform()** setters also operate on the same object.

imageFromClientXformBase

```
cc2XformBasePtrh_const imageFromClientXformBase() const;

void imageFromClientXformBase(
  const cc2XformBasePtrh_const& xform, bool copy = true);

void imageFromClientXformBase(const cc2XformBase& xform);
```

- `cc2XformBasePtrh_const imageFromClientXformBase() const;`

Returns the transformation object suitable for transforming the client's reference coordinates to the **ccRLEBuffer**'s coordinates.

- `void imageFromClientXformBase(`
  `const cc2XformBasePtrh_const& xform, bool copy = true);`

Sets this **ccBlobSceneDescription**'s transformation object suitable for transforming the client's reference coordinates to the **ccRLEBuffer**'s coordinates.

Parameters

xform	A pointer handle to the transformation object.
copy	If true, this window is assigned a copy of *xform*. If false, this window is assigned a reference to *xform*.

Notes

If *copy* is false, you must ensure that *xform* will not change during this window's lifetime.

- `void imageFromClientXformBase(const cc2XformBase& xform);`

Sets this **ccBlobSceneDescription**'s transformation object suitable for transforming the client's reference coordinates to the **ccRLEBuffer**'s coordinates.

Parameters

xform	A transformation object.

Notes

This setter always makes a copy of *xform*.

Both **imageFromClientXformBase()** and **clientFromImageXformBase()** setters set the same object. Use one or the other, but not both. The deprecated functions **imageFromClientXform()** and **clientFromImageXform()** setters also operate on the same object.

imageFromClientXform

```
cc2Xform imageFromClientXform() const;

void imageFromClientXform(
  const cc2Xform& imageFromClient);
```

- `cc2Xform imageFromClientXform() const;`

Returns a **cc2Xform** that describes the transformation between the client coordinate system associated with the **ccRLEBuffer** upon which connectivity analysis was performed and its image coordinate system.

Notes

This function is deprecated; use **imageFromClientXformBase()** instead.

- ```
  void imageFromClientXform(
    const cc2Xform& imageFromClient);
  ```

  Sets the **cc2Xform** that describes the transformation between the client coordinate system associated with the **ccRLEBuffer** upon which connectivity analysis was performed and its image coordinate system.

  Setting this **cc2Xform** also sets the **cc2Xform** that describes the transformation between image coordinates and client coordinates.

  Parameters
  imageFromClient The transformation to set.

  Notes
  This function is deprecated; use **imageFromClientXformBase()** instead.

clientFromImageXform

```
cc2Xform clientFromImageXform() const;

void clientFromImageXform(
  const cc2Xform& clientFromImage);
```

- ```
  cc2Xform clientFromImageXform() const;
  ```

  Returns a **cc2Xform** that describes the transformation between the image coordinate system associated with the **ccRLEBuffer** upon which connectivity analysis was performed and its client coordinate system.

  Notes
  This function is deprecated; use **clientFromImageXformBase()** instead.

- ```
  void clientFromImageXform(
    const cc2Xform& clientFromImage);
  ```

  Sets the **cc2Xform** that describes the transformation between the image coordinate system associated with the **ccRLEBuffer** upon which connectivity analysis was performed and its client coordinate system.

  Setting this **cc2Xform** also sets the **cc2Xform** that describes the transformation between client coordinates and image coordinates.

  Parameters
  clientFromImage The transformation to set.

  Notes
  This function is deprecated; use **clientFromImageXformBase()** instead.
  ```

numBlobs

```
c_Int32 numBlobs(bool filtered = true) const;
```

Returns the number of features in this **ccBlobSceneDescription**. In the case of grey-scale connectivity, this includes both blobs and holes.

Parameters

filtered — If *filtered* is true, only features that meet the current filtering criteria are included in the returned count.

getBlob

```
const ccBlob* getBlob(c_Int32 id) const;
```

Returns a pointer to the **ccBlob** that has the specified ID.

Parameters

id — The ID of the **ccBlob** to return. *id* must be between 1 and the number of features in this **ccBlobSceneDescription**, inclusive.

preCompute

```
void preCompute(ccBlob::Measure theMeasure,
  bool filtered = true) const;
```

Pre-computes the specified measure for all features in this **ccBlobSceneDescription**.

Ordinarily, a particular measure for a particular feature is not computed until you specifically request it, or until the measure is used as a sorting or filtering criterion. You call this function to force the computation of a particular measure for all of the features in this **ccBlobSceneDescription**.

Parameters

theMeasure — The blob measure to pre-compute. *theMeasure* must be one of the following values:

ccBlob::eLabel
ccBlob::eArea
ccBlob::eNumSteps
ccBlob::ePerimeter
ccBlob::eNumChildren
ccBlob::eCenterMassX
ccBlob::eCenterMassY
ccBlob::eInertiaX
ccBlob::eInertiaY
ccBlob::eInertiaMin
ccBlob::eInertiaMax
ccBlob::eElongation
ccBlob::eAngle
ccBlob::eAcircularity
ccBlob::eAcircularityRms
ccBlob::eIsInterior

ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY
ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY
ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

filtered — If *filtered* is true, then *theMeasure* is pre-computed only for features that meet the current filtering criteria.

setFilter

```
void setFilter(ccBlob::Measure theMeasure, double loLimit,
  double hiLimit, bool invert=false);
```

Sets a filtering criterion for the specified measure. Only features which meet the specified criterion will be considered and/or returned by certain **ccBlob** and **ccBlobSceneDescription** member functions that, optionally, take filtering into account.

You can specify only one filter per measure. If you specify a filter for a measure which already has a filter, the error *ccBlobSceneDescription:DuplicateFilter* is thrown.

You can specify any number of filters for a single **ccBlobSceneDescription**. Each filter you specify is assigned an index value, starting with 0.

Parameters

theMeasure The measure on which to apply a filter. *theMeasure* must be one of the following values:

ccBlob::eLabel
ccBlob::eArea
ccBlob::eNumSteps
ccBlob::ePerimeter
ccBlob::eNumChildren
ccBlob::eCenterMassX
ccBlob::eCenterMassY
ccBlob::eInertiaX
ccBlob::eInertiaY
ccBlob::eInertiaMin
ccBlob::eInertiaMax
ccBlob::eElongation
ccBlob::eAngle
ccBlob::eAcircularity
ccBlob::eAcircularityRms
ccBlob::eIsInterior
ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY
ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY

ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

loLimit — The low limit for the filter. Only features with values for the specified measure that are greater than or equal to *loLimit* are returned.

hiLimit — The high limit for the filter. Only features with values for the specified measure that are less than or equal to *hiLimit* are returned.

invert — If *invert* is *false* (the default), then only features where the value of *theMeasure* is between *loLimit* and *hiLimit* are returned. If *invert* is *true*, then only features where the value of *theMeasure* is less than *loLimit* or greater than *hiLimit* are returned.

Throws

ccBlobSceneDescription::DuplicateFilter
You have specified a measure for which there already is a filter.

getFilter

```
bool getFilter(ccBlob::Measure theMeasure, double& loLimit,
  double& hiLimit, bool& invert) const;

void getFilter(c_Int32 index, ccBlob::Measure& theMeasure,
  double& loLimit, double& hiLimit, bool& invert) const;
```

- `bool getFilter(ccBlob::Measure theMeasure, double& loLimit, double& hiLimit, bool& invert) const;`

Gets the currently specified filtering criteria for the specified measure.

Parameters

theMeasure — The measure about which to obtain filter information. *theMeasure* must be one of the following values:

ccBlob::eLabel
ccBlob::eArea
ccBlob::eNumSteps
ccBlob::ePerimeter
ccBlob::eNumChildren
ccBlob::eCenterMassX
ccBlob::eCenterMassY
ccBlob::eInertiaX
ccBlob::eInertiaY
ccBlob::eInertiaMin
ccBlob::eInertiaMax

ccBlob::eElongation
ccBlob::eAngle
ccBlob::eAcircularity
ccBlob::eAcircularityRms
ccBlob::eIsInterior
ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY
ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY
ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

loLimit — A reference to a **double** into which the low limit for the filter is written.

hiLimit — A reference to a **double** into which the high limit for the filter is written.

invert — A **bool** into which the value of the invert flag is written.

- `void getFilter(c_Int32 index, ccBlob::Measure& theMeasure, double& loLimit, double& hiLimit, bool& invert) const;`

  Gets the filtering criteria for the specified filter. As you apply filters to a **ccBlobSceneDescription**, the filters are assigned an index value, starting with 0 for the first filter you apply. This function lets you obtain information about a filter based on its index value.

  Parameters

index	The index of the filter. This value must be greater than or equal to 0 and less than or equal to the number of filters.
theMeasure	A reference to a **ccBlob::Measure** into which the measure associated with this filter is written.
loLimit	A reference to a **double** into which the low limit for the filter is written.
hiLimit	A reference to a **double** into which the high limit for the filter is written.
invert	A **bool** into which the value of the invert flag is written.

unSetFilter `void unSetFilter(ccBlob::Measure theMeasure);`

Clears the filter associated with the specified measure. The indices of other filters may change as a result of calling this function.

Parameters

theMeasure	The measure to clear. *theMeasure* must be one of the following values: *ccBlob::eLabel* *ccBlob::eArea* *ccBlob::eNumSteps* *ccBlob::ePerimeter* *ccBlob::eNumChildren* *ccBlob::eCenterMassX* *ccBlob::eCenterMassY* *ccBlob::eInertiaX* *ccBlob::eInertiaY* *ccBlob::eInertiaMin* *ccBlob::eInertiaMax* *ccBlob::eElongation* *ccBlob::eAngle* *ccBlob::eAcircularity* *ccBlob::eAcircularityRms*

ccBlob::eIsInterior
ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY
ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY
ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

clearFilters

```
void clearFilters();
```

Clears all filters associated with this **ccBlobSceneDescription**.

numFilters

```
c_Int32 numFilters() const;
```

Returns the number of filters applied to this **ccBlobSceneDescription**.

setSort

```
void setSort(ccBlob::Measure theMeasure,
  SortOrder theOrder);
```

Sets the sort order for this **ccBlobSceneDescription**. The sort order controls the order in which individual **ccBlob**s are returned.

Parameters

theMeasure The measure upon which to sort the features. *theMeasure* must be one of the following values:

ccBlob::eLabel
ccBlob::eArea
ccBlob::eNumSteps
ccBlob::ePerimeter
ccBlob::eNumChildren
ccBlob::eCenterMassX
ccBlob::eCenterMassY
ccBlob::eInertiaX
ccBlob::eInertiaY
ccBlob::eInertiaMin
ccBlob::eInertiaMax
ccBlob::eElongation
ccBlob::eAngle
ccBlob::eAcircularity
ccBlob::eAcircularityRms
ccBlob::eIsInterior
ccBlob::eImageBoundCenterX
ccBlob::eImageBoundCenterY
ccBlob::eImageBoundMinX
ccBlob::eImageBoundMaxX
ccBlob::eImageBoundMinY
ccBlob::eImageBoundMaxY
ccBlob::eImageBoundWidth
ccBlob::eImageBoundHeight
ccBlob::eImageBoundAspect
ccBlob::eMedianX
ccBlob::eMedianY
ccBlob::eBoundCenterX
ccBlob::eBoundCenterY
ccBlob::eBoundMinX
ccBlob::eBoundMaxX
ccBlob::eBoundMinY
ccBlob::eBoundMaxY
ccBlob::eBoundWidth
ccBlob::eBoundHeight
ccBlob::eBoundAspect
ccBlob::eBoundPrincipalMinX
ccBlob::eBoundPrincipalMaxX
ccBlob::eBoundPrincipalMinY
ccBlob::eBoundPrincipalMaxY

ccBlob::eBoundPrincipalWidth
ccBlob::eBoundPrincipalHeight
ccBlob::eBoundPrincipalAspect

theOrder — The order in which to sort the features. *theOrder* must be one of the following values:

ccBlobSceneDescription::eAscending
ccBlobSceneDescription::eDescending

getSort

```
bool getSort(ccBlob::Measure& theMeasure,
  SortOrder& theOrder) const;
```

Returns *true* if a call to **setSort()** has been made to enable sorting for this **ccBlobSceneDescription**. Otherwise the function returns *false*. If the function returns *true*, the current sort order and sort measure are placed in *theOrder* and *theMeasure*.

Parameters

theMeasure — A reference to a **ccBlob::Measure** into which is written the measure upon which the features in this **ccBlobSceneDescription** are sorted.

theOrder — A reference to a **ccBlobSceneDescription::SortOrder** into which the sort order is written.

disableSort

```
void disableSort();
```

Disables sorting for this **ccBlobSceneDescription**. If sorting is disabled, then features are returned in an unspecified order and **getSort()** returns *false*.

Calling this function is the *only* way to prevent the Blob tool from sorting features. If you have never made a call to **setSort()**, features are sorted by area. If you call **clearSort()**, features will be sorted using the measure supplied to the most recent call to **setSort()**, or by area if no call to **setSort()** has been made.

Calling this function if sorting is already disabled has no effect.

clearSort

```
void clearSort();
```

Calling this function causes **getSort()** to return false, but it does not actually disable the sorting of features. To disable the sorting of features, use **disableSort()**.

If you call this function, features will still be sorted using the measure supplied to the most recent call to **setSort()**. If no calls have been made to **setSort()**, then the features are sorted by area.

This function is present for backward compatibility only.

firstTop

```
const ccBlob* firstTop(bool filtered = true) const;
```

Returns a pointer to a **ccBlob** representing the first top-level feature in this **ccBlobSceneDescription**. You can specify that only features meeting the current filtering criteria be returned by this function.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

lastTop

```
const ccBlob* lastTop(bool filtered = true) const;
```

Returns a pointer to a **ccBlob** representing the last top-level feature in this **ccBlobSceneDescription**. You can specify that only features meeting the current filtering criteria be returned by this function.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

allBlobs

```
cmStd vector<const ccBlob*> allBlobs(bool filtered = true)
  const;
```

Returns a vector of pointers to **ccBlob**. The vector contains pointers to all the features in this **ccBlobSceneDescription**, in the current sort order. You can specify that only features meeting the current filtering criteria be returned by this function.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

Notes

There is no relationship between a feature's ID and its position in the vector returned by **allBlobs()**.

makeImage

```
ccPelBuffer<c_UInt8> makeImage(bool filtered = true,
  c_UInt8 background=0) const;
```

Returns a **ccPelBuffer<c_UInt8>** that contains an image of this **ccBlobSceneDescription**.

Parameters

filtered — If *true*, only features that meet the current filtering criteria are returned, and features are sorted according to the current sort criteria. If *false*, no filtering or sorting is performed.

background — Specifies the pixel value for the background of the returned image.

extremaExcludeArea

```
void extremaExcludeArea(double clientArea);

double extremaExcludeArea(bool& isClient, bool& isPercent)
  const;
```

- `void extremaExcludeArea(double clientArea);`

  Sets the amount of each feature to exclude when computing measures related to the arbitrarily aligned bounding box.

  Parameters

  clientArea — The amount of the feature to exclude in terms of client coordinate system-sized pixels.

- `double extremaExcludeArea(bool& isClient, bool& isPercent) const;`

  Returns the amount of each feature that this **ccBlobSceneDescription** is currently configured to exclude when computing the arbitrarily aligned bounding box.

  Parameters

  isClient — A reference to a **bool** into which *true* is written if the returned value is given in client coordinate-sized pixels. If *isClient* is set to *false*, then the return value is given in image coordinate-sized pixels.

  isPercent — A reference to a **bool** into which *true* is written if the returned value is given in as a percentage of the area of the feature. If *isPercent* is set to *false*, the return value is given in terms of pixel area.

extremaExcludeAreaPels

```
void extremaExcludeAreaPels(double pelArea);
```

Sets the amount of each feature to exclude when computing the arbitrarily aligned bounding box.

Parameters

clientArea The amount of the feature to exclude in terms of image coordinate system-sized pixels.

extremaExcludeAreaPercent

```
void extremaExcludeAreaPercent(double percent);
```

Sets the amount of each feature to exclude when computing the arbitrarily aligned bounding box.

Parameters

clientArea The amount of the feature to exclude in terms of the percentage of pixels to exclude.

extremaAngle

```
ccRadian extremaAngle() const;

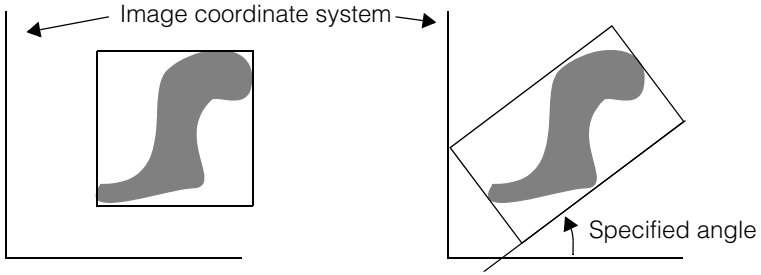
void extremaAngle(const ccRadian& angle);
```

- `ccRadian extremaAngle() const;`

  Returns the angle at which various measures are computed, relative to the client coordinate system's x-axis, in radians, for all features in this **ccBlobSceneDescription**.

- `void extremaAngle(const ccRadian& angle);`

  Sets the angle at which the bounding box is computed, relative to the client coordinate system's x-axis, in radians, for all features in this **ccBlobSceneDescription**. The following diagram illustrates the effect of specifying an angle value:



No angle specified Angle specified

Parameters

angle — The angle at which to compute bounding boxes and bounding box-related measures for features in this **ccBlobSceneDescription**.

draw

```
void draw(ccGraphicList& graphList,
 c_UInt32 drawMode = ccBlobDefs::eDrawStandard,
 bool filtered=true) const;
```

Appends result graphics for all of the features in this **ccBlobSceneDescription** to the supplied **ccGraphicList**. To append result graphics for only those features that meet the current filtering criteria, specify true for the *filtered* argument.

The graphics are drawn in client coordinates.

Parameters

graphList — The graphics list to append the graphics to.

drawMode — The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccBlobDefs::eDrawImageCenterOfMass
ccBlobDefs::eDrawCenterOfMass
ccBlobDefs::eDrawLabel
ccBlobDefs::eDrawImageBoundingBox
ccBlobDefs::eDrawBoundingBox
ccBlobDefs::eDrawBoundingTrace
ccBlobDefs::eDrawStandard

filtered — If true, only features which meet the current filtering criteria have results drawn.

ccBoard

```
#include <ch_cvl/board.h>

class ccBoard;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This abstract class is used to describe Cognex hardware such as frame grabbers. For each physical Cognex vision device (frame grabber) installed on your PC, there is a single object derived from **ccBoard** that refers to it.

For cameras that do not use frame grabbers, such as GigE Vision cameras, there is a single **ccBoard** object that represents all cameras of the same type.

Your application can get a **ccBoard** object by using the **get()** function.

Constructors/Destructors

Construction and destruction of derived classes is done automatically.

Enumerations

ceState

```
enum ceState;
```

This enumeration defines the current state of the hardware.

Value	Meaning
ckNotSupported = 0	Not supported for the board.
ckReal = 1	Board is physically connected.
ckVirtual = 2	Board is not connected/missing, for example, a GigE camera that lost power.
ckMisconfigured = 3	Board is on a different subnet from the NIC.

Public Member Functions

getHardwareStatus

```
virtual ceState getHardwareStatus(bool cached);
```

Gets the current state of the hardware. See `enum ceState` for details.

Notes

This should be used only by **ccBoard** objects that support dynamic refresh.

name

```
const TCHAR* name();
```

Return the name of this board as a null-terminated string.

serialNumber

```
ccCvlString serialNumber() const;
```

Returns an ASCII string containing the serial number of the Cognex hardware device represented by this **ccBoard**.

Throws

ccBoard::BadEERAMContents
The board serial number cannot be read because the EERAM contents are invalid.

upgradeCode

```
virtual ccCvlString upgradeCode() const;
```

Returns the upgrade code for this board.

Notes

If this board does not have an upgrade code, this function returns a zero-length string.

Throws

ccBoard::BadEERAMContents
The EERAM cannot be read.

writeEERAMData

```
void writeEERAMData(c_Int32 offset,
 const cmStd vector<c_UInt8> &data);
```

Write user-defined data into EERAM starting at the specified offset.

Parameters

offset — The location within user EERAM area at which to start writing data. Must be in the range 0 through **sizeEERAMData()**.

data — The data to write.

Throws

ccBoard::BadParams

data is too big to fit into user EERAM area.

readEERAMData

```
void readEERAMData(c_Int32 offset,
  cmStd vector<c_UInt8> &data, c_Int32 nBytes);
```

Read data from the user EERAM area.

Parameters

offset	The location within user EERAM area at which to start reading data. Must be in the range 0 through **sizeEERAMData()**.
data	The data read from user EERAM.
nBytes	The number of bytes to read.

Throws

ccBoard::BadParams

nBytes is too big and would read beyond the end of user EERAM.

sizeEERAMData

```
c_Int32 sizeEERAMData() const;
```

Return the size of the user EERAM data area.

Notes

Not all hardware devices provide a user EERAM area. If a device does not support a user EERAM data area, this function returns zero.

Static Functions

count

```
static c_Int32 count();
```

Returns the number of Cognex boards installed.

Notes

This function is not available at static initialization time.

For cameras that appear as boards to CVL (GigE Vision cameras, for example, the count of the number of cameras is available only after the cameras have finished their network negotiation. Use **isEnumerationComplete()** to determine when this is the case.

This function is intended for host use. If you call **count()** from an application running on an embedded system, such as the Cognex MVS-82400, it always returns 1 no matter how many boards are installed in the host system.

Throws

ccBoard::StaticInitDisorder
This function was called during static initialization time.

get

```
static ccBoard& get(c_Int32 i = 0);
```

Return the *i*th board installed. Board numbering starts at 0.

Parameters

i The board number.

Throws

ccBoard::BadParams
i is not within the range of 0 through **count()** - 1, or no boards are installed (**count()** returns 0).

ccBoard::StaticInitDisorder
This function was called during static initialization time.

Notes

This function is not available at static initialization time.

Boards are sorted alphabetically in increasing order according to board type. Within a given board type, the order may be operating-system and CVL-version dependent.

isEnumerationComplete

```
static bool isEnumerationComplete(double limitSec=0.0);
```

Returns True if the enumeration of boards is complete.

Parameters

limitSec The number of seconds to wait before returning if enumeration is not complete.

RefreshCameraList

```
static void RefreshCameraList();
```

Refreshes the list of hardware by detecting newly added devices.

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occurred while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

ccBoundary

```
#include <ch_cvl/pmibnd.h>

class ccBoundary;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains boundary data. The member functions of the class return information about the geometrical properties of the boundary and allow for geometrical comparisons between two boundaries. This **ccBoundary** can be the trained, matched, extra or missing boundary returned by PatInspect. The boundary information embodied by the class includes:

- The position of each boundary point
- The direction of each boundary point
- The weight of each boundary point
- The matchQuality value of each boundary point
- The minimum enclosing rectangle of the boundary
- The mean position of the boundary
- The weighted mean position of the boundary.

Constructors/Destructors

ccBoundary

```
ccBoundary();

ccBoundary(const cmStd vector<ccInspectBPoint>& points,
  ccBoundaryDefs::BoundaryType type=
                                    ccBoundaryDefs::eTrained,
  const cc2Xform &pose=cc2Xform::I);

ccBoundary(const cmStd vector<cc2Vect>& points,
  const cc2Xform &pose=cc2Xform::I);
```

- `ccBoundary();`

  Creates a **ccBoundary** that has no points.

- ```
  ccBoundary(const cmStd vector<ccInspectBPoint>& points,
    ccBoundaryDefs::BoundaryType type=
                                        ccBoundaryDefs::eTrained,
    const cc2Xform &pose=cc2Xform::I);
  ```

  Creates a **ccBoundary** from the boundary type specified by *type*.

  Parameters

points	The list of boundary points of this **ccBoundary**.
type	The type of boundary. *type* must be one of the following: *ccBoundaryDefs::eTrainedt* *ccBoundaryDefs::eMatch* *ccBoundaryDefs::eMissing* *ccBoundaryDefs::eExtra*
pose	The **cc2Xform** that maps the boundary to client coordinates.

  Notes

  If type is *ccBoundaryDefs::eTrained* only the boundary points from the trained pattern that are matched at run-time are included in this **ccBoundary**.

- ```
  ccBoundary(const cmStd vector<cc2Vect>& points,
    const cc2Xform &pose=cc2Xform::I);
  ```

  Creates a **ccBoundary** from the *points* list. The direction associated with each boundary point is computed from the supplied list of points. The weight of each boundary point is set to 1.0. The matchQuality value of each boundary point is set to 0.0.

  Parameters

points	The list of points that make up the boundary.
pose	The **cc2Xform** that maps *points* to client coordinates.

  Notes

  This constructor is provided for testing purposes.

Public Member Functions

unweightedMeanPosition

```
cc2Vect unweightedMeanPosition() const;
```

Returns the unweighted mean position of this **ccBoundary**.

Notes

The unweighted mean position may not lie on the boundary. The unweighted mean position is computed by the constructor.

weightedMeanPosition

```
cc2Vect weightedMeanPosition() const;
```

Returns the weighted mean position of this **ccBoundary**.

Notes

The weighted mean position may not lie on the boundary. The weighted mean position is computed by the constructor.

area

```
double area(
  ccBoundaryDefs::AreaMethod method=
  ccBoundaryDefs::eSimple)const;
```

Returns the area of this **ccBoundary** according to the modality specified by *method*. If *method* is ***ccBoundaryDefs::eSimple*** the function computes the area of the polygon resulting from connecting adjacent boundary points with straight segments (if the boundary is open the two end-points are connected with a straight segment to close the polygon). If *method* is ***ccBoundaryDefs::eConvex*** the function computes the area of the convex hull of this **ccBoundary** (the convex hull of a boundary is the smallest enclosing polygon of the boundary, see *ccBoundaryDefs*).

Parameters

method — The modality used to compute the area of this **ccBoundary**. *method* must be one of the following:
ccBoundaryDefs::eSimplet
ccBoundaryDefs::eConvex

Throws

ccBoundaryDefs::DegenerateShape
method is ***ccBoundaryDefs::eSimple*** and the shape of the polygon that connects the boundary points is not simple (this means that the straight line that closes the boundary intersect the boundary).

Notes

The area cannot be computed if this **ccBoundary** crosses on itself.

convexHull

```
ccBoundary convexHull() const;
```

Returns the boundary that is the convex hull of this **ccBoundary**. The convex hull is the minimum enclosing polygon of this ccBoundary.

rect

```
ccRect rect() const;
```

Returns the minimum enclosing rectangle of this **ccBoundary** in client coordinates. The minimum enclosing rectangle of this **ccBoundary** is computed by the constructor.

draw

```
void draw(ccUITablet &tablet,
  bool connected=true,
  const ccColor &color=ccColor::greenColor(),
  const ccUITablet::Layers &layer=
  ccUITablet::eImageLayer) const;
```

Draws this **ccBoundary** in the supplied **ccUITablet** *tablet*.

Parameters

tablet	The tablet used to draw this **ccBoundary**.
connected	If true the function draws the polygon obtained by connecting the adjacent boundary points of this **ccBoundary** with straight segments.
color	The color of this **ccBoundary**.
layer	The layer into which this **ccBoundary** is drawn.

minDist

```
double minDist(const ccBoundary &bnd2,
  cc2Vect &pnt1,cc2Vect &pnt2,
  ccBoundaryDefs::DistanceMethod method=
  ccBoundaryDefs::eExhaustive) const;
```

Returns the distance between this **ccBoundary** and the boundary *bnd2* according to the modality specified by *method*. The positions of the two closest points are stored in *pnt1* (for this **ccBoundary**) and *pnt2* (for *bnd2*). The two closest points depend on the modality chosen to measure the distance between the two boundaries (see *ccBoundaryDefs*).

Parameters

method	The mode used to compute the distance between boundaries. *method* must be one of the following: *ccBoundaryDefs::eExhaustive* *ccBoundaryDefs::eMinEndPnt* *ccBoundaryDefs::eMeanPosition*
pnt1	The closest boundary point of this **ccBoundary** to *bnd2*.
pnt2	The closest boundary point of *bnd2* to this **ccBoundary**.

Throws

ccBoundaryDefs::DegenerateShape	This **ccBoundary** or *bnd2* or both have no points.

length

```
double length(bool assumeClosed=false) const;
```

Returns the length of this **ccBoundary** in client coordinates.

Parameters

assumeClosed If true the function returns the length of the closed shape obtained by joining the first and last point of this **ccBoundary** with a straight line.

Notes

The length returned is not the number of points in this **ccBoundary**.

inside

```
bool inside(const cc2Vect &pnt1) const;
```

Returns true if the point *pnt1* is inside this **ccBoundary**. Returns false if *pnt1* is outside or exactly on this **ccBoundary**.

Parameters

pnt1 The point whose position relative to this **ccBoundary** is evaluated.

angleBetweenSegments

```
ccRadian angleBetweenSegments(const ccBoundary &bnd2)
 const;
```

Returns the angle between this **ccBoundary** and *bnd2*. The angle between the two boundaries is defined as the angle between the best fitting line of this **ccBoundary** and the best fitting line of *bnd2*. The angle returned is from 0 through 2π radians.

Parameters

bnd2 The boundary whose best fitting line is used together with the best fitting line of this **ccBoundary** to compute the angle between the two boundaries.

Throws

ccBoundaryDefs::InvalidBoundaryCondition
The line fit to this **ccBoundary** or *bnd2* fails.

ccBoundaryDefs::DegenerateShape
This **ccBoundary** or *bnd2* or both have only one point.

measureDifferences

```
cmStd vector <cc2Vect> measureDifferences(
 const ccBoundary &bnd,
 ccBoundaryDefs::MeasurementMethod method =
```

```
ccBoundaryDefs::eParallel,
ccBoundaryDefs::MeasurementAccuracy acc =
ccBoundaryDefs::eFast) const;
```

Returns the vector of distances between the boundary points of this **ccBoundary** and the corresponding boundary points of *bnd*. The distances are computed according to the modalities specified by *method* and *acc* (see *ccBoundaryDefs*).

Parameters

bnd	The boundary from which the distance of this **ccBoundary** is measured.
method	The measurement mode used to compute boundary point distances. *method* must be one of the following: *ccBoundaryDefs::eRadial* *ccBoundaryDefs::eParallel*
acc	The matching modality used to match the boundary points of this **ccBoundary** to the boundary points of *bnd*. *acc* must be one of the following: *ccBoundaryDefs::eFast* *ccBoundaryDefs::eAccurate*

position

```
const cmStd vector <cc2Vect> &position() const;
```

Returns a list of all the positions of the boundary points in this **ccBoundary**.

angle

```
const cmStd vector <ccRadian>& angle() const;
```

Returns a list of all the direction angles of the boundary points in this **ccBoundary**.

weight

```
const cmStd vector <double>& weight() const;
```

Returns a list of all the weights of the boundary points in this **ccBoundary**.

matchQuality

```
const cmStd vector <double>& matchQuality() const;
```

Returns a list of all the matchQuality values of the boundary points in this **ccBoundary**.

ccBoundaryDefs

```
#include <ch_cvl/pmibnd.h>

class ccBoundaryDefs;
```

A name space that holds enumerations and constants used with PatInspect.

Enumerations

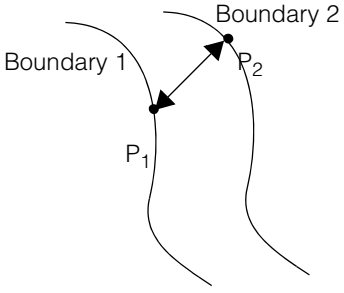
MeasurementMethod

```
enum MeasurementMethod
```

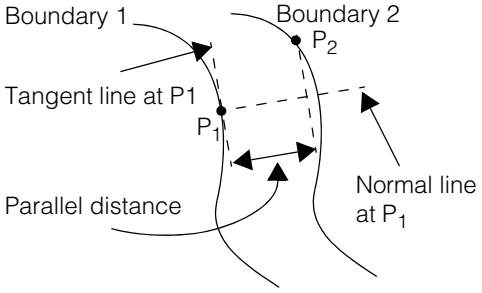
This enumeration defines the measurement methods used to compute the distance between two boundary points belonging to two distinct boundaries.

Value	Meaning
eRadial	The radial distance between boundary points is computed.
eParallel	The distance between boundary points is computed on parallel lines.

The following figure illustrates the difference between radial distance (*eRadial*) and parallel distance (*eParallel*).



Radial distance of P_2 from P_1



Parallel distance of P_2 from P_1

MeasurementAccuracy

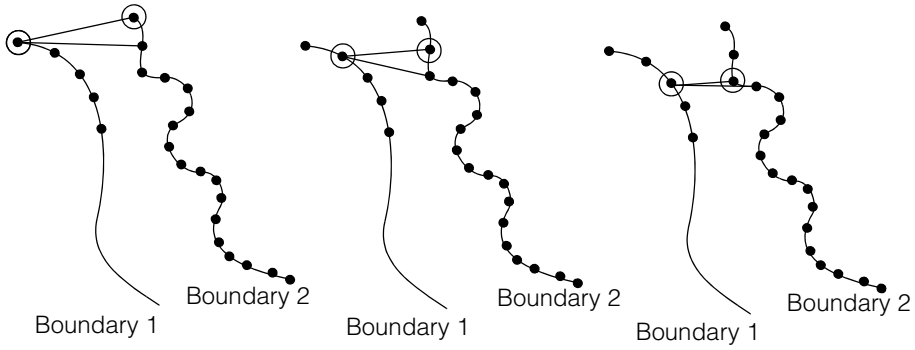
```
enum MeasurementAccuracy
```

This enumeration defines the method used to determine the matching points of two boundaries.

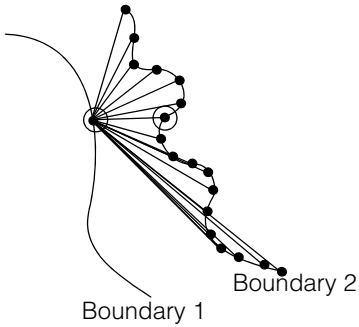
Value	Meaning
eFast	The matching is based on a local distance-comparison strategy.
eAccurate	The matching is based on an exhaustive distance-comparison strategy.

The following illustrations show the difference between the two methods:

- *eFast*
  In this mode points of Boundary 1 are matched to points of Boundary 2 on the basis of a local distance comparison strategy. The distances between a point in Boundary 1 and two points in Boundary 2 are computed and the point in Boundary 2 with the shortest distance is matched to the point in Boundary 1. The matching process is serial, starting from the first point of Boundary 1 as illustrated in the following figure (in the figure matching boundary points are circled).



- *eAccurate*
  In this mode points of Boundary 1 are matched to points of Boundary 2 on the basis of a comprehensive distance comparison strategy. A point in Boundary 1 is matched to the closest point in Boundary 2 as illustrated in the following figure (in the figure matching boundary points are circled).



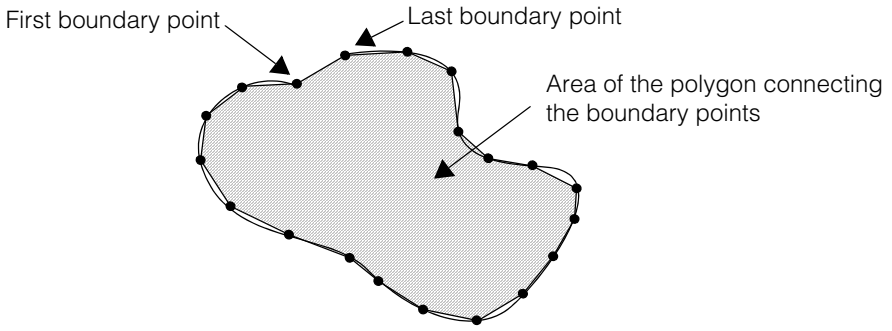
AreaMethod `enum AreaMethod`

This enumeration defines the method used to measure the area contained by an open or closed boundary.

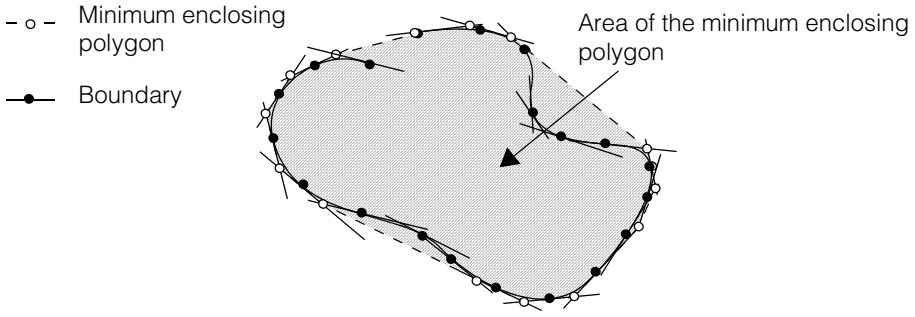
Value	Meaning
eSimple	The area of the polygon defined by the line segments between boundary points is computed.
eConvex	The area of the minimum polygon enclosing the boundary is computed.

The following illustrations show the difference between the two methods:

- *eSimple*
  The area of the polygon resulting from connecting adjacent boundary points is measured. If the boundary is open, the first and last boundary point are connected by a straight segment.



- *eConvex*
  The area of the minimum polygon enclosing the boundary is measured.



BoundaryType `enum BoundaryType`

This enumeration defines what boundary data to retain when **ccBoundary** constructors are called.

Value	Meaning
eTrained	The training boundary data associated with the matched boundary data are retained.
eMatch	The matching boundary data are retained.
eMissing	The missing boundary data that were trained but not found at run-time are retained.
eExtra	The extra boundary data that were not trained but were found at run-time are retained.

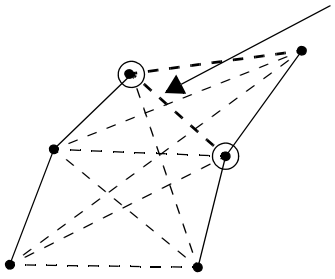
DistanceMethod `enum DistanceMethod`

This enumeration defines the method used to determine the distance between two boundaries.

Value	Meaning
eExhaustive	The distance between two boundaries is defined by the smallest distance between the boundary points.
eMinEndPnt	The distance between two boundaries is defined by the smallest distance between the end-points of the boundaries.
eMeanPosition	The distance between two boundaries is defined by the distance between the mean positions of the boundaries.

The following illustrates the difference between the three methods:

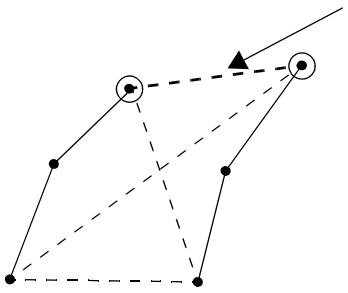
- *eExhaustive*



This is the distance between Boundary 1 and Boundary 2 according to the *eExhaustive* method. The distance between the two circled boundary points is the shortest one.

Boundary 1 Boundary 2

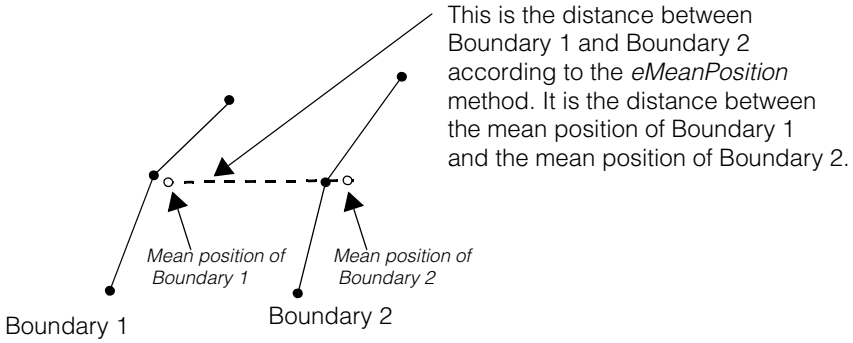
- *eMinEndPnt*



This is the distance between Boundary 1 and Boundary 2 according to the *eMinEndPnt* method. The distance between the two circled end-points is the shortest one.

Boundary 1 Boundary 2

- *eMeanPosition.*



ccBoundaryDefs

ccBoundaryInspector

```
#include <ch_cvl/bndrinsp.h>

class ccBoundaryInspector
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class encapsulates the Boundary Inspection tool. You train this tool with a **ccShape** model and then run the tool on images to determine if the image boundaries (contours) match the model boundaries. The inspection tool returns all of the matching contours and also non-matching contours in both the model and the image. The non-matching contours enable you to evaluate the match between the model and the image.

Constructors/Destructors

ccBoundaryInspector

```
ccBoundaryInspector();

ccBoundaryInspector(const ccBoundaryInspector &that);

~ccBoundaryInspector();
```

- `ccBoundaryInspector();`

  Constructs an untrained **ccBoundaryInspector** tool.

- `ccBoundaryInspector(const ccBoundaryInspector &that);`

  Copy constructor. Performs a deep copy.

- `~ccBoundaryInspector();`

  Destructor.

Operators

operator=

```
ccBoundaryInspector & operator=(
                          const ccBoundaryInspector &that);
```

Deep copy assignment operator.

operator==

```
bool operator==(const ccBoundaryInspector& that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

operator!=

```
bool operator!=(const ccBoundaryInspector& that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Public Member Functions

train

```
void train(
  const ccShape &modelBoundary,
  const cc2XformBase &clientFromImage,
  const ccShapeTol &shapeTolerance,
  const ccBoundaryInspectorTrainParams &trainParams,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);

void train(
  const ccShape &modelBoundary,
  const ccShapeMask &shapeMask,
  const cc2XformBase &clientFromImage,
  const ccShapeTol &shapeTolerance,
  const ccBoundaryInspectorTrainParams &trainParams,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);
```

-
```
void train(
  const ccShape &modelBoundary,
  const cc2XformBase &clientFromImage,
```

```
const ccShapeTol &shapeTolerance,
const ccBoundaryInspectorTrainParams &trainParams,
ccDiagObject* obj = 0,
c_UInt32 diagFlags = 0);
```

Train this tool with the given parameters. The model boundary may be any CVL shape description, including a hierarchical shape. The shape description is specified in model coordinates. The relationship between the client space and image space at train time is specified by the *clientFromImage* transform. The model boundary tolerances, which are in model coordinates, are specified by the *shapeTolerance* object.

If the object is currently trained, it untrains and then trains again.

Notes

Shape descriptions or shape description portions without a defined tangent angle are ignored by this tool.

Parameters

modelBoundary A **ccShape** object that contains the model boundary.

clientFromImage The expected client transform of the images to be inspected.

shapeTolerance The allowed shape boundary tolerances. If you are doing statistical training this will be a reference to a **ccShapeTolStats** object you have created using good test images. If you are doing manual training this will be a reference to a **ccShapeTolTable** object you have created manually.

trainParams The training parameters.

obj A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccBoundaryInspectorDefs::BadParams

If the model boundary is infinite and not a primitive,
or if the model boundary is infinite and
trainParams().clipRegion() is not a valid clipping region,
or if the *shapeTolerance* object is detectably invalid for this model boundary.

ccMathError::Singular

If *clientFromImage* or its inverse is singular.

Notes

The tool becomes untrained if it throws.

- ```
  void train(
    const ccShape &modelBoundary,
    const ccShapeMask &shapeMask,
    const cc2XformBase &clientFromImage,
    const ccShapeTol &shapeTolerance,
    const ccBoundaryInspectorTrainParams &trainParams,
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0);
  ```

Train as described above, but include a shape mask. A shape mask is applied to the **ccShape** model and allows you to ignore (mask out) portions of the model boundary.

Parameters

modelBoundary A **ccShape** object that contains the model boundary.

shapeMask The shape mask to apply to *modelBoundary*. Note that **ccShapeTol** is a typedef as follows:

typedef
ccShapePerimData<ccShapeMaskValue> ccShapeMask

Please see the **ccShapeMaskValue** reference page for more information about shape masks.

clientFromImage The expected client transform of the images to be inspected.

shapeTolerance The allowed shape boundary tolerances. If you are doing statistical training this will be a reference to a **ccShapeTolStats** object you have created using good test images. If you are doing manual training this will be a reference to a **ccShapeTolTable** object you have created manually.

trainParams The training parameters.
  ```

obj — A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

diagFlags — Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccBoundaryInspectorDefs::BadParams
If the model boundary is infinite and not a primitive,
or if the model boundary is infinite and
trainParams().clipRegion() is not a valid clipping region,
or if the *shapeTolerance* object or *shapeMask* are detectably invalid for this model boundary.

ccMathError::Singular
If *clientFromImage* or its inverse is singular.

Notes

The tool becomes untrained if it throws.

isTrained

```
bool isTrained() const;
```

Returns true if **train()** was called successfully on this object.

trainParams

```
const ccBoundaryInspectorTrainParams &trainParams() const;
```

Returns the **ccBoundaryInspectorTrainParams** object used in training.

Throws

ccBoundaryInspectorDefs::NotTrained
If this object is not trained.

modelBoundary

```
ccShapePtrh_const modelBoundary() const;
```

Returns the **ccShape** object used in training.

Throws
ccBoundaryInspectorDefs::NotTrained
If this object is not trained.

clientFromImage

```
cc2XformBasePtrh_const clientFromImage() const;
```

Returns the client-from-image transform used in training.

Throws
ccBoundaryInspectorDefs::NotTrained
If this object is not trained.

shapeTolerance

```
ccShapeTolPtrh_const shapeTolerance() const;
```

Returns the **ccShapeTol** object used in training.

Throws
ccBoundaryInspectorDefs::NotTrained
If this object is not trained.

shapeMask

```
ccShapeMaskPtrh_const shapeMask() const;
```

Returns the shape mask used in training. The portions of the model boundary masked by this shape mask will be ignored by the **ccBoundaryInspector** tool.

Throws
ccBoundaryInspectorDefs::NotTrained
If this object is not trained,
or if this object was not trained with a shape mask.

---

run

```
void run(
  const ccPelBuffer_const<c_UInt8> &image,
  const cc2XformBase &pose,
  ccBoundaryInspectorResult &results,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0) const;

void run(
  const ccPelBuffer_const<c_UInt8> &image,
  const cc2XformBase &pose,
  const ccFeatureletFilter &featureletFilter,
```

```
  ccBoundaryInspectorResult &results,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0) const;
```

- ```
  void run(
    const ccPelBuffer_const<c_UInt8> &image,
    const cc2XformBase &pose,
    ccBoundaryInspectorResult &results,
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0) const;
  ```

  Performs the geometric boundary inspection on the given image with the given parameters. The relationship between the client coordinates and the model coordinates of the trained boundary is specified by the *pose* transform.

  The scaling factors of *pose* should be close to 1.0 for correct operation.

  Parameters

  image — The image to be inspected.

  pose — A transform that specifies the relationship between client coordinates and the model coordinates of the trained boundary.

  results — Where to put the inspection results.

  obj — A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

  diagFlags — Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccBoundaryInspectorDefs::BadParams
  If *image* is not bound.

  ccBoundaryInspectorDefs::NotTrained
  If this object is not trained.
  ```

ccMathError::Singular
If *pose*, **image.clientFromImageXformBase()**, or their inverses are singular.

This function will not mask any exceptions that the featurelet filter might throw.

- ```
  void run(
    const ccPelBuffer_const<c_UInt8> &image,
    const cc2XformBase &pose,
    const ccFeatureletFilter &featureletFilter,
    ccBoundaryInspectorResult &results,
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0) const;
  ```

  Same as above except a featurelet filter is specified. The featurelet filter is applied to the image contours after the contours are transformed into the coordinate system in which the model boundary is defined.

  See **ccFeatureletFilter** for information on featurelet filters.

  Parameters

  image — The image to be inspected.

  pose — A transform that specifies the relationship between client coordinates and the model coordinates of the trained boundary.

  featureletFilter — The featurelet filter to be applied to *image*.

  results — Where to put the inspection results.

  obj — A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

  diagFlags — Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff
  ```

Throws

ccBoundaryInspectorDefs::BadParams
If *image* is not bound.

ccBoundaryInspectorDefs::NotTrained
If this object is not trained.

ccMathError::Singular
If *pose*, **image.clientFromImageXformBase()**, or their inverses are singular.

This function will not mask any exceptions that the featurelet filter might throw.

ccBoundaryInspector

ccBoundaryInspectorResult

```
#include <ch_cvl/bndrinsp.h>

class ccBoundaryInspectorResult
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class encapsulates the results of a boundary inspection (see **ccBoundaryInspector**). It contains both matched and unmatched results of the trained model against an image. Unmatched results include image contours, expressed as featurelet chain sets, that were not matched to the trained model. Unmatched model boundaries are expressed as perimeter ranges.

Matched image contours are also expressed as featurelet chain sets and matched model boundaries are expressed as perimeter ranges. For matched results, the class holds an array of image contours that corresponds to an array of model perimeter ranges where each image contour is a match to a corresponding model perimeter range.

Constructors/Destructors

ccBoundaryInspectorResult

```
ccBoundaryInspectorResult();
```

Constructs an empty **ccBoundaryInspectorResult** object.

Operators

operator==

```
bool operator==(
  const ccBoundaryInspectorResult& that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

operator!=

```
bool operator!=(
  const ccBoundaryInspectorResult& that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Public Member Functions

extraImageContours

```
ccFeatureletChainSetPtrh_const extraImageContours() const;
```

Returns the extra (unmatched) image contours as a featurelet chain set, in client coordinates.

unmatchedModelBoundary

```
const cmStd vector<ccPerimRange> &unmatchedModelBoundary()
                                                    const;
```

Returns the vector of model boundary perimeter ranges that were unmatched during the inspection.

matchedImageContours

```
const cmStd vector<ccFeatureletChainSetPtrh_const> &
                                  matchedImageContours() const;
```

Returns a vector of matched image contours as a vector of featurelet chain sets. The featurelet chain set at **matchedImageContours()**[i] matches the vector of perimeter ranges at **matchedModelBoundary()**[i].

matchedModelBoundary

```
const cmStd vector<ccPerimRange> &matchedModelBoundary()
                                                    const;
```

Returns a vector of matched model boundary perimeter ranges. The vector of perimeter ranges at **matchedModelBoundary()**[i] matches the featurelet chain set at **matchedImageContours()**[i].

ccBoundaryInspectorTrainParams

```
#include <ch_cvl/bndrinsp.h>

class ccBoundaryInspectorTrainParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class encapsulates the Boundary Inspection tool training parameters. See **ccBoundaryInspector**.

There are two training parameters; *granularity*, and *clipRegion*. Granularity specifies the degree to which inspection images are smoothed and subsampled before edges are extracted. Specifying a clip region is optional. A clip region is a closed **ccPolyline** that is applied to the model before model training. Only the model boundary within the clip region is trained.

Constructors/Destructors

ccBoundaryInspectorTrainParams

```
explicit ccBoundaryInspectorTrainParams(
  double granularity = 1.0,
  const ccPolyline &clipRegion = ccPolyline(true));
```

Constructs a **ccBoundaryInspectorTrainParams** object with the given parameters.

The default granularity is 1.0, very fine granularity.

A valid clip region is a closed convex **ccPolyline** specified in model coordinates.

Parameters

granularity	The smoothing and subsampling factor applied to inspection images. Must be in the range 1.0 through 25.0. A setting of 1.0 specifies fine granularity and a setting of 25.0 specifies very coarse granularity.
clipRegion	A closed region that specifies a subset of the model for training. Use a clip region to omit parts of a model you do not wish to train.

Throws

ccBoundaryInspectorDefs::BadParams
If *granularity* < 1.0 or *granularity* > 25.0, or if the clip region is open.

Operators

operator==

```
bool operator==(
  const ccBoundaryInspectorTrainParams& that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator!=

```
bool operator!=(
  const ccBoundaryInspectorTrainParams& that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

granularity

```
double granularity() const;

void granularity(double granularity);
```

Granularity specifies the degree to which inspection images are smoothed and subsampled before edges are extracted. Must be in the range 1.0 through 25.0. A setting of 1.0 specifies fine granularity and a setting of 25.0 specifies very coarse granularity. The default granularity value is 1.0.

- `double granularity() const;`

  Returns the current granularity setting.

- `void granularity(double granularity);`

  Sets the granularity.

Parameters

granularity The new granularity setting.

Throws

ccBoundaryInspectorDefs::BadParams
If *granularity* < 1.0 or *granularity* > 25.0.

---

clipRegion

```
const ccPolyline& clipRegion() const;
```

```
void clipRegion(const ccPolyline& clipRegion);
```

Specifying a clipping region is optional. A valid clipping region is a closed, convex **ccPolyline** that is applied to the model before model training. Only the model boundary within the clipping region is trained. The clipping region is specified in the model coordinates.

If clipping is performed, the missing and matching model boundaries found during boundary inspection are reported only if they are within the clipping region.

No clipping is performed during training unless a valid clipping region is provided here. A valid clipping region is a closed, convex **ccPolyline** with at least 3 vertices.

The default clipping region is a closed polyline with no vertices (no clipping is performed).

- `const ccPolyline& clipRegion() const;`

  Returns the **ccPolyline** that defines the clipping region.

- `void clipRegion(const ccPolyline& clipRegion);`

  Defines a new clipping region.

  Parameters

  clipRegion The new clipping region.

  Throws

  ccBoundaryInspectorDefs::BadParams
  If the clipping region is open.

ccBoundaryInspectorTrainParams

ccBoundarySet

```
#include <ch_cvl/pmibnd.h>

class ccBoundarySet;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	Simple

This class contains the set of boundary results returned by PatInspect. The class holds data from the following four sets of boundaries:

- The boundary of trained features (the boundary features that have been trained)
- The boundary of matched features (the boundary features that are present in both run-time and template image)
- The boundary of extra features (the boundary features that are present in the run-time image but not in the template image)
- The boundary of missing features (the boundary features that are present in the template image but not in the run-time image).

Constructors/Destructors

ccBoundarySet

```
ccBoundarySet();

ccBoundarySet(ccPMInspectResult &result);

ccBoundarySet(const ccPMInspectBoundaryData &diffData,
  const cc2Xform &pose=cc2Xform::I);

ccBoundarySet(const cmStd vector <ccBoundary>& points,
  ccBoundaryDefs::BoundaryType
  type=ccBoundaryDefs::eTrained,
  const cc2Xform &pose=cc2Xform::I);

ccBoundarySet(const cmStd vector <cc2Vect>& points,
  ccBoundaryDefs::BoundaryType type,
  const cc2Xform &pose=cc2Xform::I);

ccBoundarySet(const ccPMInspectAbsenceData &points,
  const cc2Xform & pose=cc2Xform::I);
```

- `ccBoundarySet();`

  Creates a **ccBoundarySet** with empty boundaries. The boundaries of trained, matched, extra and missing features of this **ccBoundarySet** have no points.

- `ccBoundarySet(ccPMInspectResult &result);`

  Creates the boundaries of trained, matched, extra and missing features of this **ccBoundarySet** from the corresponding boundaries returned by *result*. The four boundaries are expressed in client coordinates. The transformation that maps the boundaries to client coordinates is included in *results*.

  Parameters

  result — The **ccPMInspectResult** object to which this **ccBoundarySet** is initialized.

- `ccBoundarySet(const ccPMInspectBoundaryData &diffData, const cc2Xform &pose=cc2Xform::I);`

  Creates the boundaries of trained, matched, extra and missing features of this **ccBoundarySet** from the corresponding boundaries returned by *diffData*. The four boundaries are expressed in client coordinates. The transformation that maps the boundaries to client coordinates is provided by *pose*.

  Parameters

  diffData — The **ccPMInspectBoundaryData** object to which this **ccBoundarySet** is initialized.

pose The **cc2Xform** that maps the boundary features to client coordinates.

- ```
  ccBoundarySet(const cmStd vector <ccBoundary>& points,
    ccBoundaryDefs::BoundaryType
    type=ccBoundaryDefs::eTrained,
    const cc2Xform &pose=cc2Xform::I);
  ```

  Creates the boundary specified by *type* of this **ccBoundarySet** from the vector of **ccBoundary** *points*. The three remaining boundaries are all initialized to a boundary with no points. The transformation that maps the boundaries to client coordinates is provided by *pose*.

  Parameters

  points The vector of **ccBoundary** points used to initialize this **ccBoundarySet**.

  type The modifier that specifies which boundary of this **ccBoundarySet** is set to *points*. *type* must be one of the following:
  ccBoundaryDefs::eTrainedt
  ccBoundaryDefs::eMatch
  ccBoundaryDefs::eMissing
  ccBoundaryDefs::eExtra

  pose The **cc2Xform** that maps the boundary features to client coordinates.

- ```
  ccBoundarySet(const cmStd vector <cc2Vect>& points,
    ccBoundaryDefs::BoundaryType type,
    const cc2Xform &pose=cc2Xform::I);
  ```

  Sets the boundary specified by *type* of this **ccBoundarySet** to the vector of points *points*. The three remaining boundaries are all initialized to a boundary with no points. The transformation that maps the boundaries to client coordinates is provided by *pose*.

  Parameters

  points The vector of points used to initialize this **ccBoundarySet**.

  type The modifier that specifies which boundary of this **ccBoundarySet** is set to *points*.

  pose The **cc2Xform** that maps the boundary features to client coordinates.

- `ccBoundarySet(const ccPMInspectAbsenceData &points, const cc2Xform & pose=cc2Xform::I);`

  Constructs a **ccBoundarySet** from the supplied **ccPMInspectAbsenceData** object. The points are transformed by the supplied pose.

  Parameters

  points — The **ccPMInspectAbsenceData** used to initialize this **ccBoundarySet**.

  pose — The **cc2Xform** that maps the boundary features to client coordinates.

Public Member Functions

draw

```
void draw(ccUITablet &tablet,
  bool connected=true,
  const ccColor &trainedColor =ccColor::blueColor(),
  const ccColor &matchColor =ccColor::greenColor(),
  const ccColor &missingColor =ccColor::yellowColor(),
  const ccColor &extraColor=ccColor::redColor(),
  const ccUITablet::Layers &layer=
  ccUITablet::eImageLayer) const;
```

Draws all the boundaries of this **ccBoundarySet** in the supplied **ccUITablet** *tablet*.

Parameters

tablet — The tablet used to draw this **ccBoundarySet**.

connected — If true the function draws the polygon formed by connecting the adjacent boundary points of this **ccBoundarySet**.

trainedColor — The color of the trained boundary features of this **ccBoundarySet**.

matchColor — The color of the matching boundary features of this **ccBoundarySet**.

missingColor — The color of the missing boundary features of this **ccBoundarySet**.

extraColor — The color of the extra boundary features of this **ccBoundarySet.**

layer — The layer into which this **ccBoundarySet** is drawn.

boundaryVect

```
cmStd vector <ccBoundary> & boundaryVect(
  ccBoundaryDefs::BoundaryType
  type=ccBoundaryDefs::eTrained);

const cmStd vector <ccBoundary> & boundaryVect(
  ccBoundaryDefs::BoundaryType
  type=ccBoundaryDefs::eTrained) const;
```

- ```
  cmStd vector <ccBoundary> & boundaryVect(
    ccBoundaryDefs::BoundaryType
    type=ccBoundaryDefs::eTrained);
  ```

  Returns the boundary of this **ccBoundarySet** specified by *type*.

  Parameters

type	The modifier that specifies which boundary of this **ccBoundarySet** is returned by the function.

- ```
  const cmStd vector <ccBoundary> & boundaryVect(
    ccBoundaryDefs::BoundaryType
    type=ccBoundaryDefs::eTrained) const;
  ```

  Returns the boundary of this **ccBoundarySet** specified by *type*.

  Parameters

type	The modifier that specifies which boundary of this **ccBoundarySet** is returned by the function.

ccBoundarySet

ccBoundaryTol

```
#include <ch_cvl/shapetol.h>

class ccBoundaryTol
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

ccBoundaryTol is a container class for representing the acceptable (tolerable) positional and angular difference between a shape boundary point and a 2D point with a tangent angle. The Boundary Inspection tool requires that you provide acceptable variations of the boundaries to be inspected. These acceptable variations are called *shape tolerances*. **ccBoundaryTol** is used as a data type to instantiate the templated classes **ccShapePerimData** and **ccShapePerimDataTable** for creating the **ccShapeTol** and **ccShapeTolTable** classes. Typedefs creating the **ccShapeTol** and **ccShapeTolTable** classes are located on the **ccShapePerimData** and **ccShapePerimDataTable** reference pages.

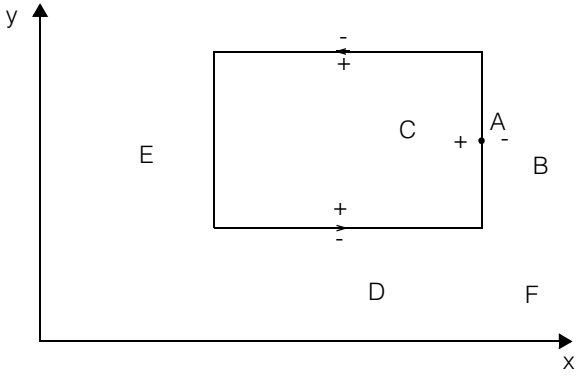
The absolute value of the positional difference between a boundary point and a 2D point is the Euclidean distance between them. If the boundary point has a defined tangent angle, then the positional difference has a sign which is positive if the 2D point is on the positive side of the boundary point and negative if the 2D point is on the negative side. In standard CVL notation, the positive side of a boundary point is the +90° direction from the tangent direction of the boundary point. Similarly, the negative side is the -90° direction from the tangent. All the points that are on the tangent line of the boundary point are assumed to have positive distance signs. Please see comments for **ccShape** for a description of tangent direction.

In a right-handed coordinate system, the +90° and -90° directions correspond to counterclockwise and clockwise rotations from the tangent vector, respectively.

The above definition of positive and negative side implies that the inside regions of right-handed closed shape descriptions (all primitive shape regions such as circles and rectangles) are the positive sides, and outside regions are the negative sides.

As an example, consider the rectangle and the boundary point A shown in the right-handed coordinate system below. The distances from boundary point A to points B and F are negative because the points B and F are in the +90° direction side from the

tangent direction of boundary point A. The points C, D, and E are a positive distance away from the boundary point A. Note that being inside or outside of a boundary region does not determine the sign of the distance to the point by itself.



Positive and negative sides of a shape should not be confused with the shape polarity defined by **ccShapeModelProps**. In particular, the positive and negative sides of a shape depend only on the shape tangent direction and cannot be changed by reversing the shape model polarity flag.

The angular difference between the angles of a boundary point and a 2D point is calculated depending on the *ignorePolarity* flag. If the *ignorePolarity* flag is false, the angular difference is calculated by taking the absolute value of the difference of the angles in the range 0 through pi. If the *ignorePolarity* flag is true, the angles are first mapped to the range 0 through pi, and then the difference is taken in range 0 through pi/2.

Constructors/Destructors

ccBoundaryTol

```
explicit ccBoundaryTol(
  const ccRange & distanceTol = ccRange::FullRange(),
  const ccRadian &angleTol = ccRadian(ckPI),
  bool ignorePolarity = false);
```

Constructs a **ccBoundaryTol** object with the given parameters.

Parameters

distanceTol	The maximum tolerable distance between a model boundary point and a corresponding image point.
angleTol	The maximum tolerable angular difference between a model boundary featurelet and a corresponding image featurelet.

ignorePolarity If true, polarity is ignored when calculating the featurelet angular difference described above. If false, featurelet polarity is used in the calculation.

Throws

ccShapePerimDataDefs::BadParams
If *angleTol* < **ccRadian(**0.0**)**.

Operators

operator==

```
bool operator== (const ccBoundaryTol &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator!=

```
bool operator!= (const ccBoundaryTol &that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

distanceTol

```
ccRange distanceTol() const;
```

```
void distanceTol(const ccRange &distanceTol);
```

The maximum tolerable distance between a model boundary point and a corresponding image point.

The default value is **ccRange::FullRange()**.

- `ccRange distanceTol() const;`

  Returns the current distance tolerance.

- `void distanceTol(const ccRange &distanceTol);`

  Sets a new distance tolerance.

Parameters
distanceTol The new distance tolerance.

angleTol

```
ccRadian angleTol() const;
void angleTol(const ccRadian &angleTol);
```

The maximum tolerable angular difference between a model boundary featurelet and a corresponding image featurelet.

The default angle tolerance value is **ccRadian(**ckPI**)**.

- `ccRadian angleTol() const;`

  Returns the current angle tolerance.

- `void angleTol(const ccRadian &angleTol);`

  Sets a new angle tolerance.

  Parameters
  angleTol The new angle tolerance.

  Throws
  ccShapePerimDataDefs::BadParams
  If *angleTol* < **ccRadian(**0.0**)**.

  Note: The state of this object remains unchanged if it throws.

ignorePolarity

```
bool ignorePolarity() const;
void ignorePolarity(bool ignorePolarity);
```

If true, polarity is ignored when calculating the featurelet angular difference described above for angle tolerance. If false, featurelet polarity is used in the calculation.

The default ignorePolarity flag value is false.

- `bool ignorePolarity() const;`

  Returns the state of the ignore polarity flag, true or false.

- `void ignorePolarity(bool ignorePolarity);`

  Sets the ignore polarity flag, true of false.

Parameters

ignorePolarity The new ignore polarity flag.

ccBoundaryTol

ccBoundaryTrackerDefs

```
#include <ch_cvl/bndtrckr.h>

class ccBoundaryTrackerDefs;
```

A name space that holds enumerations and constants used with the Symbol tool classes.

Enumerations

ModeFlags

```
enum ModeFlags;
```

This enumeration defines the Boundary Tracker tool modes.

Value	Meaning
eWhiteOnBlack	Specifies light object on dark background (default is dark object on light background)
eGradientThreshold	Specifies gradient tracking (default is threshold tracking)
eStopAtImageEdge	Stop tracking at image edge (default is to return to start point and tracking in the other direction)
kDefaulttFlags	Default modes (dark object on light background; threshold tracking; re-start tracking if image edge encountered)

ccBoundaryTrackerDefs

ccBoundaryTrackerPoint

```
#include <ch_cvl/bndtrckr.h>

class ccBoundaryTrackerPoint;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

A class that describes a single boundary point used by the Boundary Tracker tool. A boundary point contains a subpixel location and a direction.

Constructors/Destructors

ccBoundaryTrackerPoint

```
ccBoundaryTrackerPoint();

ccBoundaryTrackerPoint(const cc2Vect& c,
  const ccRadian& a);
```

- `ccBoundaryTrackerPoint();`

  Constructs a **ccBoundaryTrackerPoint** with a location of (0, 0) and an angle of 0.

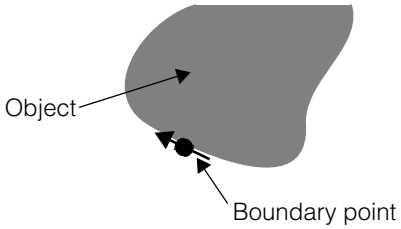
- ```
  ccBoundaryTrackerPoint(const cc2Vect& c,
    const ccRadian& a);
  ```

  Constructs a **ccBoundaryTrackerPoint** using the supplied location and angle.

  Parameters

c	The location of the **ccBoundaryTrackerPoint**.
  ```

a The angle of the **ccBoundaryTrackerPoint**. A **ccBoundaryTrackerPoint**'s angle is tangent to the object boundary and in the tracking direction, as shown in this figure:



A **ccBoundaryTrackerPoint**'s angle is in the image's client coordinate system.

Operators

operator== `bool operator==(const ccBoundaryTrackerPoint& rhs);`

Two **ccBoundaryTrackerPoint**s are equal if their locations and angles are the same.

ccBoundaryTrackerResult

```
#include <ch_cvl/bndtrckr.h>

class ccBoundaryTrackerResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

A class that contains information about a single object boundary measured by the Boundary Tracker tool. You supply an object of type **ccBoundaryTrackerResult** to the function **cfBoundaryTracker()**.

Constructors/Destructors

ccBoundaryTrackerResult

```
ccBoundaryTrackerResult();
```

Constructs a **ccBoundaryTrackerResult** with no result information.

Enumerations

StatusFlags

```
enum StatusFlags;
```

This enumeration defines the status flags returned by **statusFlags()**.

Value	Meaning
eSuccess	Valid boundary was found and tracked.
eOpenBoundary	Boundary track did not return to start point.

Value	Meaning
eMaxPoints	Boundary tracking stopped because the maximum number of points were tracked. If the tool is tracking an open boundary that extends to the edge of the image, this flag may not be set until up to twice the maximum specified number of points have been tracked.
eWeakGradient	Boundary tracking stopped because gradient fell below threshold.

Public Member Functions

area

```
double area() const;
```

Returns the area of the object enclosed by this boundary. The area is the number of pixels within the boundary, transformed into client coordinate system units.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

boundaryPoints

```
const cmStd vector<ccBoundaryTrackerPoint>&
  boundaryPoints() const;
```

Returns a vector of **ccBoundaryTrackerPoint**s describing the boundary. The angle information in the returned **ccBoundaryTrackerResult** is valid only if **isAngleDataValid()** returns true.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

centerOfMass

```
const cc2Vect& centerOfMass() const;
```

Returns the center of mass of the object enclosed by this boundary in client coordinates.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

physExtent `const ccRect& physExtent() const;`

Returns the smallest rectangle that both is aligned in the image coordinate system and completely encloses this boundary. The rectangle is returned in client coordinates.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

firstBoundaryPointIndex
`c_Int32 firstBoundaryPointIndex() const;`

Returns the index into the vector of boundary points returned by **boundaryPoints()** of the first boundary point found by the Boundary Tracker tool. If you used track-only mode, this point is the same point you specified as the starting point.

If this function returns 0, it means that the second side of the boundary was not tracked.

Notes

Due to the subpixel interpolation, the coordinates of the returned point may differ slightly from the coordinates the starting point you supplied in track-only mode.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

trackTime `double trackTime() const;`

Returns the time, in seconds, it took to find and track this boundary.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

dominantAngle `const ccRadian& dominantAngle() const;`

Returns the dominant (peak) angle from the angle histogram.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked or no angle data was computed for this boundary.

Notes

This function only returns valid data if you have computed angle data for this boundary.

dominantFoldedAngle

```
const ccRadian& dominantFoldedAngle() const;
```

Returns the dominant (peak) angle from the folded angle histogram.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked or no angle data was computed for this boundary.

Notes

This function only returns valid data if you have computed angle data for this boundary.

xProjection

```
const cmStd vector<c_Int32>& xProjection() const;
```

Returns the x-projection of the portion of the input image enclosed by the smallest rectangle that both is aligned in the image coordinate system and completely encloses this boundary.

The returned 1-dimensional image is the same size as the x-dimension of the enclosing rectangle. Each pixel in the returned image is set to the sum of all of the object pixels in the corresponding column of the input rectangle.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked.

Notes

This function only returns valid data if you have computed angle data for this boundary.

yProjection

```
const cmStd vector<c_Int32>& yProjection() const;
```

Returns the y-projection of the portion of the input image enclosed by the smallest rectangle that both is aligned in the image coordinate system and completely encloses this boundary.

The returned 1-dimensional image is the same size as the y-dimension of the enclosing rectangle. Each pixel in the returned image is set to the sum of all of the object pixels in the corresponding row of the input rectangle.

Throws

ccBoundaryTrackerDefs::UninitializedData
No valid boundary has been tracked or no angle data was computed for this boundary.

Notes

This function only returns valid data if you have computed angle data for this boundary.

isAngleDataValid

```
bool isAngleDataValid() const;
```

Returns true if angle information has been computed for this boundary, false otherwise. Whether or not angles are computed is controlled by the **ccBoundaryTrackerRunParams** used to track this boundary.

statusFlags

```
c_UInt32 statusFlags() const;
```

Returns the result status flags for this boundary. The returned value is computed by ORing together one or more of the following values:

ccBoundaryTrackerResult::eSuccess
ccBoundaryTrackerResult::eOpenBoundary
ccBoundaryTrackerResult::eMaxPoints
ccBoundaryTrackerResult::eWeakGradient
ccBoundaryTrackerResult::eInternalError

ccBoundaryTrackerResult

ccBoundaryTrackerRunParams

```
#include <ch_cvl/bndtrckr.h>

class ccBoundaryTrackerRunParams: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains the run-time parameters for the Boundary Tracker tool. You must specify whether this **ccBoundaryTrackerRunParams** is for track-only or search-and-track mode use at construction-time. You supply an object of type **ccBoundaryTrackerRunParams** to the function **cfBoundaryTracker()**.

Constructors/Destructors

ccBoundaryTrackerRunParams

```
ccBoundaryTrackerRunParams();

ccBoundaryTrackerRunParams(
  const ccBoundaryTrackerPoint& firstBoundaryPoint,
  c_Int32 threshold,
  c_UInt32 flags = ccBoundaryTrackerDefs::kDefaultFlags,
  bool decreasingAngleSideFirst = true,
  c_Int32 maxBoundaryPoints = 0,
  const ccRange& areaRange = ccRange(0, HUGE_VAL),
  c_Int32 preAnglePoints = 1, c_Int32 postAnglePoints = 1);

ccBoundaryTrackerRunParams(
  const cmStd vector<ccLineSeg>& searchVectors,
  c_Int32 threshold,
  c_UInt32 flags = ccBoundaryTrackerDefs::kDefaultFlags,
  bool decreasingAngleSideFirst = true,
  c_Int32 maxBoundaryPoints = 0,
  const ccRange& areaRange = ccRange(0, HUGE_VAL),
  c_Int32 preAnglePoints = 1, c_Int32 postAnglePoints = 1);
```

- `ccBoundaryTrackerRunParams();`

  Constructs a **ccBoundaryTrackerRunParams** that cannot be used to track object boundaries.

- ```
  ccBoundaryTrackerRunParams(
    const ccBoundaryTrackerPoint& firstBoundaryPoint,
    c_Int32 threshold,
    c_UInt32 flags = ccBoundaryTrackerDefs::kDefaultFlags,
    bool decreasingAngleSideFirst = true,
    c_Int32 maxBoundaryPoints = 0,
    const ccRange& areaRange = ccRange(0, HUGE_VAL),
    c_Int32 preAnglePoints = 1, c_Int32 postAnglePoints = 1);
  ```

  Constructs a **ccBoundaryTrackerRunParams** for track-only mode. For track-only mode, you must specify a starting point on the object boundary; the tool does not search for the boundary.

  Parameters

  firstBoundaryPoint

  The starting boundary point. *firstBoundaryPoint* is given in client coordinates and must lie within a boundary pixel. The angle component of *firstBoundaryPoint* must specify an angle that is tangent to the boundary in the direction of the search, as shown in the following figure:

  
  threshold

  The threshold value to use for object tracking. If *flags* specifies gradient tracking mode, then *threshold* is interpreted as the gradient threshold (a pixel value difference). Otherwise, *threshold* is treated as a hard binary threshold.

  If *threshold* is a hard binary threshold and *flags* specifies a light object on a dark background, then *threshold* is the minimum pixel value for an object pixel. If *threshold* is a hard binary threshold and *flags* specifies a dark object on a light background, then *threshold* is the maximum pixel value for an object pixel.

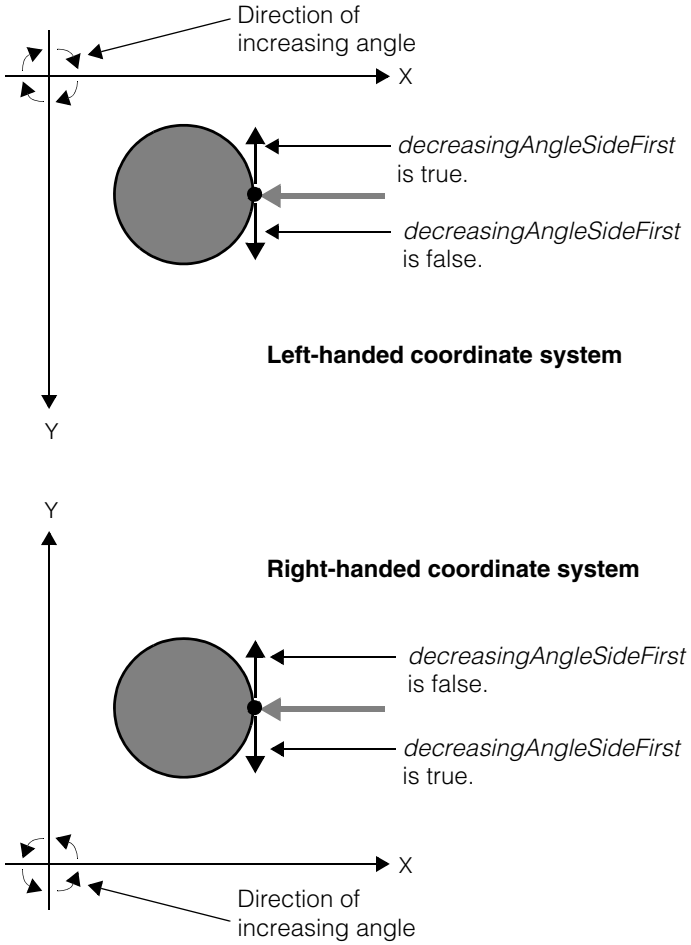
  flags

  The mode flags for this **ccBoundaryTrackerRunParams**. *flags* must be either *ccBoundaryTrackerDefs::kDefaultFlags* or a value formed by ORing together one or more of the following values:
  ```

ccBoundaryTrackerDefs::eWhiteOnBlack
ccBoundaryTrackerDefs::eGradientThreshold
ccBoundaryTrackerDefs::eStopAtImageEdge

decreasingAngleSideFirst

Set *decreasingAngleSideFirst* to true to track the boundary in the direction of decreasing client coordinate system angle. Set *decreasingAngleSideFirst* to false to track the boundary in the direction of increasing client coordinate system angle. The tracking direction is illustrated in the following figure:



maxBoundaryPoints

Specifies the maximum number of boundary points to track. The Boundary Tracker tool stops tracking after it tracks the specified number of points.

If the tool is tracking an open boundary that extends to the edge of the image, the tool may stop after it tracks up to twice as many points as you specify for *maxBoundaryPoints*.

areaRange Specifies the minimum and maximum object area size. Object sizes are positive while hole sizes are negative. To prevent the tool from tracking holes, specify a minimum object size greater than or equal to zero. To prevent the tracking of open boundaries, specify an *areaRange* that does not include 0.

For more information, see the *areaRange* definition for the **ccBoundaryTrackerRunParams** object for search-and-track mode.

preAnglePoints Specifies the number of boundary points preceding each boundary point that are used to compute that point's angle. The more points you specify, the more accurate the angle computation.

postAnglePoints Specifies the number of boundary points following each boundary point that are used to compute that point's angle. The more points you specify, the more accurate the angle computation.

Specify 0 for both *preAnglePoints* and *postAnglePoints* to not compute any angle information.

Throws

ccBoundaryTrackerDefs::ThresholdOutOfRange
threshold is greater than 255 or less than 0.

ccBoundaryTrackerDefs::BadFlags
An invalid value was specified for *flags*.

ccRangeDefs::BadParams
The value returned by **areaRange.start()** is greater than that returned by **areaRange.end()**.

ccBoundaryTrackerDefs::BadPrePostAnglePoints
preAnglePoints or *postAnglePoints* is less than 0.

ccBoundaryTrackerDefs::MaxBoundaryPointsOutOfRange
maxBoundaryPoints is less than 0.

- ```
  ccBoundaryTrackerRunParams(
    const cmStd vector<ccLineSeg>& searchVectors,
    c_Int32 threshold,
    c_UInt32 flags = ccBoundaryTrackerDefs::kDefaultFlags,
    c_Int32 maxBoundaryPoints = 0,
    const ccRange& areaRange = ccRange(0, HUGE_VAL),
    c_Int32 preAnglePoints = 1, c_Int32 postAnglePoints = 1);
  ```

  Constructs a **ccBoundaryTrackerRunParams** object for search-and-track mode. In search-and-track mode, you provide the tool with search parameters using this object. The tool then returns the first boundary that meets all specified conditions.

  The tool tracks any boundary that it finds, and then evaluates whether the boundary meets the specified conditions. If the boundary does not meet these conditions, the tool does not return data about the boundary and continues its search for a boundary that does.

  Parameters

  searchVectors — A vector of search lines. Each search line should start inside an object and extend across the object boundary. Each search line is searched for transitions of the correct polarity that exceed the specified threshold value. Each transition is used as a start point for a boundary track.

  threshold — The threshold value to use for object tracking. If *flags* specifies gradient tracking mode, then *threshold* is interpreted as the gradient threshold (a pixel value difference). Otherwise, *threshold* is treated as a hard binary threshold.

  If *threshold* is a hard binary threshold and *flags* specifies a light object on a dark background, then *threshold* is the minimum pixel value for an object pixel. If *threshold* is a hard binary threshold and *flags* specifies a dark object on a light background, then *threshold* is the maximum pixel value for an object pixel.

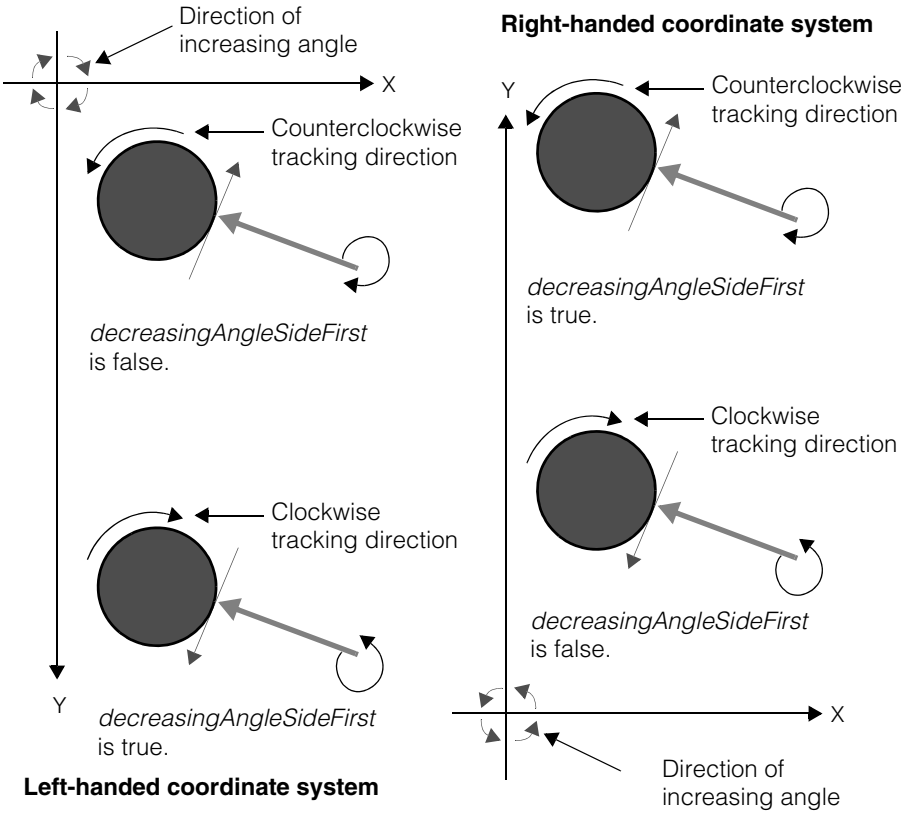
  flags — The mode flags for this **ccBoundaryTrackerRunParams**. *flags* must be either *ccBoundaryTrackerDefs::kDefaultFlags* or a value formed by ORing together one or more of the following values:

  ccBoundaryTrackerDefs::eWhiteOnBlack
  ccBoundaryTrackerDefs::eGradientThreshold
  c*cBoundaryTrackerDefs::eStopAtImageEdge*

  decreasingAngleSideFirst
  Set *decreasingAngleSideFirst* to true to track the boundary in the direction of decreasing client coordinate system angle. Set *decreasingAngleSideFirst* to false to track the boundary in the direction of increasing client coordinate system angle. The
  ```

decreasingAngleSideFirst parameter refers to the direction of the angle created if the search vector were to be rotated in an increasing or decreasing angle direction in the client coordinate system.

The tracking direction is illustrated in the following figure:



maxBoundaryPoints

Specifies the maximum number of boundary points to track. The Boundary Tracker tool will stop tracking after it tracks the specified number of points.

If the tool is tracking an open boundary that extends to the edge of the image, the tool may stop after it tracks up to twice as many points as you specify for *maxBoundaryPoints*.

areaRange Specifies the minimum and maximum object area size. Object areas are positive; hole areas are negative; and the areas of open boundaries equal 0.

Use the following table to determine the ranges that you can specify to track objects, holes, or open boundaries:

Region 1: Holes	Region 2: Open Boundaries	Region 3: Objects
areaRange < 0 (Minimum and maximum < 0.)	*areaRange = 0* (Minimum and maximum = 0.)	*areaRange > 0* (Minimum and maximum = 0.)
Track the boundaries of holes only.	Track open boundaries only.	Track the boundaries of objects only.

To track a combination objects, create ranges with overlapping regions. The following table provides examples of different ranges:

Range	Meaning
range [1 to 10000]	Track closed object boundaries only. (Do not track nonhole and open boundaries.)
range [0 to 0]	Track open boundaries only.
range [0 to 10000]	Track open and closed boundaries, but not holes.
range [-100 to 200]	Track holes whose area is smaller than 100, open boundaries, and object boundaries whose area is smaller than 200.

To prevent the tool from tracking holes, specify a minimum object size greater than or equal to zero. To prevent the tracking of open boundaries, specify that *areaRange* not include 0.

preAnglePoints Specifies the number of boundary points preceding each boundary point that are used to compute that point's angle.

postAnglePoints Specifies the number of boundary points following each boundary point that are used to compute that point's angle.

Specify 0 for both *preAnglePoints* and *postAnglePoints* to not compute any angle information.

Throws

ccBoundaryTrackerDefs::ThresholdOutOfRange
threshold is greater than 255 or less than 0.

ccBoundaryTrackerDefs::BadFlags
An invalid value was specified for *flags*.

ccRangeDefs::BadParams
The value returned by *areaRange.start()* is greater than that returned by *areaRange.end()*

ccBoundaryTrackerDefs::BadPrePostAnglePoints
preAnglePoints or *postAnglePoints* is less than 0.

ccBoundaryTrackerDefs::MaxBoundaryPointsOutOfRange
maxBoundaryPoints is less than 0.

ccBoundaryTrackerDefs::NoSearchVectors
searchVectors contains no elements.

Public Member Functions

searchVectors

```
const cmStd vector<ccLineSeg>& searchVectors() const;

void searchVectors(
  const cmStd vector<ccLineSeg>& searchVectors);
```

- `const cmStd vector<ccLineSeg>& searchVectors() const;`

  Returns the vector of search lines for this **ccBoundaryTrackerRunParams**. This **ccBoundaryTrackerRunParams** must have been constructed using the search-and-track mode constructor.

  Throws

  ccBoundaryTrackerDefs::UninitializedData
  This object was not constructed using the search-and-track mode constructor.

- ```
  void searchVectors(
    const cmStd vector<ccLineSeg>& searchVectors);
  ```

  Sets the vector of search lines for this **ccBoundaryTrackerRunParams**. This **ccBoundaryTrackerRunParams** must have been constructed using the search-and-track mode constructor.
  ```

Parameters

searchVectors A vector of search lines. A search line can start inside or outside of an object. Along each search line, the tool looks for transitions of the correct polarity that exceed the specified threshold value. Each transition is used as a start point for a boundary track.

Throws

ccBoundaryTrackerDefs::UninitializedData
This object was not constructed using the search-and-track mode constructor.

decreasingAngleSideFirst

```
bool decreasingAngleSideFirst() const;

void decreasingAngleSideFirst(
  bool decreasingAngleSideFirst);
```

- `bool decreasingAngleSideFirst() const;`

  Returns true if the tracking direction is in the decreasing client coordinate system angle direction, false if the tracking direction is in the increasing client coordinate system angle direction.

- `void decreasingAngleSideFirst(`
  `bool decreasingAngleSideFirst);`

  Sets the boundary tracking direction.

  Parameters

  decreasingAngleSideFirst
  Specify true to track in the decreasing client coordinate system angle direction, false to track in the increasing client coordinate system direction.

threshold

```
c_Int32 threshold() const;

void threshold(c_Int32 threshold);
```

- `c_Int32 threshold() const;`

  Returns the threshold value for object pixels.

- `void threshold(c_Int32 threshold);`

  Sets the threshold value for object pixels.

  Parameters

  threshold The threshold value to use for object tracking. If *flags* specifies gradient tracking mode, then *threshold* is interpreted as the gradient threshold (a pixel value difference). Otherwise, *threshold* is treated as a hard binary threshold.

  Throws

  ccBoundaryTrackerDefs::ThresholdOutOfRange
  threshold is greater than 255 or less than 0.

---

flags

```
c_UInt32 flags() const;

void flags(c_UInt32 flags);
```

- `c_UInt32 flags() const;`

  Returns the mode flags for this **ccBoundaryTrackerRunParams**. The returned value is either *ccBoundaryTrackerDefs::kDefaultFlags* or a value formed by ORing together one or more of the following values:

  ccBoundaryTrackerDefs::eWhiteOnBlack
  ccBoundaryTrackerDefs::eGradientThreshold
  c*cBoundaryTrackerDefs::eStopAtImageEdge*

- `void flags(c_UInt32 flags);`

  Sets the mode flags for this **ccBoundaryTrackerRunParams**.

  Parameters

  flags The flags to set. *flags must be* either *ccBoundaryTrackerDefs::kDefaultFlags* or a value formed by ORing together one or more of the following values:

  ccBoundaryTrackerDefs::eWhiteOnBlack
  ccBoundaryTrackerDefs::eGradientThreshold
  c*cBoundaryTrackerDefs::eStopAtImageEdge*

  Throws

  ccBoundaryTrackerDefs::BadFlags
  flags is not a legal value, as described above.

areaRange

```
const ccRange& areaRange() const;
void areaRange(const ccRange& areaRange);
```

- `const ccRange& areaRange() const;`

  Returns the minimum and maximum object area, in client units, for this **ccBoundaryTrackerRunParams**. In track-only mode, the tool will only return a boundary track if it describes an object within the specified size range. In search-and-track mode, the tool tracks boundaries until it finds an object within the specified limits.

- `void areaRange(const ccRange& areaRange);`

  Sets the minimum and maximum object area, in client units, for this **ccBoundaryTrackerRunParams**. In track-only mode, the tool returns a boundary track only if it describes an object within the specified size range. In search-and-track mode, the tool tracks boundaries until it finds an object within the specified limits.

  The minimum area is equal to the start of the range and the maximum area is equal to the end of the range.

  Object sizes are positive while hole sizes are negative. To prevent the tool from tracking holes, specify a minimum object size greater than or equal to zero. To prevent the tracking of open boundaries, specify a maximum object size of 0.

  Parameters

  areaRange The minimum and maximum object size, in client units.

preAnglePoints

```
c_Int32 preAnglePoints() const;
void preAnglePoints(c_Int32 preAnglePoints);
```

- `c_Int32 preAnglePoints() const;`

  Returns the number of boundary points preceding each boundary point that are used to compute that point's angle.

- `void preAnglePoints(c_Int32 preAnglePoints);`

  Sets the number of boundary points preceding each boundary point that are used to compute that point's angle.

  Parameters

  preAnglePoints The number of points.

Throws

ccBoundaryTrackerDefs::BadPrePostAnglePoints
preAnglePoints is less than 0.

Notes

Specify 0 for both the number of preceding and the number of following points to suppress the calculation of angle information for boundary points.

---

postAnglePoints

```
c_Int32 postAnglePoints() const;
void postAnglePoints(c_Int32 postAnglePoints);
```

- `c_Int32 postAnglePoints() const;`

  Returns the number of boundary points following each boundary point that are used to compute that point's angle.

- `void postAnglePoints(c_Int32 postAnglePoints);`

  Sets the number of boundary points following each boundary point that are used to compute that point's angle.

  Parameters

  postAnglePoints The number of points.

  Throws

  ccBoundaryTrackerDefs::BadPrePostAnglePoints
  preAnglePoints is less than 0.

  Notes

  Specify 0 for both the number of preceding and the number of following points to suppress the calculation of angle information for boundary points.

maxBoundaryPoints

```
c_Int32 maxBoundaryPoints() const;
```

Returns the maximum number of boundary points that will be tracked. This parameter can only be set at construction.

If the tool is tracking an open boundary that extends to the edge of the image, the tool may stop after it tracks up to twice as many points as you specify for *maxBoundaryPoints*.

searchAndTrack `bool searchAndTrack() const;`

Returns true if this **ccBoundaryTrackerRunParams** was constructed using the search-and-track mode constructor. Returns false if this **ccBoundaryTrackerRunParams** was constructed using the track-only mode constructor.

firstBoundaryPoint

```
const ccBoundaryTrackerPoint& firstBoundaryPoint() const;

void firstBoundaryPoint(
  const ccBoundaryTrackerPoint& firstBoundaryPoint);
```

- `const ccBoundaryTrackerPoint& firstBoundaryPoint() const;`

  Returns the starting boundary tracking point for this **ccBoundaryTrackerRunParams**. This **ccBoundaryTrackerRunParams** must have been constructed using the track-only mode constructor.

  Throws

  ccBoundaryTrackerDefs::UnintializedData,
  This object was constructed with search-and track interface and no successful tracking has been done

  Notes

  If this **ccBoundaryTrackerRunParams** was constructed using the track-only mode constructor, this function will return the same starting point that was supplied to the constructor even if no valid boundary track was found.

- ```
  void firstBoundaryPoint(
    const ccBoundaryTrackerPoint& firstBoundaryPoint);
  ```

  Sets the starting boundary point for this **ccBoundaryTrackerRunParams**. This **ccBoundaryTrackerRunParams** must have been constructed using the track-only mode constructor.

  Parameters

  firstBoundaryPoint
  The starting point, specified in the client coordinate system.

  Throws

  ccBoundaryTrackerDefs::UnintializedData,
  This object was constructed with search-and track interface.
  ```

Notes

Call this function to specify a new starting point for track-only mode boundary tracking.

ccCADFile

```
#include <ch_cvl/cadfile.h>

class ccCADFile;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Behavior

This class encapsulates the conversion of a DXF format CAD file into a **ccGeneralShapeTree**. Currently only a subset of Autodesk, Inc.'s standard ASCII DXF file format is supported. Binary DXF files are not supported. DXF files with format versions not supported result in a throw from the converter.

Returned shape trees can represent the entire file, or specific layers or groups within the file. The tree representing the entire file is organized such that each layer of the drawing is represented as a **ccGeneralShapeTree** on a separate branch of the returned parent tree.

A **ccGeneralShapeTree** representing a particular layer or group will itself contain the various primitive shapes and custom objects within that layer or group. Each **ccShape** representing a custom object will itself be a **ccGeneralShapeTree** pointer object containing the set of primitive shapes and custom objects within the custom object. If a custom object is repeated more than once within the DXF file, it will result in the creation of a new **ccGeneralShapeTree** (the object will be replicated, not shared).

Transformations (including handedness information and coordinate system information) are supported by mapping all the supported primitive shapes into a single shape coordinate system, and are not explicitly represented. Primitives that are not supported are simply ignored.

DXF Versions Supported

Currently only a subset of the Autodesk standard ASCII DXF file format is supported. **ccCADFile** supports DXF formats corresponding to AutoCAD versions R12, R13, R14, and 2000. DXF versions corresponding to AutoCAD versions R11, 2000i, and 2002 should also work, but are not tested.

DXF File Organization

DXF files are organized into sections. The following table identifies these sections and shows what information is parsed from each one.

Sections	Contents
HEADER	Units, handedness, and base angle of the drawing.
TABLES	Layer information.
BLOCKS	Custom object name and definition.
ENTITIES	Visible objects that make up the basic geometric shapes of the drawing, as listed in the following table.
CLASSES	Application-specific, non-geometric information, not used by **ccCADFile**.
OBJECTS	Information about groups.

The following DXF entities are recognized by **ccCADFile** and are converted into the **ccShape**(s) shown.

DXF Entity	ccShape
ARC	**ccEllipseArc2**
CIRCLE	**ccEllipse2**
ELLIPSE	**ccEllipseArc2**
INSERT	**ccGeneralShapeTree**
LINE	**ccLineSeg**
LWPOLYLINE	**ccPolyline** or **ccCountourTree** (see notes below)
MLINE	**ccPolyline**
POLYLINE	**ccPolyline** or **ccCountourTree** (see notes below)
RAY	**ccLine**
SOLID	**ccPolyline**
SPLINE	**ccDeBoorSpline**
POINT	**cc2Point** (any Z position information is ignored)
XLINE	**ccLine**

The following DXF entity information is ignored:

- DXF entities not in the table above
- All three dimensional information
- Fill and style information
- Rounded corner and spline representations using POLYLINE

POLYLINE and LWPOLYLINE entities are represented as either **ccPolyline** or **ccCountourTree** objects. If the DXF entity consists of straight lines, a **ccPolyline** object is returned. If the DXF object contains any arcs, a **ccCountourTree** object consisting of **ccEllipseArc2** and **ccLineSeg** objects is returned.

The INSERT entity provides a mechanism for displaying a transformed version of a custom object from the BLOCKS section. Its **ccShape** is a **ccGeneralShapeTree** whose children consist of the transformed **ccShape** versions of its defining entities (which can include other INSERTs or trees). If a BLOCK is used more than once, it is replicated into a new **ccGeneralShapeTree**.

Constructors/Destructors

ccCADFile

```
ccCADFile();

ccCADFile(
  const ccCvlString &fileName,
  c_Int32 mode = cmStd ios::in);

~ccCADFile();

ccCADFile(const ccCADFile& rhs);
```

- `ccCADFile();`

  Default constructor. Creates an empty, closed **ccCADFile** object.

- ```
  ccCADFile(
    const ccCvlString &fileName,
    c_Int32 mode = cmStd ios::in);
  ```

  Opens and loads *fileName* containing the specified DXF format text file.

  Parameters

fileName	The pathname of the DXF format text file.
mode	The operating mode. *ios::in* is currently the only supported mode.
  ```

Throws

ccCADFile::NotImplemented
If *mode* is not *ios::in*.

ccCADFile::CanNotOpenFile
If *fileName* cannot found or cannot be opened for any reason.

ccCADFile::CanNotLoadFile
If there is a parsing error while reading the file.

ccCADFile::FileFormatNotSupported
If *fileName* is not a DXF format file.

- `~ccCADFile();`

Destructor. Deletes this object and closes any open DXF file.

- `ccCADFile(const ccCADFile& rhs);`

Copy constructor. Initialize this object using *rhs*.

Parameters

rhs The source of the copy.

Enumerations

UnitTypes `enum UnitTypes`

This enumeration defines the DXF file unit IDs.

Values
eUknown = 0
eScientific = 1
eDecimal = 2
eEngineering = 3
eArchitectural = 4
eFractional = 5
eWindowsdesktop = 6

Operators

operator=

```
ccCADFile& operator=(const ccCADFile& rhs);
```

Assignment operator.

Parameters

rhs Source of the assignment.

Public Member Functions

open

```
void open(
  const ccCvlString &fileName,
  c_Int32 mode = cmStd ios::in);
```

Opens *fileName* and loads the DXF format text file.

Parameters

fileName The path to the DXF format file to open.

mode The operating mode. *ios::in* is currently the only supported mode.

Throws

ccCADFile::NotImplemented
If *mode* is not ios::in.

ccCADFile::CanNotOpenFile
If *fileName* cannot found or cannot be opened for any reason.

ccCADFile::CanNotLoadFile
If there is a parsing error while reading the file.

ccCADFile::FileFormatNotSupported
If *fileName* is not a DXF format file.

isOpen

```
bool isOpen() const;
```

Returns true if the specified DXF file is open; otherwise returns false.

close

```
void close();
```

Closes the currently open DXF file.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

getUnits

```
UnitTypes getUnits() const;
```

Returns the unit ID of the currently open DXF file.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

layerNames

```
void layerNames(
  cmStd vector<cccVlString> &names) const;
```

Returns a vector of the layer names in the currently open DXF file.

The returned names are in the same order that the layer subtrees are added to a general shape tree using the method **shapeTree()** described below. For example, *names[0]* contains the name of the layer corresponding to the first added subtree. The layer corresponding to *names[i]* can be accessed directly by passing *names[i]* or the integer index *i* as the first argument to **layerShapeTree()**.

Parameters

names A vector of layer names contained in the currently open DXF file.

ccCADFile::FileNotOpen
If there is no open DXF file.

groupNames

```
void groupNames(
  cmStd vector<cccVlString> &names) const;
```

Returns a vector of the group names in the currently open DXF fi e.

The group corresponding to *names[i]* can be accessed directly by passing *names[i]* or the integer index *i* as the first argument to **groupShapeTree()**.

Parameters

names Group names contained in the currently open DXF file.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

numLayers

```
c_Int32 numLayers() const;
```

Returns the number of layers in the currently open DXF file.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

numGroups

```
c_Int32 numGroups() const;
```

Returns the number of groups in the currently open DXF file.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

shapeTree

```
void shapeTree(ccGeneralShapeTree& tree) const;
```

Adds the contents of the currently open DXF file to *tree*. Each DXF file layer is added to a separate branch of the tree.

Parameters

tree The shape tree where the DXF file's contents are to be added.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

layerShapeTree

```
void layerShapeTree(c_Int32 layer,
 ccGeneralShapeTree& tree) const;

void layerShapeTree(const ccCvlString& name,
 ccGeneralShapeTree& tree) const;
```

Adds the contents of a specified layer of the open DXF file to *tree*, where the layer is specified by name or index. The index of a layer is the zero-based position of its name in the vector returned by **layerNames()**. The contents of the layer are added on separate branches of the passed *tree*.

-
```
void layerShapeTree(c_Int32 layer,
 ccGeneralShapeTree& tree) const;
```

Parameters

layer The index number of a layer in the vector of layer names returned by **layerNames()**.

tree The shape tree where the layer is to be added.

Throws

ccCADFile::FileNotOpen
If there is no open DXF file.

ccCADFile::BadIndex
If *layer* is invalid.

- ```
  void layerShapeTree(const ccCvlString& name,
    ccGeneralShapeTree& tree) const;
  ```

  Parameters

  name The name of the layer in the currently open DXF file to be added.

  tree The shape tree where the layer is to be added.

  Throws

  ccCADFile::FileNotOpen
  If there is no open DXF file.

  ccCADFile::BadIndex
  If *name* is invalid.

groupShapeTree

```
void groupShapeTree(
  c_Int32 group,
  ccGeneralShapeTree& tree) const;

void groupShapeTree(
  const ccCvlString& grpName,
  ccGeneralShapeTree& tree) const;
```

Adds the contents of a specified group of the currently open DXF file to *tree*. The contents of the group are added on separate branches of the passed *tree*.

A group is an AutoCAD feature that allows for an arbitrary collection of DXF entities on any layer to be grouped together for display or processing. The group must be specified and names within AutoCAD before the DXF file is saved.

The group can be specified by group name or index number. The index of a group is the zero-based position of its name in the vector returned by **groupNames()**.

- ```
  void groupShapeTree(
    c_Int32 group,
    ccGeneralShapeTree& tree) const;
  ```

  Parameters

  group The index number of a group in the vector of group names returned by **groupNames()**.

  tree The shape tree where the group is to be added.

  Throws

  ccCADFile::FileNotOpen
  If there is no open DXF file.

ccCADFile::BadIndex
If *group* is invalid.

- ```
  void groupShapeTree(
    const ccCvlString& grpName,
    ccGeneralShapeTree& tree) const;
  ```

  Parameters

  grpName The group name to be added from the currently open DXF file.

  tree The shape tree where the group is to be added.

  Throws

  ccCADFile::FileNotOpen
  If there is no open DXF file.

  ccCADFile::BadIndex
  If *grpName* is invalid.
  ```

ccCalib2ParamsExtrinsic

```
#include <ch_cvl/ccalib.h>

class ccCalib2ParamsExtrinsic;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class holds extrinsic camera calibration parameters (properties of the image acquisition system that are external to the camera). These are:

- Orientation of the physical coordinate system with respect to the camera coordinate system, specified by three angles.
- Translation of the origin of the 3-D physical coordinate system with respect to the camera coordinate system.

The extrinsic parameters describe the rigid 3-D transform between the camera coordinate system and the physical coordinates system. This transform maps a 3-D vector v to R * v + t where t is the 3-D translation and R is the 3x3 matrix of rotations through angles contained in the extrinsic parameters.

When you use multiple views for a calibration application (for example, to create a **cc2XformCalib2** object), each view has a unique set of extrinsic parameters.

Constructors/Destructors

ccCalib2ParamsExtrinsic

```
ccCalib2ParamsExtrinsic(
  const cc3AngleVect& orientation,
  const cc3Vect& translation);

ccCalib2ParamsExtrinsic();
```

- ```
  ccCalib2ParamsExtrinsic(
    const cc3AngleVect& orientation,
    const cc3Vect& translation);
  ```

  Constructs an object with the specified orientation and translation.
  ```

Parameters

orientation An object that holds the three rotation angles of the axes of a 3-D coordinate system.

translation The 3-D origin translation between the physical coordinate system and the image coordinate system.

- `ccCalib2ParamsExtrinsic();`

Default constructor. Constructs an object initialized with all rotation angles = 0 and translation = (0, 0, 1).

Public Member Functions

orientation

```
const cc3AngleVect& orientation() const;
void orientation(const cc3AngleVect& orientation);
```

- `const cc3AngleVect& orientation() const;`

Returns the orientation parameter stored in this object.

- `void orientation(const cc3AngleVect& orientation);`

Sets a new orientation parameter.

Parameters

orientation The new orientation parameter.

translation

```
const cc3Vect& translation() const;
void translation(const cc3Vect& translation);
```

- `const cc3Vect& translation() const;`

Returns the translation parameter stored in this object.

- `void translation(const cc3Vect& translation);`

Sets a new translation parameter.

Parameters

translation The new translation parameter.

ccCalib2ParamsIntrinsic

```
#include <ch_cvl/ccalib.h>

class ccCalib2ParamsIntrinsic;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class holds intrinsic camera calibration parameters (properties in an image acquisition system that are internal to the camera). The intrinsic parameters are:

- The x- and y-scale (also called focal lengths)
- Skew
- The x- and y-translation
- Coefficient of radial distortion

These parameters remain constant as long as the internal camera settings (camera itself, lens used on the camera, focal length setting, aperture setting, and so on) remain constant. Also, the intrinsic camera calibration parameters are expected to stay constant even if external settings vary such as orientation of object plane with respect to the camera, lighting conditions, and so on.

Constructors/Destructors

ccCalib2ParamsIntrinsic

```
ccCalib2ParamsIntrinsic(
  const cc2Vect& scale,
  double skew,
  const cc2Vect& translation,
  double k1);

ccCalib2ParamsIntrinsic();
```

- ```
  ccCalib2ParamsIntrinsic(
    const cc2Vect& scale,
    double skew,
    const cc2Vect& translation,
    double k1);
  ```

  Constructs an intrinsic calibration parameters object from x and y scales, skew, x and y translation, and the radial distortion coefficient.

  Parameters

  scale — The x- and y-scale. For example, (.9, 1.1) for an x-scale factor of .9 and a y-scale factor of 1.1.

  skew — Equals $-S_y(\tan\theta)$, where S_y is the y-scale (see above) and θ is the shear angle as described in the **cc2Matrix** reference page.

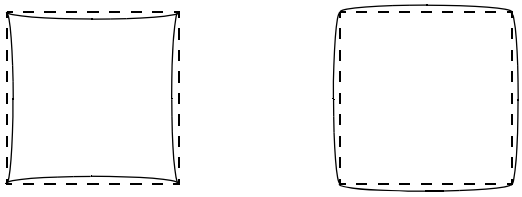
  translation — The x- and y-translation in client coordinates.

  k1 — Radial distortion coefficient. There are two types of radial distortion:

  1. Barrel distortion: This distortion bends the edges of a square outward from its center. In this case, k1 < 0.

  2. Pincushion distortion: This distortion bends the edges of a square inward towards its center. In this case, k1 > 0.
  ```

When *k1* = 0 there is no radial distortion. See the following diagram.



Pincushion distortion
k1 > 0

Barrel distortion
k1 < 1

Throws

cc2XformCalibDefs::BadParams
If **scale.x()** <= 0 or **scale.y()** <= 0.

- `ccCalib2ParamsIntrinsic();`

  Constructs an object initialized to its default state with *scale* = (1,1), *skew* = 0, *translation* = (0,0), and *k1* = 0.

Public Member Functions

scale

```
cc2Vect scale() const;
void scale(const cc2Vect& scale);
```

- `cc2Vect scale() const;`

  Returns the x- and y-scales stored in this object.

- `void scale(const cc2Vect& scale);`

  Sets new x- and y-scales.

  Parameters

  scale The new x- and y-scales.

  Throws

  cc2XformCalibDefs::BadParams
  If **scale.x()** <= 0 or **scale.y()** <= 0.

skew

```
double skew() const;
void skew(double skew);
```

See *skew* description in the constructor.

- `double skew() const;`

  Returns the skew stored in this object.

- `void skew(double skew);`

  Sets a new skew value.

  Parameters

  skew The new skew.

translation

```
cc2Vect translation() const;
void translation(const cc2Vect& trans);
```

The x- and y-translation in client coordinates.

- `cc2Vect translation() const;`

  Returns the x and y translation stored in this object.

- `void translation(const cc2Vect& trans);`

  Sets new x and y translation.

  Parameters

  trans The new x and y translation.

k1

```
double k1() const;
void k1(double k1);
```

See *k1* description in the constructor.

- `double k1() const;`

  Returns the radial distortion coefficient stored in this object.

- `void k1(double k1);`

  Sets a new radial distortion coefficient.

  Parameters

k1	The new radial distortion coefficient.

ccCalib2ParamsIntrinsic

ccCalib2VertexFeatureDefs

```
#include <ch_cvl/calibftr.h>

class ccCalib2VertexFeatureDefs;
```

Name space for calibration feature extraction related enums.

Enumerations

CorrespondMethod

```
enum CorrespondMethod;
```

This enumeration defines the modes used to set the origin and coordinate axes of the calibration plate Grid2D coordinate system. The correspondence method is also known as the *label mode* or *label method*. These enum modes are passed to **ccCalib2VertexFeatureParams::labelMode(***mode***)**.

If it is crucial to have the Grid2D coordinate system stationary with respect to the physical calibration plate (for example, in multiple view calibration), you should only use the *eUseFiducial* mode.

Mode	Meaning
eNone = 0	The origin of the Grid2D coordinate system is set at the vertex closest to the center of the image. The Grid2D x-axis is set on the row or column of vertices that passes through the origin, and is most closely aligned with the image space x-axis. The image space x-axis and the Grid2D x-axis, as viewed in the image, point in approximately the same direction. See the following figure.  Keep in mind that the checkerboard in the image can be at any oblique angle depending on the camera angle, and it can be distorted. This is the default mode.
eUseOrigin	Specifies that the vertex closest to a designated location be used as the origin of the Grid2D coordinate system. The designated origin can be set using **ccCalibrationVertexFeatureParams::origin()**. The direction of the axes is set exactly as in *eNone* mode above.

Mode	Meaning
eUseFiducial	Specifies that the use of a Cognex-specific fiducial target be found in the image and used to set the Grid2D coordinate system. The origin (0,0) and the axes (x and y) of the Grid2D coordinate system are chosen as shown in the following diagram of a calibration plate containing a fiducial marker. The Cognex part number for these calibration plates is 320-0015. If you use your own calibration plate, it must conform to specifications contained in an engineering drawing available from Cognex. This specification allows for any physical size for checkers but once physical checker size is decided, the width, length of the fiducial bars, polarities of checkers, and the fiducial must be according to specification. Note that size of all checkers in acquired images of a physical calibration plate must be at least 15x15 pixels. The following is an example calibration plate with a fiducial mark. 
Mode	Meaning
eUse DataMatrix	Specifies that standard Data Matrix codes are to be used as calibration fiducials that are uniquely identifiable in the calibration target. Each Data Matrix code must encode *either* its physical position – Version 0 format – *or* its physical position and the grid pitch – Version 1 format. This mode will ignore any information about the physical grid pitch that may be encoded in the Data Matrix codes, and will instead use the value **ccCalib2VertexFeatureParams::physicalGridPitch()** specified in the input parameters. See the API for the CVL symbol tool <*ch_cvl/acusymbl.h*> and the CVL Vision Tools Guide for more details about Data Matrix codes and any associated terminology used in the rest of this document. Also see the CVL Vision Tools Guide for the requirements this mode imposes on all Data Matrix codes in the image.
eUse DataMatrix WithGridPitch	Similar to *eUseDataMatrix*, but in this mode each Data Matrix code *must* encode its data in the Version 1 format only. In this mode, the tool will ignore the value **ccCalib2VertexFeatureParams::physicalGridPitch()** in the input parameters, and will instead use the value of physical grid pitch encoded in the Data Matrix codes. If the encoded value of the physical grid pitch is less than or equal to zero, the tool will throw *ccCalib2VertexFeatureDefs::DataMatrixParseError*

`enum`

This enumeration defines default calibration plate parameters.

Value	Meaning
kDefaultGridPitch = 1	Default grid pitch in client units.

Algorithm

```
enum Algorithm;
```

This enumeration defines the algorithms used to extract and label features (tile vertices) from the image.

Value	Meaning
eStandard = 0	Appropriate for clean images with minimal noise, contrast variations, or image defects.
eExhaustive = 1	An exhaustive algorithm is used to locate and label the tile vertices. This algorithm is significantly more robust than *eStandard*, although it may take longer to run. Cognex recommends the use of *eExhaustive* in all cases. Note, however, that the vertex locations returned by *eExhaustive* may differ slightly from those returned by *eStandard*.

Value	Meaning
eExhaustiveMultiRegion = 2	Similar to *eExhaustive*, but it returns feature correspondences from all contiguous regions of checkerboard features in which a Data Matrix was successfully decoded (unlike *eStandard* or *eExhaustive*). It can only be used with Data Matrix fiducials (that is, when label mode is *eUseDataMatrix* or *eUseDataMatrixWithGridPitch*). *eExhaustiveMultiRegion* runs slower than *eExhaustive*. However, if robustness is more important than speed, then it is recommended to use *eExhaustiveMultiRegion* instead of *eExhaustive* when Data Matrix fiducials are employed, for the following reason. Sometimes a portion of the calibration target may be obscured due to physical obstructions or poor lighting, causing the checkerboard grid to get split into distinct regions of contiguous features. When Data Matrix codes are used as fiducials, it becomes possible to extract features from these multiple regions as long as each region of contiguous features has a Data Matrix code embedded inside. This is possible because each Data Matrix code encodes its position in the grid. Also note that this mode returns features from maximally connected sub-grids. It does not intentionally separate connected features into different regions. So, when the features are fully connected, *eExhaustiveMultiRegion* returns exactly the same result as *eExhaustive*. When the image includes disconnected regions of features, *eExhaustiveMultiRegion* may return more features than *eExhaustive* because *eExhaustive* only returns features from one fully connected region and *eExhaustiveMultiRegion* can return features from multiple connected regions.
kDefaultAlgorithm = eStandard	The default algorithm (to preserve backwards compatibility.

ccCalib2VertexFeatureDefs

ccCalib2VertexFeatureParams

```
#include <ch_cvl/calibftr.h>

class ccCalib2VertexFeatureParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class encapsulates all the parameters required to configure feature extraction from a checkerboard type calibration plate image.

Constructors/Destructors

ccCalib2VertexFeatureParams

```
ccCalib2VertexFeatureParams();

ccCalib2VertexFeatureParams(
  const cc2Vect& gridPitch,
  ccCalib2VertexFeatureDefs::CorrespondMethod mode =
                          ccCalib2VertexFeatureDefs::eNone);
```

- `ccCalib2VertexFeatureParams();`

  Default constructor. Default values are:

  gridPitch = (1, 1)
  mode = *eNone*

- ```
  ccCalib2VertexFeatureParams(
    const cc2Vect& gridPitch,
    ccCalib2VertexFeatureDefs::CorrespondMethod mode =
                            ccCalib2VertexFeatureDefs::eNone);
  ```

  Constructs a vertex feature parameters object using the given parameters.

  Parameters

gridPitch	The calibration plate grid pitch.
mode	The correspondence mode.
  ```

Public Member Functions

physicalGridPitch

```
void physicalGridPitch(const cc2Vect& gridPitch);

const cc2Vect& physicalGridPitch() const;
```

Specifies physical units along the x- and y-axes of the Plate2D coordinate system. The x-component of *gridPitch* is the distance between any two adjacent checker vertices when the line joining them is parallel to the Plate2D x-axis. The y-component of *gridPitch* is the distance between any two adjacent checker vertices when the line joining them is parallel to the Plate2D y-axis.

The default physical grid pitch is (1, 1).

- `void physicalGridPitch(const cc2Vect& gridPitch);`

  Sets a new grid pitch.

  Parameters

  gridPitch The new grid pitch.

  Throws

  ccCalib2VertexFeatureDefs::BadParam
  If either component of *gridPitch* is less than or equal to zero.

- `const cc2Vect& physicalGridPitch() const;`

  Returns the current grid pitch.

origin

```
void origin(const cc2Vect& o);

const cc2Vect& origin() const;
```

An origin in client units to be used for labeling of returned feature points. The vertex closest to this point will be used as the origin for point correspondence when operating in *ccCalib2VertexFeatureDefs::eUseOrigin* mode. The default is (0, 0).

- `void origin(const cc2Vect& o);`

  Sets a new origin.

  Parameters

  o The new origin.

- `const cc2Vect& origin() const;`

  Returns the current origin.

labelMode

```
void labelMode(
  ccCalib2VertexFeatureDefs::CorrespondMethod m);

ccCalib2VertexFeatureDefs::CorrespondMethod labelMode()
                                                    const;
```

The method used for labeling detected vertex points in the calibration plate image. The default is *ccCalib2VertexFeatureDefs::eNone.*

- `void labelMode(`
  `ccCalib2VertexFeatureDefs::CorrespondMethod m);`

  Sets a new label mode.

  Parameters

  m The new label mode.

  Throws

  ccCalib2VertexFeatureDefs::BadParam
  If *m* is not a valid entry from the *ccCalib2VertexFeatureDefs::CorrespondMethod* enum

- `ccCalib2VertexFeatureDefs::CorrespondMethod labelMode()`
  `const;`

  Returns the current label mode.

algorithm

```
void algorithm(
  ccCalib2VertexFeatureDefs::Algorithm algorithm);

ccCalib2VertexFeatureDefs::Algorithm algorithm()const;
```

The algorithm to use when extracting and labeling vertices. The default is *ccCalib2VertexFeatureDefs::eStandard.* Cognex recommends the use of *ccCalib2VertexFeatureDefs::eExhaustive*, which is more robust, particularly in cases of low or uneven contrast, image blur, reflections, or plate defects.

- `void algorithm(`
  `ccCalib2VertexFeatureDefs::Algorithm algorithm);`

  Sets the algorithm.

Parameters

m The algorithm.

Throws

ccCalib2VertexFeatureDefs::BadParam
If the input is not a valid choice from the enum *ccCalib2VertexFeatureDefs::Algorithm*

- `ccCalib2VertexFeatureDefs::Algorithm algorithm()const;`

Returns the current algorithm.

dataMatrixTimeoutSeconds

```
void dataMatrixTimeoutSeconds(double timeoutSec);

double dataMatrixTimeoutSeconds() const;
```

- `void dataMatrixTimeoutSeconds(double timeoutSec);`

Sets the timeout in seconds to find a single Data Matrix code in the image (or a region in the image if algorithm is *eExhaustiveMultiRegion*). The tool will only spend the specified amount of seconds to find and decode each Data Matrix code.

Parameters

timeoutSec The timeout value in seconds to set.

Notes

This parameter is used only when *labelMode* is *eUseDataMatrix* or *eUseDataMatrixWithGridPitch*.

If the algorithm is *eExhaustiveMultiRegion* and the tool cannot find and decode a Data Matrix code inside a region of checkerboard features within the specified time, it will not include any features from that region.

Throws

ccCalib2VertexFeatureDefs::BadParam
If *timeoutSec* is less than or equal to 0.

The default is *HUGE_VAL*

- `double dataMatrixTimeoutSeconds() const;`

Gets the timeout.

Deprecated Members

The following constructor and functions are deprecated and are maintained here for backward compatibility only.

ccCalib2VertexFeatureParams

```
ccCalib2VertexFeatureParams(
  const cc2Vect& gridPitch,
  const cc2Vect& tileSize =
       cc2Vect(ccCalib2VertexFeatureDefs::kDefaultTileSize,
       ccCalib2VertexFeatureDefs::kDefaultTileSize),
  ccCalib2VertexFeatureDefs::CorrespondMethod mode =
                          ccCalib2VertexFeatureDefs::eNone);
```

nominalTileSize

```
void nominalTileSize(const cc2Vect& tileSize);

const cc2Vect& nominalTileSize();
```

ccCalib2VertexFeatureParams

ccCalib2VertexFeatureParseResult

```
#include <ch_cvl/calibftr.h>

class ccCalib2VertexFeatureParseResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class contains the result of parsing the string that was encoded in a Data Matrix code.

Constructors/Destructors

ccCalib2VertexFeatureParseResult

```
ccCalib2VertexFeatureParseResult();
```

Constructs the object using the default values.

Notes

Compiler generated destructor, copy constructor, and assignment operator are used.

Operators

operator==

```
bool operator==(
  const ccCalib2VertexFeatureParseResult& rhs) const;
```

Equality test operator. Returns true if *this is the same as rhs, or false otherwise.

Parameters

rhs	The object to compare with this object.

operator!=

```
bool operator!=(
  const ccCalib2VertexFeatureParseResult& rhs) const;
```

Inequality test operator. Returns false if *this is the same as rhs, or true otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

isComputed `bool isComputed() const;`

Returns a Boolean flag that indicates if this result object was computed or not.

The default is false.

Notes

It is set to true when **set()** is called.

hasPositionGrid2D

`bool hasPositionGrid2D() const;`

Returns whether or not this result has a valid **positionGrid2D()**.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

positionGrid2D `const cc2Vect& positionGrid2D() const;`

Returns the (X,Y) Grid2D position of the Data Matrix code.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false
or
hasPositionGrid2D() is false.

hasGridPitch `bool hasGridPitch() const;`

Returns whether or not this result has a valid **gridPitch()**.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

gridPitch `const cc2Vect& gridPitch() const;`

Returns the grid pitch of the checkerboard tiles along the X and Y axes of Plate2D in physical measurement units.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false
or
hasGridPitch() is false.

hasUnitString

```
bool hasUnitString() const;
```

Returns whether or not this result has a valid **unitString()**.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

unitString

```
const ccCvlString& unitString() const;
```

Returns the measurement units in which *gridPitch* was specified.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false
or
hasUnitString() is false.

ccCalib2VertexFeatureParseResult

ccCalib2VertexFeatureResult

```
#include <ch_cvl/calibftr.h>

class ccCalib2VertexFeatureResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class contains the result of the calibration.

Constructors/Destructors

ccCalib2VertexFeatureResult

```
ccCalib2VertexFeatureResult() : isComputed_(false);
```

Constructs a default object.

Notes

Compiler generated destructor, copy constructor, and assignment operator are used.

Operators

operator==

```
bool operator==(
  const ccCalib2VertexFeatureResult& rhs) const;
```

Equality test operator. Returns true if *this is the same as rhs, or false otherwise.

Parameters

rhs	The object to compare with this object.

operator!=

```
bool operator!=(
  const ccCalib2VertexFeatureResult& rhs) const;
```

Inequality test operator. Returns false if *this is the same as rhs, or true otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Returns a Boolean flag that indicates if this result object was computed or not.

The default is false.

client2DPlate2DPairs

```
const ccCrspPairVector& client2DPlate2DPairs() const;
```

Returns a vector of correspondence pairs. Each correspondence pair contains the Client2D position of an extracted vertex point and its corresponding Plate2D position.

Notes

If label mode is *eExhaustiveMultiRegion*, multiple regions of checkerboard features may be detected. This vector will contain feature correspondences from all grids of features that were detected.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

client2DPlate2DPairsMultiRegion

```
const cmStd vector<ccCrspPairVector>&
client2DPlate2DPairsMultiRegion() const;
```

Returns a vector of ccCrspPairVectors, where each ccCrspPairVector contains feature correspondences from a single region of contiguous checkerboard features.

Notes

If label mode is not *eExhaustiveMultiRegion*, features from only one region of checkerboard features will have been detected and this vector will contain only one element.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

symbolInfo

```
const cmStd vector<ccCalib2VertexFeatureSymbolInfo>&
symbolInfo() const;
```

Returns a vector of objects that contain the data decoded from each Data Matrix that was successfully found, decoded, and parsed.

Notes

If the tool is **not** running in *eUseDataMatrix* mode or *eUseDataMatrixWithGridPitch* mode, this vector will be empty.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

ccCalib2VertexFeatureResult

ccCalib2VertexFeatureSymbolInfo

```
#include <ch_cvl/calibftr.h>

class ccCalib2VertexFeatureSymbolInfo;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class contains data decoded from the Data Matrix code.

Constructors/Destructors

ccCalib2VertexFeatureSymbolInfo

```
ccCalib2VertexFeatureSymbolInfo() : isComputed_(false);
```

Constructs a default object.

Notes

Compiler generated destructor, copy constructor, and assignment operator are used.

Operators

operator==

```
bool operator==(
  const ccCalib2VertexFeatureSymbolInfo& rhs) const;
```

Equality test operator. Returns true if *this is the same as rhs, or false otherwise.

Parameters

rhs	The object to compare with this object.

operator!=

```
bool operator!=(
  const ccCalib2VertexFeatureSymbolInfo& rhs) const;
```

Inequality test operator. Returns false if *this is the same as rhs, or true otherwise.

Parameters

rhs	The object to compare with this object.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Returns a Boolean flag that indicates if this result object was computed or not.

The default is false.

parseResult

```
const ccCalib2VertexFeatureParseResult& parseResult()
const;
```

Returns the result of parsing the data encoded in the Data Matrix code.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

dataMatrixResult

```
const ccAcuSymbolResult& dataMatrixResult() const;
```

Returns the found and decoded Data Matrix code.

Throws

ccCalib2VertexFeatureDefs::NotComputed
If **isComputed()** is false.

ccCalibDefs

```
#include <ch_cvl/calib.h>

class ccCalibDefs;
```

A name space that holds enumerations and constants used with the Calibration tool classes.

Enumerations

CalibType

```
enum CalibType;
```

This enumeration defines the types of calibration supported by the Calibration tool.

Value	Meaning
eGridLinear	Linear calibration using a grid of dots.
eGridPolynomialOrder3	Third-order polynomial calibration using a grid of dots.
eGridPolynomialOrder5	Fifth-order polynomial calibration using a grid of dots.

Polarity

```
enum Polarity;
```

This enumeration defines the polarity of the calibration grid image used to perform the calibration.

Value	Meaning
eDarkOnLight	The image consists of dark dots on a light background.
eLightOnDark	The image consists of light dots on a dark background.
eAutoDetect	The Calibration tool automatically determines the polarity of the image.

ccCalibDefs

ccCalibrateLineScanCameraDefs

```
#include <ch_cvl/ccalibls.h>

class ccCalibrateLineScanCameraDefs;
```

Namespace for enumerations related to line scan calibration.

Enumerations

CalibrationYAxisAdjustmentMode

```
enum CalibrationYAxisAdjustmentMode;
```

This enumeration defines how the y-axis of calibrated space is established during line scan calibration.

Value	Meaning
eUsePlateOrientation	The y-axis is defined by the orientation of the fiducial mark on the calibration plate.
eAdjustOrientationToScanDirection	The y-axis is defined by the apparent motion of the calibration plate as the line scan image is acquired. To use the 1D image unwarp tool to generate a rectified image from a calibrated line scan camera, you must specify this adjustment mode.
kDefaultCalibrationYAxisAdjustmentMode	The default adjustment mode (*eUsePlateOrientation*).

ccCalibrateLineScanCameraDefs

ccCalibrateLineScanCameraParams

```
#include <ch_cvl/ccalibls.h>

class ccCalibrateLineScanCameraParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class encapsulates all the parameters required to configure the line scan camera calibration tool.

Constructors/Destructors

ccCalibrateLineScanCameraParams

```
ccCalibrateLineScanCameraParams();
```

Default-constructs an object with the following values:

- **useDistanceFromCameraToTarget**: false
- **distanceFromCameraToTarget**: 0.0
- **calibrationYAxisAdjustmentMode**: *kDefaultCalibrationYAxisAdjustmentModel*

Public Member Functions

useDistanceFromCameraToTarget

```
bool useDistanceFromCameraToTarget() const;

void useDistanceFromCameraToTarget(
   bool useDistanceFromCameraToTarget);
```

- ```
  bool useDistanceFromCameraToTarget() const;
  ```

  Returns true if this **ccCalibrateLineScanCameraParams** specifies that the supplied camera-to-target distance be used when calibrating the camera, false if the specified distance is ignored.
  ```

- ```
  void useDistanceFromCameraToTarget(
     bool useDistanceFromCameraToTarget);
  ```

  Specifies whether or not the distance specified for **distanceFromCameraToTarget()** is used when calibrating the camera. If you specify and use this distance, it must be accurate within 10%. Specifying the distance can improve the accuracy of the calibration.

  Parameters

  useDistanceFromCameraToTarget

  Specify true to use the supplied distance, false to ignore it.

distanceFromCameraToTarget

```
double distanceFromCameraToTarget() const;

void distanceFromCameraToTarget(
   double distanceFromCameraToTarget);
```

- ```
  double distanceFromCameraToTarget() const;
  ```

  Returns the currently specified camera-to-target distance for this **ccCalibrateLineScanCameraParams**. This value is only used if **useDistanceFromCameraToTarget()** is true.

- ```
  void distanceFromCameraToTarget(
     double distanceFromCameraToTarget);
  ```

  Sets the camera-to-target distance for this **ccCalibrateLineScanCameraParams**. This value is only used if **useDistanceFromCameraToTarget()** is true.

  If you specify a distance, it must be accurate to within 10% of the actual distance from the surface of the calibration plate and the surface of the image sensor in the camera. Specifying an accurate distance can improve the accuracy of the computed calibration.

  The distance must be specified in the same units in which you express the physical positions of the calibration plate vertices.

  Parameters

  distanceFromCameraToTarget

  The measured distance between the calibration plate surface and the camera image sensor surface. If the supplied value is 0, **cfCalibrateLineScanCamera()** will *ccCalibrateLineScanCameraDefs::BadParams*.
  ```

Throws

ccCalibrateLineScanCameraDefs::BadParams

distanceFromCameraToTarget is less than 0 or equal to HUGE_VAL.

calibrationYAxisAdjustmentMode

```
ccCalibrateLineScanCameraDefs::CalibrationYAxisAdjustmentMode
   calibrationYAxisAdjustmentMode() const:

void calibrationYAxisAdjustmentMode (
   ccCalibrateLineScanCameraDefs::CalibrationYAxisAdjustmentMode
   calibrationYAxisAdjustmentMode);
```

- `ccCalibrateLineScanCameraDefs::CalibrationYAxisAdjustmentMode calibrationYAxisAdjustmentMode() const:`

  Returns the y-axis adjustment mode specified for this object. The returned value is one of the following:

  ccCalibrateLineScanCameraDefs::eUsePlateOrientation
  ccCalibrateLineScanCameraDefs::eAdjustOrientationToScanDirection

- `ccCalibrateLineScanCameraDefs::CalibrationYAxisAdjustmentMode calibrationYAxisAdjustmentMode() const:`

  Sets the y-axis adjustment mode to be used when calibrating a line scan camera. If you specify *ccCalibrateLineScanCameraDefs::eUsePlateOrientation*, then the calibrated space y-axis orientation is defined by the orientation of the fiducial plate in the calibration image.

  If you specify *ccCalibrateLineScanCameraDefs::eAdjustOrientationToScanDirection*, then the calibrated space y-axis orientation is defined by the apparent motion of the plate during image acquisition.

  Parameters

  calibrationYAxisAdjustmentMode

  The mode to use. *calibrationYAxisAdjustmentMode* must be one of the following values:

  ccCalibrateLineScanCameraDefs::eUsePlateOrientation
  ccCalibrateLineScanCameraDefs::eAdjustOrientationToScanDirection

Notes

You must specify *ccCalibrateLineScanCameraDefs::eAdjustOrientationToScanDirection* in order to use the 1D warper to produce a rectified line scan image.

Operators

operator==

```
bool operator==(
   const ccCalibrateLineScanCameraParams &that) const;
```

Returns true if the supplied object is equal (all members are exactly equal) to this one.

Parameters

that	The object to compare.

ccCaliperBaseResultSet

```
#include <ch_cvl/caliper.h>

class ccCaliperBaseResultSet: public virtual ccPersistent;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	Complex

This base class contains some of the results returned by both correlation and edge mode.

Note You should not attempt to instantiate this class directly.

Constructors/Destructors

ccCaliperBaseResultSet

```
ccCaliperBaseResultSet();
```

Constructs **ccCaliperBaseResultSet** with no results.

Operators

operator==

```
bool operator== (const ccCaliperBaseResultSet& that) const;
```

Two **ccCaliperBaseResultSet** objects are equal if and only if the following items are all the same: the vectors of **ccResult**s; the vectors of **ccCaliperResultEdge**s; the caliper data; the user-specified origin in client coordinates; the unit vectors in the search direction; the run mode; the result angles; and the clipping status.

Public Member Functions

results

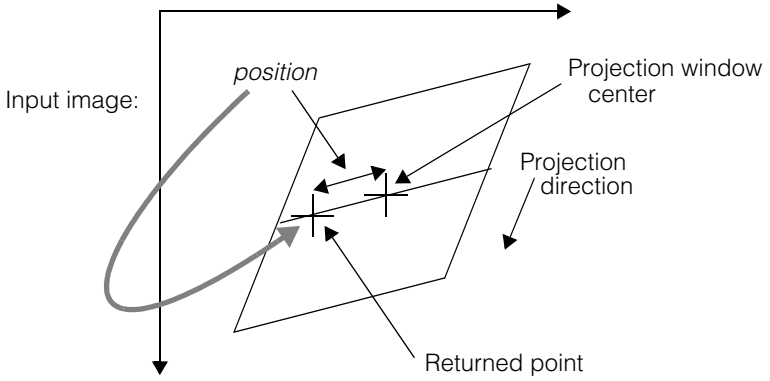
```
const cmStd vector<ccCaliperOneResult>& results () const;
```

Returns a vector of **ccCaliperOneResult**. Every edge or edge pair for which a score was computed is included in the vector returned by this function.

mapPositionToPoint

```
cc2Vect mapPositionToPoint (double position) const;
```

Map the given position within the projection region to a point in the client coordinates of the input image. If the projection image was constructed by the Caliper tool, the position is specified relative to the center of the projection region and the returned point lies on the center line of the projection region in the input image, as shown in the following figure:



If you supplied the projection image to the Caliper tool, then this function returns the two-dimensional point within the input image specified by the distance from the origin that you supplied.

Parameters

position — The position of interest, relative to either the center of the projection region or to the origin that you supplied with the projection image.

Notes

This function can be used to convert positions to 2-D client coordinates.

projectTime

```
double projectTime () const;
```

Returns the amount of time, in seconds, required to create the projection image.

filterTime

```
double filterTime () const;
```

Returns the amount of time, in seconds, required to create the filtered image.

scoreTime

```
double scoreTime () const;
```

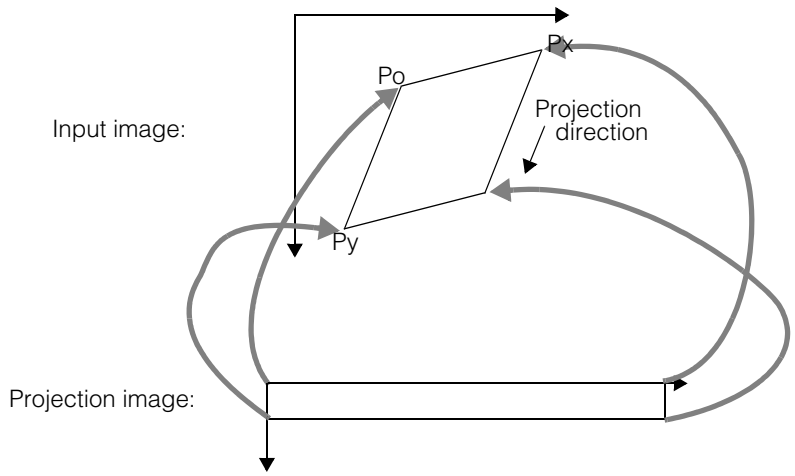
Returns the amount of time, in seconds, required to compute the scores for the edges in the input image.

projectedImage

```
ccPelBuffer_const<c_UInt32> projectedImage () const;
```

Returns the projection image. This image was created by projecting the pixels within the caliper window.

The **cc2Xform** returned by calling **projectedImage()::clientFromImageXform()** maps two-dimensional points within the projection image to the corresponding points within the input image client coordinate system, as shown in the following figure:



weightsImage

```
ccPelBuffer_const<c_UInt32> weightsImage () const;
```

Return the weights image. If clipping occurred, each pixel in this image contains the number of pixels that where summed together to produce the corresponding pixel in the projected image.

To determine if clipping occurred, call the **clipped()** member function.

The image returned by this function is only valid if clipping occurred and if auto-clipping mode is enabled.

filteredImage

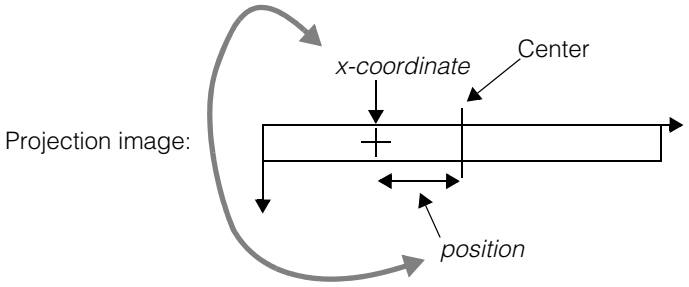
```
ccPelBuffer_const<double> filteredImage () const;
```

Return the filtered projection image. The width of the image returned by this function is smaller than that returned by **projectedImage()**, but the client coordinate system of the returned image lets you convert points between the projection image and the filtered image.

projectedXFromPosition

```
cc1Xform projectedXFromPosition() const;
```

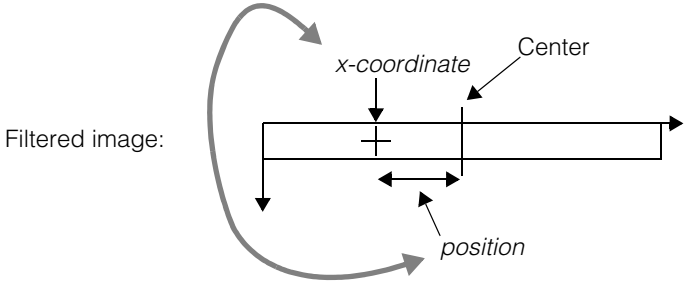
Returns a **cc1Xform** that can be used to map back and forth between a one-dimensional *position* and the corresponding *x-coordinate* in the projection image, as shown in the following figure:



filteredXFromPosition

```
cc1Xform filteredXFromPosition() const;
```

Returns a **cc1Xform** that can be used to map back and forth between a one-dimensional *position* and the corresponding *x-coordinate* in the filtered image, as shown in the following figure:



resultAngle

```
ccRadian resultAngle() const;
```

Returns the angle at which the Caliper tool was applied to generate this **ccCaliperBaseResultSet**.

clipped

```
bool clipped() const;
```

Returns true if the source image was clipped by the projection region, false if no clipping occurred.

ccCaliperBaseResultSet

ccCaliperBaseRunParams

```
#include <ch_cvl/caliper.h>

class ccCaliperBaseRunParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The **ccCaliperBaseRunParams** class is a base class from which the following two run-time parameter classes are derived:

- **ccCaliperRunParams**, which includes run-time parameters for edge mode
- **ccCaliperCorrelationRunParams**, which includes run-time parameters for correlation mode

The **ccCaliperBaseRunParams** class includes run-time parameters which are common to both edge and correlation mode.

Note You should not attempt to instantiate this class directly.

Enumerations

Timer

```
enum Timer;
```

This enumeration specifies the type of timer used to compute times in the result with the caliper tool.

Value	Meaning
eElapsedTime	Use the elapsed clock time in seconds. Produces accurate results on all machine types, but the overhead of computing the elapsed time can be noticeable (several microseconds) when using a large number of small (fast) calipers.
eScaledProcessorCycles	Use the number of processor cycles (scaled to seconds). Does not always produce accurate results on machines with a variable clock rate, but has a much lower overhead. Some machines (especially laptops) may use a variable clock rate to conserve power.

Public Member Functions

scanParams

```
const ccCaliperScanParams& scanParams() const;

void scanParams(ccRadian start, ccRadian end,
  ccRadian increment, bool interpolate);
```

- `const ccCaliperScanParams& scanParams() const;`

  Returns the **ccCaliperScanParams** object associated with this **ccCaliperBaseRunParams**.

- `void scanParams(ccRadian start, ccRadian end, ccRadian increment, bool interpolate);`

  Sets the parameters of the **ccCaliperScanParams** object associated with this **ccCaliperBaseRunParams**.

  Parameters

  start — The start of the range of angles to be scanned in radians. The angle is from the client coordinate system x-axis to the projection direction.

end The end of the range of angles to be scanned in radians. The angle is from the client coordinate system x-axis to the projection direction.

increment The amount by which to increment the angle between scans.

interpolate If true, intermediate angles are evaluated.

scanEnable

```
bool scanEnable() const;
void scanEnable(bool on);
```

- `bool scanEnable() const;`

  Returns true if scan mode is enabled, false if it is disabled.

- `void scanEnable(bool on);`

  Enables or disables scan mode. If scan mode is enabled, the caliper is successively applied at the angles specified in the **ccCaliperScanParams**. The angle which yields the highest average score for all results is used to compute the score for the tool.

  Parameters

  on If true, scan mode is enabled. If false, scan mode is disabled.

autoClip

```
bool autoClip() const;
void autoClip(bool state);
```

- `bool autoClip() const;`

  Returns true if auto-clipping mode is enabled, false if it is disabled.

- `void autoClip(bool state);`

  Enables or disables auto-clipping mode. If auto-clipping mode is enabled, if the projection region is clipped by the input image, the projection image is automatically resized to include only the pixels which were not affected by clipping. If auto-clipping mode is disabled, the tool throws an error if the projection region is clipped by the input image.

  Parameters

  state If true, auto-clipping mode is enabled. If false, auto-clipping mode is disabled.

Notes

Enabling auto-clipping mode will cause the **cfCaliperRun()** function to run as much as 10 times more slowly than when auto-clipping mode is disabled.

computeIntermediateTimes

```
bool computeIntermediateTimes() const;
void computeIntermediateTimes(bool val);
```

- `bool computeIntermediateTimes() const;`

  Returns true if the caliper tool should compute intermediate times for projection, filtering, scoring, and edge or peak detection, false otherwise. If false, the getters for these times will return zero.

- `void computeIntermediateTimes(bool val);`

  Sets whether the caliper tool should compute intermediate times for projection, filtering, scoring, and edge or peak detection. If false, the getters for these times will return zero.

  Parameters

  val — Set to true if the tool should calculate intermediate results, false otherwise. The default is true.

Note Querying the system timer with *QueryPerformanceCounter* costs, for example, ~1.7 microseconds on a 650 MHz system. Computing intermediate times can thus add nontrivial overhead for very small calipers. To get the fastest performance, turn timers off.

timerType

```
Timer timerType() const;
void timerType(Timer t);
```

- `Timer timerType() const;`

  Retrieves the type of timer used to compute times in the result.

- `void timerType(Timer t);`

  Sets the type of timer used to compute times in the result.

Parameters

t	The type of timer. Must be one of: *ccCaliperBaseRunParams::eElapsedTime* *ccCaliperBaseRunParams::eScaledProcessorCycles* (default)

Note For fastest execution of multiple calipers, set calipers once in the application code.

ccCaliperBaseRunParams

ccCaliperCircleFinderAutoRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperCircleFinderAutoRunParams :
                        public ccCaliperFinderBaseAutoRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Circle Finder tool run-time parameters for running the tool in *auto* mode.

Constructors/Destructors

ccCaliperCircleFinderAutoRunParams

```
ccCaliperCircleFinderAutoRunParams (
  const ccCircle &expectedCircle = ccCircle(),
  c_Int16 numCalipers = 0,
  const ccDPair &caliperSize = ccDPair(0, 0),
  const ccCaliperRunParams &caliperRunParams =
                                      ccCaliperRunParams(),
  const ccDPair &caliperSampling = ccDPair(1, 1),
  const ccAngleRange &angleRange =
                              ccAngleRange::FullAngleRange(),
  ccAffineSamplingParams::Interpolation
                         interpolationMethod =
                         ccAffineSamplingParams::eBilinear,
  const ccCircleFitParams &circleFitParams =
                                       ccCircleFitParams(),
  bool centrifugal = true,
  const cc2Xform& startPose = cc2Xform(),
  bool decrementNumIgnore = true,
  bool placeCalipersSymmetrically = true);

virtual ~ccCaliperCircleFinderAutoRunParams() {}
```

-
```
ccCaliperCircleFinderAutoRunParams (
  const ccCircle &expectedCircle = ccCircle(),
  c_Int16 numCalipers = 0,
  const ccDPair &caliperSize = ccDPair(0, 0),
```

```
const ccCaliperRunParams &caliperRunParams =
                                        ccCaliperRunParams(),
const ccDPair &caliperSampling = ccDPair(1, 1),
const ccAngleRange &angleRange =
                              ccAngleRange::FullAngleRange(),
ccAffineSamplingParams::Interpolation
                        interpolationMethod =
                        ccAffineSamplingParams::eBilinear,
const ccCircleFitParams &circleFitParams =
                                         ccCircleFitParams(),
bool centrifugal = true,
const cc2Xform& startPose = cc2Xform(),
bool decrementNumIgnore = true,
bool placeCalipersSymmetrically = true);
```

Constructs a Circle Finder tool run-time parameters object.

Notes

Default constructed objects do not contain valid run-time parameters.

Parameters

expectedCircle The circle you expect the tool to find in images.

numCalipers The number of calipers the tool should use to find the circle.

caliperSize The caliper size, width and height in client coordinates. All calipers are the same size.

caliperRunParams
The run-time parameters object to be used when the Caliper tool is run.

caliperSampling The sampling rate in samples/pixel for x and y, to be used on the calipers. For example, the following calculates the number of caliper samples in the x direction:

If xSize is **caliperSize.x()** in image coordinates, then the effective number of samples in the x direction will be -

c_Int16(xSize * **caliperSampling.x()** + 0.5)

angleRange The beginning angle and the ending angle of the angle range where calipers will be placed along the expected circle perimeter. Angles are measured from the x-axis in the positive direction. The default is the full angular range.

interpolationMethod
The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums. The default is *eBilinear*.

See the **ccAffineSamplingParams** reference page.

circleFitParams The run-time parameters to use with the Fitting tool.

centrifugal When set true, the caliper search direction is outward from the circle center. When set false, the caliper search direction is inward. The default is true.

startPose A transform that maps the expected circle from circle space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccCircleFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

placeCalipersSymmetrically
True specifies that the calipers should be placed at the center of each evenly spaced section of the *angleRange*. False specifies that the calipers be placed at the start of each evenly spaced section. The default is true.

Note: The default mode (true) is always the appropriate choice for placing the calipers. This is flag only exists for backward compatibility. Users who do not require backwards compatibility should not change the state of this flag.

Throws
ccCaliperFinderBaseDefs::BadParams
If *numCalipers* is not zero and is less than **minNumCalipers()**,
or if *caliperSize* is less than (0, 0),
or if *caliperSampling* is less than or equal to (0, 0),
or if *angleRange* is empty,
or if *startPose* is singular.

- `virtual ~ccCaliperCircleFinderAutoRunParams() {}`

Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperCircleFinderAutoRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperCircleFinderAutoRunParams** object to compare to this object.

Public Member Functions

expectedCircle

```
const ccCircle &expectedCircle() const;

void expectedCircle(const ccCircle &expectedCircle);
```

The circle you expect to find in images processed by the Circle Finder tool. The expected circle should be close to actual circles in the images.

- `const ccCircle &expectedCircle() const;`

  Returns the expected circle.

- `void expectedCircle(const ccCircle &expectedCircle);`

  Sets the expected circle.

  Parameters

  expectedCircle The new expected circle.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If *expectedCircle* radius is 0.

angleRange

```
const ccAngleRange &angleRange() const;

void angleRange(const ccAngleRange &angleRange);
```

The beginning angle and the ending angle of the angle range where calipers will be placed along the expected circle perimeter. Angles are measured from the x-axis in the positive direction. The default is the full angular range.

- `const ccAngleRange &angleRange() const;`

  Returns the angle range.

- `void angleRange(const ccAngleRange &angleRange);`

  Sets a new angle range.

  Parameters
  angleRange The new angle range.

  Throws
  ccCaliperFinderBaseDefs::BadParams
  If *angleRange* is empty.

circleFitParams

```
const ccCircleFitParams &circleFitParams() const;

void circleFitParams(
  const ccCircleFitParams &circleFitParams);
```

- `const ccCircleFitParams &circleFitParams() const;`

  Returns the circle fit parameters.

- ```
  void circleFitParams(
    const ccCircleFitParams &circleFitParams);
  ```

  Sets new circle fit parameters.

  Parameters
  circleFitParams The new circle fit parameters.
  ```

ccCaliperCircleFinderAutoRunParams

centrifugal

```
bool centrifugal() const;
void centrifugal(bool centrifugal);
```

When set true, the caliper search direction is outward from the circle center. When set false, the caliper search direction is inward. The default is true.

- `bool centrifugal() const;`

  Returns the centrifugal setting, true or false.

- `void centrifugal(bool centrifugal);`

  Sets the caliper search direction.

  Parameters

  centrifugal The new caliper search direction.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const;
```

Returns the minimum number of calipers required (3).

placeCalipersSymmetrically

```
bool placeCalipersSymmetrically() const;
void placeCalipersSymmetrically(bool symmetrically);
```

True specifies that the calipers should be placed at the center of each evenly spaced section of the *angleRange*. False specifies that the calipers be placed at the start of each evenly spaced section. The default is true.

Notes

The default mode (true) is always the appropriate choice for placing the calipers. This is flag only exists for backward compatibility. Users who do not require backwards compatibility should not change the state of this flag.

- `bool placeCalipersSymmetrically() const;`

  Returns the current specification, true or false.

- `void placeCalipersSymmetrically(bool symmetrically);`

  Sets a new specification.

Parameters

symmetrically The new specification.

Protected Member Functions

computeAffineSamplingParams_

```
virtual void computeAffineSamplingParams_();
```

Computes the affine sampling parameters of the calipers to be run from the current auto run parameters.

Throws

ccCaliperFinderBaseDefs::BadParams
If any members have invalid values.

ccCaliperCircleFinderAutoRunParams

ccCaliperCircleFinderManualRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperCircleFinderManualRunParams :
                    public ccCaliperFinderBaseManualRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Circle Finder tool run-time parameters for running the tool in *manual* mode.

Constructors/Destructors

ccCaliperCircleFinderManualRunParams

```
ccCaliperCircleFinderManualRunParams (
  const ccCircle &expectedCircle = ccCircle(),
  const cmStd vector<ccAffineSamplingParams>& affParams =
                  cmStd vector<ccAffineSamplingParams>(),
  const cmStd vector<ccCaliperRunParams>& clpParams =
                      cmStd vector<ccCaliperRunParams>(),
  const ccCircleFitParams &circleFitParams =
                                        ccCircleFitParams(),
  const cc2Xform &startPose = cc2Xform(),
  bool decrementNumIgnore = true);

virtual ~ccCaliperCircleFinderManualRunParams() {}
```

- ```
  ccCaliperCircleFinderManualRunParams (
    const ccCircle &expectedCircle = ccCircle(),
    const cmStd vector<ccAffineSamplingParams>& affParams =
                    cmStd vector<ccAffineSamplingParams>(),
    const cmStd vector<ccCaliperRunParams>& clpParams =
                        cmStd vector<ccCaliperRunParams>(),
    const ccCircleFitParams &circleFitParams =
                                          ccCircleFitParams(),
    const cc2Xform &startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

  Constructs a circle finder manual run-time parameters object.
  ```

Notes

Default constructed objects do not contain valid run-time parameters.

Parameters

expectedCircle The circle you expect the tool to find in images.

affParams A vector of affine rectangle sampling parameters, one parameter set for each caliper.

clpParams A vector of caliper run-time parameters, one parameter set for each caliper.

circleFitParams The run-time parameters to use with the Fitting tool.

startPose A transform that maps the expected circle from circle space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccCircleFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

Throws

ccCaliperFinderBaseDefs::BadParams
If **affParams.size()** is not equal to **clpParams.size()**, or if params sizes are not zero and less than **minNumCalipers()**, or if *startPose* is singular.

- `virtual ~ccCaliperCircleFinderManualRunParams() {}`

Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperCircleFinderManualRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperCircleFinderManualRunParams** object to compare to this object.

Public Member Functions

expectedCircle

```
const ccCircle &expectedCircle() const;

void expectedCircle(const ccCircle &expectedCircle);
```

The circle you expect to find in images processed by the Circle Finder tool. The expected circle should be close to actual circles in the images.

- `const ccCircle &expectedCircle() const;`

  Returns the expected circle.

- `void expectedCircle(const ccCircle &expectedCircle);`

  Sets the expected circle.

  Parameters

  expectedCircle The new expected circle.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If *expectedCircle* radius is 0.

circleFitParams

```
const ccCircleFitParams &circleFitParams() const;

void circleFitParams(
  const ccCircleFitParams &circleFitParams);
```

- `const ccCircleFitParams &circleFitParams() const;`

  Returns the circle fitter run-time parameters.

- ```
  void circleFitParams(
    const ccCircleFitParams &circleFitParams);
  ```

  Sets new circle fit run-time parameters.

  Parameters

  circleFitParams The new circle fit run-time parameters.
  ```

ccCaliperCircleFinderManualRunParams

minNumCalipers `virtual c_Int16 minNumCalipers() const;`

Returns the minimum number of calipers required (3).

ccCaliperCircleFinderResult

```
#include <ch_cvl/clpfind.h>

class ccCaliperCircleFinderResult :
                                public ccCaliperFinderBaseResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encapsulates the results from the Circle Finder tool.

Constructors/Destructors

ccCaliperCircleFinderResult

```
ccCaliperCircleFinderResult() {}

virtual ~ccCaliperCircleFinderResult() {}
```

- `ccCaliperCircleFinderResult() {}`

  Default constructor. Creates a default constructed (unfound) circle result object.

- `virtual ~ccCaliperCircleFinderResult() {}`

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseResult& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperCircleFinderResult** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperCircleFinderResult** object to compare to this object.

Public Member Functions

found

```
virtual bool found() const;
```

Returns true if a circle was found. Returns false otherwise.

A circle is found if its computed error is less than the error *threshold* specified in the Circle Fitting tool parameters. See **ccCircleFitParams::threshold()**.

circleFit

```
const ccCircleFitResults &circleFit() const;
```

Returns the circle fitting result.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

circle

```
const ccCircle &circle() const;
```

Returns the computed circle.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

position

```
const cc2Vect &position() const;
```

Returns the position of the computed circle.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

radius

```
double radius() const;
```

Returns the radius of the computed circle.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

circleFitTime

```
double circleFitTime() const;
```

Returns the circle fitting time, in seconds.

ccCaliperCircleFinderResult

ccCaliperCorrelationResultSet

```
#include <ch_cvl/caliper.h>

class ccCaliperCorrelationResultSet :
                                    public ccCaliperBaseResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the results returned by a single application of the Caliper tool to an input image in correlation mode. Results common to both modes can be found in **ccCaliperBaseResultSet**.

Constructors/Destructors

ccCaliperCorrelationResultSet

```
ccCaliperCorrelationResultSet ();
```

Constructs a **ccCaliperCorrelationResultSet** with no results.

operator==

```
bool operator== (const ccCaliperCorrelationResultSet& that)
  const;
```

Two **ccCaliperCorrelationResultSet** objects are equal if and only if the following items are all the same: the vectors of **ccResult**s; the caliper data; the user-specified origin in client coordinates; the unit vectors in the search direction; the run mode; the result angles; and the clipping status.

Public Member Functions

peakDetectTime

```
double peakDetectTime () const;
```

Returns the amount of time, in seconds, required to perform peak detection.

ccCaliperCorrelationResultSet

runMode

```
ccCaliperDefs::RunMode runMode();
```

Returns the mode in which the caliper was run to generate this **ccCaliperCorrelationResultSet**. The returned value is one of the following values:

ccCaliperDefs::eEdge
ccCaliperDefs::eNormalizedCorrelation
ccCaliperDefs::eRelativeCorrelation

draw

```
void draw(
  ccGraphicList& graphList,
  c_UInt32 drawMode = ccCaliperDefs::eDrawStandard,
  double plotHeight = ccCaliperDefs::kDefaultPlotHeight)
                                                    const;
```

Appends result graphics for all the results in this **ccCaliperCorrelationResultSet** to the supplied **ccGraphicList**.

Parameters

graphList — The graphics list to append the graphics to.

drawMode — The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccCaliperDefs::eDrawEdgeLine
ccCaliperDefs::eDrawLabel
ccCaliperDefs::eDrawProjFilter
ccCaliperDefs::eDrawProjectionRegion
ccCaliperDefs::eDrawStandard
ccCaliperDefs::eDrawRawEdges

plotHeight — The height of the projection and filter plots, in client coordinates.

ccCaliperCorrelationRunParams

```
#include <ch_cvl/caliper.h>

class ccCaliperCorrelationRunParams:
  public ccCaliperBaseRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the run-time parameters for the Caliper tool used in correlation mode, including the reference image.

Constructors/Destructors

ccCaliperCorrelationRunParams

```
ccCaliperCorrelationRunParams();

ccCaliperCorrelationRunParams(
  const ccPelBuffer_const<c_UInt8>& refSrc,
  ccCaliperDefs::RunMode mode =
  ccCaliperDefs::eNormalizedCorrelation,
  const cc2Vect& origin = cc2Vect(0,0));

ccCaliperCorrelationRunParams(
  const ccPelBuffer_const<c_UInt8>& src,
  ccAffineSamplingParams affSamp,
  ccCaliperDefs::RunMode mode =
  ccCaliperDefs::eNormalizedCorrelation,
  const cc2Vect& origin = cc2Vect(0,0));

ccCaliperCorrelationRunParams(
  const ccPelBuffer_const<c_UInt32>& refSrc,
  int nPelsPerBin,
```

```
ccCaliperDefs::RunMode mode =
ccCaliperDefs::eNormalizedCorrelation,
const cc2Vect& origin = cc2Vect(0,0));
```

- `ccCaliperCorrelationRunParams();`

  Constructs a **ccCaliperCorrelationRunParams** with no reference image. This **ccCaliperCorrelationRunParams** will not be usable until you supply a reference image.

- ```
  ccCaliperCorrelationRunParams(
    const ccPelBuffer_const<c_UInt8>& refSrc,
    ccCaliperDefs::RunMode mode =
    ccCaliperDefs::eNormalizedCorrelation,
    const cc2Vect& origin = cc2Vect(0,0));
  ```

  Constructs a **ccCaliperCorrelationRunParams** using the supplied one-dimensional image as the reference image. You must specify the location of the origin in client coordinates.

  Parameters

  refSrc — The image to use. *refSrc* must have an y-dimension equal to 1 pixel.

  mode — The correlation mode to use. *mode* must be one of the following values:

  ccCaliperDefs::eNormalizedCorrelation
  ccCaliperDefs::eRelativeCorrelation

  origin — The origin of the reference image. Correlation peaks will be reported with respect to this origin. *origin* must be specified in *refSrc*'s client coordinate system. The y-coordinate of *origin* is ignored.

  Notes

  The default value of the peak separation threshold is set to the width of the *refSrc*.

  Throws

  ccCaliperDefs::BadParams
  mode is not *ccCaliperDefs::eNormalizedCorrelation* or *ccCaliperDefs::eRelativeCorrelation* or *refSrc.height()* is not 1.

- ```
  ccCaliperCorrelationRunParams(
    const ccPelBuffer_const<c_UInt8>& src,
    ccAffineSamplingParams affSamp,
  ```

```
ccCaliperDefs::RunMode mode =
ccCaliperDefs::eNormalizedCorrelation,
const cc2Vect& origin = cc2Vect(0,0));
```

Constructs a **ccCaliperCorrelationRunParams**. The reference image is constructed by applying the supplied affine sampling parameters to the supplied two-dimensional image. You must specify the location of the origin in client coordinates.

Parameters

src — The image to use to generate the reference image.

affSamp — The affine sampling parameters with which to sample *src*.

mode — The correlation mode to use. *mode* must be one of the following values:

ccCaliperDefs::eNormalizedCorrelation
ccCaliperDefs::eRelativeCorrelation

origin — The origin of the reference image. Correlation peaks will be reported with respect to this origin. *origin* must be specified in *src's* client coordinate system. The origin is transformed to the projection image produced by applying *affSamp* to src.

Notes

The default value of the peak separation threshold is set to the width of the image produced by applying *affSamp* to *src*.

Throws

ccCaliperDefs::BadParams

mode is not *ccCaliperDefs::eNormalizedCorrelation* or *ccCaliperDefs::eRelativeCorrelation*.

- ```
  ccCaliperCorrelationRunParams(
    const ccPelBuffer_const<c_UInt32>& refSrc,
    int nPelsPerBin,
    ccCaliperDefs::RunMode mode =
    ccCaliperDefs::eNormalizedCorrelation,
    const cc2Vect& origin = cc2Vect(0,0));
  ```

  Constructs a **ccCaliperCorrelationRunParams** using the supplied one-dimensional image as the reference image after normalizing each pixel of the image using the supplied normalization value. You must specify the location of the origin in client coordinates.
  ```

Parameters

refSrc — The image to use. *refSrc* must have a y-dimension equal to 1 pixel.

nPelsPerBin — The number of pixels that were summed to produce each value in *refSrc*. Each pixel value in *refSrc* is divided by *nPelsPerBin*.

mode — The correlation mode to use. *mode* must be one of the following values:

ccCaliperDefs::eNormalizedCorrelation
ccCaliperDefs::eRelativeCorrelation

origin — The origin of the reference image. Correlation peaks will be reported with respect to this origin. *origin* must be specified in *refSrc*'s client coordinate system. The y-coordinate of *origin* is ignored.

Throws

ccCaliperDefs::BadParams
mode is not *ccCaliperDefs::eNormalizedCorrelation* or *ccCaliperDefs::eRelativeCorrelation*; *refSrc.height()* is not 1; or *nPelsPerBin* is less than 1.

Public Member Functions

ref1DCorrelation

```
void ref1DCorrelation(
  const ccPelBuffer_const<c_UInt8>& ref1D,
  const cc2Vect& origin= cc2Vect(0,0));

void ref1DCorrelation(cmStd vector<ccIPair> refValues,
  int smooth=0, double origin = 0.0);

void ref1DCorrelation(cmStd vector<c_UInt8> refValues,
  double origin= 0.0);

void ref1DCorrelation(
  ccCaliperDefs::PreDefined1DSignal refSignal,
  c_UInt32 width, c_UInt8 max, c_UInt8 min, int smooth=0,
  double origin = 0.0);
```

-
```
void ref1DCorrelation(
  const ccPelBuffer_const<c_UInt8>& ref1D,
  const cc2Vect& origin= cc2Vect(0,0));
```

Sets this **ccCaliperCorrelationRunParams**'s reference image to be the supplied one-dimensional image. You must specify the location of the origin in client coordinates.

Parameters

ref1D — The image to use. *ref1D* must have a y-dimension equal to 1 pixel.

origin — The origin of the reference image. Correlation peaks will be reported with respect to this origin. *origin* must be specified in *refSrc*'s client coordinate system. The y-coordinate of *origin* is ignored.

Notes

The default value of the peak separation threshold is set to the width of the *refSrc*.

Throws

ccFiltErr::BadImageSize
ref1D.height() is not 1 or *ref1D*.width() is less than 1.

- `void ref1DCorrelation(cmStd vector<ccIPair> refValues, int smooth=0, double origin = 0.0);`

Sets this **ccCaliperCorrelationRunParams**'s reference image to be the supplied vector of run-length codes. Any specified smoothing value is used as input to the Gaussian Sampling tool to smooth the image produced from the list of run-length codes. The origin is specified in the image coordinate system of the image produced from the list of run-length codes.

Parameters

refValues — A vector of run-length codes. Each element of *refValues* is interpreted as follows: *refValues.x()* is the number of pixels in the run and *refValues.y()* is the pixel value of the run.

smooth — The smoothing value.

origin — The reference image origin, specified in image coordinates of the image produced from *refValues*.

Notes

The default value of the peak separation threshold is set to the width of the *refSrc*.

Throws

ccFiltErr::BadImageSize
refValues contains less than 1 element.

ccCaliperDefs::BadParams
smooth is less than 0.

- ```
  void ref1DCorrelation(cmStd vector<c_UInt8> refValues,
    double origin= 0.0);
  ```

  Sets this **ccCaliperCorrelationRunParams**'s reference image to be the supplied vector of values. The origin is specified in the image coordinate system of the image produced from the list of values.

  Parameters

  refValues — A vector of 8-bit pixel values.

  origin — The reference image origin, specified in image coordinates of the image produced from *refValues*.

  Notes

  The default value of the peak separation threshold is set to the width of the *refSrc*.

  Throws

  ccFiltErr::BadImageSize
  refValues contains less than 1 element.

- ```
  void ref1DCorrelation(
    ccCaliperDefs::PreDefined1DSignal refSignal,
    c_UInt32 width, c_UInt8 max, c_UInt8 min, int smooth=0,
    double origin = 0.0);
  ```

  Sets this **ccCaliperCorrelationRunParams**'s reference image to be the specified pre-defined reference image. The origin is specified in the image coordinate system of the image.

  If you specify *ccCaliperDefs::ePosGauss* or *ccCaliperDefs::eNegGauss*, this function applies a Gaussian kernel with a sigma equal to one fourth of the width of the image. You can override this kernel size.

  Parameters

  refSignal — The pre-defined reference image. *refSignal* must be one of the following values:

  ccCaliperDefs::ePosPulse
  ccCaliperDefs::eNegPulse
  ccCaliperDefs::ePosGauss
  ccCaliperDefs::eNegGauss

  width — The width of the reference signal. The overall width of the resulting image is equal to *width*+2.

  max — The maximum value of the image. For *ccCaliperDefs::ePosPulse* and *ccCaliperDefs::ePosGauss*, *max* is the value of the peak.

max The minimum value of the image. For *ccCaliperDefs::eNegPulse* and *ccCaliperDefs::eNegGauss*, *max* is the value of the peak.

smooth The smoothing value to apply to produce a Gaussian reference image. Set *smooth* to a positive value to override the default smoothing value. The resulting sigma will be approximately 1.5 times *smooth*.

Throws

ccFiltErr::BadImageSize
width is less than 1.

ccCaliperDefs::BadParams
max is less than *min* or *smooth* is less than 0.

ccFiltErr::BadImageSize
width is less than 1.

acceptThreshold

```
double acceptThreshold() const;

void acceptThreshold(double thresh);
```

- `double acceptThreshold() const;`

  Returns the accept threshold for this **ccCaliperCorrelationRunParams**. Only correlation peaks with correlation scores greater than this threshold are scored.

- `void acceptThreshold(double thresh);`

  Sets the accept threshold for this **ccCaliperCorrelationRunParams**. Only correlation peaks with correlation scores greater than this threshold are scored.

  The default accept threshold is 0.

  Parameters

  thresh The accept threshold. *thresh* must be in the range 0 to 1000.

  Throws

  ccCaliperDefs::BadParams
  thresh is less than 0 or greater than 1000.

Notes

Keep in mind that correlation scores differ depending on the type of correlation. For normalized correlation, scores range between 0 and 1000. For relative correlation, scores range between 0 and the maximum value that can be stored by a pixel in the input image (255 for 8-bit images).

runMode

```
ccCaliperDefs::RunMode runMode() const;
void runMode(ccCaliperDefs::RunMode mode, double thresh);
```

- `ccCaliperDefs::RunMode runMode() const;`

  Returns the type of correlation for this **ccCaliperCorrelationRunParams**.

- `void runMode(ccCaliperDefs::RunMode mode, double thresh);`

  Sets the type of correlation for this **ccCaliperCorrelationRunParams**.

  Parameters

  mode — The correlation mode. *mode* must be one of the following values:

  ccCaliperDefs::eNormalizedCorrelation
  ccCaliperDefs::eRelativeCorrelation

  thresh — The accept threshold for this **ccCaliperCorrelationRunParams**. See **acceptThreshold()** on page 799 for information on the accept threshold.

  Throws

  ccCaliperDefs::BadParams
  mode is not *ccCaliperDefs::eNormalizedCorrelation* or *ccCaliperDefs::eRelativeCorrelation*.

maxNumResults

```
c_Int16 maxNumResults () const;
void maxNumResults (c_Int16 num);
```

- `c_Int16 maxNumResults () const;`

  Returns the maximum number of results that this **ccCaliperCorrelationRunParams** is configured to return.

  `void maxNumResults (c_Int16 num);`

  Sets the maximum number of results that this **ccCaliperCorrelationRunParams** is configured to return.

Parameters

num The maximum number of results to return. If you specify 0 for *num*, the tool will perform the projection, filtering, and peak detection steps, but it will not produce any scored results.

Throws

ccCaliperDefs::BadParams
num is less than 0.

scoringMethods

```
const cmStd vector<ccCaliperScore*> scoringMethods() const;

void scoringMethods (
  const cmStd vector<ccCaliperScore*>& methods);
```

- `const cmStd vector<ccCaliperScore*> scoringMethods() const;`

  Returns a vector of **ccCaliperScore** objects that define how correlation peaks are scored.

- ```
  void scoringMethods (
    const cmStd vector<ccCaliperScore*>& methods);
  ```

  Sets the list of **ccCaliperScore** objects that determine how correlation peaks are scored. Any existing list of **ccCaliperScore** objects is discarded.

  The only legal type of scoring object for correlation mode is **ccScoreContrast**.

  Parameters

  methods The scoring methods to set.

  Notes

  If *methods* contains no objects (has a length of 0), then any attempt to run the Caliper tool with a value for the maximum number of results other than 0 will throw an error.

  A default-constructed **ccCaliperCorrelationRunParams** object contains a single **ccScoreContrast** scoring method.

  Throws

  ccCaliperDefs::BadParams
  An element of *method* is not of type **ccScoreContrast**.
  ```

peakSeparationThreshold

```
double peakSeparationThreshold() const;

void peakSeparationThreshold(double peakSep);
```

- `double peakSeparationThreshold() const;`

  Returns the peak separation threshold configured for this **ccCaliperCorrelationRunParams**.

- `void peakSeparationThreshold(double peakSep);`

  Sets the peak separation threshold configured for this **ccCaliperCorrelationRunParams**.

  The peak separation threshold is the minimum distance, in client coordinate system units, between separate peaks. Peaks that are closer together than the threshold are treated as a single peak; the peak with the lower score is discarded.

  Parameters

  peakSep The peak separation threshold.

ccCaliperDefs

```
#include <ch_cvl/caliper.h>

class ccCaliperDefs;
```

A name space class for the Caliper tool.

Enumerations

Interpolation

```
enum Interpolation;
```

This enumeration defines the sampling types supported by the Caliper tool.

Value	Meaning
eNone	Nearest neighbor sampling is used to construct the projection image.
eBilinear	Bilinear interpolation is used to construct the projection image.
kDefaultInterpolation	The default sampling method, as defined in *caliper.h.*

RunMode

```
enum RunMode;
```

This enumeration defines the modes supported by the Caliper tool.

Value	Meaning
eEdge	Features are located by detecting and scoring of edge peaks and edge pair peaks.
eNormalizedCorrelation	Features are located be detecting and scoring normalized correlation peaks between run-time and reference images.
eRelativeCorrelation	Features are located be detecting and scoring relative correlation peaks between run-time and reference images.
kDefaultRunMode	The default mode, as defined in *caliper.h.*

PreDefined1DSignal

```
enum PreDefined1DSignal;
```

This enumeration defines the pre-defined reference signals available for correlation mode.

Value	Meaning
ePosPulse	A boxcar signal going from low to high to low.
eNegPulse	A boxcar signal going from high to low to high.
ePosGauss	A boxcar signal going from low to high to low which has been smoothed using a Gaussian filter.
eNegGauss	A boxcar signal going from high to low to high which has been smoothed using a Gaussian filter.

DrawMode

```
enum DrawMode;
```

This enumeration defines the types of result graphics you can draw for Caliper tool results.

Value	Meaning
eDrawEdgeLine	Draws a line at the location of each detected edge.
eDrawLabel	Draws a text label at each detected edge.
eDrawProjFilter	Draws a graphical representation of the filtered projection image and projection image at the top and bottom (respectively) of the bounding box for the result.
eDrawProjectionRegion	Draws a box describing the projection region.
eDrawStandard	Draws a labeled line for each detected edge, and draws a box around the projection region.

Notes

Edges and labels are drawn in **ccColor::greenColor()**, projected and filtered images are drawn in **ccColor::cyanColor()**, bounding boxes are drawn in **ccColor::magentaColor()**, and projection region is drawn in **ccColor::blueColor()**.

ResultSetDrawMode

```
enum ResultSetDrawMode;
```

This enumeration defines the types of result graphics you can draw for Caliper tool results.

Value	Meaning
eDrawRawEdges	Draws a **ccColor::redColor()** line at each edge detected in the projection image.

```
enum { kDefaultPlotHeight = 30 };
```

ccCaliperDefs

ccCaliperDesiredEdge

```
#include <ch_cvl/caliper.h>

class ccCaliperDesiredEdge;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class describes a single edge. This class is constructed automatically by the Caliper tool. You specify the location and polarity of the model edge or edges when you construct a **ccCaliperRunParams**.

Note You should not construct a **ccCaliperDesiredEdge** directly.

Constructors/Destructors

ccCaliperDesiredEdge

```
ccCaliperDesiredEdge (double position = 0.0,
  ceEdgePolarity polarity = ceDontCare);
```

Construct this edge using the specified parameters.

Parameters

position The expected position of this edge with respect to the edge model origin in input image client coordinate system units.

polarity The expected polarity of the edge. *polarity* must be one of the following values:

ceDarkToLight
ceLightToDark
ceDontCare

A value of *ceDontCare* means the edge has either polarity.

Public Member Functions

position

```
double position () const;
void position (double pos);
```

- `double position () const;`

  Return the position of this edge with respect to the model origin. The position is a signed value in client coordinate system units.

- `void position (double pos);`

  Sets the position of this edge with respect to the model origin. The position is a signed value in client coordinate units.

  Parameters

  pos The position to set.

  Notes

  The positions returned by the Caliper tool's **cfCaliperRun()** function indicate the distance between the model origin and the center of the caliper window (or another, user-supplied origin)

polarity

```
ceEdgePolarity polarity () const;
void polarity (ceEdgePolarity pol);
```

- `ceEdgePolarity polarity () const;`

  Returns the polarity of this edge. The polarity is defined as being measured in the ascending x-axis direction of the projection image. The value returned by this function is one of the following:

  ceDarkToLight
  ceLightToDark
  ceDontCare

- `void polarity (ceEdgePolarity pol);`

  Sets the polarity of this edge. The polarity is defined as being measured in the ascending x-axis direction of the projection image.

  Parameters

  pol The polarity to set. *pol* must be one of the following values:

ceDarkToLight
ceLightToDark
ceDontCare

ccCaliperDesiredEdge

ccCaliperEllipseFinderAutoRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperEllipseFinderAutoRunParams :
                        public ccCaliperFinderBaseAutoRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Ellipse Finder tool run-time parameters for running the tool in *auto* mode.

Constructors/Destructors

ccCaliperEllipseFinderAutoRunParams

```
ccCaliperEllipseFinderAutoRunParams();

ccCaliperEllipseFinderAutoRunParams (
  const ccEllipse2 &expectedEllipse,
  c_Int16 numCalipers = 0,
  const ccDPair &caliperSize = ccDPair(0, 0),
  const ccCaliperRunParams &caliperRunParams =
                                      ccCaliperRunParams(),
  const ccDPair &caliperSampling = ccDPair(1, 1),
  const ccAngleRange &angleRange =
                            ccAngleRange::FullAngleRange(),
  ccAffineSamplingParams::Interpolation
                         interpolationMethod =
                         ccAffineSamplingParams::eBilinear,
  const ccEllipseFitParams &ellipseFitParams =
                                      ccEllipseFitParams(),
  bool centrifugal = true,
  const cc2Xform& startPose = cc2Xform(),
  bool decrementNumIgnore = true);

virtual ~ccCaliperEllipseFinderAutoRunParams() {}
```

- `ccCaliperEllipseFinderAutoRunParams();`

  Default constructor.

Notes

A default constructed object is not valid for running.

- ```
  ccCaliperEllipseFinderAutoRunParams (
    const ccEllipse2 &expectedEllipse,
    c_Int16 numCalipers = 0,
    const ccDPair &caliperSize = ccDPair(0, 0),
    const ccCaliperRunParams &caliperRunParams =
                                          ccCaliperRunParams(),
    const ccDPair &caliperSampling = ccDPair(1, 1),
    const ccAngleRange &angleRange =
                              ccAngleRange::FullAngleRange(),
    ccAffineSamplingParams::Interpolation
                           interpolationMethod =
                           ccAffineSamplingParams::eBilinear,
    const ccEllipseFitParams &ellipseFitParams =
                                          ccEllipseFitParams(),
    bool centrifugal = true,
    const cc2Xform& startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

Constructs a ellipse finder run-time parameters object.

Parameters

expectedEllipse The ellipse you expect the tool to find in images.

numCalipers The number of calipers the tool should use to find the ellipse.

caliperSize The caliper size, width and height in client coordinates. All calipers are the same size.

caliperRunParams
The run-time parameters object to be used when the Caliper tool is run.

caliperSampling The sampling rate in samples/pixel for x and y, to be used on the calipers. For example, the following calculates the number of caliper samples in the x direction:

If xSize is **caliperSize.x()** in image coordinates, then the effective number of samples in the x direction will be -

c_Int16(xSize * **caliperSampling.x()** + 0.5)

angleRange The beginning angle and the ending angle of the angle range where calipers will be placed along the expected ellipse perimeter. Angles are measured from the x-axis in the positive direction around a unit circle centered inside the ellipse. The
  ```

angle range along the unit circle perimeter is projected outward onto the ellipse perimeter. See the *Shape Finder Tool* chapter of the *Vision Tools Guide* for details.

The default is the full angular range.

interpolationMethod
The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums. The default is *eBilinear*.

See the **ccAffineSamplingParams** reference page.

ellipseFitParams The run-time parameters to use with the Fitting tool.

centrifugal When set true, the caliper search direction is outward from the ellipse center. When set false, the caliper search direction is inward. The default is true.

startPose A transform that maps the expected ellipse from ellipse space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccEllipseFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

Throws

ccCaliperFinderBaseDefs::BadParams
If *numCalipers* is not zero and is less than **minNumCalipers()**,
or if *caliperSize* is less than (0, 0),
or if *caliperSampling* is less than or equal to (0, 0),
or if *angleRange* is empty,
or if *startPose* is singular.

- `virtual ~ccCaliperEllipseFinderAutoRunParams() {}`

Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperEllipseFinderAutoRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperEllipseFinderAutoRunParams** object to compare to this object.

Public Member Functions

expectedEllipse

```
ccEllipse2 &expectedEllipse2() const;

void expectedEllipse2(const ccEllipse2 &expectedEllipse);
```

The ellipse you expect to find in images processed by the Ellipse Finder tool. The expected ellipse should be close to actual ellipses in the images.

- `ccEllipse2 &expectedEllipse2() const;`

  Returns the expected ellipse.

- `void expectedEllipse2(const ccEllipse2 &expectedEllipse);`

  Sets a new expected ellipse.

  Parameters

  expectedEllipse The new expected ellipse.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If an *expectedEllipse* radius is 0.

angleRange

```
const ccAngleRange &angleRange() const;

void angleRange(const ccAngleRange &angleRange);
```

The beginning angle and the ending angle of the angle range where calipers will be placed along the expected ellipse perimeter. Angles are measured from the x-axis in the positive direction around a unit circle centered inside the ellipse. The angle range along the unit circle perimeter is projected outward onto the ellipse perimeter. See the *Shape Finder Tool* chapter of the *Vision Tools Guide* for details.

The default is the full angular range.

Notes

This angle range is not in client coordinates. It is in the intrinsic coordinates of the ellipse to be consistent with the **ccEllipseArc** and **ccEllipseAnnulusSection** classes. Therefore, be careful when the ellipse's aspect ratio changes because of a transform since the angle range will mean something very different. For more information, see the **ccEllipse**, **ccEllipseArc**, and **ccEllipseAnnulusSection** reference pages.

- `const ccAngleRange &angleRange() const;`

  Returns the angle range.

- `void angleRange(const ccAngleRange &angleRange);`

  Sets a new angle range.

  Parameters
  angleRange The new angle range.

  Throws
  ccCaliperFinderBaseDefs::BadParams
  If *angleRange* is empty.

ellipseFitParams

```
const ccEllipseFitParams &ellipseFitParams() const;

void ellipseFitParams(
  const ccEllipseFitParams &ellipseFitParams);
```

- `const ccEllipseFitParams &ellipseFitParams() const;`

  Returns the ellipse fit parameters.

- `void ellipseFitParams(`
  `const ccEllipseFitParams &ellipseFitParams);`

  Sets new ellipse fit parameters.

  Parameters
  ellipseFitParams The new ellipse fit parameters.

centrifugal

```
bool centrifugal() const;
void centrifugal(bool centrifugal);
```

When set true, the caliper search direction is outward from the ellipse center. When set false, the caliper search direction is inward. The default is true.

- `bool centrifugal() const;`

  Returns the centrifugal setting, true or false.

- `void centrifugal(bool centrifugal);`

  Sets the caliper search direction.

  Parameters
  centrifugal The new caliper search direction.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const;
```

Returns the minimum number of calipers required (5).

Deprecated Members

The following have been deprecated and are provided here for backward compatibility only.

expectedEllipse

```
const ccEllipse &expectedEllipse() const;
void expectedEllipse(const ccEllipse &expectedEllipse);
```

The ellipse you expect to find in images processed by the Ellipse Finder tool. The expected ellipse should be close to actual ellipses in the images.

ccCaliperEllipseFinderAutoRunParams

```
ccCaliperEllipseFinderAutoRunParams (
  const ccEllipse &expectedEllipse,
  c_Int16 numCalipers = 0,
  const ccDPair &caliperSize = ccDPair(0, 0),
  const ccCaliperRunParams &caliperRunParams =
                                        ccCaliperRunParams(),
  const ccDPair &caliperSampling = ccDPair(1, 1),
  const ccAngleRange &angleRange =
                              ccAngleRange::FullAngleRange(),
  ccAffineSamplingParams::Interpolation
                           interpolationMethod =
                           ccAffineSamplingParams::eBilinear,
  const ccEllipseFitParams &ellipseFitParams =
                                        ccEllipseFitParams(),
  bool centrifugal = true,
  const cc2Xform& startPose = cc2Xform(),
  bool decrementNumIgnore = true);
```

Constructor.

ccCaliperEllipseFinderAutoRunParams

ccCaliperEllipseFinderManualRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperEllipseFinderManualRunParams :
                      public ccCaliperFinderBaseManualRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Ellipse Finder tool run-time parameters for running the tool in *manual* mode.

Constructors/Destructors

ccCaliperEllipseFinderManualRunParams

```
ccCaliperEllipseFinderManualRunParams() :
   ccCaliperFinderBaseManualRunParams(cc2Xform(), true) {}

ccCaliperEllipseFinderManualRunParams (
  const ccEllipse2 &expectedEllipse,
  const cmStd vector<ccAffineSamplingParams>& affParams =
                    cmStd vector<ccAffineSamplingParams>(),
  const cmStd vector<ccCaliperRunParams>& clpParams =
                        cmStd vector<ccCaliperRunParams>(),
  const ccEllipseFitParams &ellipseFitParams =
                                       ccEllipseFitParams(),
  const cc2Xform &startPose = cc2Xform(),
  bool decrementNumIgnore = true);

virtual ~ccCaliperEllipseFinderManualRunParams() {}
```

- ```
  ccCaliperEllipseFinderManualRunParams() :
     ccCaliperFinderBaseManualRunParams(cc2Xform(), true) {}
  ```

  Default constructor.

  Notes

  A default constructed object is not valid for running.
  ```

- ```
  ccCaliperEllipseFinderManualRunParams (
    const ccEllipse2 &expectedEllipse,
    const cmStd vector<ccAffineSamplingParams>& affParams =
                        cmStd vector<ccAffineSamplingParams>(),
    const cmStd vector<ccCaliperRunParams>& clpParams =
                           cmStd vector<ccCaliperRunParams>(),
    const ccEllipseFitParams &ellipseFitParams =
                                          ccEllipseFitParams(),
    const cc2Xform &startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

  Constructs a ellipse finder manual run-time parameters object.

  Parameters

  expectedEllipse The ellipse you expect the tool to find in images.

  affParams A vector of affine rectangle sampling parameters, one parameter set for each caliper.

  clpParams A vector of caliper run-time parameters, one parameter set for each caliper.

  ellipseFitParams The run-time parameters to use with the Fitting tool.

  startPose A transform that maps the expected ellipse from ellipse space to its expected pose in the run-time client space.

  decrementNumIgnore
  When true, *ccEllipseFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If **affParams.size()** is not equal to **clpParams.size()**, or if params sizes are not zero and less than **minNumCalipers()**, or if *startPose* is singular.

- ```
  virtual ~ccCaliperEllipseFinderManualRunParams() {}
  ```

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperEllipseFinderManualRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperEllipseFinderManualRunParams** object to compare to this object.

Public Member Functions

expectedEllipse2

```
ccEllipse2 expectedEllipse() const;

void expectedEllipse2(const ccEllipse2 &expectedEllipse);
```

The ellipse you expect to find in images processed by the Ellipse Finder tool. The expected ellipse should be close to actual ellipses in the images.

- `ccEllipse2 expectedEllipse() const;`

  Returns the expected ellipse.

- `void expectedEllipse2(const ccEllipse2 &expectedEllipse);}`

  Sets a new expected ellipse.

  Parameters

  expectedEllipse The new expected ellipse.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If an *expectedEllipse* radius is 0.

ellipseFitParams

```
const ccEllipseFitParams &ellipseFitParams() const;

void ellipseFitParams(
  const ccEllipseFitParams &ellipseFitParams);
```

- `const ccEllipseFitParams &ellipseFitParams() const;`

  Returns the ellipse fitter run-time parameters.

- ```
  void ellipseFitParams(
    const ccEllipseFitParams &ellipseFitParams);
  ```

  Sets new ellipse fitter run-time parameters.

  Parameters

  ellipseFitParams The new parameters.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const;
```

Returns the minimum number of calipers required (5).

Deprecated Members

The following have been deprecated and are provided here only for backward compatibility.

expectedEllipse

```
const ccEllipse &expectedEllipse() const;

void expectedEllipse(const ccEllipse &expectedEllipse);
```

The ellipse you expect to find in images processed by the Ellipse Finder tool. The expected ellipse should be close to actual ellipses in the images.

ccCaliperEllipseFinderManualRunParams

```
ccCaliperEllipseFinderManualRunParams (
  const ccEllipse &expectedEllipse,
  const cmStd vector<ccAffineSamplingParams>& affParams =
                  cmStd vector<ccAffineSamplingParams>(),
  const cmStd vector<ccCaliperRunParams>& clpParams =
                        cmStd vector<ccCaliperRunParams>(),
  const ccEllipseFitParams &ellipseFitParams =
                                      ccEllipseFitParams(),
  const cc2Xform &startPose = cc2Xform(),
  bool decrementNumIgnore = true);
```

Constructor.
```

ccCaliperEllipseFinderResult

```
#include <ch_cvl/clpfind.h>

class ccCaliperEllipseFinderResult :
                                    public ccCaliperFinderBaseResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encapsulates the results from the Ellipse Finder tool.

Constructors/Destructors

ccCaliperEllipseFinderResult

```
ccCaliperEllipseFinderResult() {};

virtual ~ccCaliperEllipseFinderResult() {}
```

- `ccCaliperEllipseFinderResult() {};`

  Default constructor. Creates a default constructed (unfound) ellipse result object.

- `virtual ~ccCaliperEllipseFinderResult() {}`

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseResult& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperEllipseFinderResult** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperEllipseFinderResult** object to compare to this object.

Public Member Functions

found

```
virtual bool found() const;
```

Returns true if an ellipse was found. Returns false otherwise.

An ellipse is found if its computed error is less than the error *threshold* specified in the Ellipse Fitting tool parameters. See **ccEllipseFitParams::threshold()**.

ellipseFit

```
const ccEllipseFitResults &ellipseFit() const;
```

Returns the ellipse fitting result.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

ellipse2

```
const ccEllipse2 &ellipse2() const;
```

Returns the found ellipse if **found()** is true.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

position

```
const cc2Vect &position() const;
```

Returns the position of the computed ellipse.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

ellipseFitTime

```
double ellipseFitTime() const;
```

Returns the circle fitting time, in seconds.

Deprecated Members

ellipse

```
const ccEllipse &ellipse() const;
```

Returns the found ellipse if **found()** is true.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

ccCaliperEllipseFinderResult

ccCaliperFinderBaseAutoRunParams

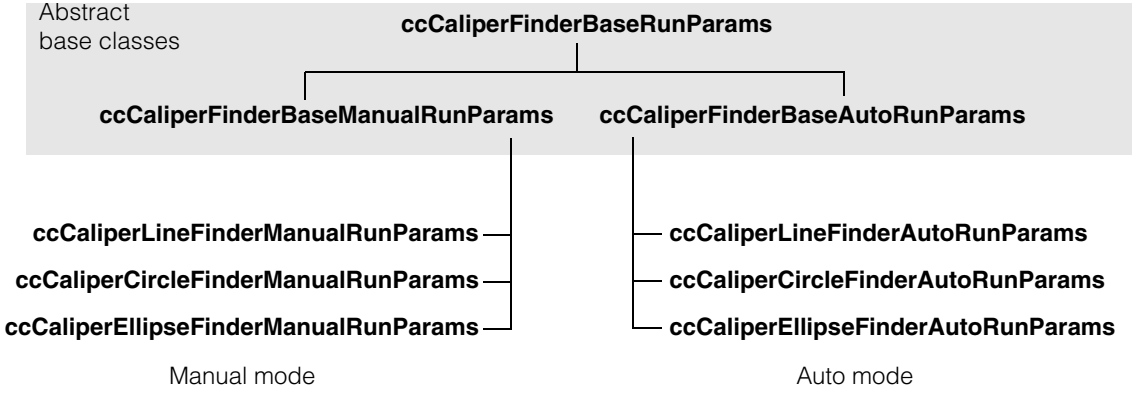
```
#include <ch_cvl/clpfind.h>

class ccCaliperFinderBaseAutoRunParams :
                              public ccCaliperFinderBaseRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is an abstract base class for the Shape Finder tool run-time parameters. See the following class hierarchy diagram.



Constructors/Destructors

ccCaliperFinderBaseAutoRunParams

```
ccCaliperFinderBaseAutoRunParams (
  c_Int16 numCalipers,
  const ccDPair &caliperSize,
  const ccCaliperRunParams &caliperRunParams,
  const ccDPair &caliperSampling,
  ccAffineSamplingParams::Interpolation
```

```
                                                    interpolationMethod,
  const cc2Xform &startPose,
  bool decrementNumIgnore);

ccCaliperFinderBaseAutoRunParams(
  const ccCaliperFinderBaseAutoRunParams&);

virtual ~ccCaliperFinderBaseAutoRunParams() = 0;
```

-
```
ccCaliperFinderBaseAutoRunParams (
  c_Int16 numCalipers,
  const ccDPair &caliperSize,
  const ccCaliperRunParams &caliperRunParams,
  const ccDPair &caliperSampling,
  ccAffineSamplingParams::Interpolation
                                                    interpolationMethod,
  const cc2Xform &startPose,
  bool decrementNumIgnore);
```

Protected; constructs a finder base auto run-time parameters object.

Parameters

numCalipers The number of calipers the tool should use to find the shape.

caliperSize The caliper size, width and height in client coordinates. All calipers are the same size. Caliper width is also called the search length and caliper height is also called the projection length.

caliperRunParams
The run-time parameters object to be used when the Caliper tool is run.

caliperSampling The sampling rate in samples/pixel for x and y, to be used on the calipers. For example, the following calculates the number of caliper samples in the x direction:

If xSize is **caliperSize.x()** in image coordinates, then the effective number of samples in the x direction will be -

c_Int16(xSize * **caliperSampling.x()** + 0.5)

interpolationMethod
The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums.

See the **ccAffineSamplingParams** reference page.

startPose A transform that maps the expected shape from shape space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *numIgnore* in the shape fit parameters is decremented for each caliper that fails to find an edge. When false, no decrement occurs. The default is true.

Throws

ccCaliperFinderBaseDefs::BadParams
If *numCalipers* is less than 0,
or if *caliperSize* is less than (0, 0),
or if *caliperSampling* is less than or equal to (0, 0),
or if *startPose* is singular.

- ```
  ccCaliperFinderBaseAutoRunParams(
    const ccCaliperFinderBaseAutoRunParams&);
  ```

  Protected copy constructor.

- ```
  virtual ~ccCaliperFinderBaseAutoRunParams() = 0;
  ```

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperFinderBaseRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The object to compare to this object.

operator=

```
ccCaliperFinderBaseAutoRunParams& operator= (
  const ccCaliperFinderBaseAutoRunParams& newObj);
```

Protected assignment operator. Prohibits copying and assignment by base pointers.

Parameters

newObj The new object that is a copy of this object.

Public Member Functions

numCalipers

```
c_Int16 numCalipers() const;
void numCalipers(c_Int16 numCalipers);
```

The number of calipers the tool should use to find the shape. The default is zero which is not valid for running the tool.

- `c_Int16 numCalipers() const;`

  Returns the number of calipers to use.

- `void numCalipers(c_Int16 numCalipers);`

  Sets a new number of calipers.

  Parameters
  numCalipers The new number of calipers.

  Throws
  ccCaliperFinderBaseDefs::BadParams
  If *numCalipers* < **minNumCalipers()**.

caliperWidth

```
double caliperWidth() const;
void caliperWidth(double caliperWidth);
```

The caliper width in pixels.

- `double caliperWidth() const;`

  Returns the caliper width.

- `void caliperWidth(double caliperWidth);`

  Sets a new caliper width.

  Parameters
  caliperWidth The new caliper width.

caliperHeight

```
double caliperHeight() const;
void caliperHeight(double caliperHeight);
```

The caliper height in pixels.

- `double caliperHeight() const;`

  Returns the caliper height.

- `void caliperHeight(double caliperHeight);`

  Sets a new caliper height.

  Parameters
  caliperHeight The new caliper height.

caliperSize

```
const ccDPair &caliperSize() const;
void caliperSize(const ccDPair &caliperSize);
```

The caliper size, width and height in client coordinates. All calipers are the same size. The default is (0, 0) which is not valid for running a tool.

- `const ccDPair &caliperSize() const;`

  Returns the caliper size.

- `void caliperSize(const ccDPair &caliperSize);`

  Sets a new caliper size.

  Parameters
  caliperSize The new caliper size.

  Throws
  ccCaliperFinderBaseDefs::BadParams
  If *caliperSize* is equal to or less than (0., 0.).

caliperRunParams

```
ccCaliperRunParams caliperRunParams() const;

void caliperRunParams(
  const ccCaliperRunParams &caliperRunParams);
```

The run-time parameters object to use when the Caliper tool is run.

- `ccCaliperRunParams caliperRunParams() const;`

  Returns the current run-time parameters.

- `void caliperRunParams(`
  `const ccCaliperRunParams &caliperRunParams);`

  Sets a new run-time parameters object.

  Parameters

  caliperRunParams
  The new run-time parameters.

caliperSampling

```
const ccDPair &caliperSampling() const;

void caliperSampling(const ccDPair &caliperSampling);
```

The sampling rate in samples/pixel for x and y (width and height), to be used on the calipers. See *caliperSampling* in the ctor.

The default is (1, 1).

- `const ccDPair &caliperSampling() const;`

  Returns the caliper sampling values.

- `void caliperSampling(const ccDPair &caliperSampling);`

  Sets new caliper sampling values.

  Parameters

  caliperSampling The new caliper sampling.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If *caliperSampling* is equal to or less than (0., 0.).

interpolationMethod

```
ccAffineSamplingParams::Interpolation
                                    interpolationMethod() const;

void interpolationMethod(
  ccAffineSamplingParams::Interpolation method);
```

The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums. See the **ccAffineSamplingParams** reference page.

The default is bilinear interpolation.

- ```
  ccAffineSamplingParams::Interpolation
                                    interpolationMethod() const;
  ```

  Returns the current interpolation method.

- ```
  void interpolationMethod(
    ccAffineSamplingParams::Interpolation method);
  ```

  Sets a new interpolation method.

  Parameters

  method The new interpolation method.

affineSamplingParamsList

```
virtual const cmStd
vector<ccAffineSamplingParams> affineSamplingParamsList(
  const cc2XformBase &clientFromImage =
                                       cc2XformLinear()) const;
```

Returns the affine sampling parameters. The parameters are computed if necessary.

Parameters

clientFromImage

The client space to image space transform.

Throws

ccCaliperFinderBaseDefs::BadParams

If any run parameter is invalid,
or if the sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

Notes

These parameters do not reflect the start pose.

Protected Member Functions

dirty

```
void dirty();
```

Sets the dirty flag to true so that affine sampling parameters are recomputed when the tool is run.

computeAffineSamplingParams

```
void computeAffineSamplingParams(
  const cc2XformBase &imageFromClient);
```

This function is for Cognex internal use only.

Throws

ccCaliperFinderBaseDefs::BadParams
If any run parameter is invalid,
or if the sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

computeAffineSamplingParams_

```
virtual void computeAffineSamplingParams_();
```

This function is for Cognex internal use only.

Throws

ccCaliperFinderBaseDefs::BadParams
If any run parameter is invalid,
or if the sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

ccCaliperFinderBaseManualRunParams

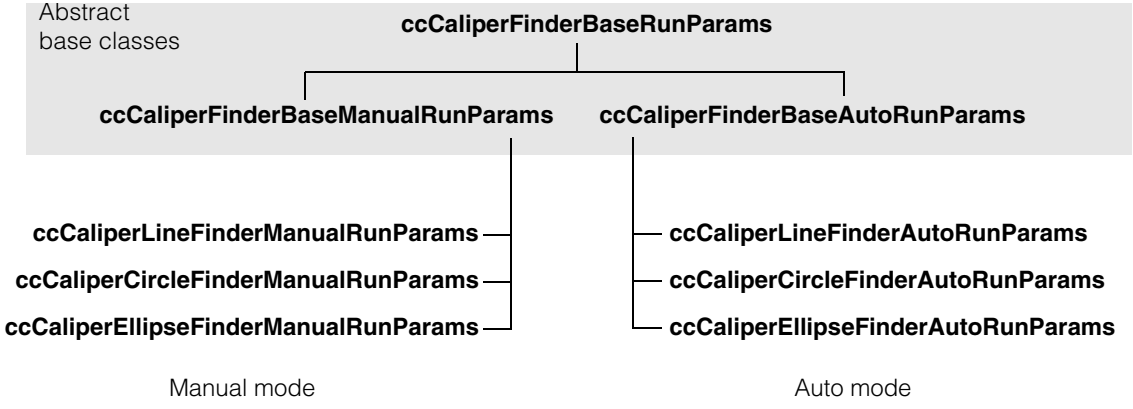
```
#include <ch_cvl/clpfind.h>

class ccCaliperFinderBaseManualRunParams :
                              public ccCaliperFinderBaseRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is an abstract base class for the Shape Finder tool run-time parameters. See the following class hierarchy diagram.



Constructors/Destructors

ccCaliperFinderBaseManualRunParams

```
ccCaliperFinderBaseManualRunParams (
  const cc2Xform &startPose,
  bool decrementNumIgnore);

ccCaliperFinderBaseManualRunParams (
  const ccCaliperFinderBaseManualRunParams&);

virtual ~ccCaliperFinderBaseManualRunParams() = 0;
```

- ```
  ccCaliperFinderBaseManualRunParams (
    const cc2Xform &startPose,
    bool decrementNumIgnore);
  ```

  Protected; constructs a finder base manual run-time parameters object.

  Parameters

  startPose A transform that maps the expected shape from shape space to its expected pose in the run-time client space. It also maps the caliper affine rectangles into client space.

  decrementNumIgnore
  When true, *numIgnore* in the shape fit parameters is decremented for each caliper that fails to find an edge. When false, no decrement occurs. The default is true.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If *startPose* is singular.

- ```
  ccCaliperFinderBaseManualRunParams (
    const ccCaliperFinderBaseManualRunParams&);
  ```

  Protected copy constructor.

- ```
  virtual ~ccCaliperFinderBaseManualRunParams() = 0;
  ```

  Destructor.
  ```

Operators

operator=

```
ccCaliperFinderBaseRunParams& operator=(
  const ccCaliperFinderBaseRunParams& newObj);
```

Protected assignment operator. Prohibits copying and assignment by base pointers.

Parameters

newObj The new object that is a copy of this object.

Public Member Functions

setAffineSamplingAndCaliperRunParams

```
void setAffineSamplingAndCaliperRunParams (
  const cmStd vector<ccAffineSamplingParams>& affParams,
  const cmStd vector<ccCaliperRunParams>& clpParams);
```

Sets the affine sampling and caliper run-time parameters. These lists are used in manual mode where each affine parameter list item corresponds to the affine sampling parameters for one caliper and each caliper parameter list item corresponds to the run-time parameters for one caliper.

The defaults are empty vectors which are not valid for running a tool.

Parameters

affParams The affine sampling parameters list.

clpParams The caliper run-time parameters list.

Throws

ccCaliperFinderBaseDefs::BadParams

If **affParams.size()** is not equal to **clpParams.size()**,
or if **affParams.size()** < **minNumCalipers()**,
or if **clpParams.size()** < **minNumCalipers()**.

ccCaliperFinderBaseManualRunParams

ccCaliperFinderBaseResult

```
#include <ch_cvl/clpfind.h>

class ccCaliperFinderBaseResult : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is an abstract base class for the Shape Finder tool results.

Constructors/Destructors

ccCaliperFinderBaseResult

```
ccCaliperFinderBaseResult();

ccCaliperFinderBaseResult(
  const ccCaliperFinderBaseResult&);

virtual ~ccCaliperFinderBaseResult();
```

- `ccCaliperFinderBaseResult();`

  Protected default constructor. **fitterResultsValid()** is set to false.

- ```
  ccCaliperFinderBaseResult(
    const ccCaliperFinderBaseResult&);
  ```

  Protected copy constructor.

- `virtual ~ccCaliperFinderBaseResult();`

  Destructor.
  ```

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseResult& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperFinderBaseResult** objects are considered equal if and only if their *fitterResultsValid*, *pose*, caliper results, and edge positions are equal.

Parameters

that The object to compare to this object.

operator=

```
ccCaliperFinderBaseResult& operator=(
  const ccCaliperFinderBaseResult& newObj);
```

Protected assignment operator. Prohibits copying and assignment by base pointers.

Parameters

newObj The new object that is a copy of this object.

Public Member Functions

found

```
virtual bool found() const;
```

Returns true for a found shape with a valid result. Otherwise returns false.

fitterResultsValid

```
bool fitterResultsValid() const;
```

Returns true if the fitter results are valid. Otherwise returns false.

pose

```
const cc2Xform& pose() const;
```

Returns the pose that maps the expected shape to the found shape.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the fitter results are invalid.

caliperResults

```
const cmStd vector<ccCaliperResultSet> &caliperResults();
```

Returns the caliper results.

edgePositions

```
const cmStd vector<cc2Vect> &edgePositions() const;
```

Returns the found edge positions.

caliperTime

```
double caliperTime() cons;
```

Returns the time (in seconds) spent running calipers.

totalTime

```
double totalTime() const;
```

Returns the total time (in seconds) to find the shape.

Protected Member Functions

checkFitterResults

```
void checkFitterResults() const;
```

Checks whether or not the fitter results are valid. If the results are valid, the function returns. If the results are not valid it throws the error below.

Throws

ccCaliperFinderBaseDefs::NotComputed

If the fitter results are invalid because they were not computed.

ccCaliperFinderBaseResult

ccCaliperFinderBaseRunParams

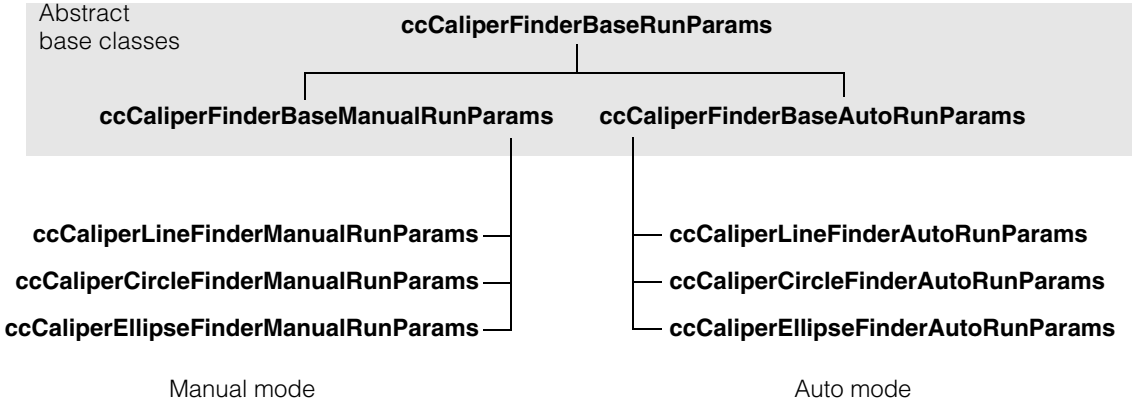
```
#include <ch_cvl/clpfind.h>

class ccCaliperFinderBaseRunParams : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is an abstract base class for the Shape Finder tool run-time parameters. See the following class hierarchy diagram.



Constructors/Destructors

ccCaliperFinderBaseRunParams

```
ccCaliperFinderBaseRunParams(
  const cc2Xform& startPose,
  bool decrementNumIgnore);

ccCaliperFinderBaseRunParams(
  const ccCaliperFinderBaseRunParams&);

virtual ~ccCaliperFinderBaseRunParams() = 0;
```

- ```
  ccCaliperFinderBaseRunParams(
    const cc2Xform& startPose,
    bool decrementNumIgnore);
  ```

  Protected; constructs a finder base run-time parameters object.

  Parameters

  startPose A transform that maps the expected shape from shape space to its expected pose in the run-time client space. It also maps the caliper affine rectangles into client space.

  decrementNumIgnore When true, *numIgnore* in the shape fit parameters is decremented for each caliper that fails to find an edge. When false, no decrement occurs. The default is true.

  Throws

  ccCaliperFinderBaseDefs::BadParams If *startPose* is singular.

- ```
  ccCaliperFinderBaseRunParams(
    const ccCaliperFinderBaseRunParams&);
  ```

  Protected copy constructor.

- ```
  virtual ~ccCaliperFinderBaseRunParams() = 0;
  ```

  Destructor.
  ```

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperFinderBaseRunParams** objects are considered equal if, and only if, all their members are equal.

Parameters

that	The object to compare to this object.

operator=

```
ccCaliperFinderBaseRunParams& operator=(
  const ccCaliperFinderBaseRunParams& newObj);
```

Protected assignment operator. Prohibits copying and assignment by base pointers.

Parameters

newObj	The new object that is a copy of this object.

Public Member Functions

startPose

```
const cc2Xform& startPose() const;

void startPose(const cc2Xform& startPose);
```

A transform that maps the expected shape from shape space to its expected pose in the run-time client space. It also maps the caliper affine rectangles into client space.

The default is the identity transform.

- `const cc2Xform& startPose() const;`

  Returns the current start pose.

- `void startPose(const cc2Xform& startPose);`

  Sets a new start pose.

  Parameters

startPose	The new start pose.

Throws

ccCaliperFinderBaseDefs::BadParams
If *startPose* is singular.

decrementNumIgnore

```
bool decrementNumIgnore() const;

void decrementNumIgnore(bool ignore);
```

When true, *numIgnore* in the shape fit parameters is decremented for each caliper that fails to find an edge. When false, no decrement occurs. The default is true.

Notes

An internal copy is decremented not the actual fitter parameters given by the user.

- `bool decrementNumIgnore() const;`

  Returns the current setting, true or false.

- `void decrementNumIgnore(bool ignore);`

  Sets the ignore flag.

  Parameters

  ignore The new flag, true or false.

affineSamplingParamsList

```
virtual const cmStd
vector<ccAffineSamplingParams> affineSamplingParamsList(
  const cc2XformBase &clientFromImage =
                                    cc2XformLinear()) const;
```

Parameters

clientFromImage
The client space to image space transform.

Returns the affine sampling parameters list. This list is used in manual mode where each list item corresponds to the affine sampling parameters for one caliper.

Notes

These sampling parameters do not reflect the start pose.

If you call this function on a default constructed object, it returns an empty vector which is not valid for running a tool. You must first set valid values for caliper size, number of calipers, and caliper sampling.

caliperRunParamsList

```
const cmStd vector<ccCaliperRunParams>
                                &caliperRunParamsList() const;
```

Returns the caliper run-time parameters list. This list is used in manual mode where each list item corresponds to the run-time parameters for one caliper.

Notes

The default is an empty vector which is not valid for running a tool.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const = 0;
```

Returns the minimum number of calipers required.

Protected Member Functions

affineSamplingParamsList

```
void affineSamplingParamsList (
  const cmStd vector<ccAffineSamplingParams>&
                                    affineSamplingParamsList);
```

Sets the affine sampling parameters list. This list is used in manual mode where each list item corresponds to the affine sampling parameters for one caliper.

Parameters

affineSamplingParamsList
The new list.

caliperRunParamsList

```
void caliperRunParamsList (
  const cmStd vector<ccCaliperRunParams>&
                                        caliperRunParamsList);
```

Sets the caliper run-time parameters list. This list is used in manual mode where each list item corresponds to the run-time parameters for one caliper.

Parameters

caliperRunParamsList
The new list.

ccCaliperFinderBaseRunParams

ccCaliperLineFinderAutoRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperLineFinderAutoRunParams :
                        public ccCaliperFinderBaseAutoRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Line Finder tool run-time parameters for running the tool in *auto* mode.

Constructors/Destructors

Notes

Default constructed objects do not contain valid run-time parameters.

ccCaliperLineFinderAutoRunParams

```
ccCaliperLineFinderAutoRunParams (
  const ccLineSeg& expectedLine = ccLineSeg(),
  c_Int16 numCalipers = 0,
  const ccDPair& caliperSize = ccDPair(0, 0),
  const ccCaliperRunParams& caliperRunParams =
                                      ccCaliperRunParams(),
  const ccDPair& caliperSampling = ccDPair(1, 1),
  const ccRadian& skew = ccRadian(0),
  ccAffineSamplingParams::Interpolation
                  interpolationMethod =
                  ccAffineSamplingParams::eBilinear,
  const ccLineFitParams& lineFitParams = ccLineFitParams(),
  const cc2Xform& startPose = cc2Xform(),
  bool decrementNumIgnore = true);

ccCaliperLineFinderAutoRunParams (
  const ccAffineRectangle &affineRectangle,
  c_Int16 numCalipers = 0,
  double caliperHeight = 0,
  const ccCaliperRunParams &caliperRunParams =
                                      ccCaliperRunParams(),
  const ccDPair &caliperSampling = ccDPair(1, 1),
  ccAffineSamplingParams::Interpolation
                        interpolationMethod =
```

```
                                ccAffineSamplingParams::eBilinear,
  const ccLineFitParams& lineFitParams = ccLineFitParams(),
  const cc2Xform& startPose = cc2Xform(),
  bool decrementNumIgnore = true);

virtual ~ccCaliperLineFinderAutoRunParams() {}
```

- ```
  ccCaliperLineFinderAutoRunParams (
    const ccLineSeg& expectedLine = ccLineSeg(),
    c_Int16 numCalipers = 0,
    const ccDPair& caliperSize = ccDPair(0, 0),
    const ccCaliperRunParams& caliperRunParams =
                                          ccCaliperRunParams(),
    const ccDPair& caliperSampling = ccDPair(1, 1),
    const ccRadian& skew = ccRadian(0),
    ccAffineSamplingParams::Interpolation
                    interpolationMethod =
                    ccAffineSamplingParams::eBilinear,
    const ccLineFitParams& lineFitParams = ccLineFitParams(),
    const cc2Xform& startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

  Constructs a line finder auto run parameters object where the expected line is defined by a **ccLineSeg** object.

  Parameters

  expectedLine The line you expect the tool to find in images.

  numCalipers The number of calipers the tool should use to find the line.

  caliperSize The caliper size, width and height in client coordinates. All calipers are the same size.

  caliperRunParams
  The run-time parameters object to be used when the Caliper tool is run.

  caliperSampling The sampling rate in samples/pixel for x and y, to be used on the calipers. For example, the following calculates the number of caliper samples in the x direction:

  If xSize is **caliperSize.x()** in image coordinates, then the effective number of samples in the x direction will be -

  c_Int16(xSize * **caliperSampling.x()** + 0.5)
  ```

skew A skew angle. Normally calipers are perpendicular to the expected line. You may wish to skew the calipers to avoid features in the image that could be confused with the line. See *skew* on page 854.

interpolationMethod
The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums. The default is *eBilinear*.

See the **ccAffineSamplingParams** reference page.

lineFitParams The run-time parameters to use with the Fitting tool.

startPose A transform that maps the expected line from line space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccLineFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

Throws

ccCaliperFinderBaseDefs::BadParams
If *numCalipers* is not zero and is less than **minNumCalipers()**,
or if *caliperSize* is less than (0, 0),
or if *caliperSampling* is less than or equal to (0, 0),
or if *skew* is +90° or -90°,
or if *startPose* is singular.

- ```
  ccCaliperLineFinderAutoRunParams (
    const ccAffineRectangle &affineRectangle,
    c_Int16 numCalipers = 0,
    double caliperHeight = 0,
    const ccCaliperRunParams &caliperRunParams =
                                        ccCaliperRunParams(),
    const ccDPair &caliperSampling = ccDPair(1, 1),
    ccAffineSamplingParams::Interpolation
                          interpolationMethod =
                          ccAffineSamplingParams::eBilinear,
    const ccLineFitParams& lineFitParams = ccLineFitParams(),
    const cc2Xform& startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

  Constructs a line finder auto run parameters object where the expected line is defined by an affine rectangle. Specifying the affine rectangle also sets *caliperWidth* and the skew.
  ```

Parameters

affineRectangle A rectangle that defines the expected line segment.

numCalipers The number of calipers the tool should use to find the line.

caliperHeight The caliper height in pixels. The caliper width is defined by the *affineRectangle* width. All calipers are the same size.

caliperRunParams
The run-time parameters object to be used when the Caliper tool is run.

caliperSampling The sampling rate in samples/pixel for x and y, to be used on the calipers. For example, the following calculates the number of caliper samples in the x direction:

If xSize is **caliperSize.x()** in image coordinates, then the effective number of samples in the x direction will be -

c_Int16(xSize * **caliperSampling.x()** + 0.5)

interpolationMethod
The interpolation method used with the calipers. Must be one of the **ccAffineSamplingParams::Interpolation** enums. The default is *eBilinear*.

See the **ccAffineSamplingParams** reference page.

lineFitParams The run-time parameters to use with the Fitting tool.

startPose A transform that maps the expected line from line space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccLineFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

Throws

ccCaliperFinderBaseDefs::BadParams
If *numCalipers* is not zero and is less than **minNumCalipers()**,
or if **affineRectangle.degen()** is true,
or if *caliperHeight* is less than 0,
or if *caliperSampling* is less than or equal to (0, 0),
or if *startPose* is singular.

- `virtual ~ccCaliperLineFinderAutoRunParams() {}`

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperLineFinderAutoRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperLineFinderAutoRunParams** object to compare to this object.

Public Member Functions

expectedLine

```
const ccLineSeg &expectedLine() const;

void expectedLine(const ccLineSeg &expectedLine);
```

- `const ccLineSeg &expectedLine() const;`

  Returns the expected line segment.

- `void expectedLine(const ccLineSeg &expectedLine);`

  Sets the expected line segment.

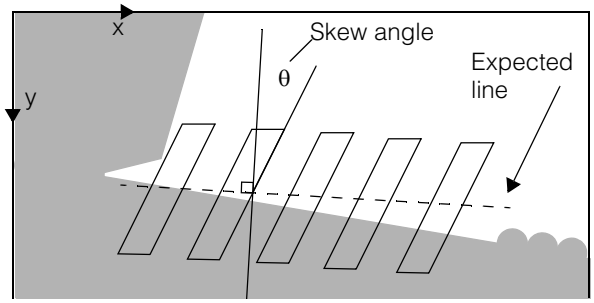
  Throws

  ccCaliperFinderBaseDefs::BadParams
  If **expectedLine.p1()** == **expectedLine.p2()**.

skew

```
const ccRadian &skew() const;
void skew(const ccRadian &skew);
```

When skew is 0°, calipers are perpendicular to the expected line. You may wish to skew the calipers to avoid features in the image that could be confused with the line. See the following example.



- `const ccRadian &skew() const;`

  Returns the current skew angle. The default is 0°.

- `void skew(const ccRadian &skew);`

  Sets a new skew angle.

  Parameters

  skew The new skew angle.

  Throws

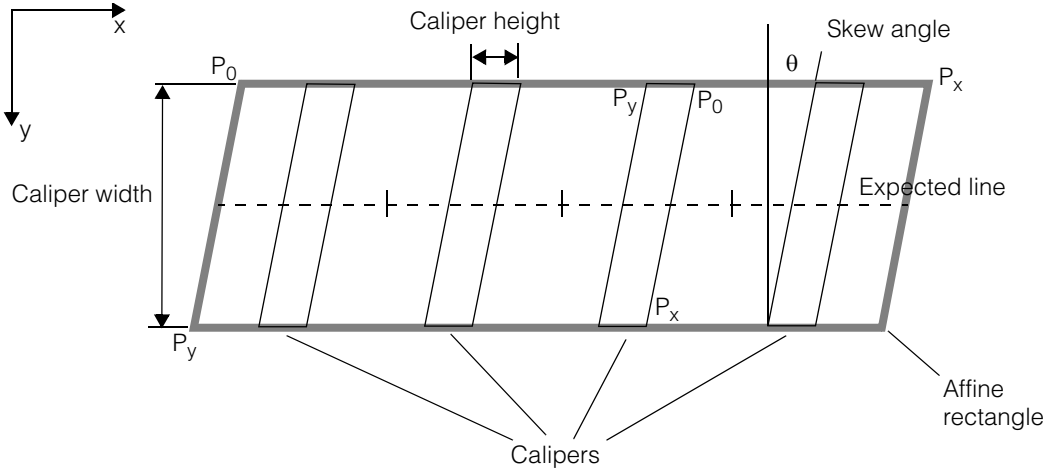
  ccCaliperFinderBaseDefs::BadParams
  If f *skew* is +90° or -90°.

affineRectangle

```
void affineRectangle(
  const ccAffineRectangle &affineRectangle);

ccAffineRectangle affineRectangle() const;
```

You can use an affine rectangle to define the expected line, caliper width, and skew. See the example below.



The expected line bisects the rectangle as shown, and the calipers are evenly distributed along the expected line.

- `ccAffineRectangle affineRectangle() const;`

  Returns the current affine rectangle.

- `void affineRectangle(`
  `const ccAffineRectangle &affineRectangle);`

  Sets a new affine rectangle.

  Parameters

  affineRectangle The new affine rectangle.

  Throws

  ccCaliperFinderBaseDefs::BadParams
  If **affineRectangle.degen()** is true.

  ccCaliperFinderBaseDefs::BadParams if affineRectangle.degen().

ccCaliperLineFinderAutoRunParams

lineFitParams

```
const ccLineFitParams &lineFitParams() const;
void lineFitParams(const ccLineFitParams &lineFitParams);
```

- `const ccLineFitParams &lineFitParams() const;`

  Returns the line fit parameters.

- `void lineFitParams(const ccLineFitParams &lineFitParams);`

  Sets new line fit parameters.

  Parameters

  lineFitParams The new parameters.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const;
```

Returns the minimum number of calipers required (2).

ccCaliperLineFinderManualRunParams

```
#include <ch_cvl/clpfind.h>

class ccCaliperLineFinderManualRunParams :
                      public ccCaliperFinderBaseManualRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Encapsulates the Line Finder tool run-time parameters for running the tool in *manual* mode.

Constructors/Destructors

ccCaliperLineFinderManualRunParams

```
ccCaliperLineFinderManualRunParams (
  const ccLineSeg& expectedLine = ccLineSeg(),
  const cmStd vector<ccAffineSamplingParams>& affParams =
                    cmStd vector<ccAffineSamplingParams>(),
  const cmStd vector<ccCaliperRunParams>& clpParams =
                          cmStd vector<ccCaliperRunParams>(),
  const ccLineFitParams& lineFitParams = ccLineFitParams(),
  const cc2Xform &startPose = cc2Xform(),
  bool decrementNumIgnore = true);

virtual ~ccCaliperLineFinderManualRunParams() {}
```

- ```
  ccCaliperLineFinderManualRunParams (
    const ccLineSeg& expectedLine = ccLineSeg(),
    const cmStd vector<ccAffineSamplingParams>& affParams =
                      cmStd vector<ccAffineSamplingParams>(),
    const cmStd vector<ccCaliperRunParams>& clpParams =
                          cmStd vector<ccCaliperRunParams>(),
    const ccLineFitParams& lineFitParams = ccLineFitParams(),
    const cc2Xform &startPose = cc2Xform(),
    bool decrementNumIgnore = true);
  ```

  Constructs a line finder manual run-time parameters object.
  ```

Notes

Default constructed objects do not contain valid run-time parameters.

Parameters

expectedLine The line you expect the tool to find in images.

affParams A vector of affine rectangle sampling parameters, one parameter set for each caliper.

clpParams A vector of caliper run-time parameters, one parameter set for each caliper.

lineFitParams The run-time parameters to use with the Fitting tool.

startPose A transform that maps the expected line from line space to its expected pose in the run-time client space.

decrementNumIgnore
When true, *ccLineFitParams::numIgnore* is decremented for each caliper that fails to find an edge. When false, no decrement occurs.

Throws

ccCaliperFinderBaseDefs::BadParams
If **affParams.size()** is not equal to **clpParams.size()**, or if params sizes are not zero and less than **minNumCalipers()**, or if *startPose* is singular.

- `virtual ~ccCaliperLineFinderManualRunParams() {}`

Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseRunParams& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperLineFinderManualRunParams** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperLineFinderManualRunParams** object to compare to this object.

Public Member Functions

expectedLine

```
const ccLineSeg &expectedLine() const;
void expectedLine(const ccLineSeg &expectedLine);
```

The line segment you expect to find in images processed by the Line Finder tool. The expected line should be close to actual lines in the images.

- `const ccLineSeg &expectedLine() const;`

  Returns the expected line segment.

- `void expectedLine(const ccLineSeg &expectedLine);`

  Sets the expected line segment.

  Throws
  ccCaliperFinderBaseDefs::BadParams
  If **expectedLine.p1()** == **expectedLine.p2()**.

lineFitParams

```
const ccLineFitParams &lineFitParams() const;
void lineFitParams(const ccLineFitParams &lineFitParams);
```

- `const ccLineFitParams &lineFitParams() const;`

  Returns the line fitter run-time parameters.

- `void lineFitParams(const ccLineFitParams &lineFitParams);`

  Sets new line fitter run-time parameters.

  Parameters
  lineFitParams The new parameters.

minNumCalipers

```
virtual c_Int16 minNumCalipers() const;
```

Returns the minimum number of calipers required (2).

ccCaliperLineFinderManualRunParams

ccCaliperLineFinderResult

```
#include <ch_cvl/clpfind.h>

class ccCaliperLineFinderResult :
                                public ccCaliperFinderBaseResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encapsulates the results from the Line Finder tool.

Constructors/Destructors

ccCaliperLineFinderResult

```
ccCaliperLineFinderResult() {};

virtual ~ccCaliperLineFinderResult() {}
```

- `ccCaliperLineFinderResult() {};`

  Default constructor. Creates a default constructed (unfound) line result object.

- `virtual ~ccCaliperLineFinderResult() {}`

  Destructor.

Operators

operator==

```
virtual bool operator==(
  const ccCaliperFinderBaseResult& that) const;
```

Compares this object to another object of the same type. Returns true if this object equals *that*. Returns false otherwise.

Two **ccCaliperLineFinderResult** objects are considered equal if, and only if, all their members and base classes are equal.

Parameters

that The **ccCaliperLineFinderResult** object to compare to this object.

Public Member Functions

found

```
virtual bool found() const;
```

Returns true if a line was found. Returns false otherwise.

A line is found if its computed error is less than the error *threshold* specified in the Line Fitting tool parameters. See **ccLineFitParams::threshold()**.

lineFit

```
const ccLineFitResults &lineFit() const;
```

Returns the line fitting result.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

line

```
const ccFLine &line() const;
```

Returns the computed line.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

lineSeg

```
const ccLineSeg &lineSeg() const;
```

Returns the best-fit line segment of the found line (the found line is an infinite length line). The best-fit line segment center is aligned with the expected line center and is the same length as the expected line.

Throws

ccCaliperFinderBaseDefs::NotComputed
If the Fitting tool results are invalid.

lineFitTime

```
double lineFitTime() const;
```

Returns the line fitting time, in seconds.

ccCaliperOneResult

```
#include <ch_cvl/caliper.h>

class ccCaliperOneResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single edge or edge pair result produced by the Caliper tool.

Note You should not construct a **ccCaliperOneResult** directly.

Constructors/Destructors

ccCaliperOneResult

```
ccCaliperOneResult ();
```

Do not construct **ccCaliperOneResult**s directly.

Public Member Functions

position

```
double position () const;
```

Returns the position at which this edge or edge pair was found. The returned position is a signed value indicating the distance between the center of the projection region (or another user-specified origin) and the origin of the edge model.

Notes

The position of an edge pair is computed so that the midpoint between the desired edges is aligned with the midpoint of the result edges.

score

```
double score () const;
```

Returns the overall score that this edge or edge pair received. The score is between 0.0 and 1.0. This is the geometric mean of all scores computed for the individual **ccCaliperScore** scoring methods.

resultEdges

```
const cmStd vector<ccCaliperResultEdge>& resultEdges ()
  const;
```

Returns a vector containing each of the individual **ccCaliperOneResult** edges that contribute to this result. They are listed in order of increasing position.

scores

```
const cmStd vector<double>& scores () const;
```

Returns a vector containing each of the individual scores contributing to this result. The order of the scores is the same as the order of the vector of **ccCaliperScore** scoring methods you specified when calling **ccCaliperRunParams()::scoringMethods()**.

draw

```
void draw(
  ccGraphicList& graphList,
  const ccCaliperBaseResultSet& set,
  c_UInt32 drawMode=ccCaliperDefs::eDrawStandard,
  const ccCvlString& label=ccCvlString(),
  double plotHeight=ccCaliperDefs::kDefaultPlotHeight)
                                                    const;
```

Appends result graphics for this **ccCaliperOneResult** to the supplied **ccGraphicList**.

Parameters

graphList — The graphics list to append the graphics to.

set — You must supply a reference to a **ccCaliperBaseResultSet** that contains this **ccCaliperOneResult**.

drawMode — The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccCaliperDefs::eDrawEdgeLine
ccCaliperDefs::eDrawLabel
ccCaliperDefs::eDrawProjFilter
ccCaliperDefs::eDrawProjectionRegion
ccCaliperDefs::eDrawStandard

label — If you include *ccCaliperDefs::eDrawLabel* in *drawMode*, then the contents of *label* are used to label the center of mass.

plotHeight — The height of the projection and filter plots, in client coordinates.

ccCaliperProjectionParams

```
#include <ch_cvl/caliper.h>

class ccCaliperProjectionParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

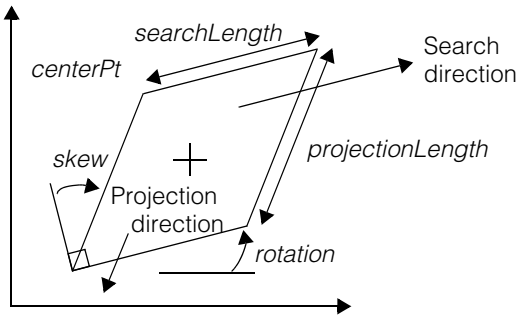
In general, you should not use this class to specify projection parameters. Instead, specify the projection region as a **ccAffineRectangle** and **ccAffineRectangleSamplingParams**.

Constructors/Destructors

ccCaliperProjectionParams

```
ccCaliperProjectionParams (const cc2Vect& centerPt,
  double searchLength, double projectionLength,
  const ccRadian& rotation =
  ccRadian(ccCaliperDefs::kDefaultRotation),
  const ccRadian& skew =
  ccRadian(ccCaliperDefs::kDefaultSkew),
  ccCaliperDefs::Interpolation method =
  ccCaliperDefs::kDefaultInterpolation);
```

Constructs a **ccCaliperProjectionParams** using the supplied parameters. The following diagram shows how the supplied parameters define the projection region:



Parameters

centerPt The center point of the projection region, specified in the client coordinate system of the input image.

searchLength The size of the projection region in the direction perpendicular to the projection direction, in client coordinates. The Caliper tool will convert this quantity into image coordinates and round it to the next higher integer value to determine the number of rays in the projection region. This in turn determines the dimensions of the projection image.

projectionLength The size of the projection region in the projection direction, in client coordinates. The Caliper tool will convert this quantity into image coordinates and round it to the next highest value to determine the number of interpolated pixels each ray.

rotation The rotation angle. This is defined as the angle from the client coordinate system x-axis to the search direction side of the projection region.

skew The skew angle. This is defined as the angle from a line perpendicular to the base of the projection region to the side of the projection region.

rotation plus *skew* is equal to the angle of the projection direction with respect to the client coordinate system y-axis.

method The sampling method to use to determine the values to sum to form the projection image. *method* must be one of the following values:

ccCaliperDefs::eNone
ccCaliperDefs::eBilinear

Public Member Functions

windowCenter

```
cc2Vect windowCenter () const;

void windowCenter (const cc2Vect& point);
```

- `cc2Vect windowCenter () const;`

  Returns the center point of the projection region in the input image client coordinate system. If you supply a **ccCaliperProjectionParams** as input to **cfCaliperRun**, then all positions reported by the tool are relative to this center point.

- `void windowCenter (const cc2Vect& point);`

  Sets the center point of the projection region in the input image client coordinate system. If you supply a **ccCaliperProjectionParams** as input to **cfCaliperRun**, then all positions reported by the tool are relative to this center point.

  Parameters

  point The center point to set.

windowSearchLength

```
double windowSearchLength () const;

void windowSearchLength (double length);
```

- `double windowSearchLength () const;`

  Returns the search length of the projection region in client coordinate system units.

- `void windowSearchLength (double length);`

  Sets the search length of the projection region in client coordinate system units. The search length specifies the size of the projection region in the search direction.

  Parameters

  length The length to set. *length* must be greater than 0.

  Throws

  ccCaliperDefs::BadParams

  length is less than or equal to zero.

  Notes

  The search length value is converted to input image coordinates, then rounded up to the next integral value, to determine the number of rays in the projection region and the number of pixels in the projection image.

windowProjectionLength

```
double windowProjectionLength () const;

void windowProjectionLength (double length);
```

- `double windowProjectionLength () const;`

  Returns the projection length of the projection region in client coordinate system units.

- `void windowProjectionLength (double length);`

  Sets the projection length of the projection region in client coordinate units. The projection length specifies the size of the window in the projection direction.

  Parameters

  length The length to set. *length* must be greater than 0.

  Throws

  ccCaliperDefs::BadParams
  length is less than or equal to zero.

windowRotation

```
ccRadian windowRotation () const;
void windowRotation (const ccRadian& angle);
```

- `ccRadian windowRotation () const;`

  Returns the rotation angle for the projection region. The rotation angle is the angle from the client coordinate system x-axis to the search direction side of the projection region.

- `void windowRotation (const ccRadian& angle);`

  Sets the rotation angle for the projection region. The rotation angle is the angle from the client coordinate system x-axis to the search direction side of the projection region. If this angle is 0, the search direction is parallel to the x-axis and points toward increasing x. If the angle is 90 degrees, the search direction is parallel to the y-axis and points toward increasing y.

  Parameters

  angle The angle to set

windowSkew

```
ccRadian windowSkew () const;
void windowSkew (const ccRadian& angle);
```

- `ccRadian windowSkew () const;`

  Returns the skew angle for the projection region. The skew angle is the angle from a line drawn perpendicular to the search direction to the projection direction. The skew angle plus the rotation angle gives the projection direction, relative to the client coordinate system x-axis.

- `void windowSkew (const ccRadian& angle);`

  Sets the skew angle for the projection region. The skew angle is the angle from a line drawn perpendicular to the search direction to the projection direction. The skew angle plus the rotation angle gives the projection direction, relative to the client coordinate system x-axis.

  Parameters

  angle The angle to set

  Throws

  ccCaliperDefs::BadParams
  angle is greater than $\pi/2$ radians or less than $-\pi/2$ radians.

interpolation

```
ccCaliperDefs::Interpolation interpolation () const;
void interpolation (ccCaliperDefs::Interpolation method);
```

- `ccCaliperDefs::Interpolation interpolation () const;`

  Returns the sampling method specified for this **ccCaliperProjectionParams**. This function returns one of the following values:

  ccCaliperDefs::eNone
  ccCaliperDefs::eBilinear

- `void interpolation (ccCaliperDefs::Interpolation method);`

  Sets the sampling method specified for this **ccCaliperProjectionParams**.

  Parameters

  method The sampling method to set. *method* must be one of the following values:

  ccCaliperDefs::eNone
  ccCaliperDefs::eBilinear

ccCaliperProjectionParams

ccCaliperResultEdge

```
#include <ch_cvl/caliper.h>

class ccCaliperResultEdge;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single edge located by the Caliper tool in the input image.

Caution *You should not attempt to construct a* **ccCaliperResultEdge** *yourself, and you should not attempt to call any member function that sets a value within a* **ccCaliperResultEdge***.*

Constructors/Destructors

ccCaliperResultEdge

```
ccCaliperResultEdge (double position = 0.0,
  double contrast = 0.0);
```

Construct this **ccCaliperResultEdge** with the given parameters.

Parameters

position	The location of the edge.
contrast	The contrast of the edge.

Public Member Functions

position

```
double position () const;
void position (double pos);
```

- `double position () const;`

  Returns the position at which this edge was found. The returned value is a signed quantity indicating the distance from the center of the caliper window (or other user-supplied origin) and the edge, in client coordinate system units.

- `void position (double pos);`

  This function is for internal use only. Do not call this function.

  Parameters

  pos The position to set

contrast

```
double contrast () const;
void contrast (double con);
```

- `double contrast () const;`

  Returns the contrast of this edge. The contrast is expressed as the difference in normalized grey level between the pixels on the two sides of the edge.

- `void contrast (double con);`

  This function is for internal use only. Do not call this function.

  Parameters

  con The contrast to set

ccCaliperResultSet

```
#include <ch_cvl/caliper.h>

class ccCaliperResultSet: public ccCaliperBaseResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the results returned by a single application of the Caliper tool to an input image in edge mode. Results common to both modes can be found in **ccCaliperBaseResultSet**.

Constructors/Destructors

ccCaliperResultSet

```
ccCaliperResultSet ();
```

Constructs **ccCaliperResultSet** with no result information.

Public Member Functions

edgeDetectTime

```
double edgeDetectTime () const;
```

Returns the amount of time, in seconds, required to locate all the edges in the image.

resultEdges

```
const cmStd vector<ccCaliperResultEdge>& resultEdges ()
  const;
```

Returns a vector of **ccCaliperResultEdge**s containing all the edges from the projection image. The edges are returned in order of increasing position in the search direction.

draw

```
void draw(
  ccGraphicList& graphList,
  c_UInt32 drawMode = ccCaliperDefs::eDrawStandard,
  double plotHeight = ccCaliperDefs::kDefaultPlotHeight)
                                                    const;
```

Appends result graphics for all the results in this **ccCaliperResultSet** to the supplied **ccGraphicList**.

Parameters

graphList	The graphics list to append the graphics to.
drawMode	The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values: *ccCaliperDefs::eDrawEdgeLine* *ccCaliperDefs::eDrawLabel* *ccCaliperDefs::eDrawProjFilter* *ccCaliperDefs::eDrawProjectionRegion* *ccCaliperDefs::eDrawStandard* *ccCaliperDefs::eDrawRawEdges*
plotHeight	The height of the projection and filter plots, in client coordinates.

ccCaliperRunParams

```
#include <ch_cvl/caliper.h>

class ccCaliperRunParams: public ccCaliperBaseRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the run-time parameters for the Caliper tool used in edge mode, including the definition of the expected edge or edge pair and the scoring methods to apply to candidate edges in the input image.

Constructors/Destructors

ccCaliperRunParams

```
ccCaliperRunParams (double edgePosition = 0.0,
  ceEdgePolarity edgePolarity = ceDontCare);

ccCaliperRunParams (double edge1Position,
  ceEdgePolarity edge1Polarity, double edge2Position,
  ceEdgePolarity edge2Polarity);
```

- ```
  ccCaliperRunParams (double edgePosition = 0.0,
    ceEdgePolarity edgePolarity = ceDontCare);
  ```

  Constructs a **ccCaliperRunParams** to search for a single-edge model.

  Parameters

  edgePosition The position of the edge with respect to the edge model origin.

  edgePolarity The polarity of the edge, defined as the polarity in the search direction. *edgePolarity* must be one of the following values:

  ceDarkToLight
  ceLightToDark
  ceDontCare

  A value of *ceDontCare* means the edge can have either polarity.
  ```

- ```
  ccCaliperRunParams (double edge1Position,
    ceEdgePolarity edge1Polarity,
    double edge2Position, ceEdgePolarity edge2Polarity);
  ```

  Constructs a **ccCaliperRunParams** to search for an edge-pair edge model.

  Parameters

  edge1Position — The position of the first edge with respect to the edge model origin.

  edge1Polarity — The polarity of the first edge, defined as the polarity in the search direction. *edge1Polarity* must be one of the following values:

  ceDarkToLight
  ceLightToDark
  ceDontCare

  A value of *ceDontCare* means the edge can have either polarity.

  edge2Position — The position of the second edge with respect to the edge model origin.

  edge2Polarity — The polarity of the second edge, defined as the polarity in the search direction. *edge2Polarity* must be one of the following values:

  ceDarkToLight
  ceLightToDark
  ceDontCare

  A value of *ceDontCare* means the edge can have either polarity.

Public Member Functions

filterHalfSize

```
c_Int16 filterHalfSize () const;

void filterHalfSize (c_Int16 halfSize);
```

- ```
  c_Int16 filterHalfSize () const;
  ```

  Returns the half-size, in units of the projection image's image coordinate system, of the filter defined for this **ccCaliperRunParams**.

- `void filterHalfSize (c_Int16 halfSize);`

  Sets the half-size, in units of the projection image's image coordinate system, of the filter defined for this **ccCaliperRunParams**. The filter is constructed by composing a Gaussian curve with a σ equal to one fourth of the specified half size, computing the first derivative of the curve, then taking its negative.

  Parameters

  halfSize The half-size of the filter. The resulting filter kernel is 2**halfSize*+1 pixels in size.

  Notes

  halfSize is specified in pixels defined by the projection region, not client coordinate units.

  Throws

  ccCaliperDefs::BadParams
  halfSize is less than 1.

contrastThreshold

```
double contrastThreshold () const;

void contrastThreshold (double thresh);
```

- `double contrastThreshold () const;`

  Returns the contrast threshold for 1-D edge detection. Any result edge whose contrast value is less than the contrast threshold is ignored. The threshold is specified as the difference in normalized pixel values on the two sides of the edge.

- `void contrastThreshold (double thresh);`

  Sets the contrast threshold for 1-D edge detection. Any result edge whose contrast value is less than the contrast threshold is ignored. The threshold is specified as the difference in normalized pixel values on the two sides of the edge.

  Parameters

  thresh The threshold to set

maxNumResults

```
c_Int16 maxNumResults () const;

void maxNumResults (c_Int16 num);
```

- `c_Int16 maxNumResults () const;`

  Returns the maximum number of results that the tool returns.

- `void maxNumResults (c_Int16 num);`

  Sets the maximum number of results that the tool returns.

  Parameters

  num The maximum number of results to return

  Notes

  If you specify 0 for *num,* the tool performs the projection, filtering, and edge detection steps, but does not produce any scored results.

  When using the Caliper tool on a multiprocessor PC, use the **ccCaliperRunParams::maxNumResults()** setter with the maximum number of expected individual results as its argument to reduce memory contention between multiple threads running on different processors. This method results in improved Caliper performance on a multiprocessor PC over that expected of a single-processor PC. This setting is necessary to improve performance on a multiprocessor PC, as *maxNumResults* is set to one by default.

  Throws

  ccCaliperDefs::BadParams

  num is less than 0.

scoringMethods

```
const cmStd vector<ccCaliperScore*> scoringMethods ()
  const;

void scoringMethods (
  const cmStd vector<ccCaliperScore*>& methods);
```

- `const cmStd vector<ccCaliperScore*> scoringMethods ()
  const;`

  Returns a vector of **ccCaliperScore** objects that define how edge candidates are scored.

- ```
  void scoringMethods (
    const cmStd vector<ccCaliperScore*>& methods);
  ```

  Sets the list of **ccCaliperScore** objects that determine how edge candidates are scored. Any existing list of **ccCaliperScore** objects is discarded.

  Parameters

  methods The scoring methods to set

  Notes

  If *methods* contains no objects (has a length of 0), then any attempt to run the Caliper tool with a value for the maximum number of results other than 0 will throw an error.

  A default-constructed **ccCaliperRunParams** object contains a single **ccScoreContrast** scoring method.

  Throws

  ccCaliperDefs::BadParams

  One or more of the **ccCaliperScore** objects in *method* cannot produce a score for the number of edges specified when you constructed this **ccCaliperRunParams**.

  You can determine which element of *methods* is causing the problem by calling the **ccCaliperScore::willScore()** function.

desiredEdges

```
const cmStd vector<ccCaliperDesiredEdge>& desiredEdges ()
  const;
```

Returns the model edges that you specified when you constructed this **ccCaliperRunParams**. If you specified a single edge, the returned vector has a size of 1; if you specified an edge pair, the returned vector has a size of 2.
```

ccCaliperRunParams

ccCaliperScanParams

```
#include <ch_cvl/caliper.h>

class ccCaliperScanParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the run-time parameters for operating the Caliper tool using scan mode. Scan mode automatically rotates the projection window about the application point to determine the orientation that produces the highest overall score.

Constructors/Destructors

ccCaliperScanParams

```
ccCaliperScanParams();

ccCaliperScanParams(ccRadian start, ccRadian end,
  ccRadian incr, bool interpolate, bool enable);
```

- `ccCaliperScanParams(};`

  Construct a **ccCaliperScanParams** with all parameters set to 0 or false.

- `ccCaliperScanParams(ccRadian start, ccRadian end, ccRadian incr, bool interpolate, bool enable);`

  Construct a **ccCaliperScanParams** initialized to the supplied values. For more information on the individual parameters, see the member functions in this class

  Parameters

start	The start of the range of angles to be scanned. The angle is from the client coordinate system x-axis to the projection direction.
end	The end of the range of angles to be scanned. The angle is from the client coordinate system x-axis to the projection direction.
incr	The amount by which to increment the angle between scans.

interpolate If true, intermediate angles are evaluated.

enable If true, scan mode is enabled for this object. If false, scan mode is disabled.

Operators

operator==

```
bool operator== (const ccCaliperScanParams& that) const;
```

Two **ccCaliperScanParams** objects are considered equal if their corresponding start angles, end angles, angle increments, interpolation settings, and enabled settings are the same.

Public Member Functions

scanStart

```
const ccRadian& scanStart() const;
```

```
void scanStart(const ccRadian& angle);
```

- `const ccRadian& scanStart() const;`

  Returns the start of the range of angles to be scanned.

- `void scanStart(const ccRadian& angle);`

  Sets the start of the range of angles to be scanned.

  Parameters

  angle The start angle measured from the client coordinate system x-axis to the projection direction.

scanEnd

```
const ccRadian& scanEnd() const;
```

```
void scanEnd(const ccRadian& angle);
```

- `const ccRadian& scanEnd() const;`

  Returns the end of the range of angles to be scanned.

- `void scanEnd(const ccRadian& angle);`

  Sets the end of the range of angles to be scanned.

Parameters

angle The end angle measured from the client coordinate system x-axis to the projection direction.

scanIncrement

```
const ccRadian& scanIncrement() const;
void scanIncrement(const ccRadian& angle);
```

- `const ccRadian& scanIncrement() const;`

  Returns the amount by which to increment the projection direction between scans.

- `void scanIncrement(const ccRadian& angle);`

  Sets the amount by which to increment the projection direction between scans.

  Parameters

  angle The increment value.

scanInterpol

```
bool scanInterpol() const;
void scanInterpol(bool interpol);
```

- `bool scanInterpol() const;`

  Returns whether or not this **ccCaliperScanParams** is configured to evaluate angles between the specified angle increments.

  `void scanInterpol(bool interpol);`

  Sets whether or not this **ccCaliperScanParams** is configured to evaluate angles between the specified angle increments. If interpolation is enabled, the Caliper tool will evaluate scan angles between the highest scoring angles specified by the start, stop, and increment values.

  Enabling interpolation increases the execution time required by the tool.

  Parameters

  interpol If true, interpolation is enabled. If false, interpolation is disabled.

ccCaliperScanParams

scanEnable

```
bool scanEnable() const;
void scanEnable(bool on);
```

- `bool scanEnable() const;`

  Returns true if this **ccCaliperScanParams** has scan mode enabled, false if scan mode is disabled.

- `void scanEnable(bool on);`

  Enables or disables scan mode for this **ccCaliperScanParams**. Since a single **ccCaliperRunParams** or **ccCaliperCorrelationRunParams** (both of which contain a **ccCaliperScanParams** object) can be used for multiple calipers, this function lets you enable or disable scan mode easily.

  Parameters

on	If true, scan mode is enabled. If false, scan mode is disabled.

ccCaliperScore

```
#include <ch_cvl/clpscore.h>

class ccCaliperScore : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	By Cognex-supplied classes only
Archiveable	Complex

A class from which intermediate classes such as **ccScoreOneSided** and **ccScoreTwoSided** are derived.

Note You can neither instantiate nor derive from this class. You should be familiar with the public member functions in this class; they are implemented in Cognex-supplied classes derived from this class.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const = 0;
```

Returns true if this **ccCaliperScore** is equivalent to the supplied **ccCaliperScore**.

Parameters

that The **ccCaliperScore** to compare to this one.

Public Member Functions

score

```
virtual double score (const ccCaliperModel& model,
  ccCaliperResult& candidate, ccCaliperData& res) const = 0;
```

Returns a score for the given edge in the input image. The method for computing the score depends on the scoring method type. The returned score is normalized to a value between 0.0 and 1.0.

Parameters

model The ideal edge, as defined by the user.

candidate The edge encountered in the input image

res The result for this edge

Notes

If the implementation of this function returns -1, the score will not be considered as part of the overall score.

clone

```
virtual ccCaliperScore* clone () const = 0;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const = 0;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccCallback

```
#include <ch_cvl/callback.h>

class ccCallback : public virtual ccRepBase;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	Complex

ccCallback is an abstract class for defining callback functions. Some CVL classes allow you to specify a function that will be called at a specific time. For example, the **ccAcqFifo** class, allows you to specify a function when it is safe to move the object in the camera's field of view.

To define a callback function, you derive a class from **ccCallback** and define **operator()**, the function call operator. Your derived class can define data members if necessary.

Constructors/Destructors

The default constructor and destructors do nothing. If you derive classes from this class, your constructor and destructors are responsible for allocating and releasing memory used by data members.

Operators

operator()

```
virtual void operator()() = 0;
```

Your derived class must define this operator to perform the actions that your callback function takes.

Typedefs

ccCallbackPtrh

```
typedef ccPtrHandle<ccCallback> ccCallbackPtrh;
```

ccCallbackPtrh_const

```
typedef ccPtrHandle_const<ccCallback>
  ccCallbackPtrh_const;
```

ccCallback

ccCallback1

```
#include <ch_cvl/callback.h>

template <class P> class ccCallback1 : public virtual ccRepBase;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	No

ccCallback1 is an template class for defining one-argument callback functions. See **ccCallback** for additional information.

P — The type of the lone argument passed to the function call operator.

To define a callback function, derive a class from **ccCallback1** and define **operator()**, the function call operator. Your derived class can define data members if necessary.

Constructors/Destructors

The default constructor and destructors do nothing. If you derive classes from this class, your constructor and destructors are responsible for allocating and releasing memory used by data members.

Operators

operator()

```
virtual void operator()(P arg1) = 0;
```

Your derived class must define this operator to perform the actions that your callback function takes.

Parameters

arg1 — The argument of type *P* passed to the function call operator.

Typedefs

CB1

```
typedef ccCallback1<const void*> CB1;
```

ccCallback1Ptrh

```
typedef ccPtrHandle<CB1> ccCallback1Ptrh;
```

ccCallback1Ptrh_const

```
typedef ccPtrHandle_const<CB1> ccCallback1Ptrh_const;
```

ccCallback2

```
#include <ch_cvl/callback.h>

template <class P, class Q> class ccCallback2 :
  public virtual ccRepBase;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	No

ccCallback2 is an template class for defining two-argument callback functions. See **ccCallback** for additional information.

P — The type of the first argument passed to the function call operator.

Q — The type of the second argument passed to the function call operator.

To define a callback function, derive a class from **ccCallback2** and define **operator()**, the function call operator. Your derived class can define data members if necessary.

Constructors/Destructors

The default constructor and destructors do nothing. If you derive classes from this class, your constructor and destructors are responsible for allocating and releasing memory used by data members.

Operators

operator()

```
virtual void operator()(P arg1,Q arg2) = 0;
```

Your derived class must define this operator to perform the actions that your callback function takes.

Parameters

arg1 — The argument of type *P* passed to the function call operator.

arg2 — The argument of type *Q* passed to function call operator.

ccCallback2

ccCameraPort

```
#include <ch_cvl/cogdevc.h>

class ccCameraPort;
```

Class Properties

Copyable	Not intended
Derivable	Yes
Archiveable	No

ccCameraPort is a class used to represent a camera port. This is useful for systems where the camera and camera type can be detected. For these systems the camera location property (**ccCameraLocationProp**) can be set via a reference to the found camera port.

Constructors/Destructors

ccCameraPort

```
protected: ccCameraPort(ccFrameGrabber& fg);

virtual ~ccCameraPort() {};
```

- `protected: ccCameraPort(ccFrameGrabber& fg);`

  Protected constructor, for Cognex use only.

  Parameters

  fg Frame grabber type.

- `virtual ~ccCameraPort();`

  Destructor.

Public Member Functions

frameGrabberOwner

```
ccFrameGrabber& frameGrabberOwner() const;
```

Returns a reference to the frame grabber that owns this camera port.

supportedFormat

```
bool supportedFormat(const ccVideoFormat&) const;

virtual bool supportedFormat(const cc_VideoFormat&)
   const = 0;
```

Parameters

ccVideoFormat A video format.

Returns true if the given video format is supported for this camera; otherwise returns false.

supportedFormats

```
virtual const ccVideoFormatList& supportedFormats()
   const = 0;
```

Returns a list of video formats supported by this camera.

newAcqFifo

```
ccStdGreyAcqFifo* newAcqFifo(
     const ccStdGreyVideoFormat& vf) const;
```

Parameters

vf A supported video format for this camera.

Returns a newly created acquisition FIFO for this camera using the given video format.

Notes

The **ccCameraLocationProp** is automatically set to use this camera.

Throws

ccCameraPort::BadParams()

If the given video format is not compatible with this camera.

Typedefs

ccVideoFormatList

```
typedef cmStd vector<const ccVideoFormat*>
   ccVideoFormatList;
```

ccCameraPortProp

```
#include <ch_cvl/prop.h>

class ccCameraPortProp;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes the camera port property of an acquisition FIFO queue.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccCameraPortProp

```
ccCameraPortProp();

explicit ccCameraPortProp(c_Int32 port);
```

- `ccCameraPortProp();`

  Creates a new camera port property not associated with any FIFO. The camera port is set to *ccCameraPort::defaultCameraPort*.

- `explicit ccCameraPortProp(c_Int32 port);`

  Creates a new camera port property not associated with any FIFO. The camera port is set to *port*.

  Parameters

port	The camera port to use.

Throws

ccCameraPortProp::BadParams
port is not in the range 0 to **numCameraPort()** - 1.

Public Member Functions

cameraPort

```
void cameraPort(c_Int32 port);
c_Int32 cameraPort();
```

- `void cameraPort(c_Int32 port);`

Sets the camera port that the acquisition FIFO this property is associated with should use.

Parameters

port The camera port to use.

Throws

ccCameraPortProp::BadParams
port is not in the range 0 to **numCameraPort()** - 1.

- `c_Int32 cameraPort() const;`

Returns the camera port that the acquisition FIFO associated with this property uses.

numCameraPort

```
c_Int32 numCameraPort() const;
```

Returns the number of camera ports that the underlying frame grabber supports.

Throws

ccCameraPortProp::NoFrameGrabber
This property is not associated with a **ccAcqFifo** object (and thus has no underlying frame grabber).

Constants

defaultCameraPort

```
static const c_Int32 defaultCameraPort;
```

The default camera port: 0.

ccCDBFile

```
#include <ch_cvl/cdb.h>

class ccCDBFile;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

The **ccCDBFile** lets you read from, write to, and navigate through a CDB file.

Constructors/Destructors

ccCDBFile

```
ccCDBFile();

ccCDBFile(const ccCvlString &name);

ccCDBFile(const ccCvlString &name, c_Int32 mode);

ccCDBFile(cmStd iostream* str,
  c_Int32 mode = cmStd ios::in | cmStd ios::out,
  bool becomeOwner = true);

~ccCDBFile();
```

- `ccCDBFile();`

  Constructs an unnamed and unbound **ccCDBFile** object.

- `ccCDBFile(const ccCvlString &name);`

  Constructs a **ccCDBFile** for read-only access to a CDB file.

  Parameters

  name The name of the CDB file.

  Throws

  ccCDBFile::CanNotOpenFile
  Cannot open the specified file. Verify that it exists and that it is not already open.

ccCDBFile::BadFileFormat
The specified file is not a valid CDB file.

- `ccCDBFile(const ccCvlString &name, c_Int32 mode);`

Constructs a **ccCDBFile** using the specified access mode on the specified CDB file.

Parameters

name The name of the CDB file.

mode The mode with which to open the file. *mode* must be formed by ORing together one or more of the following values:

cmStd ios::in
cmStd ios::out
cmStd ios::trunc

If you specify *cmStd ios::in*, the file is opened for read-only access. If you specify *cmStd ios::out*, the file is opened for writing. If you specify *cmStd ios::trunc* and *cmStd ios::out*, the file's contents are deleted as it is opened.

Throws

ccCDBFile::CanNotOpenFile
Cannot open the specified file. Verify that it exists, that it is not already open, and that you have write permission.

ccCDBFile::BadFileFormat
The specified file is not a valid CDB file.

ccCDBFile::InvalidArgument
mode is not a valid combination of *cmStd ios::in*, *cmStd ios::out*, and *cmStd ios::trunc*.

- ```
  ccCDBFile(cmStd iostream* str,
    c_Int32 mode = cmStd ios::in | cmStd ios::out,
    bool becomeOwner = true);
  ```

Constructs a **ccCDBFile** object that uses the specified **iostream** for input and output operations. If the specified **iostream** does not derive from **cmStd fstream**, calling **open()**, **filename()**, or **isOpen()** on this **ccCDBFile** throws *ccCDBFile::FileNotBound*.

Parameters

str The **iostream** to use for I/O.

mode The mode with which *str* was opened.
  ```

becomeOwner If true, then *str* will be deleted by **ccCDBFile**'s destructor when it is called. If false, then *str* will not be deleted.

Throws

ccCDBFile::InvalidArgument
str is null.

Notes

Calling **close()** flushes the CDB contents to *str*. **close()** is also called by **ccCDBFile**'s destructor.

- `~ccCDBFile();`

If the file associated with this **ccCDBFile** is open, calling the destructor closes the file.

Throws

ccCDBFile::WriteError
There was a file error trying to close the file.

Public Member Functions

open

```
void open(const ccCvlString &name,
  c_Int32 mode = cmStd ios::in);
```

Opens or creates a file with the specified name and mode. File pointer is positioned at the beginning of the first record; a subsequent call to **loadRecord()** loads the first record in the file.

Parameters

name The name of the CDB file.

mode The mode with which to open the file. *mode* must be formed by ORing together one or more of the following values:

cmStd ios::in
cmStd ios::out
cmStd ios::trunc

If you specify *cmStd ios::in*, the file is opened for read-only access. If you specify *cmStd ios::out*, the file is opened for writing. If you specify *cmStd ios::trunc* and *cmStd ios::out*, the file's contents are deleted as it is opened.

Throws

ccCDBFile::CanNotOpenFile
Cannot open the specified file. Verify that it exists, that it is not already open, and that you have write permission.

ccCDBFile::BadFileFormat
The specified file is not a valid CDB file.

ccCDBFile::InvalidArgument
mode is not a valid combination of *cmStd ios::in*, *cmStd ios::out*, and *cmStd ios::trunc*.

close `void close();`

Flushes the contents of the stream and closes the file. This **ccCDBFile** becomes unbound.

Throws

ccCDBFile::WriteError
There was a file error trying to close the file.

ccCDBFile::FileNotOpen
The file was not open.

filename `ccCvlString filename() const;`

Returns the name of the file associated with this **ccCDBFile**.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

isOpen `bool isOpen() const;`

Returns true if an open file is associated with this **ccCDBFile**.

loadRecord `void loadRecord(ccCDBRecord &rec);`

Reads the record at the current file pointer position in this **ccCDBFile**'s file into the supplied **ccCDBRecord**.

Parameters

rec A **ccCDBRecord** into which the record is read.

Throws

ccCDBFile::BadFileFormat
The specified file is not a valid CDB file.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

ccCDBFile::BadRecordFormat
The current record is an image record that has a bit depth other than 8.

ccCDBFile::RecordNotFound
The current record is END_OF_FILE.

storeRecord `void storeRecord(const ccCDBRecord &rec);`

Writes the supplied **ccCDBRecord** to the current file pointer position in this **ccCDBFile**'s open file.

Parameters
rec The **ccCDBRecord** to write.

Throws
ccCDBFile::RecordNotBound
The supplied **ccCDBRecord** does not have a type.

ccCDBFile::WriteError
There was a file error trying to write to the file.

ccCDBFile::RecordSizeMismatch
The size of the record being overwritten does not match the size of the supplied **ccCDBRecord**.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

appendRecord `void appendRecord(const ccCDBRecord &rec);`

Appends the supplied **ccCDBRecord** to the end of this **ccCDBFile**'s open file.

Parameters
rec The **ccCDBRecord** to write.

Throws
ccCDBFile::RecordNotBound
The supplied **ccCDBRecord** does not have a type.

ccCDBFile::WriteError
There was a file error trying to write to the file.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

deleteRecord `void deleteRecord();`

Deletes the last record from the end of this **ccCDBFile**'s open file.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

This function works by changing the type of the last record in the file to *DELETE_TYPE*.

Records of type *INDEX_TYPE*, *EOF_TYPE* or *DELETE_TYPE* are not affected by this function.

seekToMatchingRecord

```
void seekToMatchingRecord(c_Int32 rec_count,
  const ccCDBRecord &rec,
  c_Int32 mode = ccCDBRecord::SM_TYPE,
  cmStd ios::seekdir origin = cmStd ios::beg);
```

Advances the file pointer in this **ccCDBFile**'s open file by the specified number of records that match the supplied template **ccCDBRecord**.

Parameters

rec_count — The number of records to advance. Specify a negative value for *rec_count* to move backwards through the file.

rec — The template **ccCDBRecord**. Only records that match the template record are counted as the file pointer is advanced.

mode — The search mode. *mode* lets you specify what constitutes a match between a record in this **ccCDBFile**'s open file and the supplied template record. *mode* must be formed by ORing together one or more of the following values:

ccCDBRecord::SM_TYPE
ccCDBRecord::SM_STYPE
ccCDBRecord::SM_DSIZE
ccCDBRecord::SM_SEQ
ccCDBRecord::SM_COMMENT

origin — Specify *cmStd ios::beg* to search from the start of the file, *cmStd ios::cur* to search from the current file pointer location, and *cmStd ios::end* to search from the end of the file.

Throws

ccCDBFile::InvalidArgument
rec_count is 0, *mode* or *origin* is invalid.

ccCDBFile::RecordNotFound
No matching record was found.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

The file pointer is set at the beginning of the found record. Calling **loadRecord()** loads the found record.

findNextRecord

```
void findNextRecord(const ccCDBRecord &rec,
 c_Int32 mode = ccCDBRecord::SM_TYPE);
```

Advances the file pointer in this **ccCDBFile**'s open file to the next record that matches the supplied template **ccCDBRecord**.

Parameters

rec — The template **ccCDBRecord**. The file pointer is advanced to the next record that matches the template record.

mode — The search mode. *mode* lets you specify what constitutes a match between a record in this **ccCDBFile**'s open file and the supplied template record. *mode* must be formed by ORing together one or more of the following values:

ccCDBRecord::SM_TYPE
ccCDBRecord::SM_STYPE
ccCDBRecord::SM_DSIZE
ccCDBRecord::SM_SEQ
ccCDBRecord::SM_COMMENT

Throws

ccCDBFile::InvalidArgument
mode is invalid.

ccCDBFile::RecordNotFound
No matching record was found.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

The file pointer is set at the beginning of the found record. Calling **loadRecord()** will load the found record.

findPrevRecord

```
void findPrevRecord(const ccCDBRecord &rec,
  c_Int32 mode = ccCDBRecord::SM_TYPE);
```

Moves the file pointer in this **ccCDBFile**'s open file to the first preceding record that matches the supplied template **ccCDBRecord**.

Parameters

rec — The template **ccCDBRecord**. The file pointer is moved to the first preceding record that matches the template record.

mode — The search mode. *mode* lets you specify what constitutes a match between a record in this **ccCDBFile**'s open file and the supplied template record. *mode* must be formed by ORing together one or more of the following values:

ccCDBRecord::SM_TYPE
ccCDBRecord::SM_STYPE
ccCDBRecord::SM_DSIZE
ccCDBRecord::SM_SEQ
ccCDBRecord::SM_COMMENT

Throws

ccCDBFile::InvalidArgument
mode is invalid.

ccCDBFile::RecordNotFound
No matching record was found.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

The file pointer is set at the beginning of the found record. Calling **loadRecord()** will load the found record.

goToRecord

```
void goToRecord(c_Int32 recnum,
  cmStd ios::seekdir origin = cmStd ios::beg);
```

Moves the file pointer in this **ccCDBFile**'s open file to the specified record.

Parameters

recnum — The record number to advance to.

origin — Specify *cmStd ios::beg* to advance from the start of the file, *cmStd ios::cur* to advance from the current file pointer location, and *cmStd ios::end* to move backward from the end of the file.

Throws

ccCDBFile::InvalidArgument
origin is invalid.

ccCDBFile::RecordNotFound
The specified record number is not present in this file.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

The number of the first record in the file is 0.

If *recnum* = **numRecords()**, the file pointer is set to immediately after the last record (END_OF_FILE).

nextRecord

```
void nextRecord();
```

Advances to the next record in this **ccCDBFile**'s open file.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

ccCDBFile::RecordNotFound
The specified record number is not present in this file.

prevRecord

```
void prevRecord();
```

Moves to the previous record in this **ccCDBFile**'s open file.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

ccCDBFile::RecordNotFound
The specified record number is not present in this file.

firstRecord

```
void firstRecord();
```

Sets the file pointer to point to the first record in this **ccCDBFile**'s open file.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

lastRecord `void lastRecord();`

Sets the file pointer to point to the last record in this **ccCDBFile**'s open file.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

currentRecord `c_Int32 currentRecord() const;`

Returns the number of the current record. If the file pointer is immediately after the last record, this function returns *ccCDBFile::END_OF_FILE*.

Throws

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

numRecords

```
c_Int32 numRecords(const ccCDBRecord &rec,
  c_Int32 mode = ccCDBRecord::SM_TYPE) const;

c_Int32 numRecords() const;
```

- ```
  c_Int32 numRecords(const ccCDBRecord &rec,
    c_Int32 mode = ccCDBRecord::SM_TYPE) const;
  ```

  Returns the number of records in this **ccCDBFile**'s open file that match the supplied template **ccCDBRecord**.

  Parameters

  rec — The template **ccCDBRecord**. Only records that match the template record are counted.

  mode — The search mode. *mode* lets you specify what constitutes a match between a record in this **ccCDBFile**'s open file and the supplied template record. *mode* must be formed by ORing together one or more of the following values:

  ccCDBRecord::SM_TYPE
  ccCDBRecord::SM_STYPE
  ccCDBRecord::SM_DSIZE
  ccCDBRecord::SM_SEQ
  ccCDBRecord::SM_COMMENT

  Throws

  ccCDBFile::InvalidArgument
  mode is invalid.
  ```

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

- `c_Int32 numRecords() const;`

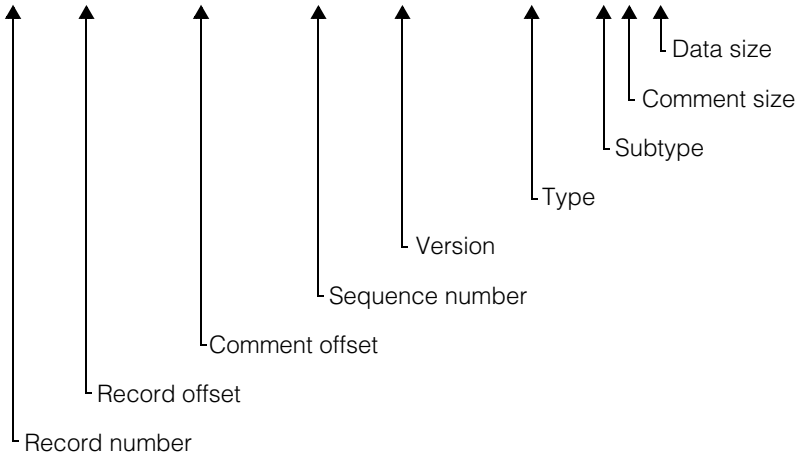
  Returns the total number of records in this **ccCDBFile**'s open file.

  Throws
  ccCDBFile::FileNotBound
  There is no open file associated with this **ccCDBFile**.

dumpIndex `ccCvlOStream& dumpIndex(cmStd ccCvlOStream& out) const;`

Prints the index from this **ccCDBFile**'s open file using the same format as the Cognex PVE function **cdb_dump_index()**. An example of this format is shown below:

```
0000      0      36: 00000 19910404 IMAG 1 0  30798
0001  30834   30870: 00001 19910404 RSLT 1 0     34
0002  30904   30940: 00002 19910404 IMAG 0 0 230702
```



Parameters
out The stream to which to print the index.

getRecordHeader

`ccCDBRecordHeader getRecordHeader(c_Int32 recnum) const;`

Returns a **ccCDBRecordHeader** containing information about the specified record in this **ccCDBFile**'s open file.

Parameters

recnum The record about which to obtain information.

Throws

ccCDBFile::RecordNotFound
The specified record number is not present in this file.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Deprecated Members

findRecord

```
void findRecord(c_Int32 rec_count, const ccCDBRecord &rec,
  c_Int32 mode = ccCDBRecord::SM_TYPE,
  cmStd ios::seekdir origin = cmStd ios::beg);
```

Notes

This function has been deprecated. Use **seekToMatchingRecord()** instead.

Advances the file pointer in this **ccCDBFile**'s open file by the specified number of records that match the supplied template **ccCDBRecord**. If the first record in this **ccCDBFile**'s open file matches the supplied template **ccCDBRecord**, the pointer is advanced by the specified number of records plus one.

Parameters

rec_count The number of records to advance. Specify a negative value for *rec_count* to move backwards through the file.

rec The template **ccCDBRecord**. Only records that match the template record are counted as the file pointer is advanced.

mode The search mode. *mode* lets you specify what constitutes a match between a record in this **ccCDBFile**'s open file and the supplied template record. *mode* must be formed by ORing together one or more of the following values:

ccCDBRecord::SM_TYPE
ccCDBRecord::SM_STYPE
ccCDBRecord::SM_DSIZE
ccCDBRecord::SM_SEQ
ccCDBRecord::SM_COMMENT

origin Specify *cmStd ios::beg* to search from the start of the file, *cmStd ios::cur* to search from the current file pointer location, and *cmStd ios::end* to search from the end of the file.

Throws

ccCDBFile::InvalidArgument
rec_count is 0, *mode* or *origin* is invalid.

ccCDBFile::RecordNotFound
No matching record was found.

ccCDBFile::FileNotBound
There is no open file associated with this **ccCDBFile**.

Notes

The file pointer is set at the beginning of the found record. Calling **loadRecord()** loads the found record.

ccCDBRecord

```
#include <ch_cvl/cdb.h>

class ccCDBRecord;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccCDBRecord** class implements a single CDB record. The **ccCDBFile** class provides support for reading **ccCDBRecord**s from and writing **ccCDBRecord**s to a CDB file.

Constructors/Destructors

ccCDBRecord

```
ccCDBRecord();

ccCDBRecord(c_Int32 type, c_Int32 subtype = 0,
  size_t dataSize = 0, const void *data = 0,
  const ccCvlString comment = cmT(""),
  c_Int32 dataVersion = 0, c_Int32 seqNum = 1);
```

- `ccCDBRecord();`

  Constructs an unbound **ccCDBRecord**.

- ```
  ccCDBRecord(c_Int32 type, c_Int32 subtype = 0,
    size_t dataSize = 0, const void *data = 0,
    const ccCvlString comment = cmT(""),
    c_Int32 dataVersion = 0, c_Int32 seqNum = 1);
  ```

  Constructs and initializes a **ccCDBRecord**.

  Parameters

  type — The record type. *type* must be one of the following values:

  ccCDBRecord::COMMAND_TYPE
  ccCDBRecord::RESULT_TYPE
  ccCDBRecord::IMAGE_TYPE
  ccCDBRecord::PERF_TYPE
  ccCDBRecord::ACQUIRE_TYPE
  ```

ccCDBRecord::MODEL_TYPE
ccCDBRecord::HEADER_TYPE
ccCDBRecord::RESPONSE_TYPE
ccCDBRecord::INDEX_TYPE
ccCDBRecord::EOF_TYPE
ccCDBRecord::TDB_TYPE
ccCDBRecord::IMAGE_ROI_TYPE
ccCDBRecord::DELETE_TYPE

subtype	The record subtype. This field is not used in CVL.
dataSize	The number of bytes of data to include in this record.
data	A pointer to the data for this record. *data* should point to at least *dataSize* bytes of storage.
comment	Comment data to store as part of this record. *comment* must point to a null-terminated string.
dataVersion	A version number to write as part of this record. You can specify any value for *dataVersion*.
seqNum	A sequence number. You can specify any value for *seqNum*.

Enumerations

Record Type This enumeration defines the CDB record types.

Value	Meaning
COMMAND_TYPE	Cognex internal use.
RESULT_TYPE	Cognex internal use.
IMAGE_TYPE	Image data
PERF_TYPE	Cognex internal use.
ACQUIRE_TYPE	Image data
MODEL_TYPE	Cognex internal use.
HEADER_TYPE	Cognex internal use.
RESPONSE_TYPE	Cognex internal use.
INDEX_TYPE	Cognex internal use.
EOF_TYPE	End of file marker record

Value	Meaning
TDB_TYPE	Cognex internal use.
IMAGE_ROI_TYPE	Cognex internal use.
DELETE_TYPE	This record marked for deletion

Notes

Unlike most CVL enumerations, there is no type associated with this enumeration.

Search Mode

This enumeration defines the types of search modes supported when searching for a **ccCDBRecord** within a CDB file.

Value	Meaning
SM_SEQ	Match the sequence number.
SM_TYPE	Match the record type.
SM_STYPE	Match the record subtype.
SM_DSIZE	Match the data size.
SM_COMMENT	Match the comment data.

Notes

Unlike most CVL enumerations, there is no type associated with this enumeration.

Sub-Type

This enumeration defines the types of images that may be contained in an image record.

Value	Meaning
SUBTYPE_IMG_GRAY6	6-bit greyscale image.
SUBTYPE_IMG_GRAY8	8-bit greyscale image.
SUBTYPE_IMG_COLOR24	24-bit color image.
SUBTYPE_IMG_GRAY16	16-bit greyscale image.

Notes

Not all 8-bit images have a sub-type of SUBTYPE_IMG_GRAY8; to test if an image is an 8-bit image, the sub-type must be neither SUBTYPE_IMG_COLOR24 nor SUBTYPE_IMG_GRAY16.

Unlike most CVL enumerations, there is no type associated with this enumeration.

Public Member Functions

fillRecord

```
void fillRecord(c_Int32 type, c_Int32 subtype = 0,
  size_t dataSize = 0, const void *data = 0,
  const ccCvlString comment = cmT(""),
  c_Int32 dataVersion = 0, c_Int32 seqNum = 1);
```

Initializes an unbound **ccCDBRecord**.

Parameters

type The record type. *type* must be one of the following values:

ccCDBRecord::COMMAND_TYPE
ccCDBRecord::RESULT_TYPE
ccCDBRecord::IMAGE_TYPE
ccCDBRecord::PERF_TYPE
ccCDBRecord::ACQUIRE_TYPE
ccCDBRecord::MODEL_TYPE
ccCDBRecord::HEADER_TYPE
ccCDBRecord::RESPONSE_TYPE
ccCDBRecord::INDEX_TYPE
ccCDBRecord::EOF_TYPE
ccCDBRecord::TDB_TYPE
ccCDBRecord::IMAGE_ROI_TYPE
ccCDBRecord::DELETE_TYPE

subtype The record subtype. This meaning of the *subtype* depends on the record type.

dataSize The number of bytes of data to include in this record.

data A pointer to the data for this record. *data* should point to at least *dataSize* bytes of storage.

comment Comment data to store as part of this record. *comment* must point to a null-terminated string.

dataVersion A version number to write as part of this record. You can specify any value for *dataVersion*.

seqNum A sequence number. You can specify any value for *seqNum*.

Throws

ccCDBRecord::WrongType
type is not one of the enumerated record types.

freeRecord

```
void freeRecord();
```

Unbinds this **ccCDBRecord**.

type

```
c_Int32 type();
```

Returns the type of this **ccCDBRecord**. The value returned by this function is one of the following:

ccCDBRecord::COMMAND_TYPE
ccCDBRecord::RESULT_TYPE
ccCDBRecord::IMAGE_TYPE
ccCDBRecord::PERF_TYPE
ccCDBRecord::ACQUIRE_TYPE
ccCDBRecord::MODEL_TYPE
ccCDBRecord::HEADER_TYPE
ccCDBRecord::RESPONSE_TYPE
ccCDBRecord::INDEX_TYPE
ccCDBRecord::EOF_TYPE
ccCDBRecord::TDB_TYPE
ccCDBRecord::IMAGE_ROI_TYPE
ccCDBRecord::DELETE_TYPE

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

version

```
c_Int32 version() const;
```

Returns the version of the CDB software used to create this **ccCDBRecord**.

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

dataVersion

```
c_Int32 dataVersion() const;
void dataVersion(c_Int32 vers);
```

- `c_Int32 dataVersion() const;`

Returns the data version of this **ccCDBRecord**.

- `void dataVersion(c_Int32 vers);`

  Sets the data version of this **ccCDBRecord**. You can set the data version to any value.

  Parameters
  vers The data version to set.

  Throws
  ccCDBRecord::RecordNotBound
  This record is unbound.

sequenceNumber

```
c_Int32 sequenceNumber() const;

void sequenceNumber(c_Int32 num);
```

- `c_Int32 sequenceNumber() const;`

  Returns the sequence number of this **ccCDBRecord**.

- `void sequenceNumber(c_Int32 vers);`

  Sets the sequence number of this **ccCDBRecord**. You can set the sequence number to any value.

  Parameters
  vers The sequence number to set.

  Throws
  ccCDBRecord::RecordNotBound
  This record is unbound.

subtype

```
c_Int32 subtype() const;

void subtype(c_Int32 num);
```

- `c_Int32 subtype() const;`

  Returns the subtype of this **ccCDBRecord**. The value returned by this function is one of the following:

  ccCDBRecord::SUBTYPE_IMG_GRAY6
  ccCDBRecord::SUBTYPE_IMG_GRAY8
  ccCDBRecord::SUBTYPE_IMG_COLOR24
  ccCDBRecord::SUBTYPE_IMG_GRAY16

- `void sequenceNumber(c_Int32 type);`

  Sets the subtype of this **ccCDBRecord**.

  Parameters

  type The subtype to set.

  Throws

  ccCDBRecord::RecordNotBound
  This record is unbound.

  Notes

  The subtype is used internally; you should not attempt to set the subtype of a record yourself.

dataSize

`size_t dataSize() const;`

Returns the number of bytes of data in this record. If the record type is *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*, then this function returns the number of bytes in the image.

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

image

`ccPelBuffer_const<c_UInt8> image() const;`

`void image(const ccPelBuffer_const<c_UInt8>& img);`

- `ccPelBuffer_const<c_UInt8> image() const;`

  Returns a **ccPelBuffer** representation of this **ccCDBRecord**'s image data. This **ccCDBRecord**'s type must be *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*.

  Throws

  ccCDBRecord::WrongSubType
  This record has a subtype of *ccCDBRecord::SUBTYPE_IMG_GRAY16*.

- `void image(const ccPelBuffer_const<c_UInt8>& img);`

  Sets the contents of this **ccCDBRecord** to be the supplied **ccPelBuffer** image data. This **ccCDBRecord**'s type must be *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*

Parameters

img The image to store.

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

ccCDBRecord::WrongType
This **ccCDBRecord**'s type is not *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*.

ccCDBRecord::WrongSubType
This **ccCDBRecord**'s has a subtype of *ccCDBRecord::SUBTYPE_IMG_GRAY16*.

Notes

The **ccPelBuffer**'s offset and client coordinate system are not saved in the CDB file. When you load a **ccPelBuffer**, the offset is set to (0,0) and the client coordinate system is the same as the image coordinate system.

---

image16

```
ccPelBuffer_const<c_UInt16> image16() const;

void image16(const ccPelBuffer_const<c_UInt16>&,
   ceImageFormat = ceImageFormat_Unknown);
```

- `ccPelBuffer_const<c_UInt16> image16() const;`

Returns a **ccPelBuffer** representation of this **ccCDBRecord**'s 16-bit image data. This **ccCDBRecord**'s type must be *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*.

Throws

ccCDBRecord::WrongSubType
This record has a subtype of *ccCDBRecord::SUBTYPE_IMG_GRAY16*.

- `void image16(const ccPelBuffer_const<c_UInt16>&, ceImageFormat = ceImageFormat_Unknown);`

Sets the contents of this **ccCDBRecord** to be the supplied **ccPelBuffer** image data. This **ccCDBRecord**'s type must be *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*

Parameters

img The image to store.

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

ccCDBRecord::WrongType
This **ccCDBRecord**'s type is not *ccCDBRecord::IMAGE_TYPE* or *ccCDBRecord::ACQUIRE_TYPE*.

ccCDBRecord::WrongSubType
This **ccCDBRecord**'s has a subtype of *ccCDBRecord::SUBTYPE_IMG_GRAY16*.

Notes

The **ccPelBuffer**'s offset and client coordinate system are not saved in the CDB file. When you load a **ccPelBuffer**, the offset is set to (0,0) and the client coordinate system is the same as the image coordinate system.

comment

```
ccCvlString comment() const;
void comment(const ccCvlString &str);
```

- `ccCvlString comment() const;`

Returns the comment string for this **ccCDBRecord**.

- `void comment(const ccCvlString &str);`

Sets the comment string for this **ccCDBRecord**. You can store any value in this string. You can use the **ccCDBFile::findRecord()** function to search a CDB file for **ccCDBRecord**s with a particular comment string.

Parameters

str The comment string. *str* must be a null-terminated string.

Throws

ccCDBRecord::RecordNotBound
This record is unbound.

Static Functions

typeString

```
static ccCvlString typeString(int subtype);
```

Returns a 4-character string description of the type.

subtypeString `static ccCvlString subtypeString(int subtype);`

Returns a 4-character string description of the subtype.

ccCharCode

```
#include <ch_cvl/charcode.h>

class ccCharCode;
```

A name space for constants and utility functions for character codes.

Public Member Functions

isReserved16 `static bool isReserved16(c_Char32 c);`

Returns whether *c* is within the Cognex-reserved 16-bit range.

Parameters

c The character code.

isReserved `static bool isReserved(c_Char32 c);`

Return whether *c* is within a Cognex-reserved range.

Parameters

c The character code.

isSpace `static bool isSpace(c_Char32 characterCode);`

Returns whether *characterCode* is any whitespace character according to the UTF-32 code table.

Parameters

characterCode The character code.

Notes

This returns false for any Cognex-reserved character code.

isRepresentableAsChar
`static bool isRepresentableAsChar(c_Char32 c);`

Returns whether *c* is representable as type char. A character code is representable only if it keeps the same value when cast to the given type.

Parameters

c The character code.

isRepresentableAsChar16

```
static bool isRepresentableAsChar16(c_Char32 c);
```

Returns whether *c* is representable as type c_Char16. A character code is representable only if it keeps the same value when cast to the given type.

Parameters

c The character code.

isRepresentableAsWChar

```
static bool isRepresentableAsWChar(c_Char32 c);
```

Returns whether *c* is representable as type wchar_t. A character code is representable only if it keeps the same value when cast to the given type.

Parameters

c The character code.

isRepresentableAsTChar

```
static bool isRepresentableAsTChar(c_Char32 c);
```

Returns whether *c* is representable as type TCHAR. A character code is representable only if it keeps the same value when cast to the given type.

Parameters

c The character code.

getAsChar `static char getAsChar(c_Char32 c);`

Convert *c* to the type char if possible.

Parameters

c The character code.

getAsChar16 `static c_Char16 getAsChar16(c_Char32 c);`

Convert *c* to the type c_Char16 if possible.

Parameters

c The character code.

getAsWChar `static wchar_t getAsWChar(c_Char32 c);`

Convert *c* to the type wchar_t if possible.

Parameters

c The character code.

getAsTChar

```
static TCHAR getAsTChar(c_Char32 c);
```

Convert *c* to the type TCHAR if possible.

Parameters

c The character code.

Throws

ccCharCodeDefs::NotRepresentable
c is not representable as the given type.

Constants

eReserved16Low

```
static const c_Char16 eReserved16Low = 0xF800;
```

eReserved16High

```
static const c_Char16 eReserved16High = 0xF8FF;
```

eReserved32Low

```
static const c_Char32 eReserved32Low = 0xFF000;
```

eReserved32High

```
static const c_Char32 eReserved32High = 0xFFFFD;
```

The bounds of the Cognex-reserved private use ranges.

eUnknown

```
static const c_Char16 eUnknown = 0xF800;
```

Specifies that the character code is unknown.

Notes

This value is in a Cognex-reserved private use range.

eAnyCharacter

```
static const c_Char16 eAnyCharacter = 0xF801;
```

This is used to specify that all non-reserved character codes are allowed.

Notes

This value is in a Cognex-reserved private use range.

eAnyNonspaceCharacter

```
static const c_Char16 eAnyNonspaceCharacter = 0xF802;
```

This is used to specify that all non-reserved character codes except the space character 0x20 are allowed.

Notes

This value is in a Cognex-reserved private use range.

ccCircle

```
#include <ch_cvl/shapes.h>

class ccCircle : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	Complex

This class describes a circle specified by a center and a radius.

Constructors/Destructors

ccCircle

```
ccCircle(const cc2Vect& c = cc2Vect(0.0, 0.0),
  double r = 0.0);
```

Constructs a circle with the specified center and radius.

Parameters

c The location of the center of the circle. The default location, if no value is supplied, is (0.0, 0.0).

r The radius of the circle. The default radius, if no value is supplied, is 0.0.

Operators

operator==

```
bool operator==(const ccCircle& other) const;
```

Returns true if this circle is equal to another circle.

Parameters

other The other circle.

operator!=

```
bool operator!=(const ccCircle& other) const;
```

Returns true if this circle is not equal to another circle.

Parameters

other The other circle.

Public Member Functions

center

```
const ccPoint& center() const;
```

Returns the center of the circle.

radius

```
double radius() const;
```

Returns the radius of the circle.

map2

```
ccEllipse2 map2(const cc2Xform& c) const;
```

Returns this circle mapped by the given transformation object.

Parameters

c	The transformation object.

degen

```
bool degen() const;
```

Returns true if this circle is degenerate (its radius is less than or equal to zero).

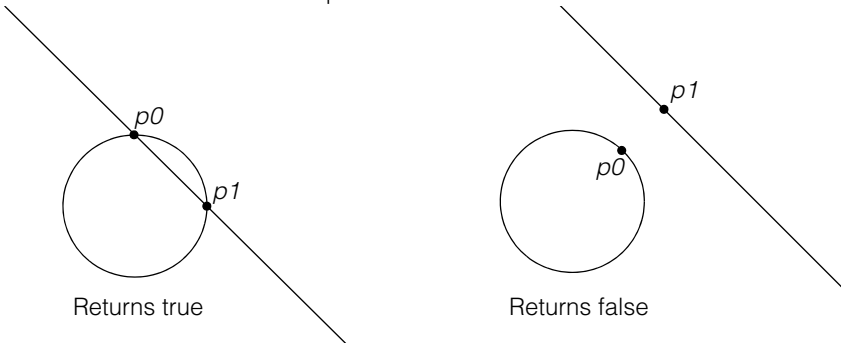
intersections

```
bool intersections(const ccLine &line, cc2Vect &point0,
  cc2Vect &point1) const;

bool intersections(const ccCircle &other, cc2Vect &point0,
  cc2Vect &point1) const;
```

- ```
  bool intersections(const ccLine &line, cc2Vect &point0,
    cc2Vect &point1) const;
  ```

  Returns true if this circle intersects the given line, and false if it does not. If the function returns true, *point0* and *point1* are returned as the intersection points. If the function returns false, *point0* and *point1* are returned as a pair of closest points between the circle and line. In this case, *point0* is the closest point on the circle, and *point1* is the closest point on the line. See the examples below:



Parameters

line	The given line to test for intersection with this circle.
point0	A returned point, dependent on whether the line and circle intersect. See description above.
point1	A returned point, dependent on whether the line and circle intersect. See description above.

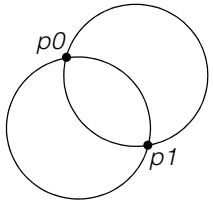
Notes

Regardless of the return value, if the computed *point0* and *point1* are very close, the circle and line are approximately tangent. The closeness criterion is application specific and likely depends on the circle's radius. If the circle and line are exactly tangent, the function returns true, and *point0* and *point1* are identical.

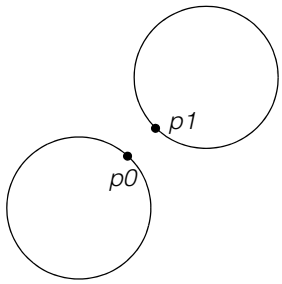
If the function returns true, the intersection points are returned in the order such that **line.offset(***point0***)** <= **line.offset(***point1***)**.
  ```

- `bool intersections(const ccCircle &other, cc2Vect &point0, cc2Vect &point1) const;`

Returns true if this circle intersects another circle, and false if it does not. If the function returns true, *point0* and *point1* are returned as the intersection points. If the function returns false, *point0* and *point1* are returned as a pair of closest points between the two circles. In this case, *point0* is the closest point on this circle, and *point1* is the closest point on the other circle.



Returns true



Returns false

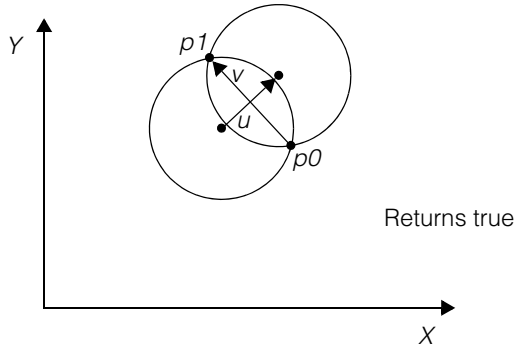
Parameters

other	The other circle to test for intersection with this circle.
point0	A returned point, dependent on whether the two circles intersect. See description above.
point1	A returned point, dependent on whether the two circles intersect. See description above.

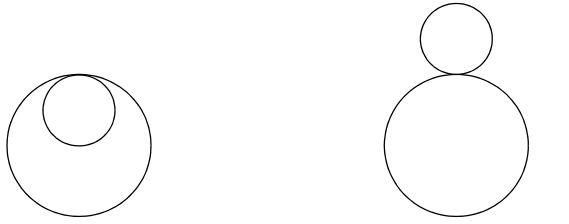
Notes

1. Regardless of the return value, if the computed *point0* and *point1* are very close, the circles are approximately tangent. The closeness criterion is application specific and likely depends on the circles' radii. If the two circles are exactly tangent, the function returns true, and *point0* and *point1* are identical.
2. Concentric circles have either an infinite number of intersection points or an infinite number of closest points, depending on whether their radii are equal or not. This function returns true when the radii are equal, and false if the radii are not equal. In either case, the returned points are arbitrarily chosen as the intersections of the circles with a ray passing through the circles' common center and aligned with the positive x-axis.

3. If the function returns true, the intersection points are returned in the order such that if u is the vector from this circle's center to the other circle's center, and v is the vector from *point0* to *point1*, then the cross product u x v is positive. See the following example:



4. The return value and returned points do not completely define all possible cases. For example, if the function returns true and the returned points are equal, the circles are tangent, however further analysis is required to determine if the tangency is exterior or interior. See the following examples.



Also, if the function returns false this circle may enclose the other circle, or vice versa, or neither may enclose the other. Here again, further analysis is required if these distinctions are significant.

clone `virtual ccShapePtrh clone() const;`

Returns a pointer to a copy of this circle.

isOpenContour `virtual bool isOpenContour() const;`

Returns true if this shape is an open contour. For circles, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion `virtual bool isRegion() const;`

Returns true if this shape is a region. For circles, this function always returns true, even circles that are degenerate. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

For circles, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For circles, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

Thus function returns true for most circles. It returns false for circles that are degenerate.See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For circles, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For circles, this function always returns false. See **ccShape::reverse()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the smallest rectangle that encloses this circle. See **ccShape::boundingBox()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns the nearest point on the boundary of this circle to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this circle.

See **ccShape::perimeter()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores circles for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

For circles, this function always returns true. Circles are always right-handed. See **ccShape::isRightHanded()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this circle mapped by *X*.

Parameters

X	The transformation object.

Notes

The returned shape is a **ccEllipse2**, unless *X* is the identity transform.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccEllipseArc2**s. See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect& p) const;
```

Returns true if the given point is within this circle.

Parameters

p The point.

See **ccShape::within()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccCircle

```
ccCircle(const ccEllipse&);
```

Use the constructor that specifies a center and radius instead of this constructor.

map

```
ccEllipse map(const cc2Xform& c);
```

Use **map2()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

closestPoint

```
cc2Vect closestPoint(const cc2Vect &p) const;
```

Use **nearestPoint()** instead of this function.

ccCircleFitDefs

```
#include <ch_cvl/fit.h>

class ccCircleFitDefs;
```

A name space that holds enumerations and constants used with the Circle Fitting tool (**cfCircleFit()**).

Enumerations

fit_mode

```
enum fit_mode
```

This enumeration defines types of fitting supported by the Circle Fitting tool.

Value	Meaning
eLeastSquaresMeasureRadius	Fits a circle by minimizing the least squares error. Calculates the radius of the circle.
eLeastSquaresUseExpectedRadius	Fits a circle whose radius you specify by minimizing the least squares error.
kDefaultFitMode = eLeastSquaresMeasureRadius	

ccCircleFitDefs

ccCircleFitParams

```
#include <ch_cvl/fit.h>

class ccCircleFitParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the Circle Fitting tool parameters. See **cfCircleFit()**.

Constructors/Destructors

ccCircleFitParams

```
ccCircleFitParams(
  enum ccCircleFitDefs::fit_mode fitMode =
                          ccCircleFitDefs::kDefaultFitMode,
  double radius=1.,
  c_UInt32 numIgnore=0,
  double threshold=HUGE_VAL);
```

Constructs a **ccCircleFitParams** object.

Parameters

fitMode — The type of fitting to perform. Must be one of the following:

ccCircleFitDefs:: eLeastSquaresMeasureRadius; the tool computes the circle radius.

ccCircleFitDefs::eLeastSquaresUseExpectedRadius; you provide the radius (see *radius* below). Can cause the tool to run faster but may produce a less accurate found circle position.

radius — The radius of the circle to fit. If *fitMode* is *ccCircleFitDefs::eLeastSquaresMeasureRadius*, then this value is ignored.

numIgnore — The number of outlying points to ignore. The tool always discards this number of points from the point set used to find the circle.

threshold — The maximum RMS error for a valid fit. If the fitted circle has an RMS error greater than *threshold*, it is not considered a valid fit.

Throws

ccCircleFitDefs::BadParams
radius is less than 0 or *threshold* is less than 0.

operator==

```
bool operator== (const ccCircleFitParams& that) const;
```

True if **this* equals *that*; false otherwise.

Two **ccCircleFitParams** objects are considered equal if and only if their fitMode, radius, numIgnore, and threshold values are each equal

Parameters

that The **ccCircleFitParams** object compared with this object.

Public Member Functions

fitMode

```
enum ccCircleFitDefs::fit_mode fitMode() const;
void fitMode(enum ccCircleFitDefs::fit_mode fitMode);
```

- `enum ccCircleFitDefs::fit_mode fitMode() const;`

  Returns the type of fitting this **ccCircleFitParams** is configured to perform. The function returns one of the following values:

  ccCircleFitDefs:: eLeastSquaresMeasureRadius
  ccCircleFitDefs::eLeastSquaresUseExpectedRadius

- `void fitMode(enum ccCircleFitDefs::fit_mode fitMode);`

  Sets the type of fitting this **ccCircleFitParams** is configured to perform.

  Parameters

  fitMode The type of fitting to perform. Supplying the radius of the circle requires less time; computing the radius of the circle is more flexible. *fitMode* must be one of the following values:

  ccCircleFitDefs:: eLeastSquaresMeasureRadius
  ccCircleFitDefs::eLeastSquaresUseExpectedRadius

radius

```
double radius() const;
void radius(double radius);
```

- `double radius() const;`

  Returns the expected radius of the circle being fit in client coordinate system units.

- `void radius(double radius);`

  Sets the expected radius of the circle being fit in client coordinate system units. This value is ignored if the tool is configured to compute the radius of the circle.

  Parameters

  radius The expected radius in client coordinate system units.

  Throws

  ccCircleFitDefs::BadParams
  radius is less than 0.

numIgnore

```
c_UInt32 numIgnore() const;
void numIgnore(c_UInt32 numIgnore);
```

- `c_UInt32 numIgnore() const;`

  Returns the number of outlying points ignored by this **ccCircleFitParams**.

- `void numIgnore(c_UInt32 numIgnore);`

  Sets the number of outlying points ignored by this **ccCircleFitParams**.

  Parameters

  numIgnore The number of points to ignore.

threshold

```
double threshold() const;
void threshold(double threshold);
```

- `double threshold() const;`

  Returns the maximum RMS error which a fit circle can receive and still be considered found.

- `void threshold(double threshold);`

  Sets the maximum RMS error which a fit circle can receive and still be considered found. If the RMS error is greater than or equal to the supplied threshold, the circle is not considered found.

  Parameters

  threshold The RMS error threshold. *threshold* can have any positive value.

  Throws

  ccCircleFitDefs::BadParams
  threshold is less than 0.

ccCircleFitResults

```
#include <ch_cvl/fit.h>

class ccCircleFitResults;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the results from the Circle Fitting tool. See **cfCircleFit()**.

Constructors/Destructors

ccCircleFitResults

```
ccCircleFitResults();
```

Construct a **ccCircleFitResults** with no result.
found() = false, **error()** = 0, **time()** = 0.

Operators

operator==

```
bool operator== (const ccCircleFitResults& rhs) const;
```

Two **ccCircleFitResults** objects are considered equal if and only if the values returned by **found**, **circle**, and **error** are equal.

Public Member Functions

found

```
bool found() const;
```

Returns true if the RMS error of this circle is less than the threshold you supplied. Returns false otherwise.

reset

```
void reset();
```

Reset this **ccCircleFitResults**. Calling **found** returns false after calling this function.

ccCircleFitResults

circle

```
const ccCircle &circle() const;
```

Returns the fitted circle.

error

```
double error() const;
```

The measured RMS error between the data and the estimated circle.

The default value is 0.

runParams

```
const ccCircleFitParams &runParams() const;
```

Returns the **ccCircleFitParams** used to fit this circle. If **found** returns false, then this function's return value is undefined.

outliers

```
const cmStd vector<c_UInt32> &outliers() const;
```

Returns the indices of the points which were ignored. If **found** returns false, then this function's return value is undefined.

time

```
double time() const;
```

Returns the time in milliseconds required to compute this result. If **found** returns false, then this function's return value is undefined.

ccCircularLabeledProjectionModel

```
#include <ch_cvl/lablproj.h>

template <class M>
class ccCircularLabeledProjectionModel:
  ccLabeledProjectionModel<M>;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is a templated class that contains a circular or radial projection model.

M — Template parameter specifying the value associated with each pixel in the model. CVL provides instantiations of **ccCircularLabeledProjectionModel** for the types **c_UInt8**, **c_UInt16**, and **c_UInt32**

This class is a specialization of the **ccLabeledProjectionModel** class. You specify parameters upon construction to create a circular or radial projection model. The constructor allocates an image and initializes it according to the parameters you supply.

Constructors/Destructors

ccCircularLabeledProjectionModel

```
ccCircularLabeledProjectionModel();
```

Returns an untrained **ccCircularLabeledProjectionModel**.

Public Member Functions

train

```
void train (c_Int32 radius,
  cc2Vect centerOffset=cc2Vect(0,0), double rMin=0,
  double rMax=0, c_Int32 numAnnuli=1, c_Int32 numSectors=1,
  enum ccLabeledProjection::BinOrder
  binOrder= ccLabeledProjection::kDefaultBinOrder,
  enum ccLabeledProjection::Orientation
```

```
orientation= ccLabeledProjection::kDefaultOrientation,
ccDegree startAngle=ccDegree(0.0),
ccDegree endAngle=ccDegree(360.0));
```

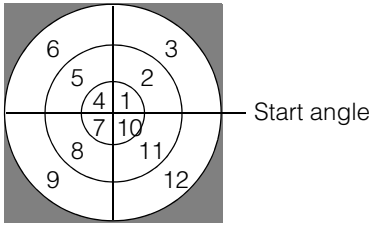
Trains this **ccCircularLabeledProjectionModel** according to the parameters you supply. This function will allocate and bind an image of the pixel type you specify with a height and width of *radius**2 + 1.

The constructor will initialize the pixel values in the image as follows:

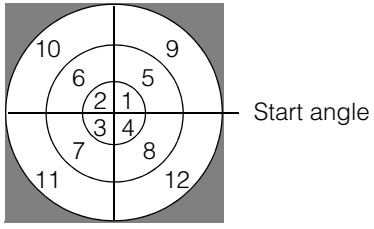
1. All pixels inside or on a circle of radius *rMin* or outside a circle of radius *rMax* are set to 0, indicating that they are *don't care* pixels. If *rMax* is 0, then no pixels outside of *rMin* are set to 0. Set *rMin* to zero to extend bins to the corners of the projection model.
2. If *orientation* is *ccLabeledProjection::eClockwise* (the default), pixels in the counter-clockwise range *endAngle* to *startAngle* are set to zero. The positive side of the client coordinate system x-axis is 0.
3. Divide up the sector between *startAngle* and *endAngle* into *numSectors* and then divide each sector between *rMin* and *rMax* into *numAnnuli*.
4. If *binOrder* is *ccLabeledProjection::eRadial*, then the bins are numbered starting with the innermost annulus of the first sector, then moving outward within the first sector, then from innermost to outermost in the next sector in the direction specified by *orientation*.

   If *binOrder* is *ccLabeledProjection::eAngular*, then the bins are numbered starting with the innermost annulus of the first sector in the direction specified by *orientation* from *startAngle*, then moving to the innermost annulus of the second sector, continuing until the entire inner annulus was filled, then moving to the next annulus.

   The following diagram shows the two bin numbering methods:



ccLabeledProjection::eRadial



ccLabeledProjection::eAngular

Parameters

radius	The radius of the circular projection model, in pixels.
centerOffset	The initial value for the image offset for the projection model.

rMin The inner radius for the projection model. All pixels inside the inner radius are set to the don't care value.

rMax The outer radius for the projection model. All pixels outside this radius are set to the don't care value. If you specify 0 for *rMax*, then the bins extend to edges of the projection model.

numAnnuli The number of annuli in this model. If you are creating a circular projection model, you should set this to be the same as *radius.*

numSectors The number of sectors in this model.

binOrder The bin ordering method. *binOrder* must be one of the following values:

ccLabeledProjection::eRadial
ccLabeledProjection::eAngular

orientation The bin ordering orientation. *orientation* must be one of the following values:

ccLabeledProjection::eClockwise
ccLabeledProjection::eCounterClockwise

startAngle The starting angle for the first sector, specified relative to the positive side of the client coordinates system x-axis.

endAngle The end angle for the last sector, specified relative to the positive side of the client coordinates system x-axis. Pixels between *endAngle* and *startAngle* are set to the don't care value.

Throws

ccLabeledProjection::BadParams
The parameters you specified produced a projection model with every pixel set to 0.

radius

```
c_Int32 radius() const;
```

Returns the radius of the projection model.

Throws

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

centerOffset

```
cc2Vect centerOffset()const;
```

Returns the center offset of the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

centerPosition

```
cc2Vect centerPosition() const;
```

Returns the center position of the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

rMin

```
double rMin() const;
```

Returns the minimum radius of the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

rMax

```
double rMax() const;
```

Returns the maximum radius of the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

numAnnuli

```
c_Int32 numAnnuli() const;
```

Returns the number of annuli in the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

numSectors

```
c_Int32 numSectors() const;
```

Returns the number of sectors in the projection model.

Throws
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

orientation

```
enum ccLabeledProjection::Orientation orientation() const;
```

Returns the orientation of this circular projection model. The orientation determines whether angles increase in the clockwise or counter-clockwise direction and the order in which sectors are numbered. The value returned by this function is one of the following:

ccLabeledProjection::eClockwise
ccLabeledProjection::eCounterClockwise

Throws

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

startAngle

```
ccDegree startAngle() const;
```

Returns the start angle of the projection model.

Throws

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

endAngle

```
ccDegree endAngle() const;
```

Returns the end angle of the projection model.

Throws

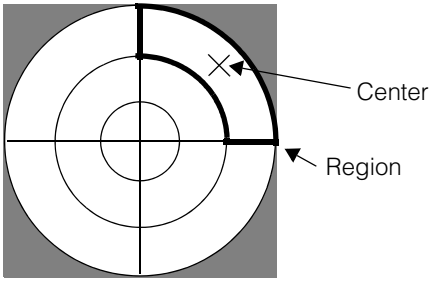
ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

binCenter

```
cc2Vect binCenter(int index) const;
cc2Vect binCenter(int annulus, int sector) const;
```

- `cc2Vect binCenter(int index) const;`

Returns the center of the region within this **ccCircularLabeledProjectionModel** that corresponds to the specified pixel in the projection image. The center of the region is defined as the point equidistant between the inner and outer boundary at the midpoint between the lower and higher edge of the region, as shown in the following figure:



The position is reported with sub-pixel accuracy in image coordinates.

Parameters

index The bin within the projection image.

Throws

ccLabeledProjection::BadParams
index does not correspond to a bin.

ccLabeledProjection::BadSectorCount
This **ccCircularLabeledProjectionModel** has no sectors.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

- `cc2Vect binCenter(int annulus, int sector) const;`

  Returns the center of the specified region within this **ccCircularLabeledProjectionModel**. The center of the region is defined as the point equidistant between the inner and outer boundary at the midpoint between the lower and higher edge of the region, as shown in the following figure:

  The position is reported with sub-pixel accuracy in image coordinates.

  Parameters

  annulus The annulus number of the region

  sector The sector number of the region

  Throws

  ccLabeledProjection::BadParams
  annulus and *sector* do not specify a region in this **ccCircularLabeledProjectionModel**.

  ccLabeledProjection::NotTrained
  This **ccCircularLabeledProjectionModel** has not been trained.

sectorAngle `ccDegree sectorAngle() const;`

Returns the angle of the given sector, defined as the angle between the image coordinate system x-axis and a line drawn from the center of the model through the center of the sector.

Throws

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

ccLabeledProjection::BadParams
sector does not specify a sector.

sectorOrientation

```
ccDegree sectorOrientation(int sector) const;
```

Returns the orientation from the center of the **ccCircularLabeledProjectionModel** to the middle of the given sector.

Parameters

sector The sector

Throws

ccLabeledProjection::BadParams
sector does not correspond to a sector.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

angleSector

```
int angleSector(ccDegree angle) const;
```

Returns the number of the sector in this **ccCircularLabeledProjectionModel** through which a line drawn at the specified angle from the image coordinate system x-axis passes.

Parameters

angle The angle

Throws

ccLabeledProjection::BadParams
The line specified by *angle* does not pass through a sector.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

annulusWidth

```
double annulusWidth() const;
```

Returns the width of each annulus in image coordinate system units.

Throws

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

annulusDistance

```
double annulusDistance(int annulus) const;
```

Returns the distance from the center of this **ccCircularLabeledProjectionModel** to the center of the specified annulus.

Parameters

annulus The annulus

Throws

ccLabeledProjection::BadParams
annulus not specify an annulus.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

distanceAnnulus

```
int distanceAnnulus(double distance) const;
```

Returns the annulus which lies at the specified distance from the center of this **ccCircularLabeledProjectionModel**.

Parameters

distance The distance

Throws

ccLabeledProjection::BadParams
No annulus is present at *distance* from the center.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

sectorWindow

```
ccPelRect sectorWindow(int sector) const;
```

Returns a **ccPelRect** that describes the portion of the projection image that was formed by summing the annuli within the specified sector. The returned **ccPelRect** is in the image coordinate system of the projection image.

Parameters

sector The sector

Throws

ccLabeledProjection::WrongOrder
This **ccCircularLabeledProjectionModel**'s bin ordering method is angular.

ccLabeledProjection::BadParams
sector does not specify a sector.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

annulusWindow

```
ccPelRect annulusWindow(int annulus) const;
```

Returns a **ccPelRect** that describes the portion of the projection image that was formed by summing the sectors within the specified annulus. The returned **ccPelRect** is in the image coordinate system of the projection image.

Parameters

annulus The annulus

Throws

ccLabeledProjection::WrongOrder
This **ccCircularLabeledProjectionModel**'s bin ordering method is radial.

ccLabeledProjection::BadParams
annulus does not specify an annulus.

ccLabeledProjection::NotTrained
This **ccCircularLabeledProjectionModel** has not been trained.

ccClassifierFeatureScore

```
#include <ch_cvl/clsscore.h>

class ccClassifierFeatureScore: public ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

An abstract base class from which all Classifier scoring functions are derived. You should not instantiate objects of this type, nor should you attempt to derive your own scoring functions from this class.

Constructors/Destructors

ccClassifierFeatureScore

```
virtual ~ccClassifierFeatureScore();
```

Public Member Functions

score

```
virtual double score(double featureValue) const = 0;
```

Returns a score for the given feature value. The exact calculation depends upon the derived implementation. The returned score is normalized to a value between 0.0 and 1.0.

This function returns -1 to indicate that the score should be ignored (not included in the computation of the overall score for a feature vector).

Parameters

featureValue The value to score.

clone

```
virtual ccClassifierFeatureScore *clone() const=0;
```

Constructs a **ccClassifierFeatureScore** identical to this one.

ccClassifierFeatureScore

ccClassifierFeatureScoreIgnore

```
#include <ch_cvl/clsscore.h>

class ccClassifierFeatureScoreIgnore:
  public ccClassifierFeatureScore;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A scoring function that always returns -1.

Public Member Functions

score

```
virtual double score(double featureValue) const;
```

Returns a score of -1 which means that this score is ignored when the geometric mean is computed.

Parameters

featureValue The value not to score.

clone

```
virtual ccClassifierFeatureScore *clone() const;
```

Constructs a **ccClassifierFeatureScoreIgnore** identical to this one.

ccClassifierFeatureScoreIgnore

ccClassifierFeatureScoreOneSided

```
#include <ch_cvl/clsscore.h>

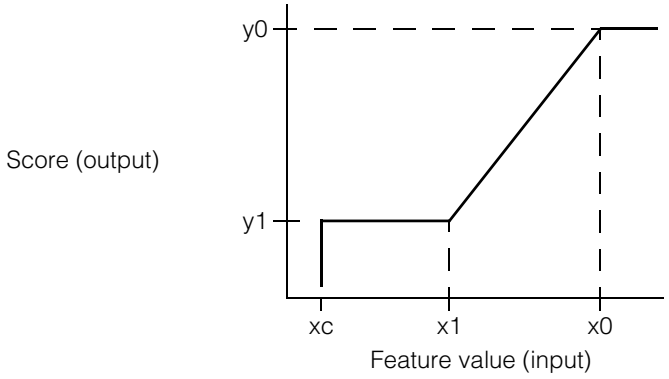
class ccClassifierFeatureScoreOneSided:
  public ccClassifierFeatureScore;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A scoring function that lets you configure a one-sided scoring function.

A one-sided scoring function maps a feature value to an output score using a function defined by the points shown in the following figure:



Constructors/Destructors

ccClassifierFeatureScoreOneSided

```
ccClassifierFeatureScoreOneSided();
```

Constructs a **ccClassifierFeatureScoreOneSided** with the default values shown in the **init** function signature.

Public Member Functions

init

```
void init (double x0 = 0.0, double x1 = 1.0,
  double xc = 1.0, double y0 = 1.0, double y1 = 0.0);
```

Initializes the breakpoints in this **ccClassifierFeatureScoreOneSided** to the supplied values.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be between 0.0 and 1.0.

---

x0

```
double x0 () const;
void x0 (double x0);
```

- `double x0 () const;`

  Returns the *x0* value.

- `void x0 (double x0);`

  Sets the *x0* value.

  Parameters

x0	The value to set.

---

x1

```
double x1 () const;
void x1 (double x1);
```

- `double x1 () const;`

  Returns the *x1* value.

- `void x1 (double x1);`

  Sets the *x1* value.

Parameters

x1 The value to set. *x1* must be between *xc* and *x0*.

xc

```
double xc () const;
void xc (double xc);
```

- `double xc () const;`

  Returns the *xc* value.

- `void xc (double xc);`

  Sets the *xc* value.

  Parameters

  xc The value to set.

y0

```
double y0 () const;
void y0 (double y0);
```

- `double y0 () const;`

  Returns the *y0* value.

- `void y0 (double y0);`

  Sets the *y0* value.

  Parameters

  y0 The value to set. *y0* must be between 0.0 and 1.0.

  Throws

  ccClassifierDefs::BadParams

  y0 is outside the range 0.0 to 1.0.

y1

```
double y1 () const;
void y1 (double y1);
```

- `double y1 () const;`

  Returns the *y1* value.

- `void y1 (double y1);`

  Sets the *y1* value.

  Parameters

  y1 The value to set. *y1* must be between 0.0 and 1.0.

  Throws

  ccClassifierDefs::BadParams
  y1 is outside the range 0.0 to 1.0.

score `virtual double score(double featureValue) const;`

Returns the score for the given feature value.

Parameters

featureValue The value to score.

clone `virtual ccClassifierFeatureScore *clone() const;`

Constructs a **ccClassifierFeatureScoreOneSided** identical to this one.

ccClassifierFeatureScoreTwoSided

```
#include <ch_cvl/clsscore.h>

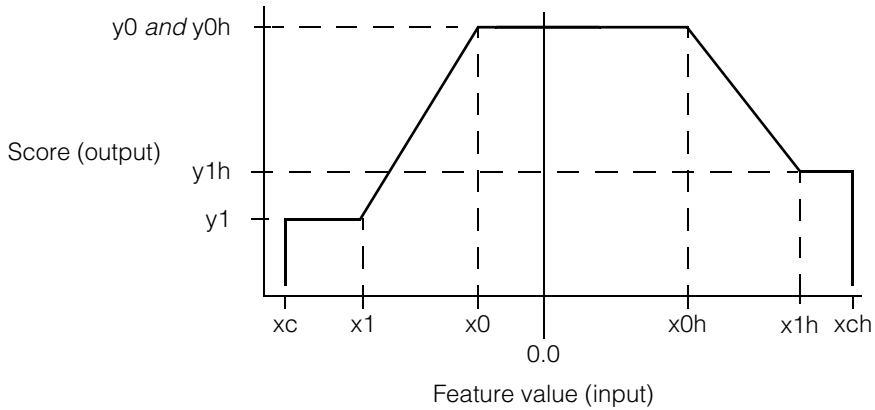
class ccClassifierFeatureScoreTwoSided:
  public ccClassifierFeatureScore;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A scoring function which lets you configure a two-sided scoring function.

A two-sided scoring function maps a feature value to an output score using a function defined by the points shown in the following figure:



A two-sided scoring function is implemented as two one-sided scoring functions.

Constructors/Destructors

ccClassifierFeatureScoreTwoSided

```
ccClassifierFeatureScoreTwoSided();
```

Constructs a **ccClassifierFeatureScoreTwoSided** with the default values shown in the **init** function signature.

Public Member Functions

init

```
void init (double x0 = 0.0, double x1 = -1.0,
  double xc = -1.0, double x0h = 0.0,
  double x1h = 1.0, double xch = 1.0, double y0 = 1.0,
  double y1 = 0.0, double y0h = 1.0, double y1h = 0.0);
```

Initializes the breakpoints in this **ccClassifierFeatureScoreTwoSided** to the supplied values.

Parameters

x0	The value for the *x0* point
x1	The value for the *x1* point
xc	The value for the *xc* point
x0h	The value for the *x0h* point
x1h	The value for the *x1h* point
xch	The value for the *xch* point
y0	The value for the *y0* point
y1	The value for the *y1* point
y0h	The value for the *y0h* point
y1h	The value for the *y1h* point

---

x0

```
double x0 () const;
void x0 (double x0);
```

- `double x0 () const;`

  Returns the *x0* value.

- `void x0 (double x0);`

  Sets the *x0* value.

  Parameters

x0	The value to set. *x0* should be less than *x0h*, *x1h*, and *xch*.

x1

```
double x1 () const;
void x1 (double x1);
```

- `double x1 () const;`

  Returns the *x1* value.

- `void x1 (double x1);`

  Sets the *x1* value.

  Parameters

x1	The value to set. *x1* should be between *xc* and *x0* and less than *x0h*, *x1h*, and *xch*.

xc

```
double xc () const;
void xc (double xc);
```

- `double xc () const;`

  Returns the *xc* value.

- `void xc (double xc);`

  Sets the *xc* value.

  Parameters

xc	The value to set. *xc* should be less than *x0h*, *x1h*, and *xch*.

x0h

```
double x0h () const;
void x0h (double x0h);
```

- `double x0h () const;`

  Returns the *x0h* value.

- `void x0h (double x0h);`

  Sets the *x0h* value.

Parameters

x0h	The value to set. *x0h* should be greater than *xc*, *x1*, and *x0*.

x1h

```
double x1h () const;
void x1h (double x1h);
```

- `double x1h () const;`

  Returns the *x1h* value.

- `void x1h (double x1h);`

  Sets the *x1h* value.

  Parameters

x1h	The value to set. *x1h* should be between *x0h* and *xch* and be greater than *xc*, *x1*, and *x0*.

xch

```
double xch () const;
void xch (double xch);
```

- `double xch () const;`

  Returns the *xch* value.

- `void xch (double xch);`

  Sets the *xch* value.

  Parameters

xch	The value to set. *xch* should be greater than *xc*, *x1*, and *x0*.

y0

```
double y0 () const;
void y0 (double y0);
```

- `double y0 () const;`

  Returns the *y0* value.

- `void y0 (double y0);`

  Sets the *y0* value.

  Parameters

  y0 The value to set. *y0* must be between 0.0 and 1.0.

  Throws

  ccClassifierDefs::BadParams
  y0 is outside the range 0.0 to 1.0.

y1

```
double y1 () const;
void y1 (double y1);
```

- `double y1 () const;`

  Returns the *y1* value.

- `void y1 (double y1);`

  Sets the *y1* value.

  Parameters

  y1 The value to set. *y1* must be between 0.0 and 1.0.

  Throws

  ccClassifierDefs::BadParams
  y1 is outside the range 0.0 to 1.0.

y0h

```
double y0h () const;
void y0h (double y0h);
```

- `double y0h () const;`

  Returns the *y0h* value.

- `void y0h (double y0h);`

  Sets the *y0h* value.

  Parameters

  y0h The value to set. *y0h* must be between 0.0 and 1.0.

  Throws

ccClassifierDefs::BadParams
y0h is outside the range 0.0 to 1.0.

y1h

```
double y1h () const;
void y1h (double y1h);
```

- `double y1h () const;`

  Returns the *y1h* value.

- `void y1h (double y1h);`

  Parameters
  y1h The value to set. *y1h* must be between 0.0 and 1.0.

  Throws
  ccClassifierDefs::BadParams
  y1h is outside the range 0.0 to 1.0.

Low

```
const ccClassifierFeatureScoreOneSided &Low() const;
```

Returns the **ccClassifierFeatureScoreOneSided** object that makes up the low side of this **ccClassifierFeatureScoreTwoSided**.

High

```
const ccClassifierFeatureScoreOneSided &High() const;
```

Returns the **ccClassifierFeatureScoreOneSided** object that makes up the high side of this **ccClassifierFeatureScoreTwoSided**.

score

```
virtual double score(double featureValue) const;
```

Returns the score for the given feature value.

Parameters
featureValue The value to score.

clone

```
virtual ccClassifierFeatureScore *clone() const;
```

Constructs a **ccClassifierFeatureScoreTwoSided** identical to this one.

ccClassifierFeatureVector

```
#include <ch_cvl/clssfier.h>

class ccClassifierFeatureVector;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that defines a single feature vector. A feature vector represents a collection of measurements of a single object or feature.

Constructors/Destructors

ccClassifierFeatureVector

```
ccClassifierFeatureVector(
  cmStd vector<double> &featureValues);
```

Constructs a **ccClassifierFeatureVector** using the supplied values.

Parameters

featureValues A vector of values.

Public Member Functions

featureValues

```
const cmStd vector<double> &featureValues();
```

Returns the feature values used to construct this **ccClassifierFeatureVector**.

ccClassifierFeatureVector

ccClassifierRule

```
#include <ch_cvl/clssfier.h>

class ccClassifierRule;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds a single Classifier tool rule. A rule contains a vector of scoring methods, one method for each dimension of the feature vectors being scored.

Constructors/Destructors

ccClassifierRule

```
ccClassifierRule();
```

Constructs a **ccClassifierRule** with a label value of 0 and no scoring methods.

Public Member Functions

init

```
void init(
  cmStd vector<ccClassifierFeatureScorePtrh>
  &scoringMethods, c_Int32 label);
```

Initializes this **ccClassifierRule** using the supplied vector of scoring methods and the supplied label.

Parameters

scoringMethods A vector of scoring methods. The elements of *scoringMethods* must be **ccPointerHandle** objects derived from the **ccClassifierFeatureScore** class. The **ccClassifierFeatureScorePtrh** type is a typedef defined in *clsscore.h.*

label The label for this rule. This value is returned by the Classifier tool when it classifies a feature vector.

Throws

ccClassifierDefs::BadParams

label is less than 0 or *scoringMethods* has no elements.

score

```
double score(
  const ccClassifierFeatureVector &featureVector) const;
```

Computes the overall score for the supplied **ccClassifierFeatureVector** using the scoring methods that comprise this rule.

The overall score is the geometric mean of the scores returned by the individual scoring methods (ignoring any scores of -1).

Parameters

featureVector The feature vector to score. *featureVector* must have the same number of elements as there are scoring methods in this **ccClassifierRule**.

Throws

ccClassifierDefs::BadParams

featureVector does not contain the same number of elements as this **ccClassifierRule** contains scoring methods; one or more of the one-sided scoring functions contained in this **ccClassifierRule** do not meet the requirement that *x1* must be between *x0* and *xc*; or one or more of the two-sided scoring functions contained in this **ccClassifierRule** do not meet the requirement that *x1* must be between *x0* and *xC* and *x1h* must be between *x0h* and *xch*.

scoringMethods

```
const cmStd vector<ccClassifierFeatureScorePtrh>
  &scoringMethods() const;
```

Returns the vector of scoring methods defined for this **ccClassifierRule**.

label

```
c_Int32 label() const;
```

Return the label of this **ccClassifierRule**.

ccClassifierRuleTable

```
#include <ch_cvl/clssfier.h>

class ccClassifierRuleTable;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds a rule table. A rule table is a vector of rules, one for each category into which you are classifying feature vectors.

Public Member Functions

train

```
void train(const cmStd vector<ccClassifierRule> &rules);
```

Initializes this **ccClassifierRuleTable** using the supplied vector of rules.

Parameters

rules A vector of **ccClassifierRule**s. You should supply as many elements as you have classifications. Each of the **ccClassifierRule**s in *rules* must be the same size.

Throws

ccClassifierDefs::BadParams
rules has no elements or the elements of *rules* are not all the same size.

classifyHardThreshold

```
c_Int32 classifyHardThreshold (
  const ccClassifierFeatureVector &featureVector,
  double hardThreshold) const;
```

Classifies the supplied feature vector. This function computes the score for the supplied feature vector using each rule contained in this **ccClassifierRuleTable**. The function returns the label of the first rule that produces a score greater than or equal to the supplied threshold.

If no rule produces a score greater than the threshold, the function returns -1.

Parameters

featureVector The feature vector to classify. *featureVector* must have the same number of elements that each of the rules in this **ccClassifierRuleTable** has.

hardThreshold The score threshold.

Throws

ccClassifierDefs::BadParams
hardThreshold is less than 0.0 or greater than 1.0; *featureVector* does not have the same number of elements as the first rule in this **ccClassifierRuleTable**; one or more of the one-sided scoring functions contained in one of this **ccClassifierRuleTable**'s rules do not meet the requirement that *x1* must be between *x0* and *xc*; or one or more of the two-sided scoring functions contained in one of this **ccClassifierRuleTable**'s rules do not meet the requirement that *x1* must be between *x0* and *xC* and *x1h* must be between *x0h* and *xch*.

ccClassifierDefs::NotTrained
This **ccClassifierRuleTable** has not been trained (no rules have been supplied).

rules

```
const cmStd vector<ccClassifierRule> &rules() const;
```

Returns the rules contained within this **ccClassifierRuleTable**.

ccCnlSearchDefs

```
#include <cnlsrch.h>

class ccCnlSearchDefs;
```

A name space that holds enumerations and constants used with CNLSearch.

Enumerations

Accuracy

`enum Accuracy`

This enumeration defines CNLSearch accuracy levels.

Value	Meaning
eVeryFine	Specifies highest-accuracy search
eFine	Specifies intermediate-accuracy search
eCoarse	Specifies coarse search
kDefaultAccuracy	The default accuracy, as defined in *cnlsearch.h*

Notes

You can only search at accuracies which were trained. Use the **ccCnlSearchTrainParams::accuracies()** function to specify the accuracies for training.

Algorithm

`enum Algorithm`

This enumeration defines the CNLSearch algorithms.

Value	Meaning
eNormalizedCnlpas	Specifies linear mode search using a conservative search strategy and normalized scoring. Correlation coefficients less than 0 produce scores of 0.0.
eAbsoluteCnlpas	Same as *eNormalizedCnlpas* except that absolute scoring is used. Both negative and positive correlation coefficients produce positive scores.

Value	Meaning
eNonlinearCnlpas	Specifies nonlinear mode search.
eNormalizedSearch	Specifies linear-mode search using an aggressive search strategy and normalized scoring. Correlation coefficients less than 0 produce scores of 0.0.
eAbsoluteSearch	Same as *eNormalizedSearch* except that absolute scoring is used. Both negative and positive correlation coefficients produce positive scores.
kDefaultAlgorithm	Default search algorithm, as defined in *cnlsrch.h*.

Notes

These enumerations may be OR'd together when you train a model. When you search for a model, you can specify only an algorithm for which the model has been trained.

You can train absolute and normalized versions of an algorithm with no memory or performance cost at training time or run time. Aside from this, training a model for additional algorithms takes more time and requires more memory for the model.

DrawMode

```
enum DrawMode;
```

This enumeration defines the types of result graphics you can draw for CNLSearch results.

Value	Meaning
eDrawOrigin	Draws a cross at the location of the model origin.
eDrawLabel	Labels the model origin with a text label.
eDrawBoundingBox	Draws a box around the model area.
eDrawStandard	Draws a labeled cross at the model origin and a box around the model area.

Constants

The following constants provide default values for certain training-time and run-time parameters:

Value	Meaning
kDefaultAcceptTimes1000	An integer containing the default acceptance threshold times 1000.
kDefaultConfusionTimes1000	An integer containing the default confusion threshold times 1000.
kDefaultMaxNumResults	An integer containing the default value for the number of results.
kDefaultLowThreshold	An integer containing the default edge detection low threshold value.
kDefaultHighThreshold	An integer containing the default edge detection high threshold value.
kMaxModelWidth	An integer specifying the maximum width, in pixels, of a model training image.
kMaxModelPelCount	An integer specifying the maximum size, in pixels, of a model training image.

ccCnlSearchDefs

ccCnlSearchModel

```
#include <ch_cvl/cnlsrch.h>

class ccCnlSearchModel: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains a CNLSearch model. A **ccCnlSearchModel** contains all of the information required to search for a pattern in an image.

Constructors/Destructors

ccCnlSearchModel

```
ccCnlSearchModel();

virtual ~ccCnlSearchModel();

ccCnlSearchModel(const ccCnlSearchModel& src);
```

- `ccCnlSearchModel();`

  Constructs a model. The model contains no training information but does have an origin of (0.0, 0.0).

Public Member Functions

name

```
ccCvlString name() const;

void name(const ccCvlString& name);
```

- `ccCvlString name() const;`

  Return the name of this model.

- `void name(const ccCvlString& name);`

  Set the name of this model. The model name is provided as a user convenience only.

  Parameters

  name — A const string reference containing the name to assign to this **ccCnlSearchModel**.

origin

```
cc2Vect origin() const;
void origin(const cc2Vect& origin);
```

- `cc2Vect origin() const;`

  Return the model origin.

- `void origin(const cc2Vect& origin);`

  Set the model origin. The origin must be specified in the client coordinate system of the image supplied to the **train()** member function. The origin is a point attached to the model, but it may reside outside of the model. When an instance of the model is found, the result location is defined by the position of the origin in the search image.

  Parameters

  origin — A reference to a const **cc2Vect** containing the origin of this model.

  Notes

  You can set and get a model's origin whether the model is trained or untrained. Training a model does not affect its origin.

train

```
void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccCnlSearchTrainParams& params,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccCnlSearchTrainParams& params,
  const ccPelRect& partialMatchRange, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccCnlSearchTrainParams& params,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccCnlSearchTrainParams& params,
  const ccPelRect& partialMatchRange, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);
```

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccCnlSearchTrainParams& params,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

  Train this **ccCnlSearchModel** using the supplied model image and model training parameters. If the model is already trained, the existing training information is discarded.

  Parameters

  image — A **const** reference to an image that contains the pattern to train as a model. *image* must be at least 8 x 8 pixels in size.

  params — A **ccCnlSearchTrainParams** that contains the parameters to use to train this model.

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff
  ```

Throws

ccCnlSearchDefs::BadParams
params.algorithms specifies a nonlinear algorithm but *params.lowThreshold* is greater than *params.highThreshold*.

ccCnlSearchDefs::BadImageSize
image is too small.

ccCnlSearchDefs::BadImageContent
image does not contain enough information to create a reliable model.

ccCnlSearchDefs::BadImage
image is unbound.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccCnlSearchTrainParams& params,
    const ccPelRect& partialMatchRange, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

Train this **ccCnlSearchModel** using the supplied model image, model training parameters, and partial match search range. If the model is already trained, the existing training information is discarded.

The partial match search range is only used if you have selected advanced training mode. In general, you should specify the same region that you expect to specify at run time. See the function **maxPartialMatchRange()** for a description of how the partial match search range is specified.

Parameters

image A **const** reference to an image that contains the pattern to train as a model. *image* must be at least 8 x 8 pixels in size.

params A **ccCnlSearchTrainParams** that contains the parameters to use to train this model.

partialMatchRange
An **ccPelRect** that specifies the amount by which a model instance may lie outside the search image and still be found.

The value you supply for *partialMatchRange* is clipped to the value you supplied to **maxPartialMatchRange()**.

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:
  ```

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadParams
params.algorithms specifies a nonlinear algorithm but *params.lowThreshold* is greater than *params.highThreshold*.

ccCnlSearchDefs::BadImageSize
image is too small.

ccCnlSearchDefs::BadImageContent
image does not contain enough information to create a reliable model.

ccCnlSearchDefs::BadImage
image is unbound.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccCnlSearchTrainParams& params,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

Train this **ccCnlSearchModel** using the supplied model image, model training parameters, and mask image. If the model is already trained, the existing training information is discarded.

Parameters

image — A **const** reference to an image that contains the pattern to train as a model. *image* must be at least 8 x 8 pixels.

mask — A **const** reference to an image containing a mask to use when training this model. *mask* must have the same dimensions as *image*. Only pixels in *image* which correspond to pixels in *mask* that have zero values are included in the trained model. Nonzero pixels are treated as don't care pixels.

params — A **ccCnlSearchTrainParams** that contains the parameters to use to train this model.

dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
  ```

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadParams
params.algorithms specifies a nonlinear algorithm but *params.lowThreshold* is greater than *params.highThreshold*.

ccCnlSearchDefs::BadImageSize
image is too small.

ccCnlSearchDefs::BadMaskSize
mask is not the same size as *image*.

ccCnlSearchDefs::BadImageContent
image does not contain enough information to create a reliable model.

ccCnlSearchDefs::BadImage
image is unbound.

ccCnlSearchDefs::NotImplemented
A mask was supplied but the algorithms included one of the following:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas

Notes

If *mask* is unbound, the model is trained as if no mask had been supplied; no exception is thrown.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccCnlSearchTrainParams& params,
    const ccPelRect& partialMatchRange, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

  Train this **ccCnlSearchModel** using the supplied model image, model training parameters, mask image, and partial match search range. If the model is already trained, the existing training information is discarded.

  The partial match search range is only used if you have selected advanced training mode. In general, you should specify the same region that you expect to specify at run time. See the function **maxPartialMatchRange()** for a description of how the partial match search range is specified.

  Parameters

  image — A **const** reference to an image that contains the pattern to train as a model. *image* must be at least 8 x 8 pixels in size.

  mask — A **const** reference to an image containing a mask to use when training this model. *mask* must have the same dimensions as *image*. Only pixels in *image* which correspond to pixels in *mask* that have zero values are included in the trained model. Nonzero pixels are treated as don't care pixels.

  params — A **ccCnlSearchTrainParams** that contains the parameters to use to train this model.

  partialMatchRange
  An **ccPelRect** that specifies the amount by which a model instance may lie outside the search image and still be found.

  The value you supply for *partialMatchRange* is clipped to the value you supplied to **maxPartialMatchRange()**.

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff
  ```

Throws

ccCnlSearchDefs::BadParams
params.algorithms specifies a nonlinear algorithm but *params.lowThreshold* is greater than *params.highThreshold*.

ccCnlSearchDefs::BadImageSize
image is too small.

ccCnlSearchDefs::BadMaskSize
mask is not the same size as *image*.

ccCnlSearchDefs::BadImageContent
image does not contain enough information to create a reliable model.

ccCnlSearchDefs::BadImage
image is unbound.

ccCnlSearchDefs::NotImplemented
A mask was supplied but the algorithms included one of the following:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas

Notes

If *mask* is unbound, the model is trained as if no mask had been supplied; no exception is thrown.

transmitPveModel

```
void transmitPveModel(const ccCvlString& fname,
 c_UInt32 depth = 8);

void transmitPveModel(cmStd ostream& out,
 c_UInt32 depth = 8);
```

- ```
  void transmitPveModel(const ccCvlString& fname,
   c_UInt32 depth = 8);
  ```

Writes the CnlSearch model data to the specified file in PVE format, using *depth* bits. The bit depth must be less than or equal to 8 bits.

Parameters

fname	The name of the file to write the model data to.
depth	The bits per pixel of the stored model data.
  ```

Throws

ccCnlSearchDefs::NotTrained
The model is not trained.

ccCnlSearchDefs::NotImplemented
The model was trained with one of the following algorithms:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas

depth was greater than 8 bits.

ccCnlSearchDefs::TransmitErr
An error occurred writing the PVE data to the file.

ccCnlSearchDefs::BadPveModelSize
The model image does not conform to PVE model size restrictions.

ccCnlSearchDefs::BadImage
The training image was more than *depth* bits deep.

- ```
  void transmitPveModel(cmStd ostream& out,
    c_UInt32 depth = 8);
  ```

Writes the CnlSearch model data to the specified stream in PVE format, using *depth* bits. The bit depth must be less than or equal to 8 bits.

Parameters

out The stream to write the model data to.

depth The bits per pixel of the stored model data.

Throws

ccCnlSearchDefs::NotTrained
The model is not trained.

ccCnlSearchDefs::NotImplemented
The model was trained with one of the following algorithms:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas

depth was greater than 8 bits.

ccCnlSearchDefs::TransmitErr
An error occurred writing the PVE data to the stream.
  ```

ccCnlSearchDefs::BadPveModelSize
The model image does not conform to PVE model size restrictions.

ccCnlSearchDefs::BadImage
The training image was more than *depth* bits deep.

unTrain `void unTrain();`

Untrain this model. All training information is discarded and all memory associated with the training information is freed. The model origin is not affected.

Throws
ccCnlSearchDefs::NotTrained
This model is not currently trained.

isTrained `bool isTrained() const;`

Return *true* if this model is currently trained, *false* otherwise.

trainParams `ccCnlSearchTrainParams trainParams() const;`

Return the **ccCnlSearchTrainParams** used to train this model.

Throws
ccCnlSearchDefs::NotTrained
This model is not currently trained.

modelWidth `c_Int16 modelWidth() const;`

Return the width (in pixels) of the model image used to train this model.

Throws
ccCnlSearchDefs::NotTrained
This model is not currently trained.

modelHeight `c_Int16 modelHeight() const;`

Return the height (in pixels) of the model image.

Throws
ccCnlSearchDefs::NotTrained
This model is not currently trained.

trainImage

```
ccPelBuffer_const<c_UInt8> trainImage() const;
```

Return the image used to train this model.

Throws

ccCnlSearchDefs::NotTrained
This model is not currently trained.

trainEdgeImage

```
ccPelBuffer_const<c_UInt8> trainEdgeImage() const;
```

Return an image containing the edge map generated from the model image.

Throws

ccCnlSearchDefs::NotTrained
ccCnlsSearchDefs::eNonlinearCnlpas was not among the algorithms used to train this model.

trainMask

```
ccPelBuffer_const<c_UInt8> trainMask() const;
```

Return an image containing the mask used to train this model.

Throws

ccCnlSearchDefs::NotTrained
This model is not currently trained, or was not trained with a mask image.

minSearchImageSize

```
ccIPair minSearchImageSize(ccCnlSearchDefs::Algorithm alg)
  const;
```

Returns the size in pixels of smallest image which can be searched with this model using the specified algorithm. The minimum size is typically slightly larger than the dimensions of the training image.

Parameters

alg The algorithm for which to return the minimum model size. *alg* must be one of the following values:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas
ccCnlSearchDefs::eNormalizedSearch
ccCnlSearchDefs::eAbsoluteSearch
ccCnlSearchDefs::kDefaultAlgorithm

For more information, see the description of *ccCnlSearchDefs* on page 973.

Throws

ccCnlSearchDefs::NotTrained
This model is not currently trained.

---

run

```
void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccCnlSearchRunParams& params,
  ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccCnlSearchRunParams& params,
  const ccPelRect& partialMatchRange,
  ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccIPair& point, const ccCnlSearchRunParams& params,
  ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccIPair& point, const ccCnlSearchRunParams& params,
  const ccPelRect& partialMatchRange,
  ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0) const;
```

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccCnlSearchRunParams& params,
    ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0) const;
  ```

  Search for this model within the supplied image. You supply a **ccCnlSearchRunParams** containing parameters for the search and a **ccCnlSearchResultSet** in which to store the results. The results are stored in decreasing order of score.

  Parameters

image	The image to search for the model.
params	The search parameters.
resultSet	A **ccCnlSearchResultSet** in which to store the results. *resultSet* is cleared before the search results are stored in it.
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
  ```

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadImageSize
image is too small to fully contain the model.

ccCnlSearchDefs::NotTrained
This model is not currently trained; the model was not trained at the accuracy level that you specified for the search; or the model was not trained for the algorithm specified for the search.

ccCnlSearchDefs::BadParams
params.confusion is less than *params.accept*; *params.maxNumResults* is less than or equal to 0; or *params.algorithm* is *ccCnlSearchDefs::eNonlinearCnlpas* and *params.lowThreshold* is greater than *params.highThreshold*.

ccCnlSearchDefs::BadImage
image is unbound.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccCnlSearchRunParams& params,
    const ccPelRect& partialMatchRange,
    ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0) const;
  ```

Search for this model within the supplied image. You supply a **ccCnlSearchRunParams** containing parameters for the search, a **ccPelRect** specifying a partial match search range, and a **ccCnlSearchResultSet** in which to store the results. The results are stored in decreasing order of score.

See the function **maxPartialMatchRange()** for a description of how the partial match search range is specified.

Parameters

image The image to search for the model.

params The search parameters.
  ```

partialMatchRange
: An **ccPelRect** that specifies the amount by which a model instance may lie outside the search image and still be found.

  The value you supply for *partialMatchRange* is clipped to the value you supplied to **maxPartialMatchRange()**.

  If you specify a range of **ccPelRect(0, 0, 1, 1)**, then no partial matches are allowed.

resultSet
: A **ccCnlSearchResultSet** in which to store the results. *resultSet* is cleared before the search results are stored in it.

dObj
: An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags
: The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadImageSize
: *image* is too small to fully contain the model.

ccCnlSearchDefs::NotTrained
: This model is not currently trained; the model was not trained at the accuracy level that you specified for the search; or the model was not trained for the algorithm specified for the search.

ccCnlSearchDefs::BadParams
: *params.confusion* is less than *params.accept*; *params.maxNumResults* is less than or equal to 0; *params.algorithm* is *ccCnlSearchDefs::eNonlinearCnlpas* and *params.lowThreshold* is greater than *params.highThreshold*; or *partialMatchRange* does not contain the point 0,0.

ccCnlSearchDefs::BadImage
: *image* is unbound.

ccCnlSearchDefs::NotImplemented
partialMatchRange is not (0, 0, 1, 1) and *params.algorithm* is not *ccCnlSearchDefs::eNormalizedSearch* or *ccCnlSearchDefs::eAbsoluteSearch*.

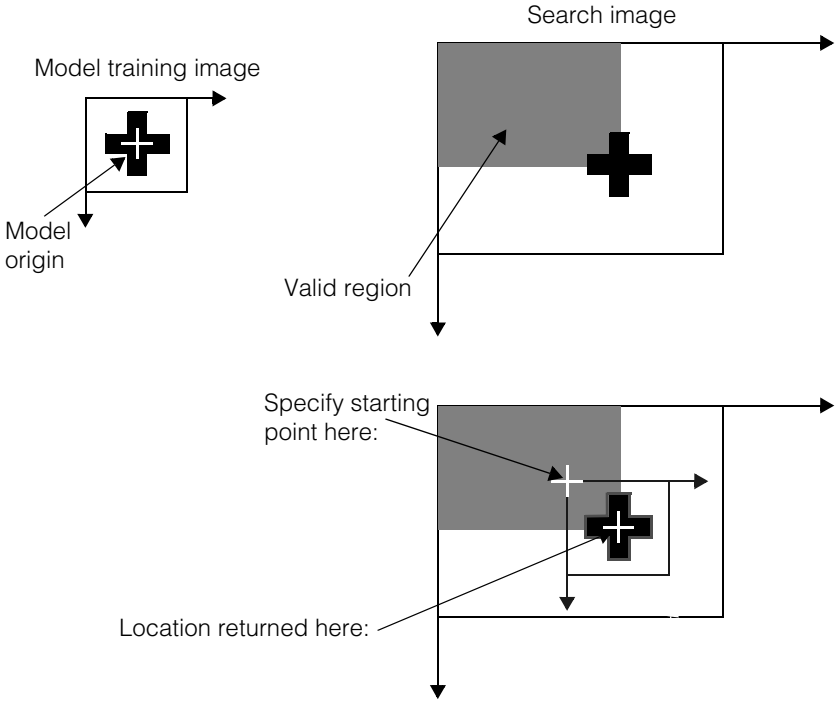
- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccIPair& point, const ccCnlSearchRunParams& params,
    ccCnlSearchResult& result, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0) const;
  ```

  Search for a single instance of this model within the supplied image starting at the supplied point. If the starting point you specify is close to the actual location of the model in the search image, this *point search* can be faster than a search that considers the entire area of the search image.

  The initial point, specified in whole pixel units relative to the origin of the search image, must lie within the following region of the search image:

  The search will be confined to the immediate vicinity of the point you specify. The point you specify corresponds to the upper-left corner of the model image. The model location
  ```

is returned, as usual, in terms of the model origin, as shown in the following figure:



You supply a **ccCnlSearchRunParams** containing parameters for the search and a **ccCnlSearchResult** in which to store the result.

Notes

Point search is only supported for the *ccCnlSearchDefs::eAbsoluteSearch* and *ccCnlSearchDefs::eNormalizedSearch* algorithms.

Parameters

image	The image to search for the model.
params	The search parameters.
result	A **ccCnlSearchResult** in which to store the result. *result* is cleared before the search result is stored in it.
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadImageSize
image is too small to fully contain the model.

ccCnlSearchDefs::BadImage
image is unbound.

ccCnlSearchDefs::NotTrained
This model is not currently trained; the model was not trained at the accuracy level that you specified for the search; or the model was not trained for the algorithm specified for the search.

ccCnlSearchDefs::BadParams
params.algorithm is neither *ccCnlSearchDefs::eAbsoluteSearch* nor *ccCnlSearchDefs::eNormalizedSearch*.

ccSearch::BadPoint
point does not lie within the valid region.

Notes

image must be bound.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccIPair& point, const ccCnlSearchRunParams& params,
    const ccPelRect& partialMatchRange,
    ccCnlSearchResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0) const;
  ```

  Search for a single instance of this model within the supplied image starting at the supplied point. If the starting point you specify is close to the actual location of the model in the search image, this *point search* can be faster than a search that considers the entire area of the search image.

  See the previous overload of **run()** for a description of how the starting point is specified.

  You supply a **ccCnlSearchRunParams** containing parameters for the search, a **ccPelRect** specifying a partial match search range, and a **ccCnlSearchResult** in which to store the result.

  See the function **maxPartialMatchRange()** for a description of how the partial match search range is specified.

  Notes

  Point search is only supported for the *ccCnlSearchDefs::eAbsoluteSearch* and *ccCnlSearchDefs::eNormalizedSearch* algorithms.

  Parameters

  image — The image to search for the model.

  params — The search parameters.

  partialMatchRange — An **ccPelRect** that specifies the amount by which a model instance may lie outside the search image and still be found.

  The value you supply for *partialMatchRange* is clipped to the value you supplied to **maxPartialMatchRange()**.

  If you specify a range of **ccPelRect(0, 0, 1, 1)**, then no partial matches are allowed.

  result — A **ccCnlSearchResult** in which to store the result. *result* is cleared before the search result is stored in it.

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:
  ```

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCnlSearchDefs::BadImageSize
image is too small to fully contain the model.

ccCnlSearchDefs::BadImage
image is unbound.

ccCnlSearchDefs::NotTrained
This model is not currently trained; the model was not trained at the accuracy level that you specified for the search; or the model was not trained for the algorithm specified for the search.

ccCnlSearchDefs::BadParams
params.algorithm is neither *ccCnlSearchDefs::eAbsoluteSearch* nor *ccCnlSearchDefs::eNormalizedSearch* or *partialMatchRange* does not contain the point 0,0.

ccSearch::BadPoint
point does not lie within the valid region.

Notes

image must be bound.

resultStatistics

```
void resultStatistics(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccCnlSearchResult& result, double* sumImage,
  double* sumSquareImage, double* sumImageTimesModel,
  double* contrast);
```

Return information about the pixel values for a model image-sized location within a search image. The model location is rounded to the nearest whole pixel location and the following quantities are computed:

- The sum of all image pixels which correspond to care pixels in the model image
- The sum of the squares of all image pixels which correspond to care pixels in the model image
- The sum of the products of image pixels and model pixels, for all image pixels which correspond to care pixels in the model image

- The ratio of the standard deviation of the image pixels to the standard deviation of the model pixels, for all image pixels which correspond to care pixels in the model image

Parameters

image The image for which these statistics are computed

result A single **ccCnlSearchResult** describing the location within the *image* at which the statistics are to be computed

sumImage A pointer to a **double** into which the sum of all of the pixels in the image that correspond to care pixels in the model is copied

sumSquareImage
A pointer to a **double** into which the sum of the squares of all of the pixels in the image that correspond to care pixels in the model is copied

sumImageTimesModel
A pointer to a **double** into which the sum of the products of each pair of model and image pixels that correspond to care pixels in the model is copied

contrast A pointer to a **double** into which the ratio of the standard deviation of pixel values in the image to the standard deviation of pixel values in the model, for all pixels corresponding to care pixels in the model, is copied

Notes

If this model was trained using a mask, only pixels corresponding to care pixels in the model are included when the statistics are computed.

Throws

ccCnlSearchDefs::BadImageSize
The image is too small to contain the model.

ccCnlSearchDefs::NotTrained
This model is not trained.

---

saveImage

```
bool saveImage() const;
void saveImage(bool save);
```

- `bool saveImage() const;`

This function returns whether or not this **ccCnlSearchModel** is configured to save the image pixels used for training.

- `void saveImage(bool save);`

  Sets whether or not a copy of the image pixels used to train this **ccCnlSearchModel** are to be saved at training. If you call this function with an argument of false after training any saved training image pixels are discarded.

  Parameters

  save — If true, the pixels are saved at training. If false, the pixels are not saved.

  Throws

  ccCnlSearchDefs::BadParams — This function was called with *save* set to true after this **ccCnlSearchModel** was trained (and no pixels had been saved when it was trained).

  Notes

  You cannot archive a trained **ccCnlSearchModel** unless this function had been called with an argument of true prior to training. (To archive a trained **ccCnlSearchModel**, the training image pixels must be available.)

maxPartialMatchRange

```
ccPelRect maxPartialMatchRange() const;

void maxPartialMatchRange(const ccPelRect& range);
```

- `ccPelRect maxPartialMatchRange() const;`

  This function returns the maximum partial match search range that can be specified for searches using this **ccCnlSearchModel**.

- `void maxPartialMatchRange(const ccPelRect& range);`

  This function sets the maximum partial match search range that can be specified for searches using this **ccCnlSearchModel**. When you specify a partial match search range for a particular search, the range is always clipped to the maximum value you specify with this function.

  The partial match search range is specified as a **ccPelRect**. The **ccPelRect** defines the tolerance of this **ccCnlSearchModel** for finding model instances that are partially outside of the search image. The **ccPelRect** is interpreted as a dilation region that is applied to the search image to produce the region in which matches are allowed. The simplest way to specify the partial match search range is to construct a **ccPelRect** as follows:

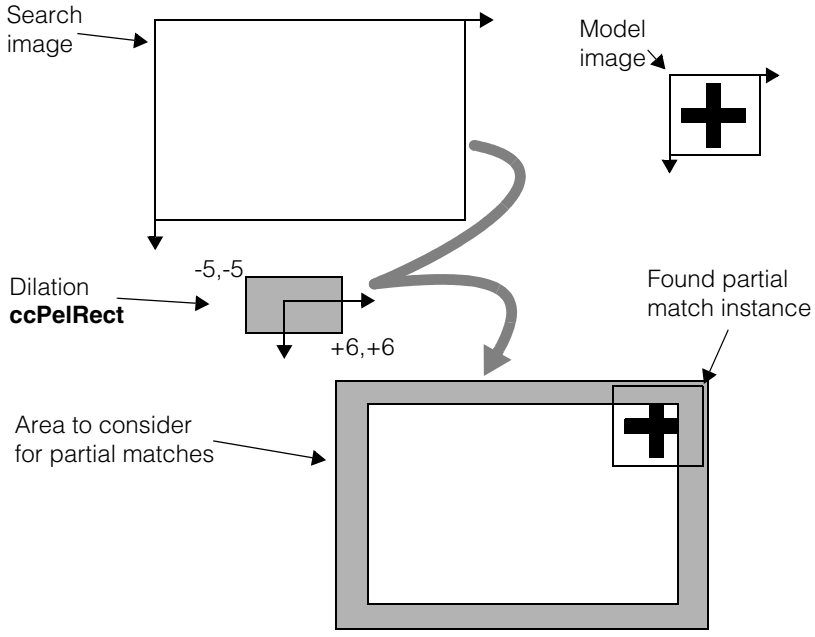
  ```
  ccPelRect(ccIPair(-left, -up), ccIPair(right+1, down+1))
  ```

where *left*, *right*, *up*, and *down* are the amount in pixels by which a model is allowed to lie outside that side of the search image.

For example, if you wanted to allow partial matches up to 5 pixels outside of the search image in any direction, you would supply the following **ccPelRect**:

```
ccPelRect(ccIPair(-5, -5), ccIPair(6, 6))
```

The following figure shows how the **ccPelRect** specifies the partial match search range.



If you specify a maximum search range of **ccPelRect(0, 0, 0, 0)**, CNLSearch will allow all partial matches (even as small as a single pixel). This special value (**ccPelRect(0, 0, 0, 0)**) is the default maximum partial match search range.

To specify that no partial matches are allowed, supply a value of **ccPelRect(0, 0, 1, 1)**.

Parameters

range The maximum partial match search range.

Throws

ccCnlSearchDefs::BadParams

range is not **ccPelRect(0, 0, 0, 0)** and *range* does not contain the point 0,0.

Notes

You can change the maximum partial match search range for a **ccCnlSearchModel** without needing to re-train the model.

Keep in mind that as the size of the partial match area increases, the potential for meaningless matches increases. For example, it is possible to specify a partial match range that will match a single pixel; such a match would provide no useful information. Also, as the size of the partial match area increases, search times will increase.

ccCnlSearchResult

```
#include <ch_cvl/cnlsrch.h>

class ccCnlSearchResult: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that holds a single CNLSearch search result.

Constructors/Destructors

ccCnlSearchResult

```
ccCnlSearchResult();
```

Constructs an empty **ccCnlSearchResult**.

Public Member Functions

found

```
bool found() const;
```

Returns *true* if this result received a score greater than or equal to the acceptance threshold specified for this search, *false* otherwise.

location

```
cc2Vect location() const;
```

Returns the location of the model origin in the client coordinate system of the search image.

score

```
double score() const;
```

Returns the result score (a number between 0 and 1). If **ccCnlSearchRunParams::weightScoreByOverlap()** is false, this value is equal to **ccCnlSearchResult::areaScore()**. **ccCnlSearchRunParams::weightScoreByOverlap()** is true, this value is equal to **ccCnlSearchResult::areaScore()*ccCnlSearchResult::areaCoverageScore()**.

edgeHit `c_UInt8 edgeHit() const;`

Returns a **c_UInt8** indicating whether the model was found against one or more edges of the search image. The return value is composed by ORing together one or more of the following values

ccCnlSearchResult::eNone
ccCnlSearchResult::eUnknownEdge
ccCnlSearchResult::eLeftEdge
ccCnlSearchResult::eTopEdge
ccCnlSearchResult::eRightEdge
ccCnlSearchResult::eBottomEdge

Notes

If you have specified *ccCnlSearchDefs::eAbsoluteSearch* or *ccCnlSearchDefs::eNormalizedSearch* for this search, **edgeHit()** will return either *ccCnlSearchResult::eNone* (if no edge was hit) or *ccCnlSearchResult::eUnknownEdge* (if any edge was it). Only searches performed using the *ccCnlSearchDefs::eNormalizedCnlpas* or *ccCnlSearchDefs::eNonlinearCnlpas* algorithms can report which edge was hit.

areaScore `double areaScore() const;`

Returns the area score (a number between 0 and 1). The area score represents the quality of the match regardless of the amount of model that appears in the image.

areaCoverageScore
`double areaCoverageScore() const;`

Returns the fraction of the model that lies within the search image. The returned value is in the range 0.0 through 1.0.

edgeScore `double edgeScore() const;`

Returns the edge score, a number between 0.0 and 1.0. The edge score is only valid for nonlinear mode searches.

Throws

ccCnlSearchDefs::NotComputed
The algorithm specified for this search was not *ccCnlSearchDefs::eNonlinearCnlpas*.

contrast `double contrast() const;`

Returns the ratio of the standard deviation of the pixels in the located instance of the model to the standard deviation of the care pixels in the model.

Throws

ccCnlSearchDefs::NotComputed
The algorithm specified for this search was *ccCnlSearchDefs::eNonlinearCnlpas*.

draw

```
void draw(ccGraphicList& graphList,
 c_UInt32 drawMode=ccCnlSearchDefs::eDrawStandard,
 const ccCvlString& label=ccCvlString()) const;
```

Appends result graphics for this **ccCnlSearchResult** to the supplied **ccGraphicList**.

Parameters

graphList The graphics list to append the graphics to.

drawMode The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccCnlSearchDefs::eDrawOrigin
ccCnlSearchDefs::eDrawLabel
ccCnlSearchDefs::eDrawBoundingBox
ccCnlSearchDefs::eDrawStandard

label If you include *ccCnlSearchDefs::eDrawLabel* in *drawMode*, then the contents of *label* are used to label the center of mass.

ccCnlSearchResult

ccCnlSearchResultSet

```
#include <ch_cvl/cnlsrch.h>

class ccCnlSearchResultSet: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that holds a list of **ccCnlSearchResult**s.

Constructors/Destructors

ccCnlSearchResultSet

```
ccCnlSearchResultSet();
```

The number of results and search time are initialized to zero.

Public Member Functions

results

```
const cmStd vector<ccCnlSearchResult>& results() const;
```

Return a vector containing a **ccCnlSearchResult** search result for each instance of the model found in the search image. If there are no results, the vector will have a size of zero.

time

```
double time() const;
```

Returns the execution time required to produce this result set (in seconds). This is the amount of time required to execute the **run()** member of **ccCnlSearchModel**.

algorithm

```
ccCnlSearchDefs::Algorithm algorithm() const;
```

Returns the algorithm used to generate this result set. Possible values are:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas

ccCnlSearchDefs::eNormalizedSearch
ccCnlSearchDefs::eAbsoluteSearch
ccCnlSearchDefs::kDefaultAlgorithm

For more information, see the description of *ccCnlSearchDefs* on page 973.

draw

```
void draw(ccGraphicList& graphList,
  c_UInt32 drawMode=ccCnlSearchDefs::eDrawStandard,
  bool drawOnlyFound = false) const;
```

Appends result graphics for this **ccCnlSearchResultSet** to the supplied **ccGraphicList**.

Parameters

graphList The graphics list to append the graphics to.

drawMode The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccCnlSearchDefs::eDrawOrigin
ccCnlSearchDefs::eDrawLabel
ccCnlSearchDefs::eDrawBoundingBox
ccCnlSearchDefs::eDrawStandard

drawOnlyFound If true, only found results are drawn. If false, all results are drawn.

ccCnlSearchRunParams

```
#include <ch_cvl/cnlsrch.h>

class ccCnlSearchRunParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that holds the parameters used to perform a search. This class is supplied as an argument to **ccCnlSearchModel::run()**.

Constructors/Destructors

ccCnlSearchRunParams

```
ccCnlSearchRunParams(
  ccCnlSearchDefs::Algorithm alg =
  ccCnlSearchDefs::kDefaultAlgorithm);
```

Constructs a **ccCnlSearchRunParams** using the given algorithm choice. The remaining members are assigned to the default values in **ccCnlSearchDefs**.

Parameters

alg — The algorithm to use in this search. *alg* must be one of the following:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas
ccCnlSearchDefs::eNormalizedSearch
ccCnlSearchDefs::eAbsoluteSearch
ccCnlSearchDefs::kDefaultAlgorithm

Public Member Functions

accuracy

```
ccCnlSearchDefs::Accuracy accuracy() const;
void accuracy(ccCnlSearchDefs::Accuracy acc);
```

- `ccCnlSearchDefs::Accuracy accuracy() const;`

  Returns the accuracy value specified in this **ccCnlSearchRunParams**. Returns one of the values listed below.

- `void accuracy(ccCnlSearchDefs::Accuracy acc);`

  Sets the accuracy for this **ccCnlSearchRunParams**. This determines the accuracy of the search. You must have trained the **ccCnlSearchModel** for the accuracy specified by *acc*.

  Parameters

  acc — The accuracy to set. *acc* must be one of the following values:

  ccCnlSearchDefs::eVeryFine
  ccCnlSearchDefs::eFine
  ccCnlSearchDefs::eCoarse
  ccCnlSearchDefs::kDefaultAccuracy

  Notes

  The **run()** member of **ccCnlSearchModel** may search at a higher accuracy than you specify with this function if the model image is not suitable for low-accuracy searching.

algorithm

```
ccCnlSearchDefs::Algorithm algorithm() const;
void algorithm(ccCnlSearchDefs::Algorithm alg);
```

- `ccCnlSearchDefs::Algorithm algorithm() const;`

  Returns the algorithm specified in this **ccCnlSearchRunParams**.

- `void algorithm(ccCnlSearchDefs::Algorithm alg);`

  Sets the algorithm for this **ccCnlSearchRunParams**.

Parameters

alg The algorithm for this search. *alg* must be one of the following values:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas
ccCnlSearchDefs::eNormalizedSearch
ccCnlSearchDefs::eAbsoluteSearch
ccCnlSearchDefs::kDefaultAlgorithm

For more information, see the description of *ccCnlSearchDefs* on page 973.

Notes

A model can only be searched for using an algorithm it was trained for.

accept

```
double accept() const;
void accept(double thresh);
```

- `double accept() const;`

Returns the acceptance threshold specified in this **ccCnlSearchRunParams**.

- `void accept(double thresh);`

Sets the acceptance threshold for this **ccCnlSearchRunParams**. The acceptance threshold must be between 0.0 and 1.0 inclusive. Set the acceptance threshold to be below the lowest score that an actual instance of the model is expected to receive.

Parameters

thresh The acceptance threshold to use.

Throws

ccCnlSearchDefs::BadParams
If *thresh* is not between 0.0 and 1.0.

confusion

```
double confusion() const;
void confusion(double thresh);
```

- `double confusion() const;`

Returns the confusion threshold specified in this **ccCnlSearchRunParams**.

- `void confusion(double thresh);`

  Sets the confusion threshold for this **ccCnlSearchRunParams**. The confusion threshold must be between 0.0 and 1.0 inclusive. Set the confusion threshold to be equal to the highest score that a feature in the model that is *not* an instance of the model is expected to receive.

  Parameters

  thresh The confusion threshold to use.

  Notes

  The tool uses the confusion threshold as a hint regarding how confusing the search image is likely to be. A high value for confusion slows the search but ensures that wrong features are not found in a confusing scene. A low confusion threshold increases the search speed for scenes that are not confusing.

  The confusion threshold must be greater than or equal to the acceptance threshold.

  Throws

  ccCnlSearchDefs::BadParams
  If *thresh* is not between 0.0 and 1.0.

maxNumResults

```
c_Int16 maxNumResults() const;
void maxNumResults(c_Int16 num);
```

- `c_Int16 maxNumResults() const;`

  Returns the maximum number of results specified in this **ccCnlSearchRunParams**.

- `void maxNumResults(c_Int16 num);`

  Sets the maximum number of results for this **ccCnlSearchRunParams**. The **run()** member of **ccCnlSearchModel** will return up to this number of search results.

  Parameters

  num The maximum number of results.

highThreshold

```
c_UInt8 highThreshold() const;
void highThreshold(c_UInt8 hiThresh);
```

- `c_UInt8 highThreshold() const;`

  Returns the edge detection high threshold value specified in this **ccCnlSearchRunParams**.

- `void highThreshold(c_UInt8 hiThresh);`

  Sets the edge detection high threshold value for **ccCnlSearchRunParams**. All edges with strength above this threshold are included in the edge map of the search image.

  Parameters

  hiThresh The high threshold value.

  Notes

  This parameter is only used when the search algorithm is *ccCnlSearchDefs::eNonlinearCnlpas*. The high threshold must be greater than the low threshold.

lowThreshold

```
c_UInt8 lowThreshold() const;
void lowThreshold(c_UInt8 loThresh);
```

- `c_UInt8 lowThreshold() const;`

  Returns the edge detection low threshold value specified in this **ccCnlSearchRunParams**.

- `void lowThreshold(c_UInt8 loThresh);`

  Sets the edge detection low threshold value for this **ccCnlSearchRunParams**. Edges with strengths below this threshold are excluded from the edge map. Edges with strengths between the low threshold and the high threshold are included in the edge map if they are 8-connected to an edge above the high threshold, either directly or through one or more other edges above the low threshold but below the high threshold.

  Parameters

  loThresh The low threshold value.

  Notes

  This parameter is only used when the search algorithm is *ccCnlSearchDefs::eNonlinearCnlpas*. The low threshold must be less than the high threshold.

xyOverlap

```
double xyOverlap() const;
void xyOverlap(double overlapThresh);
```

- `double xyOverlap() const;`

  Returns the maximum allowed percentage of overlap between two search results.

- `void xyOverlap(double overlapThresh);`

  Sets the maximum allowed percentage of overlap between two search results. If more than the specified percentage of the results' areas are overlapped, then the result with the lower score is discarded. If the percentage of overlap is below the threshold, then both results are returned.

  Parameters

  overlapThresh The overlap percentage threshold, specified in the range 0.0 through 1.0. Specify a value of 1.0 (the default) to obtain the behavior seen in earlier CNLSearch releases.

  Throws

  ccCnlSearchDefs::BadParams
  overlapThresh is not in the range 0.0 through 1.0.

weightScoreByOverlap

```
bool weightScoreByOverlap() const;

void weightScoreByOverlap(bool);
```

- `bool weightScoreByOverlap() const;`

  This function returns true if CNLSearch weights the scores of found model instances by the percentage of the model that appears within the search window, false otherwise.

  Notes

  This value is only meaningful if you are using partial match searching.

  Note that this function is not related to the **xyOverlap()** function.

- `void weightScoreByOverlap(bool weight);`

  This function controls whether CNLSearch weights the scores of found model instances by the percentage of the model that appears within the search window.

  Parameters

  weight If true, CNLSearch will multiply model scores by the percentage of the model that lies within the search image. If false, scores will not be weighted.

Notes

This value is only meaningful if you are using partial match searching.

Note that this function is not related to the **xyOverlap()** function.

Regardless of **ccCnlSearchRunParams::weightScoreByOverlap()**, **ccCnlSearchResult::areaScore()** will return the quality of the match of whatever part of the model in the image.

Regardless of **ccCnlSearchRunParams::weightScoreByOverlap()**, **ccCnlSearchResult::areaCoverageScore()** will return the fraction of the area of the model that is in the image.

If **ccCnlSearchRunParams::weightScoreByOverlap()** is true, then **ccCnlSearchResult::score()** is equal to **areaScore() * areaCoverageScore()**. If **ccCnlSearchRunParams::weightScoreByOverlap()** is false, then **ccCnlSearchResult::score()** is equal to **areaScore()**.

ccCnlSearchRunParams

ccCnlSearchTrainParams

```
#include <ch_cvl/cnlsrch.h>

class ccCnlSearchTrainParams: public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that holds the parameters used to train a CNLSearch model. This class is supplied as an argument to the **train()** member of the **ccCnlSearchModel** class.

Constructors/Destructors

ccCnlSearchTrainParams

```
ccCnlSearchTrainParams();

ccCnlSearchTrainParams(c_UInt16 algs);
```

- `ccCnlSearchTrainParams();`

  Constructs a **ccCnlSearchTrainParams** using the default values in **ccCnlSearchDefs**.

- `ccCnlSearchTrainParams(c_UInt16 algs);`

  Constructs a **ccCnlSearchTrainParams** using the given algorithm choices. The remaining members are assigned to the default values in **ccCnlSearchDefs**.

  Parameters

  algs — The algorithms for which to train this model. *algs* must be formed by ORing together any of the following values:

  ccCnlSearchDefs::eNormalizedCnlpas
  ccCnlSearchDefs::eAbsoluteCnlpas
  ccCnlSearchDefs::eNonlinearCnlpas
  ccCnlSearchDefs::eNormalizedSearch
  ccCnlSearchDefs::eAbsoluteSearch
  ccCnlSearchDefs::kDefaultAlgorithm

For more information, see the description of *ccCnlSearchDefs* on page 973.

Public Member Functions

accuracies

```
c_UInt16 accuracies() const;

void accuracies(c_UInt16 accs);
```

- `c_UInt16 accuracies() const;`

  Returns a **c_UInt16** that is formed by ORing together all of the accuracies for which this **ccCnlSearchTrainParams** is trained. The return value is formed by ORing together one or more of the following values:

  ccCnlSearchDefs::eVeryFine
  ccCnlSearchDefs::eFine
  ccCnlSearchDefs::eCoarse

- `void accuracies(c_UInt16 accs);`

  Sets the accuracies for which this **ccCnlSearchTrainParams** is to be trained. You can only search using an accuracy which was specified at training.

  Parameters

  accs — The accuracies to set. *acc* must be formed by ORing together one or more of the following values:

  ccCnlSearchDefs::eVeryFine
  ccCnlSearchDefs::eFine
  ccCnlSearchDefs::eCoarse

  Notes

  The **train()** member of **ccCnlSearchModel** may train the model at a higher accuracy than you specify with this function if the model image is not suitable for low-accuracy searching.

  In most cases, you should specify *ccCnlSearchDefs::eVeryFine*.

accuracy

```
ccCnlSearchDefs::Accuracy accuracy() const;
void accuracy(ccCnlSearchDefs::Accuracy acc);
```

- `ccCnlSearchDefs::Accuracy accuracy() const;`

  Return the accuracy value specified in this **ccCnlSearchTrainParams**. Returns one of the values listed below.

  ccCnlSearchDefs::eVeryFine
  ccCnlSearchDefs::eFine
  ccCnlSearchDefs::eCoarse

- `void accuracy(ccCnlSearchDefs::Accuracy acc);`

  Sets the accuracy for this **ccCnlSearchTrainParams**. The accuracy you set determines the accuracy with which you can search at run time.

  Parameters

  acc The accuracy to set. *acc* must be one of the following values:

  ccCnlSearchDefs::eVeryFine
  ccCnlSearchDefs::eFine
  ccCnlSearchDefs::eCoarse
  ccCnlSearchDefs::kDefaultAccuracy

  Notes

  The **train()** member of **ccCnlSearchModel** may train the model at a higher accuracy than you specify with this function if the model image is not suitable for low-accuracy searching.

  In most cases, you should specify *ccCnlSearchDefs::eVeryFine*.

algorithms

```
c_UInt16 algorithms() const;
void algorithms(c_UInt16 alg);
```

- `c_UInt16 algorithms() const;`

  Returns the algorithm specified in this **ccCnlSearchTrainParams**.

- `void algorithms(c_UInt16 alg);`

  Sets the algorithm for this **ccCnlSearchTrainParams**.

Parameters

alg The algorithm for which to train the model. *alg* must be formed by ORing together any of the following values:

ccCnlSearchDefs::eNormalizedCnlpas
ccCnlSearchDefs::eAbsoluteCnlpas
ccCnlSearchDefs::eNonlinearCnlpas
ccCnlSearchDefs::eNormalizedSearch
ccCnlSearchDefs::eAbsoluteSearch
ccCnlSearchDefs::kDefaultAlgorithm

For more information, see the description of *ccCnlSearchDefs* on page 973.

Notes

When you perform the search, you can specify only an algorithm that is among those that you specify when you train the model.

Throws

ccCnlSearchDefs::BadParams
algs is not the result of ORing together the values in *ccCnlSearchDefs::Algorithm*.

ccCnlSearchDefs::NotImplemented
algs includes *ccCnlSearchDefs*::*eAbsoluteCnlpas*.

highThreshold

```
c_UInt8 highThreshold() const;}

void highThreshold(c_UInt8 highThresh);
```

- `c_UInt8 highThreshold() const;`

  Returns the edge detection high threshold value specified in this **ccCnlSearchTrainParams**.

- `void highThreshold(c_UInt8 highThresh);`

  Sets the edge detection high threshold value for this **ccCnlSearchTrainParams**. All edges with strengths above this threshold are included in the edge map of the model image.

  Parameters

  hiThresh The high threshold value.

Notes

This parameter is only used when the search algorithm is *ccCnlSearchDefs::eNonlinearCnlpas*. The high threshold must be greater than the low threshold.

lowThreshold

```
c_UInt8 lowThreshold() const;

void lowThreshold(c_UInt8 lowThresh);
```

- `c_UInt8 lowThreshold() const;`

  Returns the edge detection low threshold value specified in this **ccCnlSearchTrainParams**.

- `void lowThreshold(c_UInt8 lowThresh);`

  Sets the edge detection low threshold value for this **ccCnlSearchTrainParams**. Edges with strengths below this threshold are excluded from the edge map. Edges with strengths between the low threshold and the high threshold are included in the edge map if they are 8-connected to an edge above the high threshold, either directly or through one or more other edges above the low threshold but below the high threshold.

  Parameters

  lowThresh The low threshold value.

  Notes

  This parameter is only used when the search algorithm is *ccCnlSearchDefs::eNonlinearCnlpas*. The low threshold must be less than the high threshold.

useAdvancedTrainingSearch

```
void useAdvancedTrainingSearch(bool u);

bool useAdvancedTrainingSearch() const;
```

- `void useAdvancedTrainingSearch(bool u);`

  If *u* is true, CNLSearch models trained using this **ccCnlSearchTrainParams** object will use advanced training; if *u* is false, they will use standard model training.

  Parameters

  u Boolean parameter: if true use advanced training, if false use standard training

- `bool useAdvancedTrainingSearch() const;`

  Returns true if CNLSearch models trained using this **ccCnlSearchTrainParams** object will use advanced training, false if they will use standard model training.

  A default-constructed **ccCnlSearchTrainParams** will not use advanced training; you must explicitly enable it by using **useAdvancedTrainingSearch()**.

ccColor

```
#include <ch_cvl/color.h>

class ccColor;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class is used to specify colors. CVL allows you to describe colors two ways: as an RGB color composed of red, green, and blue components, or as an indexed color whose actual color depends on its index within a color table.

CVL provides sixteen stock colors that you can use in your application.

Constructors/Destructors

ccColor

```
ccColor(const ccRGB& color);
ccColor(c_UInt8 index = 0);
ccColor(c_UInt8 r, c_UInt8 g, c_UInt8 b);
```

- `ccColor(const ccRGB& color);`

  Creates a new RGB color.

  Parameters

  color The color object that specifies the RGB color.

- `ccColor(c_UInt8 index = 0);`

  Creates a new indexed color.

  Parameters

  index The index in the color palette used to specify this color.

- `ccColor(c_UInt8 r, c_UInt8 g, c_UInt8 b);`

  Creates a new RGB color.

Parameters

r	The red component. Must be a value from 0 to 255.
g	The green component. Must be a value from 0 to 255.
b	The blue component. Must be a value from 0 to 255.

Enumerations

These enumerated values specify the type of color.

Value	Meaning
eStockColor = 0x1	A CVL stock color
eRGBColor = 0x2	An RGB color
eIndexColor = 0x4	An index color

Operators

operator==

```
bool operator==(const ccColor& other) const;
```

Returns true if this color is equal to another color.

Parameters

other	The other color to compare to this color.

operator!=

```
bool operator!=(const ccColor& other) const;
```

Returns true if this color is not equal to another color.

Parameters

other	The other color to compare to this color.

Public Member Functions

isStockColor

```
bool isStockColor() const;
```

Returns true if this is one of the stock colors defined on page 1024. If this function returns true, then **isIndexColor()** and **isRGBColor()** will also return true.

isIndexColor `bool isIndexColor() const;`

Returns true if this color is an indexed color.

isRGBColor `bool isRGBColor() const;`

Returns true if this color is an RGB color.

Notes

Base class RGB getters return true only if this method is true.

index `c_UInt8 index() const;`

Returns the index of this color within the color map.

Notes

The result is valid only if the color is an indexed color such that **ccColor::isIndexColor()** is true. If not, **ccColor::index()** returns the value 0.

rgb `c_UInt32 rgb() const;`

Returns this color's RGB value as a single 32-bit value in the format `0x00rrggbb`.

Notes

The result is valid only if **isRGBColor()** is true. If it is not, the application terminates with an error message.

bgr `c_UInt32 bgr() const;`

Returns this color's RGB value as a single 32-bit value in the format `0x00bbggrr`.

Notes

The result is valid only if **isRGBColor()** is true. If it is not, the application terminates with an error message.

rgb15 `c_UInt16 rgb15() const;`

Returns this color's RGB value as a single "5-5-5" 16-bit value, using 5 bits for each component. The low-order 3 bits of each original component are ignored.

Notes

The result is valid only if **isRGBColor()** is true. If it is not, the application terminates with an error message.

rgb16 `c_UInt16 rgb16() const;`

Returns this color's RGB values as a single "5-6-5" 16-bit value, using 5 bits for the red component, 6 bits for this green component, and 5 bits for the blue component. The low-order bits of the original red and blue components and the low-order 2 bits of the green component are ignored.

Notes

The result is valid only if **isRGBColor()** is true. If it is not, the application terminates with an error message.

rgbStruct `const ccRGB& rgbStruct() const;`

Returns the **ccRGB** structure for this color.

Notes

The result is valid only if **isRGBColor()** is true. If it is not, the application terminates with an error message.

Static Functions

The following static functions return stock RGB colors that are available at static initialization time. Stock colors are defined as both indexed colors and RGB colors: **isRGBColor()** and **isIndexColor()** return true for these colors.

blackColor `static const ccColor& blackColor();`

dkGreyColor `static const ccColor& dkGreyColor();`

greyColor `static const ccColor& greyColor();`

ltGreyColor `static const ccColor& ltGreyColor();`

whiteColor `static const ccColor& whiteColor();`

redColor `static const ccColor& redColor();`

dkRedColor `static const ccColor& dkRedColor();`

orangeColor `static const ccColor& orangeColor();`

yellowColor `static const ccColor& yellowColor();`

greenColor `static const ccColor& greenColor();`

dkGreenColor `static const ccColor& dkGreenColor();`

cyanColor `static const ccColor& cyanColor();`

blueColor `static const ccColor& blueColor();`

purpleColor `static const ccColor& purpleColor();`

magentaColor `static const ccColor& magentaColor();`

passColor `static const ccColor& passColor();`

ccColorMatchDefs

```
#include <ch_cvl/colmatch.h>

class ccColorMatchDefs
```

Enumerations

ColorMatchColorDistanceMetric

```
enum ColorMatchColorDistanceMetric
```

This enumeration defines constants for the Color Match tool distance metric.

Value	Meaning
eWeightedEuclideanDistance = 0x1	The square root of the weighted sum of squared distance in each color plane. $\sqrt{\sum_{i=0,1,2} w_i(c1_i - c2_i)^2}$
kDefaultColorDistanceMetric = *eWeightedEuclideanDistance*	Default

ccColorMatchDefs

ccColorMatchResult

```
#include <ch_cvl/colmatch.h>

class ccColorMatchResult
```

Class Properties

Copyable	Yesy
Derivable	Yes
Archiveable	Simple

This class contains the results obtained by calling **cfColorMatch()** or **ccColorMatchTool::run()**.

Constructors/Destructors

ccColorMatchResult

```
ccColorMatchResult();
```

Creates a default ccColorMatchResult object with the following defaults:

Parameter	Default value
label	0
maxScore	0
confidenceScore	0
matchScores	empty vector
colorDistances	empty vector

Public Member Functions

maxScore

```
double maxScore() const;
```

Returns the maximum match score for al the color references in the color classification.The score ranges from 0.0 to 1.0, where 1.0 is a perfect match.

Notes

If there is only one reference color, the result is the match score for the reference color.

ccColorMatchResult

confidenceScore

```
double confidenceScore() const;
```

Return the confidence score of the color classification. The score ranges from 0.0 to 1.0, where 1.0 is the highest confidence.

Notes

Confidence is computed as:

$$\frac{\text{ghest score} - \text{second highest scor}}{\text{ghest score} + \text{second highest scor}}$$

label

```
c_Int32 label() const;
```

Returns the zero-based index that specifies the position of the color with the highest score in the color collection.

numberOfReferenceColors

```
c_Int32 numberOfReferenceColors() const;
```

Returns the number of color references used for color match.

matchScores

```
const cmStd vector<double>& matchScores() const;
```

Return the vector of match scores for all the color references.

ccColorMatchRunParams

```
#include <ch_cvl/colmatch.h>

class ccColorMatchRunParams
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class defines the parameters used by the Color Match tool: the color space used, the distance metric used to calculate the color distance, and the weights for each color component.

See **cfColorMatch()**.

Constructors/Destructors

ccColorMatchRunParams

```
ccColorMatchRunParams();
```

Creates a ccColorMatchRunParams object with the following default values:

Parameter	Default value
colorSpace	**ccColorSpaceDefs::kDefaultColorSpace**
distanceMetricType	**ccColorMatchDefs::eWeightedEuclideanDistance**
weights	(1.0, 1.0, 1.0)

Public Member Functions

distanceMetricType

```
ccColorMatchDefs::ColorMatchColorDistanceMetric
   distanceMetricType() const;

void distanceMetricType(
   ccColorMatchDefs::ColorMatchColorDistanceMetric
         distanceMetricType);
```

- `ccColorMatchDefs::ColorMatchColorDistanceMetric distanceMetricType() const;`

  Returns the distance metric used in color distance calculation.

- `void distanceMetricType( ccColorMatchDefs::ColorMatchColorDistanceMetric distanceMetricType);`

  Sets the distance metric used in color distance calculation.

  Parameters

  distanceMetricType
  The distance metric to use.

  Throws

  ccColorMatchDefs::BadParams
  distanceMetricType is not defined in **ccColorMatchDefs::ColorMatchColorDistanceMetric**.

colorSpace

```
ccColorSpaceDefs::ColorSpace colorSpace() const;

void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);
```

- `ccColorSpaceDefs::ColorSpace colorSpace() const;`

  Returns the color space used to perform color distance calculations.

- `void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);`

  Sets the color space used to perform color distance calculations.

  Parameters

  colorSpace The color space used: RGB or HSI.

Throws

ccColorMatchDefs::BadColorSpace
colorSpace is neither **ccColorSpaceDefs::eRGB** nor **ccColorSpaceDefs::eHSI**

weights

```
cc3Vect weights() const;
void weights(const cc3Vect& newValue);
```

- `cc3Vect weights() const;`

  Returns the weights used in calculating color distance for each color component.

- `void weights(const cc3Vect& newValue);`

  Sets the weights used in calculating color distance for each color component.

  Parameters

  newValue The weights.

  Throws

  ccColorMatchDefs::BadParams
  an element of *newValue* < 0
  newValue is (0,0,0)

ccColorMatchRunParams

ccColorRange

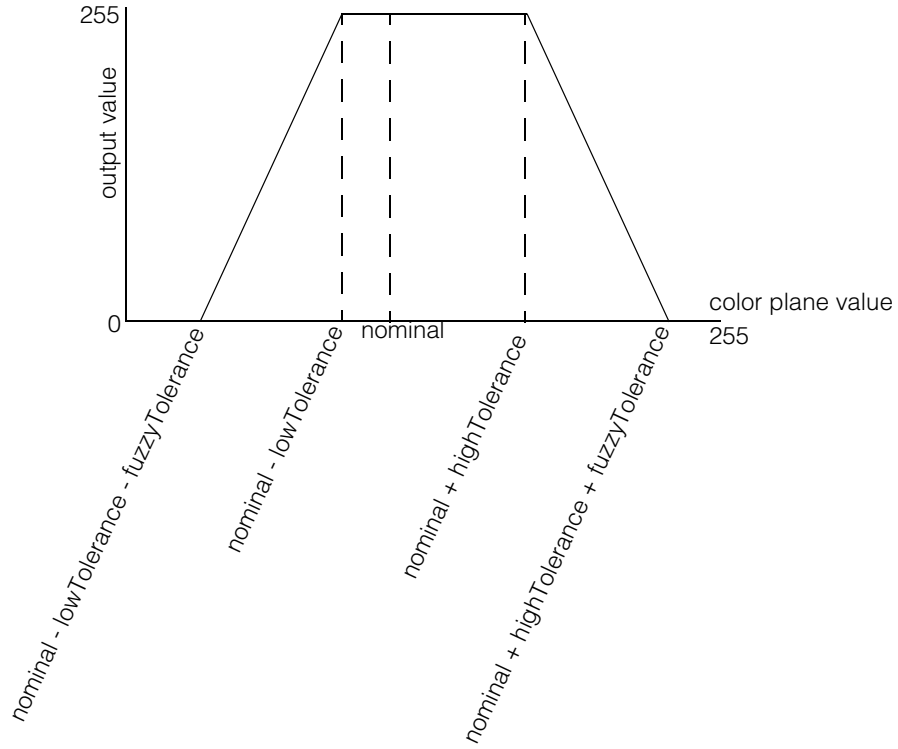
```
#include <ch_cvl/coltool.h>

class ccColorRange
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a color range that defines a nominal color value and high and low tolerance values.



Constructors/Destructors

ccColorRange `ccColorRange();`

Creates a color range object with the following default values:

Parameter	Default value
nominal	default **ccColorValue**
lowTolerance	(0,0.0)
highTolerance	(0,0,0)
fuzzyTolerance	(0,0,0)

Public Member Functions

nominal

```
ccColorValue nominal() const;
void nominal(const ccColorValue& newColor);
```

- `ccColorValue nominal() const;`

  Returns the nominal color value for this color range.

- `void nominal(const ccColorValue& newColor);`

  Sets the nominal color value for this color range.

  Parameters
  newColor The nominal color value.

lowTolerance

```
cc3Vect lowTolerance() const;
void lowTolerance(const cc3Vect& newValue);
```

- `cc3Vect lowTolerance() const;`

  Returns the low tolerance for this color range.

- `void lowTolerance(const cc3Vect& newValue);`

  Sets the low tolerance for this color range.

Parameters
newValue The low tolerance for this color range.

Throws
ccColorToolDefs::BadColorValue
one or more of the values in newValue is less than zero.

highTolerance

```
cc3Vect highTolerance() const;
void highTolerance(const cc3Vect& newValue);
```

- `cc3Vect highTolerance() const;`

  Returns the high tolerance for this color range.

- `void highTolerance(const cc3Vect& newValue);`

  Sets the high tolerance for this color range.

  Parameters
  newValue The high tolerance for this color range.

  Throws
  ccColorToolDefs::BadColorValue
  one or more of the values in newValue is less than zero.

fuzzyTolerance

```
cc3Vect fuzzyTolerance() const;
void fuzzyTolerance(const cc3Vect& newValue);
```

- `cc3Vect fuzzyTolerance() const;`

  Returns the fuzzy tolerance for this range.

- `void fuzzyTolerance(const cc3Vect& newValue);`

  Sets the fuzzy tolerance for this color range. Fuzzy tolerance is the same on both side of the nominal value.

  Parameters
  newValue The fuzzy tolerance for this color range.

  Throws
  ccColorToolDefs::BadColorValue
  one or more of the values in newValue is less than zero.

ccColorRange

ccColorSpaceDefs

```
#include <ch_cvl/colspace.h>
```

```
class ccColorSpaceDefs
```

A name space that decribes how a 3-plane color space is interpreted.

Enumerations

ColorSpace

```
enum ColorSpace
```

This enumeration defines how the values of a 3-plane image are interpreted.

Value	Meaning
eRGB = 0x1	Pixel values refer to RGB color space.
eHSI = 0x2	Pixel values refer to HSI color space.
eUnknown = 0x3	The color space is not known.

ccColorSpaceDefs

ccColorStatisticsParams

```
#include <ch_cvl/coltool.h>

class ccColorStatisticsParams
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class defines the values needed to compute color statistics from a three-plane color image. This class is used by

- **cfGetColorRangeFromImage()**
- **cfGetColorRangeFromImageRegion()**
- **cfGetColorStatisticsFromImage()**
- **cfGetColorStatisticsFromImageRegion()**
- **cfGetSimpleColorFromImage()**
- **cfGetSimpleColorFromImageRegion()**

Constructors/Destructors

ccColorStatisticsParams

```
ccColorStatisticsParams();

ccColorStatisticsParams(double minIntensity,
                        double minSaturation);
```

```
ccColorStatisticsParams();
```

Creates a default **ccColorStatisticsParams** with the following default values:

Parameter	Default value
minIntensity()	0
minSaturation()	0

```
ccColorStatisticsParams(double minIntensity,
                        double minSaturation);
```

Creates a **ccColorStatisticsParams** with the specified *minIntensity* and *minSaturationvalues*.

Parameters

minIntensity The minimum intensity value.

minSaturation The minimum saturation value.

Throws

ccColorToolDefs::BadParams
at least one parameter is less than zero.

Public Member Functions

minIntensity

```
double minIntensity() const;

void minIntensity(double newValue);
```

```
double minIntensity() const;
```

Returns the minimum intensity.

```
void minIntensity(double newValue);
```

Sets the minimum intensity.

Parameters

newValue The new minimum intensity.

Throws

ccColorToolDefs::BadParams
newvalue is less than zero.

minSaturation

```
double minSaturation() const;

void minSaturation(double newValue);
```

```
double minSaturation() const;
```

Returns the minimum saturation.

```
void minSaturation(double newValue);
```

Sets the minimum saturation.

Parameters

newValue The new minimum saturation.

Throws

ccColorToolDefs::BadParams
newvalue is less than zero.

ccColorStatisticsParams

ccColorStatisticsResult

```
#include <ch_cvl/coltool.h>

class ccColorStatisticsResult
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class is used by **cfGetColorStatisticsFromImage()** and **cfGetColorStatisticsFromImageRegion()** to return the mean color and standard deviations of an image.

Constructors/Destructors

ccColorStatisticsResult

```
ccColorStatisticsResult(){};
```

Creates a ccColorStatisticsResult object with the mean color set the the default XX and the standard deviation vector set to (0,0,0).

Public Member Functions

meanColor

```
ccColorValue meanColor() const { return meanColor_;}
```

Returns the mean color.

standardDeviation

```
cc3Vect standardDeviation() cons;
```

Returns the vector of standard deviations.

ccColorStatisticsResult

ccColorValue

```
#include <ch_cvl/coltool.h>

class ccColorValue
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes the value of a color as a triplet and specifies the color space of those values, typically RGB or HSI.

Constructors/Destructors

ccColorValue

```
ccColorValue();
```

Creates a color value using whose color values is (0,0,0) and whose color space is **ccColorSpaceDefs::kDefaultColorSpace**.

Public Member Functions

colorSpace

```
ccColorSpaceDefs::ColorSpace colorSpace() const;

void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);
```

- ```
  ccColorSpaceDefs::ColorSpace colorSpace() const;
  ```

  Returns the color space of the color value.

- ```
  void colorSpace(ccColorSpaceDefs::ColorSpace colorSpace);
  ```

  Sets the color space of the color value.

  Parameters

  colorSpace The color space.

  Throws

  ccColorToolDefs::BadColorSpace
  colorSpace is not defined in **ccColorSpaceDefs::ColorSpace**.

ccColorValue

colorValues

```
cc3Vect colorValues() const;
void colorValues(const cc3Vect& newValue);
```

- `cc3Vect colorValues() const;`

  Returns the three plane values that correspond to this color.

- `void colorValues(const cc3Vect& newValue);`

  Sets the three plane values that correspond for this color.

  Parameters

  newValue The 3-plane values

  Throws

  ccColorToolDefs::BadColorValue
  any of the values in *newValue* is less than zero

ccCompleteCallbackProp

```
#include <ch_cvl/prop.h>

class ccCompleteCallbackProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

As of CVL 6.1, this class is one of two ways to register a callback class for the complete state:

Method	Features	See
ccAcqFifo:: completeInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	*completeInfoCallback* on page 232
ccCompleteCallbackProp	Calls your callback function.	this section

If you are writing a new CVL application, consider using **ccAcqFifo::completeInfoCallback()** to register your completion callback function.

This class describes the completion callback property of an acquisition FIFO queue. The class contains a pointer to a function you write that is called by the acquisition engine when acquisition is complete.

The callback function you write should set flags or semaphores in your application that allow your program to proceed to another state the next time it executes. Your callback function is executed internally by the acquisition software, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

An acquisition enters the complete state (**ccAcqFifo::isComplete()** returns true) when the next invocation of **ccAcqFifo::baseComplete()** would return the acquired image (if the acquisition was successful) or an unbound pel buffer (if the acquisition was not successful).

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccCompleteCallbackProp

```
ccCompleteCallbackProp();

ccCompleteCallbackProp(const ccCallbackPtrh& callback);
```

- `ccCompleteCallbackProp();`

  Creates a new acquisition complete callback property not associated with any FIFO. The default callback function is an unbound handle, meaning no callback function is invoked.

- `ccCompleteCallbackProp(const ccCallbackPtrh& callback);`

  Creates a new acquisition complete callback property not associated with any FIFO, registering the function pointed to by *callback* as the completion callback function.

  Parameters

  callback — Effectively, the callback function to be invoked when the acquisition process enters the complete state. This is generally when the next invocation of **ccAcqFifo::baseComplete()** would return the acquired image (if the acquisition is successful). An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

  Notes

  The acquisition complete callback function is invoked whether the acquisition completed successfully or not.

Public Member Functions

completeCallback

```
void completeCallback(const ccCallbackPtrh& callback);

const ccCallbackPtrh& completeCallback() const;
```

- `void completeCallback(const ccCallbackPtrh& callback);`

  callback points to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

  Parameters

callback	Effectively, the callback function to be invoked when the acquisition process enters the complete state. This is generally when the next invocation of **ccAcqFifo::baseComplete()** would return the acquired image (if the acquisition is successful). An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

  Notes

  The acquisition complete callback function is invoked whether the acquisition completed successfully or not.

- `const ccCallbackPtrh& completeCallback() const;`

  Returns the callback function to be invoked when the acquisition enters the completed state.

ccCompleteCallbackProp

ccCompositeColorMatchRunParams

```
#include <ch_cvl/colmatch.h>

class ccCompositeColorMatchRunParams
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes the parameters used to run the Composite Color Match tool.

Constructors/Destructors

ccCompositeColorMatchRunParams

```
ccCompositeColorMatchRunParams();
```

Creates a **ccCompositeColorMatchRunParams** with the following default values:

Parameter	Default value
normalizeIntensity	False
matchingAccuracy	1.0

Public Member Functions

normalizeIntensity

```
bool normalizeIntensity() const;

void normalizeIntensity(bool newValue);
```

- `bool normalizeIntensity() const;`

  Returns whether the Composite Color Match tool should normalize the image intensity.

- `void normalizeIntensity(bool newValue);`

  Sets whether the Composite Color Match tool should normalize the image intensity.

Parameters

newValue True to normalize intensity, False otherwise. The default is False.

matchingAccuracy

```
double matchingAccuracy() const;

void matchingAccuracy(double newValue);
```

- `double matchingAccuracy() const;`

  Returns the matching accuracy,

- `void matchingAccuracy(double newValue);`

  Sets the matching accuracy,

  Parameters

  newValue The matching accuracy.

  Throws

  ccColorMatchDefs::BadParams
  newValue > 1 or <= 0

ccCompositeColorMatchTool

```
#include <ch_cvl/colmatch.h>

class ccCompositeColorMatchTool;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

Use this tool for composite color matching. For simple color matching, use **cfColorMatch()**.

The composite color tool compares the color content of images, Images with the same or similar color distribution (similar color content) are considered with good match.

Constructors/Destructors

ccCompositeColorMatchTool

```
ccCompositeColorMatchTool();
```

Creates an untrained **ccCompositeColorMatchTool** object

Public Member Functions

train

```
void train(
   const cmStd vector<cc3PlanePelBuffer>& colorImages,
   const ccCompositeColorMatchTrainParams& trainParams);

void train(
   const cmStd vector<cc3PlanePelBuffer>& colorImages,
   const cmStd vector<ccShapePtrh> & regions,
   const ccCompositeColorMatchTrainParams& trainParams);

void train(
   const cmStd vector<cc3PlanePelBuffer>& colorImages,
   const cmStd vector<ccPelBuffer_const<c_UInt8> >& masks,
   const ccCompositeColorMatchTrainParams& trainParams);

void train(
   const cc3PlanePelBuffer& colorImage,
   const ccCompositeColorMatchTrainParams& trainParams);
```

- ```
  void train(
     const cmStd vector<cc3PlanePelBuffer>& colorImages,
     const ccCompositeColorMatchTrainParams& trainParams);
  ```

  Trains the *colorImages* using the *trainParams*. If the tool is already trained, it is untrained and retrained.

  Parameters

  colorImages The images used to train.

  trainParams A **ccCompositeColorMatchTrainParams** object that specifies the sampling percentage and the size of the Gaussian smoothing kernel used to train the images.

  Throws

  ccColorMatchDefs::BadParams
  colorImages is empty.

  ccColorMatchDefs::BadImage
  colorImages contains an unbound image.

  ccColorMatchDefs::NotEnoughSamples
  Not enough pels (< 1) in the image.

  ccColorMatchDefs::BadColorSpace
  colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.
  ```

- ```
  void train(
     const cmStd vector<cc3PlanePelBuffer>& colorImages,
     const cmStd vector<ccShapePtrh> & regions,
     const ccCompositeColorMatchTrainParams& trainParams);
  ```

  Trains the portion of *colorImages* that intersect the corresponding region using the *trainParams*. If the tool is already trained, it is untrained and retrained.

  Parameters

  colorImages The images used to train.

  regions A vector of shapes that defines a region for each image. If a region is NULL, the whole image is used.

  trainParams A **ccCompositeColorMatchTrainParams** object that specifies the sampling percentage and the size of the Gaussian smoothing kernel used to train the images.

  Throws

  ccColorMatchDefs::BadParams
  colorImages is empty.

  ccColorMatchDefs::BadParams
  The number of images in *colorImages* does not match the number of regions in *regions*.

  ccColorMatchDefs::BadImage
  colorImages contains an unbound image.

  ccColorMatchDefs::NotEnoughSamples
  Not enough pels (< 1) in the image.

  ccColorMatchDefs::BadColorSpace
  colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.

  ccColorMatchDefs::ShapeIsNotRegion
  one of the regions in *regions* is not a region shape.

- ```
  void train(
     const cmStd vector<cc3PlanePelBuffer>& colorImages,
     const cmStd vector<ccPelBuffer_const<c_UInt8> >& masks,
     const ccCompositeColorMatchTrainParams& trainParams);
  ```

  Trains the portion of *colorImages* that are described by the corresponding mask using the *trainParams*. If the tool is already trained, it is untrained and retrained.

Parameters

colorImages The images used to train.

masks A vector of image masks. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

trainParams A **ccCompositeColorMatchTrainParams** object that specifies the sampling percentage and the size of the Gaussian smoothing kernel used to train the images.

Throws

ccColorMatchDefs::BadParams
colorImages is empty.

ccColorMatchDefs::BadParams
The number of images in *colorImages* does not match the number of masks in *masks*.

ccColorMatchDefs::BadImage
colorImages contains an unbound image.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image.

ccColorMatchDefs::BadColorSpace
colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.

ccColorMatchDefs::ShapeIsNotRegion
one of the regions in *regions* is not a region shape.

- ```
  void train(
     const cc3PlanePelBuffer& colorImage,
     const ccCompositeColorMatchTrainParams& trainParams);
  ```

Trains the *colorImage* using the *trainParams*. If the tool is already trained, it is untrained and retrained.

Parameters

colorImages The image used to train.

trainParams A **ccCompositeColorMatchTrainParams** object that specifies the sampling percentage and the size of the Gaussian smoothing kernel used to train the images.
  ```

Throws

ccColorMatchDefs::BadImage
colorImage is unbound.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image.

ccColorMatchDefs::BadColorSpace
colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.

untrain

```
void untrain();
```

Untrains the tool and releases any memory that was required for training. This function has no effect if the tool is already untrained.

isTrained

```
bool isTrained() const;
```

Returns True if the tool is trained; False otherwise.

run

```
void run(const cc3PlanePelBuffer &image,
         const ccCompositeColorMatchRunParams &runParams,
         ccColorMatchResult &result) const;

void run(const cc3PlanePelBuffer &image,
         const ccShapePtrh& region,
         const ccCompositeColorMatchRunParams &runParams,
         ccColorMatchResult &result) const;

void run(const cc3PlanePelBuffer &image,
         const ccPelBuffer_const<c_UInt8>& mask,
         const ccCompositeColorMatchRunParams &runParams,
         ccColorMatchResult &result) const;
```

-
```
void run(const cc3PlanePelBuffer &image,
         const ccCompositeColorMatchRunParams &runParams,
         ccColorMatchResult &result) const;
```

Runs the color match tool on *image* using the specified *runParams* and returns the results in *result*.

Parameters

image The color image.

runParams A **ccCompositeColorMatchRunParams** object the specifies the matching accuracy and whether the tool should normalize intensity

result A **ccColorMatchResult** object that contains the results of running the tool.

Throws

ccColorMatchDefs::BadImage
image is unbound.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image.

ccColorMatchDefs::BadColorSpace
colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.

- ```
  void run(const cc3PlanePelBuffer &image,
           const ccShapePtrh& region,
           const ccCompositeColorMatchRunParams &runParams,
           ccColorMatchResult &result) const;
  ```

Runs the color match tool on the intersection of *image* and *region* using the specified *runParams* and returns the results in *result*.

Parameters

image The color image.

region A shape that defines a region. If *region* is NULL, the whole image is used.

runParams A **ccCompositeColorMatchRunParams** object the specifies the matching accuracy and whether the tool should normalize intensity

result A **ccColorMatchResult** object that contains the results of running the tool.

Throws

ccColorMatchDefs::BadImage
image is unbound.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image.

ccColorMatchDefs::BadColorSpace
colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.

ccColorMatchDefs::ShapeIsNotRegion
region is not a region shape.
  ```

- ```
  void run(const cc3PlanePelBuffer &image,
           const ccPelBuffer_const<c_UInt8>& mask,
           const ccCompositeColorMatchRunParams &runParams,
           ccColorMatchResult &result) const;
  ```

  Runs the color match tool on *image* using the *mask* and the specified *runParams* and returns the results in *result*.

  Parameters

  image — The color image.

  mask — An image mask. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

  runParams — A **ccCompositeColorMatchRunParams** object the specifies the matching accuracy and whether the tool should normalize intensity

  result — A **ccColorMatchResult** object that contains the results of running the tool.

  Throws

  ccColorMatchDefs::BadImage
  image or *mask* is unbound.
  image window is not the same as *mask* window
  mask contains pel whose values are other than 0 and 255

  ccColorMatchDefs::NotEnoughSamples
  Not enough pels (< 1) in the image.

  ccColorMatchDefs::BadColorSpace
  colorImages contains an image whose color space is not **ccColorSpaceDefs::eRGB**.
  ```

ccCompositeColorMatchTool

ccCompositeColorMatchTrainParams

```
#include <ch_cvl/colmatch.h>

class ccCompositeColorMatchTrainParams
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes the parameters used to train the Composite Color Match tool.

ccCompositeColorMatchTrainParams

```
ccCompositeColorMatchTrainParams(
      double samplingPercentage,
      c_Int32 gaussianSmoothing);
```

Creates a **ccCompositeColorMatchTrainParams** object with the following default values:

Parameter	Default value
samplingPercentage	100.0
gaussianSmoothing	0

Public Member Functions

samplingPercentage

```
double samplingPercentage() const;

void samplingPercentage(double newValue);
```

- `double samplingPercentage() const;`

  Returns the sampling percentage.

- `void samplingPercentage(double newValue);`

  Sets the sampling percentage to use in composite color training.

Parameters
newValue The percentage.

Throws
ccColorMatchDefs::BadParams
newValue is greater than 100 or less than or equal to 0

gaussianSmoothing

```
c_Int32 gaussianSmoothing() const;

void gaussianSmoothing(c_Int32 newValue);
```

- `c_Int32 gaussianSmoothing() const;`

  Returns the size of the Gaussian smoothing kernel.

- `void gaussianSmoothing(c_Int32 newValue);`

  Sets the size of the Gaussian smoothing kernel.

  Parameters
  newValue The kernel size.

  Throws
  ccColorMatchDefs::BadParams
  newValue is greater than 24 or less than 0

ccConStream

```
#include <ch_cvl/constrea.h>

class ccConStream: public ccCvlOStream;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

The **ccConStream** class implements a console with which you can perform stream-based output. You can use a **ccConStream** to print text messages and other output in a scrolling text window on the host system.

You cannot use a **ccConStream** to display output on an embedded display, only on the host system.

You cannot obtain input using a **ccConStream**.

Constructors/Destructors

ccConStream

```
ccConStream(const TCHAR* consoleTitle,
  c_UInt32 consoleStyle = 0, c_UInt32 bufferSize = 20000);

ccConStream(const TCHAR* consoleTitle,
  c_UInt32 width, c_UInt32 height, c_UInt32 xPos,
  c_UInt32 yPos, c_UInt32 consoleStyle = 0,
  c_UInt32 buffersize = 20000);

~ccConStream();
```

- ```
  ccConStream(const TCHAR* consoleTitle,
    c_UInt32 consoleStyle = 0, c_UInt32 bufferSize = 20000);
  ```

  Creates a new console window at the default location and with the default size. The default console location is the upper-left corner of the screen.

  Parameters

  consoleTitle The title to display in the console window's title bar.

  consoleStyle The console style. *consoleStyle* must be formed by ORing together one or more of the following values:
  ```

ccGUI::kStyleCreateNormal
ccGUI::kStyleCreateMinimized
ccGUI::kStyleCreateMaximized
ccGUI::kStyleCreateGUI
ccGUI::kStyleCreateNow
ccGUI::kStyleCreateOnOutput
ccGUI::kStyleCloseIsHide

If *consoleStyle* does not include *ccGUI::kStyleCreateGUI*, then output sent through this **ccConStream** will be sent to **cout**, if it is available. If **cout** is not available, then a console window is created when output is sent.

If *consoleStyle* includes *ccGUI::kStyleCreateGUI*, then the console window is created immediately if *consoleStyle* includes *ccGUI::kStyleCreateNow*. If *consoleStyle* does not include *ccGUI::kStyleCreateNow*, then the console window is not created until output is sent through this **ccConStream**.

bufferSize — The number of bytes to store in the scroll back area of the console.

- ```
  ccConStream(const TCHAR* consoleTitle,
    c_UInt32 width, c_UInt32 height, c_UInt32 xPos,
    c_UInt32 yPos, c_UInt32 consoleStyle = 0,
    c_UInt32 buffersize = 20000);
  ```

  Creates a new console window at the specified location and with the specified size.

  Parameters

  consoleTitle — The title to display in the console window's title bar.

  width — The width of the console window in host display pixels. *width* includes the width of the GUI elements included with the console such as scroll bars.

  height — The height of the console window in host display pixels. *height* includes the height of the GUI elements included with the console such as scroll bars.

  xPos — The x-position of the upper-left corner of the console window in host display pixels.

  yPos — The y-position of the upper-left corner of the console window in host display pixels.

  consoleStyle — The console style. *consoleStyle* must be formed by ORing together one or more of the following values:
  ```

ccGUI::kStyleCreateNormal
ccGUI::kStyleCreateMinimized
ccGUI::kStyleCreateMaximized
ccGUI::kStyleCreateGUI
ccGUI::kStyleCreateNow
ccGUI::kStyleCreateOnOutput
ccGUI::kStyleCloseIsHide

If *consoleStyle* does not include *ccGUI::kStyleCreateGUI*, then output sent through this **ccConStream** will be sent to **cout**, if it is available. If **cout** is not available, then a console window is created when output is sent.

If *consoleStyle* includes *ccGUI::kStyleCreateGUI*, then the console window is created immediately if *consoleStyle* includes *ccGUI::kStyleCreateNow*. If *consoleStyle* does not include *ccGUI::kStyleCreateNow*, then the console window is not created until output is sent through this **ccConStream**.

bufferSize — The number of bytes to store in the scroll back area of the console.

Notes

Depending on the host operating system and environment, the console title, style, size and position arguments may or may not be used.

The **Close** command and close box in console windows created by this constructor are disabled by default. You can enable the **Close** command and close box in a console window by calling the **release()** function.

- `~ccConStream();`

Destroys and cleans up any GUI elements created to support this console. If you are transcripting this console to a **ccCvlOStream**, any buffered text is flushed to that **ccCvlOStream**.

Public Member Functions

useGUI

```
void useGUI(bool use);
bool useGUI() const;
```

- `void useGUI(bool use);`

Sets this **ccConStream** to use a GUI console window or to use **cout**. By default, a **ccConStream** sends its output to **cout**. If **cout** is not available, the **ccConStream** creates and uses a console window. You can force a **ccConStream** to create and use a console window by calling this function with a value of true.

You can also control this behavior at construction time using the *consoleStyle* argument to the constructor.

Parameters

use	If true, a console window is always created. If false, output is sent to **cout** if it is available and any existing console window is closed.

Notes

The *consoleStyle* argument to the **ccConStream** constructor determines whether the console window is created immediately or at the time that output is first sent to it.

- `bool useGUI() const;`

Returns true if this **ccConStream** is configured to always create and use a GUI console window; returns false if this **ccConStream** is configured to use **cout** if available.

release

```
void release();
```

Enables the **Close** command and close box in this console window. Until you call this function, a user cannot close a console window interactively.

You should not send any data to a **ccConStream** after calling this function.

bringToTop

```
void bringToTop();
```

Places this **ccConStream**'s console window in front of all other overlapping windows. If this **ccConStream**'s console window is minimized, it is restored, then brought to the front.

Notes

If this **ccConStream** is not using a console window, then this function has no effect.

windowRect

```
ccPelRect windowRect();
void windowRect(const ccPelRect& rect);
```

- `ccPelRect windowRect();`

  Returns a rectangle that describes the overall size and location of this **ccConStream**'s console window. The locations are in the screen pixel coordinate system.

- `void windowRect(const ccPelRect& rect);`

  Sets the overall size and location of this **ccConStream**'s console window to be the supplied rectangle. The locations are in screen pixels.

  Parameters

  rect — A **ccPelRect** describing the location of the console window in screen pixel coordinates.

  Notes

  If this **ccConStream** is not using a console window, the values are saved and used the next time a console window is created for this **ccConStream**.

minimize

```
bool minimize() const;
void minimize(bool flag);
```

- `bool minimize() const;`

  Return true if this **ccConStream**'s console window is minimized, false otherwise.

  Notes

  If this **ccConStream** is not using a console window, the value indicates whether a newly created console window will be minimized or not.

- `void minimize(bool flag);`

  Either minimizes or restores the state of this **ccConStream**'s console window.

  Parameters

  flag — If true, this **ccConStream**'s console window is minimized. If false, this **ccConStream**'s console window is restored.

  Notes

  If this **ccConStream** is not using a console window, the value determines whether a newly created console window will be minimized or not.

font

```
void font(c_UInt32 f);
c_UInt32 font(void) const;
```

- `void font(c_UInt32 f);`

  Sets the font to use to display text in this **ccConStream**'s console window. The font representation depends on the host operating system.

  Parameters

  f The font to use.

  Notes

  If this **ccConStream** is not using a console window, the value you specify is used when a new console window is created.

- `c_UInt32 font() const;`

  Returns the font used to display text in this **ccConStream**'s console window. The font representation depends on the host operating system.

transcript

```
ccCvlOStream* transcript() const;
void transcript(ccCvlOStream *stream);
```

- `ccCvlOStream* transcript() const;`

  Returns the **ccCvlOStream** to which data sent to this **ccConStream** is being transcripted.

- `void transcript(ccCvlOStream *stream);`

  Specifies that all data sent to this **ccConStream** be copied to the supplied **ccCvlOStream**.

  Parameters

  stream The **ccCvlOStream** to use. If you supply 0 for *stream*, no transcripting is performed.

clear

```
void clear(bool wait = false);
```

Clears all text from this **ccConStream**'s console window. You can specify that the text be cleared immediately or that it be cleared just before the next time output is sent to this **ccConStream**'s console window.

Parameters

wait	If true, do not clear the text until just before the next output is sent to the console window.

Notes

If this **ccConStream** is not using a console window, this function has no effect.

Functions

cfCogOut

```
ccConStream& cfCogOut();
```

Returns a **ccConStream** that refers to Cognex standard output.

cfCogDebug

```
ccConStream& cfCogDebug();
```

Returns a **ccConStream** that refers to Cognex debugging output.

ccContourTree

```
#include <ch_cvl/shaptree.h>

class ccContourTree : public ccShapeTree;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccContourTree** class is a concrete class for maintaining hierarchies of connectable (open contour) shapes, joined into a composite shape that may be open or closed. Generally, the base class methods of **ccShape** are implemented by treating the complete composite shape as a single contour, just like any primitive contour.

The children of a **ccContourTree** can be either primitive or hierarchical, but must all be open contours. Currently, the only non-primitive shapes that are open contours are themselves open **ccContourTree**s.

There is an implied ordering of primitives in a **ccContourTree** defined as the order in which the primitives, which are necessarily all leaf nodes, are encountered during a standard traversal of the tree. Two primitives are adjacent if they are adjacent in the ordered list of primitives.

The **ccContourTree** class assumes that the endpoint of one child is approximately equal to the start point of the next child, and if the **ccContourTree** is closed that the endpoint of the last child is approximately equal to the start point of the first child. Because of floating point inaccuracies, exact equality is not enforced. For example, decomposing a **ccGenRect** yields a valid **ccContourTree**, even though the rounded corner endpoints may not exactly coincide with the straight side endpoints. Such small discrepancies do not pose a problem. However, since coincidence of endpoints is not enforced, it is possible (though not advised) to create **ccContourTree**s with gaps between the endpoints of adjacent children that are large relative to the scale of the children themselves. This may produce unpredictable results, as many **ccContourTree** methods (for example, **sample()** and **isRightHanded()**) assume that the gaps are of negligible size.

Constructors/Destructors

```
explicit ccContourTree(bool closed = false);
```

Constructs a **ccContourTree** containing no children, with the given open/closed status. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

closed — If true, a closed **ccContourTree** is constructed; if false (the default), an open **ccContourTree** is constructed.

Notes

Copies and assignments are shallow, that is, they are achieved by copying pointer handles. Hence, these operations lead to sharing of children between different **ccShapeTree**s.

Operators

operator==

```
bool operator==(const ccContourTree &rhs) const;
```

Returns true if and only if this **ccContourTree** is equal to *rhs*. Two **ccContourTree**s are equal if they are equal as **ccShapeTree**s, and if they are either both open or both closed.

Public Member Functions

isClosed

```
bool isClosed() const;
void isClosed(bool closed);
```

- `bool isClosed() const;`

Gets the open/closed status of this **ccContourTree**. A **ccContourTree** is open if and only if it is not closed.

Notes

ccContourTrees are open by default.

- `void isClosed(bool closed);`

Sets the open/closed status of a **ccContourTree**.

Parameters

closed — If true, the **ccContourTree** is set to closed; if false, it is set to open.

insertChild

```
virtual void insertChild(c_Int32 idx,
  const ccShape &child);

virtual void insertChild(c_Int32 idx,
  const ccShapePtrh_const &child, bool direct = false);
```

- ```
  virtual void insertChild(c_Int32 idx,
    const ccShape &child);
  ```

  Inserts the given child into this **ccContourTree** at the given index.

  Parameters

  idx The index.

  child The child to insert.

  Throws

  ccShapesError::BadGeom
  An attempt was made to insert a child that is not an open contour.

  ccShapesError::BadIndex
  idx is less than zero or greater than **numChildren()** before the insertion.

  See **ccShapeTree::insertChild()** for more information.

- ```
  virtual void insertChild(c_Int32 idx,
    const ccShapePtrh_const &child, bool direct = false);
  ```

  Inserts the given child into this **ccContourTree** at the given index. The child is inserted by copy insertion or direct insertion, depending on the status of the *direct* flag.

  Parameters

  idx The index.

  child The child to insert.

  direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

  Throws

  ccShapesError::BadGeom
  An attempt was made to insert a child that is not an open contour.

  ccShapesError::BadIndex
  idx is less than zero or greater than **numChildren()** before the insertion.

See **ccShapeTree::insertChild()** for more information.

insertChildren

```
virtual void insertChildren(c_Int32 idx,
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Inserts the given children into this **ccContourTree** at the given index. The children are inserted by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

idx The index.

children The vector of children to insert.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to insert a child that is not an open contour.

ccShapesError::BadIndex
idx is less than zero or greater than **numChildren()** before the insertion.

See **ccShapeTree::insertChildren()** for more information.

---

addChild

```
virtual void addChild(const ccShape &child);

virtual void addChild(const ccShapePtrh_const &child,
  bool direct = false);
```

- ```
  virtual void addChild(const ccShape &child);
  ```

  Appends the given child to the end of this **ccContourTree**.

  Parameters

  child The child to add.

  Throws

  ccShapesError::BadGeom
  An attempt was made to add a child that is not an open contour.

  See **ccShapeTree:addChild()** for more information.
  ```

- ```
  virtual void addChild(const ccShapePtrh_const &child,
    bool direct = false);
  ```

  Appends the given child to the end of this **ccContourTree**. The child is added by copy insertion or direct insertion, depending on the status of the *direct* flag.

  Parameters

  child — The child to add.

  direct — If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

  Throws

  ccShapesError::BadGeom
  An attempt was made to add a child that is not an open contour.

  See **ccShapeTree::addChild()** for more information.

addChildren

```
virtual void addChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Appends the given children to the end of this **ccContourTree**. The children are added by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

children — The vector of children to add.

direct — If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to add a child that is not an open contour.

See **ccShapeTree::addChildren()** for more information.
```

replaceChild

```
virtual void replaceChild(c_Int32 idx,
  const ccShape &child);

virtual void replaceChild(c_Int32 idx,
  const ccShapePtrh_const &child, bool direct = false);
```

- ```
  virtual void replaceChild(c_Int32 idx,
    const ccShape &child);
  ```

  Replaces the child at the given index with the given child.

  Parameters

  idx The index.

  child The child replacing the indexed child.

  Throws

  ccShapesError::BadGeom
  An attempt was made to replace with a child that is not an open contour.

  ccShapesError::BadIndex
  idx is less than zero or greater than or equal to **numChildren()** before the replacement.

  See **ccShapeTree::replaceChild()** for more information.

- ```
  virtual void replaceChild(c_Int32 idx,
    const ccShapePtrh_const &child, bool direct = false);
  ```

  Replaces the indexed child with the given child. The child is replaced by copy insertion or direct insertion, depending on the status of the *direct* flag.

  Parameters

  idx The index.

  child The child replacing the indexed child.

  direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to replace with a child that is not an open contour.

ccShapesError::BadIndex
idx is less than zero or greater than or equal to **numChildren()** before the replacement.

See **ccShapeTree::replaceChild()** for more information.

replaceChildren

```
virtual void replaceChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Replaces all of the children of this **ccContourTree** with the given children. The children are replaced by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

children The vector of children replacing the current children.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to replace with a child that is not an open contour.

See **ccShapeTree::replaceChildren()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this contour tree.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if and only if this **ccContourTree** is open overall, and has at least one primitive shape. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if and only if this **ccContourTree** is closed overall, and not empty. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

For **ccContourTree**s, this function always returns true. All open contours are necessarily finite. See **ccShape::isFinite()** for more information.

startPoint `virtual cc2Vect startPoint() const;`

Returns the start point of the first primitive in the hierarchy if this **ccContourTree** is open.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this **ccContourTree**.

See **ccShape::startPoint()** for more information.

endPoint `virtual cc2Vect endPoint() const;`

Returns the end point of the last primitive in the hierarchy if this **ccContourTree** is open.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this **ccContourTree**.

See **ccShape::endPoint()** for more information.

startAngle `virtual ccRadian startAngle() const;`

Returns the start angle of the first primitive in the hierarchy if this **ccContourTree** is open.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this contour tree.

ccShapesError::NoTangent
hasTangent() is false for this contour tree.

See **ccShape::startAngle()** for more information.

endAngle `virtual ccRadian endAngle() const;`

Returns the end angle of the last primitive in the hierarchy if this **ccContourTree** is open.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this **ccContourTree**.

ccShapesError::NoTangent
hasTangent() is false for this contour tree.

See **ccShape::endAngle()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Reverses the individual primitives of the hierarchy, and their order within the hierarchy. See **ccShape::reverse()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns the net signed angle through which the tangent vector rotates along this **ccContourTree** from the start point to the end point.

Throws
ccShapesError::NoTangent
hasTangent() is false for this contour tree.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve from the start point to the end point of this **ccContourTree**.

Parameters
p The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

See **ccShape::windingAngle()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the given point is within the region defined by this **ccContourTree**, if it is a closed shape.

Parameters
p The point.

Throws
ccShapesError::NotRegion
This contour tree is not a region.

See **ccShape::within()** for more information.

isRightHanded `virtual bool isRightHanded() const;`

Returns true if this **ccContourTree** is both right-handed and closed.

Throws

ccShapesError::NotRegion
This contour tree is not a region.

Notes

The return value of this function is undefined for self-intersecting **ccContourTree**s.

See **ccShape::isRightHanded()** for more information.

isReversible `virtual bool isReversible() const;`

For **ccContourTree**s, this function always returns true.

Notes

A **ccContourTree** can be reversed even when it is closed.

See **ccShape::isReversible()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this **ccContourTree** to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
 ccShape::ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this **ccContourTree**.

Parameters

params	Parameters object specifying details of how the sampling should be done.
result	Result object to which position and tangent chains are stored.

Notes

A single chain is generated for the entire **ccContourTree**.

See **ccShape::sample()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this contour tree over the given perimeter range.

Parameters

info Shape information for this contour tree.

range The perimeter range.

See **ccShape::subShape()** for more information.

ccContrastBrightnessProp

```
#include <ch_cvl/prop.h>

class ccContrastBrightnessProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a property that controls the contrast and brightness of a digitizer associated with an acquisition FIFO.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

This property does not apply to users of digital cameras on CVM6, CVM9, and CVM11. You can adjust contrast and brightness on these cameras with switches or a menu interface provided by the camera manufacturer. Consult your camera's documentation for the right procedure for your camera. Users of the Dalsa Spyder SP-xx series on CVM11 can also use **ccDigitalCameraControlProp::selectHighGain()** to adjust gain.

Contrast and brightness values control how light levels are mapped to pixel values. With 8-bit images, all light levels entering the camera must be mapped to pixel values from 0 to 255. The contrast setting determines how light levels are mapped to the 256 pixel values. Brightness determines where the center of the contrast mapping window falls relative to the range of pixel values. The mapping behavior differs depending on which analog-to-digital conversion chip (ADC) is used by the frame grabber hardware.

Fusion™ 878A Based Hardware

Cognex hardware that uses the Fusion™ 878A ADC includes the MVS-8100L. With this type of hardware, pixel value changes caused by contrast and brightness settings are applied after the A/D conversion takes place. Contrast values map to a digital multiplier, or gain, that is applied to the converted value. Brightness values map to a digital offset.

With Fusion™ 878A based hardware, *gain* is a value between 1 and 3.

Contrast	Gain
0.00	1x
0.25	1.5x
0.50	2x
0.75	2.5x
1.00	3x

The gain is calculated as follows:

*gain = 2.0 * contrast + 1.0*

With Fusion™ 878A based hardware, *offset* is a value between -128 and +127.

Brightness	Offset
0.00	-128
0.25	-64
0.50	0
0.75	+64
1.00	+127

The offset is calculated as follows:

*offset = (2 * 255 * brightness + 1)/2 - 128*

In both cases, the result is truncated to the nearest integer going towards zero. Once gain and offset values are calculated, the calculation performed to convert the digitized levels to pixel values is as follows:

pixel_value = (*digitized_level* ∗ *gain*) + *offset*

An adjusted level is first calculated from (*digitized_level* ∗ *gain*), and then an *offset* is applied to the intermediate result. At all stages of the calculation, the value must be kept within the range of 0 through 255. To keep the value within this range, a clipping algorithm is applied to both the adjusted level and the final pixel value:

adjusted_level = *digitized_level* ∗ *gain;*

if (*adjusted_level* > 255) *adjusted_level* = 255;

pixel_value = *adjusted_level* + *offset*;

if (*pixel_value* > 255) *pixel_value* = 255;

if (*pixel_value* < 0) *pixel_value* = 0;

Note The above calculation is performed entirely in hardware. It cannot be controlled in software.

TI THS8083A Based Hardware

Cognex hardware that uses the Texas Instruments THS8083A ADC includes the MVS-8501/8504, MVS-8504e, MVS-8500Le, MVS-8102, and CVM14. With these frame grabbers, contrast settings are translated into an analog gain or multiplier, and brightness settings map to a digital offset.

The THS8083A has 1.6 V as its internal full scale. This is why the minimum gain is 1.33, so that a 1.2 V input will be increased to 1.6 V. In other words, the device's designed input range is 0.4 to 1.2 V.

With THS8083A based hardware, gain is a value between 1.33 and 3.96.

Contrast	Gain
0.00	1.33x
0.25	2.0x
0.50	2.64x
0.75	3.3x
1.00	3.96x

The gain is calculated as follows:

*gain = (4/3 + (63 * contrast)/24) * (1.002)*

With THS8083A based hardware, offset is a value between -64 to +63.

Brightness	Offset
0.00	-64
0.25	-32
0.50	0
0.75	+32
1.00	+63

The offset is calculated as follows:

*offset = (brightness * 255) / 2 - 64*

TI TVP7002 Based Hardware

Cognex hardware that uses the Texas Instruments TVP7002 ADC includes the MVS-8510 grabbers (MVS-8511, 8514, 8511e, and 8514e). With these frame grabbers, contrast settings are translated into a combination of analog and digital gain, and brightness settings map to a digital offset.

The TVP7002 has 1.0 V as its internal full scale. This is why the minimum gain is 0.83, so that a 1.2 V input will be reduced to 1.0 V. The maximum gain is 2.50. In other words, the device's designed input range is 0.4 to 1.2 V.

With TVP7002 based hardware, the effective gain (the combination of analog and digital gains) is a value between 0.83 and 2.50.

Contrast	Gain
0.00	0.83x
0.25	1.25x
0.50	1.67x
0.75	2.09x
1.00	2.50x

With TVP7002 based hardware, offset is a value between -64 and +63.

Brightness	Offset
0.00	-64
0.25	-32
0.50	0
0.75	+32
1.00	+63

Constructors/Destructors

ccContrastBrightnessProp

```
ccContrastBrightnessProp();

ccContrastBrightnessProp(double contrast,
  double brightness);
```

- `ccContrastBrightnessProp();`

  Creates a new contrast and brightness property not associated with any FIFO. Brightness is set to **ccContrastBrightnessProp::defaultBrightness**. Contrast is set to **ccContrastBrightnessProp::defaultContrast**.

- `ccContrastBrightnessProp(double contrast, double brightness);`

  Creates a new contrast and brightness property not associated with any FIFO. Contrast is set to *contrast* and brightness is set to *brightness*.

  Parameters

  contrast The contrast: a value between 0.0 and 1.0.

  brightness The brightness: a value between 0.0 and 1.0.

  Throws

  ccContrastBrightnessProp::BadParams
  Value of *contrast* or *brightness* is less than 0 or greater than 1.

Enumerations

Channel

```
enum Channel;
```

This enumeration specifies the channels on a dual-tap **ccAcqFifo**.

Value	Meaning
eOdd	The input channel that produces the field that contains the first line of the image.
eEven	The input channel that produces the field that contains the second line of the image.

Public Member Functions

contrastBrightness

```
void contrastBrightness(double contrast,
  double brightness);

void contrastBrightness(double contrast,
  double brightness,
  ccContrastBrightnessProp::Channel channel);
```

- ```
  void contrastBrightness(double contrast,
    double brightness);
  ```

  Set the contrast to *contrast* and the brightness to *brightness*. If this **ccContrastBrightnessProp** is associated with a dual-tap **ccAcqFifo**, this function sets both channels to the specified brightness and contrast.

  Parameters

  contrast The contrast; a value between 0.0 and 1.0.

  brightness The brightness; a value between 0.0 and 1.0.

  Throws

  ccContrastBrightnessProp::BadParams
  Value of *contrast* or *brightness* is less than 0 or greater than 1.

- ```
  void contrastBrightness(double contrast,
    double brightness,
    ccContrastBrightnessProp::Channel channel);
  ```

  Set the contrast to *contrast* and the brightness to *brightness*.

Parameters

contrast The contrast; a value between 0.0 and 1.0.

brightness The brightness; a value between 0.0 and 1.0.

channel If this **ccContrastBrightnessProp** is associated with a dual-tap **ccAcqFifo**, *channel* specifies which tap's brightness and contrast values to set.

channel must be one of the following values:

ccContrastBrightnessProp::eEven
ccContrastBrightnessProp::eOdd

Throws

ccContrastBrightnessProp::BadParams
Value of *contrast* or *brightness* is less than 0 or greater than 1.

Notes

If you call this function on a **ccAcqFifo** associated with a single-tap camera, *ccContrastBrightnessProp::eEven* sets the brightness and contrast for the **ccAcqFifo**.

contrast

```
double contrast(ccContrastBrightessProp::Channel channel =
  ccContrastBrightnessProp::eEven);
```

Return the contrast value.

Parameters

channel If this **ccContrastBrightnessProp** is associated with a dual-tap **ccAcqFifo**, *channel* specifies which tap's contrast value is returned.

channel must be one of the following values:

ccContrastBrightnessProp::eEven
ccContrastBrightnessProp::eOdd

brightness

```
double brightness(ccContrastBrightessProp::Channel
  channel = ccContrastBrightnessProp::eEven);
```

Return the brightness value.

Parameters

channel If this **ccContrastBrightnessProp** is associated with a dual-tap **ccAcqFifo**, *channel* specifies which tap's brightness value is returned.

channel must be one of the following values:

ccContrastBrightnessProp::eEven
ccContrastBrightnessProp::eOdd

setContrast `void setContrast(double contrast);`

Set contrast only.

Parameters
contrast The new contrast.

Note **setContrast()** is not intended for use with dual-tap cameras. Use **contrastBrightness()** instead.

setBrightness `void setBrightness(double brightness);`

Sets brightness only.

Parameters
brightness The new brightness.

Note **setBrightness()** is not intended for use with dual-tap cameras. Use **contrastBrightness()** instead.

Constants

defaultContrast `static const double defaultContrast;`

The default contrast value is 0.5.

defaultBrightness
`static const double defaultBrightness;`

The default brightness value is 0.5.

ccContrastBrightnessProp

ccConvolveParams

```
#include <ch_cvl/convolve.h>

class ccConvolveParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccConvolveParams** class contains the parameters you use to control the operation of the Discrete Convolution tool (same as *Vision Tool Guide*). The Discrete Convolution tool convolves an image using a 3x3 kernel that you supply; you invoke the tool by calling the **cfConvolve()** function.

Constructors/Destructors

ccConvolveParams

```
ccConvolveParams();

explicit ccConvolveParams(ccIPair kernOriginOffset);

explicit ccConvolveParams(c_Int32 dstNorm);

ccConvolveParams(ccIPair kernOriginOffset,
  c_Int32 dstNorm);
```

- `ccConvolveParams();`

  Constructs a **ccConvolveParams** object with default parameter values (automatic kernel prescaling and normalization and a kernel origin in the center of the kernel).

- `explicit ccConvolveParams(ccIPair kernOriginOffset)`

  Constructs a **ccConvolveParams** that specifies automatic kernel prescaling and normalization and the supplied kernel origin.

  You specify the kernel origin by supplying a **ccIPair** interpreted as shown in the following figure:

-1, -1	0, -1	1, -1
-1, 0	0, 0	1, 0
-1, 1	0, 1	1, 1

  Parameters

  kernOriginOffset The kernel origin.

- `explicit ccConvolveParams(c_Int32 dstNorm);`

  Constructs a **ccConvolveParams** that specifies a manual normalization factor and a kernel origin in the center of the kernel.

  Parameters

  dstNorm The normalization factor. The result of applying the kernel is right-shifted by the specified number of bits.

- `ccConvolveParams(ccIPair kernOriginOffset, c_Int32 dstNorm);`

  Constructs a **ccConvolveParams** that specifies a manual normalization factor and the supplied kernel origin.

  You specify the kernel origin by supplying a **ccIPair** interpreted as shown in the following figure:

-1, -1	0, -1	1, -1
-1, 0	0, 0	1, 0
-1, 1	0, 1	1, 1

Parameters

kernOriginOffset The kernel origin.

dstNorm The normalization factor. The result of applying the kernel is right-shifted by the specified number of bits.

Public Member Functions

originOffset

```
ccIPair originOffset() const;
void originOffset(ccIPair kernOriginOffset);
```

- `ccIPair originOffset() const;`

  Returns the kernel origin specified by this **ccConvolveParams**.

- `void originOffset(ccIPair kernOriginOffset);`

  Sets the kernel origin specified by this **ccConvolveParams**.

  Parameters

  kernOriginOffset A **ccIPair** that specifies the kernel origin. A value of 0,0 indicates the center of the kernel.

isNormalized

```
bool isNormalized() const;
```

Returns true if this **ccConvolveParams** is configured to perform automatic kernel prescaling and normalization, false if it is configured to use a manual normalization factor.

norm

```
c_Int32 norm() const;
```

```
void norm(c_Int32 dstNorm);
```

- `c_Int32 norm() const;`

  Returns the manual normalization factor specified for this **ccConvolveParams**. If this **ccConvolveParams** is configured to perform automatic kernel prescaling and normalization, the value returned by this function is undefined.

- `void norm(c_Int32 dstNorm);`

  Sets the manual normalization factor for this **ccConvolveParams**. The result of applying the kernel is right-shifted by the specified number of bits to compute the output pixel value.

  Parameters

  dstNorm The normalization factor.

  Notes

  This function has no effect if this **ccConvolveParams** is configured to perform automatic kernel prescaling and normalization.

ccCoordAxes

```
#include <ch_cvl/simpshap.h>

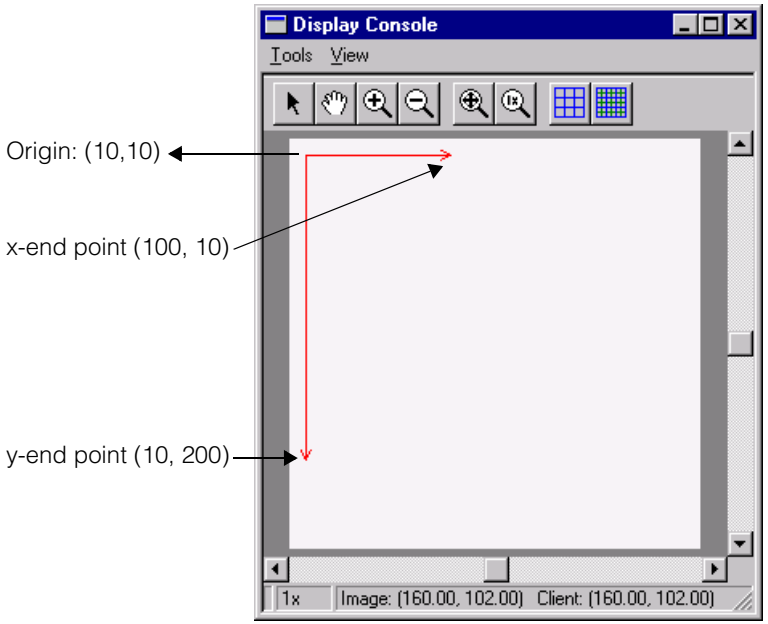
class ccCoordAxes;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

Use this class to draw coordinate axes by specifying an origin point and the end points for each axis. The following figure illustrates a **ccCoordAxes** shape.

```
ccCoordAxes(cc2Vect(10,10), cc2Vect(100,10), cc2Vect(10,200))
```



Note **ccCoordAxes** is one of the few shapes that does not inherit from **ccShape**.

Constructors/Destructors

ccCoordAxes

```
ccCoordAxes();

ccCoordAxes(const cc2Vect& or, const cc2Vect& x,
  const cc2Vect& y);
```

- `ccCoordAxes();`

  The default constructor creates a degenerate coordinate axis object whose origin, x-axis end point and y-axis end point are all (0,0).

- `ccCoordAxes(const cc2Vect& or, const cc2Vect& x, const cc2Vect& y);`

  Creates a coordinate axis object with the specified origin and end points.

  Parameters

or	The origin.
x	The x-axis end point.
y	The y-axis end point.

Operators

operator==

```
bool operator==(const ccCoordAxes& other) const;
```

Returns true if this coordinate axis object is equal to another one.

Parameters

other	The other coordinate axis object.

operator!=

```
bool operator!=(const ccCoordAxes& other) const;
```

Returns true if this coordinate axis object is not equal to another one.

Parameters

other	The other coordinate axis object.

Public Member Functions

origin

```
const ccPoint& origin() const;
```

Returns the origin of this coordinate axis object.

xEnd

```
const ccPoint& xEnd () const;
```

Returns the x-axis end point of this coordinate axis object.

yEnd

```
const ccPoint& yEnd () const;
```

Returns the y-axis end point of this coordinate axis object.

xAxis

```
ccLineSeg xAxis() const;
```

Returns the line segment from the origin to the x-axis end point.

yAxis

```
ccLineSeg yAxis() const;
```

Returns the line segment from the origin to the y-axis end point.

map

```
ccCoordAxes map(const cc2Xform& c) const;
```

Returns a coordinate axis object that is the result of mapping this object with the transformation object *c*.

Parameters

c	The transformation object.

distanceToPoint

```
double distanceToPoint(const cc2Vect& v) const;
```

Returns the nearest point on these coordinate axes to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

v	The point.

boundingBox

```
ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses these coordinate axes. See **ccShape::boundingBox()** for more information.

degen

```
bool degen() const;
```

Returns true if the distance from the origin to the x-axis end point or the y-axis end point is zero.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

ccCriticalSection

```
#include <ch_cvl/threads.h>

class ccCriticalSection;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A critical section is an object that only one thread of execution can own at a time. A thread may claim the critical section as many times as it wishes, but it must release the critical section once for every time it claims the critical section. A thread that tries to claim a critical section that is already claimed by some other thread will block until the critical section becomes available. A thread usually claims a critical section by using a **ccCriticalSectionLock** object.

Critical sections are generally faster to claim and release than mutexes. However, there is no timeout available on lock, named critical sections are not available, and a critical section does not throw *BrokenLock*.

Constructors/Destructors

ccCriticalSection

```
ccCriticalSection();
```

Constructs a new **ccCriticalSection**.

~ccCriticalSection

```
~ccCriticalSection();
```

Destroys a **ccCriticalSection**.

Public Member Functions

lock

```
void lock();
```

Locks the **ccCriticalSection**. Any other thread that attempts to lock this critical section will block until it is released.

unlock

```
void unlock();
```

Unlocks this **ccCriticalSection**.

Notes

ccCriticalSection::unlock() must be called as many times as **ccCriticalSection::lock()**.

ccCriticalSectionLock

```
#include <ch_cvl/threads.h>

class ccCriticalSection;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A critical section lock sets a lock on a critical section. The destructor automatically unlocks, so unlocking is assured.

Constructors/Destructors

ccCriticalSectionLock

```
ccCriticalSectionLock(ccCriticalSection& cs,
  bool locked = true);
```

Constructs a new **ccCriticalSectionLock**.

Parameters

cs	The critical section to be locked.
locked	If *true* (the default), the critical section is claimed, possibly blocking access to it by others indefinitely. If *false*, the critical section is not immediately claimed.

~ccCriticalSectionLock

```
~ccCriticalSectionLock();
```

Destroys a **ccCriticalSectionLock** object, undoing all outstanding lock operations done by this object.

Notes

At the time of the critical section lock's destruction, if there have been fewer unlock invocations than lock invocations, the destructor invokes **ccCriticalSectionLock::unlock()** enough times to make up the difference.

Public Member Functions

lock `void lock();`

Locks the critical section. Any other thread that attempts to lock the same critical section will block until the critical section is released.

unlock `void unlock();`

Unlocks the critical section.

Notes

ccCriticalSectionLock::unlock() must be called as many times as **ccCriticalSectionLock::lock()**.

ccCross

```
#include <ch_cvl/simpshap.h>

class ccCross;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a rotated cross with a fixed arm length. The arm length is constant when the cross is displayed in different coordinate systems or zoomed in a display console. **ccCross** objects are primarily used in drawing vision tool results. They are not generally used as geometric objects for describing shapes.

Note **ccCross** is one of the few shapes that does not inherit from **ccShape**.

Constructors/Destructors

ccCross

```
ccCross();

ccCross(const ccPoint& or, const ccRadian& angle,
  int armLength = 7);
```

- `ccCross();`

  Default constructor. Creates a degenerate cross with origin at (0,0), an angle of 0°, and an arm length of 0.

- `ccCross(const ccPoint& or, ccRadian& angle, int armLength = 7);`

  Constructs a cross with the specified origin, angle, and arm length.

  Parameters

or	The origin specified as a **ccPoint** object.
angle	The angle of rotation specified in radians as a **ccRadian** object.
armLength	The arm length specified in pixels (default = 7 pixels).

Operators

operator==

```
bool operator==(const ccCross& that) const;
```

Returns true if this cross is equal to *that*, false otherwise.

Parameters

that	The other cross.

operator!=

```
bool operator!=(const ccCross& that) const;
```

Returns true if this cross is not equal to *that*, false otherwise.

Parameters

that	The other cross.

Public Member Functions

origin

```
const ccPoint& origin() const;
void origin(const ccPoint& or);
```

- `const ccPoint& origin() const;`

  Returns the origin of the cross as a **ccPoint**.

- `void origin(const ccPoint& or);`

  Sets the origin of the cross.

  Parameters

or	Origin of the cross specified as a **ccPoint** containing the x and y coordinates.

angle

```
void angle(const ccRadian& angle);
ccRadian& angle() const;
```

- `void angle(const ccRadian& angle);`

  Sets the angle of the cross.

  Parameters

angle	Angle of rotation of the cross, specified in radians as a **ccRadian** object.

- `ccRadian& angle() const;`

  Returns the angle of rotation of the cross in radians as a **ccRadian** object.

armLength

```
void armLength(int armLength);
int armLength() const;
```

- `void armLength(int armLength);`

  Sets the arm length of the cross.

  Parameters

  armLength Arm length of the cross specified in pixels.

- `int armLength() const;`

  Returns the arm length of the cross in pixels as a non-const integer.

map

```
ccCross map(const cc2Xform& c) const;
```

Returns the cross mapped by the specified transform. The arm length is not mapped.

Parameters

c The transformation object.

ccCross

ccCubicSpline

```
#include <ch_cvl/spline.h>

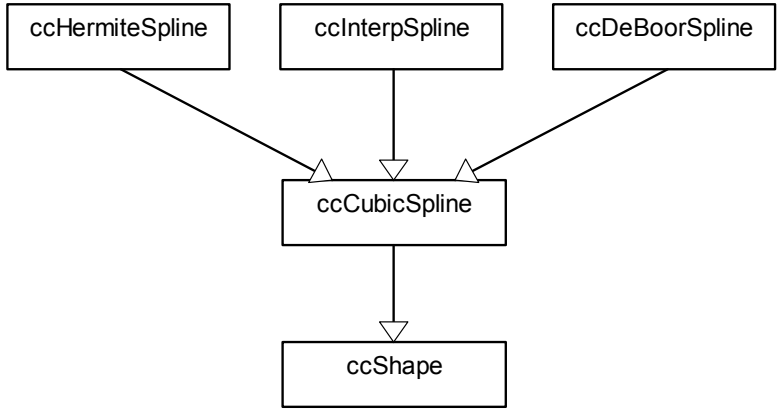
class ccCubicSpline : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccCubicSpline** class is an abstract base class for classes that implement various types of 2D cubic splines.

There are many flavors of splines (including Hermite splines, interpolation splines, and De Boor splines), but almost all of them can be viewed as a sequence of component Bezier curves joined end to end. The **ccCubicSpline** class supports examination of the component cubic Bezier curves; querying and manipulation of the parameterization via intervals; interrogation of the spline curve, such as finding points and tangents along it; and some basic geometric queries, such as finding the nearest point and intersection.



The above figure shows the **ccCubicSpline** class inheritance hierarchy.

Control Points

Like Bezier curves, splines are defined by control points. Spline control points are not the same points as the Bezier control points of the component Bezier curves. Rather, the spline control points and other spline control data determine the Bezier control points. Although n individual Bezier curves require 4n Bezier control points, a spline comprising n Bezier curves typically has fewer spline control points, often on the order of one spline control point per Bezier curve. Differentiability constraints imposed between adjacent Bezier curves supply the extra information needed to generate the Bezier control points. This reduction in degrees of freedom makes the spline easier to manipulate, and also forces it to be the sort of well-behaved, smooth curve that is useful in modeling and design.

Parameterizations

An important aspect of a cubic spline is its parameterization. Imagine a point [x(*t*), y(*t*)] moving along an entire spline. The parameterization determines what fraction of the total time the point spends on each component Bezier curve. One way of specifying a parameterization is through a knot vector. This is a non-decreasing sequence of scalar values, starting at zero. As the parameterized point moves along spline, it travels along the *i*'th Bezier curve while *t* is between the *i*'th and (*i*+1)th knot values. The knots are where the parameterized point moves from one Bezier curve to another.

For example, consider a spline comprising four Bezier curves with the knot vector (0, 2, 6, 7, 8). Then the parameterized point [x(*t*), y(*t*)] traverses the curve as follows:

1. It traverses the first curve for 0 <= *t* <= 2.
2. It traverses the second curve for 2 <= *t* <= 6.
3. It traverses the third curve for 6 <= *t* <= 7.
4. Finally, it traverses the fourth curve for 7 <= *t* <= 8.

For the spline classes in CVL, it is more convenient to work with intervals rather than knots. An interval vector is a sequence of non-negative scalar values, interval *i* corresponding to the difference between the *i*'th and (*i+1*)th knot. Thus, there is one interval for each Bezier curve. For this example, the interval vector is (2, 4, 1, 1).

Changing the parameterization actually changes the shape of the curve in order to maintain differentiability constraints at the junctions between Bezier curves. Certain parameterizations may produce better shaped curves than others. If the designer would rather not think about parameterizations, there are several standard strategies for generating them automatically:

Parameterization	Intervals Description
Uniform	All equal to 1.0
Chord length	Proportional to the Euclidean distance between relevant control points
Centripetal	Proportional to square root of Euclidean distance between relevant control points
Fixed	Not modified

The fixed parameterization is described in the section *Interval Mode* on page 1111).

The chord length and centripetal parameterizations, which are based on the geometry of the control points, typically give better-shaped splines than uniform parameterization. Centripetal parameterization is often preferred, as it tends to produce less *loopy* splines than chord length parameterization. One distinct advantage of uniform parameterization is that it alone is invariant under affine transformation of the spline control points. This has certain advantages when mapping splines (see *Reparameterizing Splines* on page 1112).

Interval Mode

The interval mode specifies the parameterization strategy used for a cubic spline. Changing the interval mode does not in itself affect any of the intervals. However, the interval mode does determine how the intervals are adjusted when you manipulate control points. When you add, remove, or move control points, the intervals that depend on those control points are automatically recomputed according to the current interval mode; the other intervals remain unchanged.

Individual intervals may also be adjusted manually. Hence, there is a distinction between the current interval mode, which is always one of the valid strategies, and the actual intervals of the spline, which may correspond to the current interval mode, or some combination of interval modes, or some completely arbitrary parameterization. The spline's parameterization is considered *conforming* if and only if all intervals correspond to the current interval mode. This is the case by default. A parameterization can only be made non-conforming by doing one of the following:

- Changing the interval mode of a non-empty spline
- Manually adjusting intervals

- Generating a new spline by mapping (see *Mapping Splines* below)

The fixed parameterization is similar to the uniform one, except that intervals are not adjusted when control points are moved. When control points are added or removed, or when the entire parameterization is recomputed using **reparameterize()**, the relevant intervals are computed as if the parameterization were uniform.

Mapping Splines

The **map()** method operates by transforming all spline control points by a supplied transform. It does *not* adjust the parameterization. The advantage of this behavior is that the locus of points of the mapped spline is exactly the locus of points of the original spline mapped by the supplied transform. More precisely, for an arbitrary spline *s*, transform *X*, and parameter *t*:

X.mapPoint(s.point(t)) == s.map(X).point(t)

within floating point tolerances. This is the behavior of the **map()** methods of all other shapes as well. The unavoidable disadvantage is that a mapped spline may not have a conforming parameterization, even if the original one does. For example, mapping by a non-rigid affine transform changes the distances between control points. If the transform has shear or aspect, even the relative distances change. In these cases, even if the original spline has, for example, a conforming chord-length parameterization, the mapped spline will not. If the control points of the mapped spline are subsequently manipulated, affected intervals will be automatically recomputed according to the current interval mode. To avoid surprising shape changes, the mapped spline may need to be reparameterized (see *Reparameterizing Splines* on page 1112).

Reparameterizing Splines

All spline classes provide a **reparameterize()** method to recompute all intervals according to the current interval mode and control point positions. This reestablishes a conforming parameterization, although it may alter the shape of the spline curve. It is sometimes desirable to invoke **reparameterize()** on a newly mapped spline to restore conformance. There are two cases in which invoking **reparameterize()** on a mapped spline is guaranteed to leave the intervals (and therefore the shape of the curve) unchanged:

- The first is when the original spline had a conforming uniform parameterization.
- The second is when the original spline had a conforming parameterization of any kind and the mapping transform was rigid.

Reparameterizing a spline after mappings that only involve translation, rotation, and uniform scaling also leaves the shape of the spline curve unchanged in many cases. Most splines are invariant with respect to a uniform scaling of the parameterization: multiplying all intervals by a constant factor does not change the curve. Exceptions to this rule are splines that have control knobs involving tangent vectors, such as Hermite

splines, and C^2 interpolation splines with clamped end conditions (see below). Since these tangent vectors are derivatives with respect to the parameter, scaling the parameterization changes the shape of the curve.

Global and Local Parameterization

Under global parameterization, points along a spline are given by two coordinate functions, x(*t*) and y(*t*), over the parameter range 0 through *M*. The values *t* = 0 and *t* = *M* correspond to the start and end points of the spline, respectively. *M* is the sum of the spline's intervals, and is available through the **maxParam()** method. All spline methods that take or return a single parameter value use global parameterization unless otherwise noted. Also, parametric tangent vectors are determined with respect to global parameterization. It is sometimes convenient to use an alternative scheme for referencing points on the spline. This scheme uses an integer index and a local parameter in the range 0 through 1. The index specifies a particular component Bezier curve, and the local parameter specifies a point within that Bezier curve. The **ccCubicSpline** class provides methods for converting between local and global parameter values.

B-Splines

Cubic B-splines are a particular type of cubic spline for which the functions x(*t*) and y(*t*) are generally twice differentiable at the junction between two cubic Bezier curves (that is, at the knot values). Along the Bezier curves, between the knots, x(*t*) and y(*t*) are infinitely differentiable, as always. Thus, the overall curve is C^2.

The B-spline coordinate functions x(*t*) and y(*t*) are always continuous, but they can exhibit less than C^2 differentiability when there are intervals of length zero, which occur when knot values are repeated. If an interval is zero (that is, when two consecutive knot values are equal), x(*t*) and y(*t*) are only once differentiable at the knot. This is the case, for example, where a straight segment tangentially meets a circular arc. If two or more consecutive intervals are zero (that is, when three or more consecutive knots are equal), x(*t*) and y(*t*) are not differentiable at the knot. This is the case, for example, where two straight segments meet at a corner.

B-splines may be open or closed. For closed B-splines, there is a C^2 connection between the first and last Bezier curves unless knots are repeated.

CVL supports two types of cubic B-splines: de Boor splines (implemented with the **ccDeBoorSpline** class) and C^2 interpolation splines (implemented with the **ccInterpSpline** class). The two types differ in how the spline control points, along with additional shaping parameters, are used to generate the Bezier control points.

Note For in-depth information on the theory and use of cubic Bezier curves and splines, see any textbook on the subject, such as *Curves and Surfaces for Computer Aided Geometric Design* by Gerald Farin, Second Edition, Academic Press, 1990, ISBN 0-12-249051-7.

Note All methods defined for this class leave the cubic spline object unchanged when they throw an error.

Enumerations

IntervalMode `enum IntervalMode;`

Interval mode is one of the parameterization strategies used with cubic splines. See *Interval Mode* on page 1111 for more information.

Parameters

eUniform	Parameterization intervals are all equal.
eChordLength	Parameterization intervals are proportional to the Euclidean distance between relevant control points.
eCentripetal	Parameterization intervals are proportional to the square root of the Euclidean distance between relevant control points.
eFixed	Parameterization intervals are not modified when control points are moved.

Operators

operator== `bool operator==(const ccCubicSpline &rhs) const;`

Returns true if and only if this **ccCubicSpline** is equal to *rhs*. Two splines are equal if all of their defining parameters are identical (no tolerance is used).

Parameters

rhs	The other **ccCubicSpline**.

Notes

Splines that describe identical curves are not necessarily equal.

operator!= `bool operator!=(const ccCubicSpline &rhs) const;`

Returns the opposite truth value of **operator==()**.

Constructors/Destructors

ccCubicSpline

```
explicit
ccCubicSpline(bool isClosed = false,
  IntervalMode intervalMode = eUniform);
```

Constructs an empty cubic spline, that is, one with no Bezier curves. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

isClosed The open/closed state of this cubic spline (default = open).

intervalMode The interval mode. Must be one of the following:
ccCubicSpline::eUniform (default)
ccCubicSpline:eChordLength
ccCubicSpline::eCentripetal
ccCubicSpline::eFixed

Notes

As a **ccCubicSpline** is an abstract class, only derived class constructors can call this constructor.

Public Member Functions

intervalMode

```
IntervalMode intervalMode() const;

virtual void intervalMode(IntervalMode intervalMode);
```

- `IntervalMode intervalMode() const;`

  Gets the interval mode of this spline.

- `virtual void intervalMode(IntervalMode intervalMode);`

  Sets the interval mode of this spline.

  Parameters

  intervalMode The interval mode. Must be one of the following:
  ccCubicSpline::eUniform (default)
  ccCubicSpline:eChordLength
  ccCubicSpline::eCentripetal
  ccCubicSpline::eFixed

Throws

ccShapesError::BadParams

The specified interval mode is not valid for this **ccCubicSpline**. Derived spline classes are not required to support all possible interval modes. Those that do not should override the default method, which never throws, and should indicate which interval modes are valid.

---

interval

```
double interval(c_Int32 idx) const;

void interval(c_Int32 idx, double val);
```

- `double interval(c_Int32 idx) const;`

Gets the interval with the given index.

Parameters

idx The index.

Throws

ccShapesError::BadIndex

idx is less than zero, or greater than or equal to **numBezierCurves()**.

- `void interval(c_Int32 idx, double val);`

Sets the interval with given index.

Parameters

idx The index.

val The interval.

Throws

ccShapesError::BadIndex

idx is less than zero or greater than or equal to **numBezierCurves()**.

ccShapesError::BadParams

The new interval is negative.

intervals

```
const cmStd vector<double> &intervals() const;
void intervals(const cmStd vector<double> &vals);
```

- `const cmStd vector<double> &intervals() const;`

  Gets the interval vector.

- `void intervals(const cmStd vector<double> &vals);`

  Sets the interval vector.

  Parameters

  val The interval vector.

  Throws

  ccShapesError::BadParams
  The length of the new interval vector is not equal to **numBezierCurves()**.

  ccShapesError::BadParams
  Any of the new intervals are negative.

maxParam

```
double maxParam() const;
```

Returns the global parameter value of the end point of the spline. This is the sum of all the intervals.

Notes

Points along a spline are parameterized over the range 0 through **maxParam()**.

globalParam

```
double globalParam(c_Int32 idx, double localParam) const;
```

Given the index of a Bezier curve and a local parameter in the range 0 through 1 along that curve, this function returns the corresponding global spline parameter in the range 0 through **maxParam()**.

Parameters

idx The index of one of the component Bezier curves.

localParam The local parameter. Must be in the range 0 through 1.

Notes

localParam is internally clipped if it falls outside the range 0 through 1.

Throws

ccShapesError::BadIndex
idx is less than zero or greater than or equal to **numBezierCurves()**.

ccShapesError::EmptyShape
This spline is empty.

localParam

```
c_Int32 localParam(double globalParam, double &localParam)
  const;
```

Given a global parameter along the spline in the range 0 through **maxParam()**, this function returns the corresponding Bezier curve index and local parameter in the range 0 through 1.

Parameters

globalParam	The global parameter along this spline.
localParam	The returned local parameter.

Notes

globalParam is internally clipped if it falls outside the range 0 through **maxParam()**.

Throws

ccShapesError::EmptyShape
This spline is empty.

reparameterize

```
virtual void reparameterize() = 0;
```

Recomputes all intervals based on the current control points and interval mode.

Notes

Invoking this method reestablishes a conforming parameterization, but may alter the shape of the spline curve. See *Reparameterizing Splines* on page 1112.

numControlPoints

```
c_Int32 numControlPoints() const;
```

Returns the number of control points of this spline.

isClosed

```
bool isClosed() const;

virtual void isClosed(bool) = 0;
```

- `bool isClosed() const;`

  Gets the open/closed state of this spline (true = closed, false = open).

- `virtual void isClosed(bool) = 0;`

  Sets the open/closed state of this spline.

  Parameters

  bool True sets the spline to closed, false sets it to open.

  Notes

  This setter automatically invokes **reparameterize()** to recompute the entire parameterization if and only if the open/closed state of the spline is changed.

controlPoint

```
cc2Vect controlPoint(c_Int32 idx) const;

virtual void controlPoint(c_Int32 idx,
  const cc2Vect &ctrlPt) = 0;
```

- `cc2Vect controlPoint(c_Int32 idx) const;`

  Gets the control point with the given index.

  Parameters

  idx The index.

  Throws

  ccShapesError::BadIndex

  idx is less than 0, or greater than or equal to **numControlPoints()**.

- `virtual void controlPoint(c_Int32 idx, const cc2Vect &ctrlPt) = 0;`

  Sets the control point with given index.

  Parameters

  idx The index.

  ctrlPt The control point.

Notes

Affected intervals are recomputed according to the current interval mode.

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than or equal to **numControlPoints()**.

---

controlPoints

```
const cmStd vector<cc2Vect> &controlPoints() const;

virtual void controlPoints(
  const cmStd vector<cc2Vect> &ctrlPts) = 0;
```

- ```
  const cmStd vector<cc2Vect> &controlPoints() const;
  ```

  Gets the entire vector of control points.

- ```
  virtual void controlPoints(
    const cmStd vector<cc2Vect> &ctrlPts) = 0;
  ```

  Sets the entire vector of control points.

  Parameters

  ctrlPts The vector of control points.

  Notes

  This setter automatically invokes **reparameterize()** to recompute the entire parameterization.

insertControlPoint

```
virtual void insertControlPoint(c_Int32 idx,
  const cc2Vect &point) = 0;
```

Inserts a control point into the sequence of control points. The new point is inserted before the current control point with given index. The new point has index *idx* after the insertion, and the indices of all control points that were previously indexed *idx* or higher are incremented. Affected intervals are recomputed according to the current interval mode.

Parameters

idx The index.

Index Value	Effect
0	Inserts the control point at the beginning of the sequence
numControlPoints()	Inserts the control point at the end of the sequence

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than **numControlPoints()** before the insertion.

addControlPoint `void addControlPoint(const cc2Vect &point);`

Convenience function. Appends a control point at the end of the sequence of control points. Equivalent to **insertControlPoint(numControlPoints(), point)**.

Parameters

point The control point to insert.

removeControlPoint

```
virtual void removeControlPoint(c_Int32 idx) = 0;
```

Removes the control point with given index.

Parameters

idx The index.

Notes

Affected intervals are recomputed according to the current interval mode.

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than or equal to **numControlPoints()** before the removal.

numBezierCurves

```
c_Int32 numBezierCurves() const;
```

Returns the number of component Bezier curves of this spline.

bezierCurve `const ccBezierCurve &bezierCurve(c_Int32 idx) const;`

Returns the component Bezier curve with given index.

Parameters

idx The index.

Throws

ccShapesError::BadIndex

idx is less than 0 or greater than or equal to **numBezierCurves()**.

point `cc2Vect point(double t) const;`

Returns the point at global parameter value *t* along the spline. *t* is internally clipped if it falls outside the range 0 through **maxParam()**. The value returned is an exact value, not an approximation.

Parameters

t The global parameter value along this spline.

Notes

Splines are not parameterized by arc length, so sampling at equally spaced values of *t* does not correspond to sampling uniformly along the curve.

Throws

ccShapesError::EmptyShape

This spline is empty.

tangent `cc2Vect tangent(double t) const;`

Parameters

t The global parameter value along this spline.

Returns the tangent vector at global parameter value *t* along this spline. *t* is internally clipped if it falls outside the range 0 through **maxParam()**. The value returned is an exact value, not an approximation.

Notes

The returned tangent vector is a derivative with respect to the global spline parameter, not with respect to the local (unit interval) parameter on a component Bezier curve.

Throws

ccShapesError::NoTangent

A tangent vector does not exist at the given parameter value.

ccShapesError::EmptyShape

This spline is empty.

pointAndTangent

```
void pointAndTangent(double t, cc2Vect &point,
  cc2Vect &tangent) const;
```

Returns the point and tangent vector at global parameter value *t* along this spline. *t* is internally clipped if it falls outside the range 0 through **maxParam()**. The value returned is an exact value, not an approximation.

Parameters

t	The global parameter value along this spline.
point	Return parameter for the point computed by this function.
tangent	Return parameter for the tangent vector computed by this function.

Notes

The returned tangent vector is a derivative with respect to the global spline parameter, not with respect to the local (unit interval) parameter on a component Bezier curve.

Throws

ccShapesError::NoTangent
No tangent vector exists at the given parameter value.

ccShapesError::EmptyShape
This spline is empty.

nearestPoint

```
cc2Vect nearestPoint(const cc2Vect& p, double &t) const;

virtual cc2Vect nearestPoint(const cc2Vect& p) const;
```

- `cc2Vect nearestPoint(const cc2Vect& p, double &t) const;`

Returns the nearest point on this cubic spline to the given point as well as the nearest point's global parameter value in the range 0 through **maxParam()**.

Parameters

p	The point.
t	Return parameter for the nearest point's global parameter value.

Throws

ccShapesError::EmptyShape
This spline is empty.

See **ccShape::nearestPoint()** for more information.

- `virtual cc2Vect nearestPoint(const cc2Vect& p) const;`

  Returns the nearest point on this cubic spline to the given point. If the nearest point is not unique, one of the nearest points is returned.

  Parameters

  p The point.

  Throws

  ccShapesError::EmptyShape
  This spline is empty.

  See **ccShape::nearestPoint()** for more information.

intersections

```
cmStd vector<cc2Vect> intersections(const ccLineSeg &seg)
 const;
```

Returns the global parameter values at which this spline curve intersects the given line segment.

Parameters

seg The line segment.

Notes

If a portion of the spline curve lies exactly on the line segment, then there are infinite intersections. In this case, only a single intersection from this infinite set is returned.

This function returns an empty vector if this cubic spline is empty.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if both **isClosed()** and **isEmpty()** are false for this cubic spline. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if **isClosed()** is true and **isEmpty()** is false for this cubic spline. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For cubic splines, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if this cubic spline does not have enough points to define at least one Bezier curve. The minimum number of points required to define at least one Bezier curve depends on the type of spline and whether it is open or closed. For example, an open **ccDeBoorSpline** is empty if it has fewer than four control points; a closed **ccDeBoorSpline** is empty if it has fewer than three control points.

See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

Returns true if this cubic spline has at least one Bezier curve for which **hasTangent()** is true. See **ccShape::hasTangent()** for more information.

isReversible `virtual bool isReversible() const;`

For cubic splines, this function always returns true. See **ccShape::reverse()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For cubic splines, this function always returns false. See **ccShape::isDecomposed()** for more information.

startPoint `virtual cc2Vect startPoint() const;`

Returns the starting point of this cubic spline.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

See **ccShape::startPoint()** for more information.

endPoint `virtual cc2Vect endPoint() const;`

Returns the ending point of this cubic spline.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

See **ccShape::endPoint()** for more information.

startAngle `virtual ccRadian startAngle() const;`

Returns the starting angle of this cubic spline.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this cubic spline.

See **ccShape::startAngle()** for more information.

endAngle `virtual ccRadian endAngle() const;`

Returns the ending angle of this cubic spline.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this cubic spline.

See **ccShape::endAngle()** for more information.

tangentRotation `virtual ccRadian tangentRotation() const;`

Returns the net signed angle through which the tangent vector rotates along this cubic spline from the start point to the end point.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this cubic spline.

See **ccShape::tangentRotation()** for more information.

windingAngle `virtual ccRadian windingAngle(const cc2Vect &p) const;`

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

Parameters

p The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

Throws

ccShapesError::NotOpenContour
This cubic spline is not an open contour.

See **ccShape::windingAngle()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if this cubic spline is both a region and right handed.

Notes

The return value is undefined for self-intersecting cubic splines.

Throws

ccShapesError::NotRegion
This cubic spline is not a region.

See **ccShape::isRightHanded()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the given point is within the region defined by this cubic spline.

Parameters

p The point.

Throws

ccShapesError::NotRegion
This cubic spline is not a region.

See **ccShape::within()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this cubic spline.

Notes

This function returns a tight rectangle based on the curve itself, not the control points.

Throws

ccShapesError::EmptyShape
This cubic spline is empty.

See **ccShape::boundingBox()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this **ccCubicSpline**. Returned sample points are generally not equally spaced along the curve.

Parameters

params Parameters object specifying details of how the sampling should be done.

result Result object to which position and tangent chains are stored.

Notes

If **params.computeTangents()** is true, this function ignores cubic splines for which **hasTangent()** is false.

Throws

ccShapesError::SampleOverflow

Supplied spacing and tolerance bounds require more than *maxPoint* samples to be generated. See **ccSampleParams** for details.

See **ccShape::sample()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccBezierCurve**s. See **ccShape::decompose()** for more information.

ccCustomProp

```
#include <ch_cvl/prop.h>

class ccCustomProp : virtual public ccPersistent ;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class encapsulates a collection of property values associated with an acquisition FIFO. You use this class to specify FIFO properties for devices such as GigE cameras.

Like other properties, the properties in this class are written to the hardware before an image is acquired when either of the following conditions are true:

- The properties have been changed since the last image was acquired.
- Another acquisition FIFO has written its properties to the hardware since the last image was acquired through this FIFO.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccCustomProp

```
ccCustomProp();
```

Constructs a **ccCustomProp** with no property values.

Public Member Functions

customValues

```
void customValues(ccCustomPropertyBag values);

ccCustomPropertyBag customValues() const;
```

- ```
  void customValues(ccCustomPropertyBag values);
  ```

  Sets the properties and values for this FIFO.
  ```

Parameters

values	A **ccCustomPropertyBag** containing the properties and values. The supplied properties and values are applied before each acquisition.

- `ccCustomPropertyBag customValues() const;`

  Returns a **ccCustomPropertyBag** containing the current properties and values for this FIFO.

  .

ccCustomPropertyBag

```
#include <ch_cvl/prop.h>

class ccCustomPropertyBag ;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class provides a simple container for a collection of properties, where each property is made up of a name and a value, both of type **ccCvlString**, and a type, which defines whether the item is a property that is written or a command that is executed.

This class is intended ti be a light-weight container that allows you to create a collection of properties in a single function call. You can only add to and enumerate the items in a **ccCustomPropertyBag**. To change the contents of a **ccCustomPropertyBag**, destroy it and create a new one.

Enumerations

ceType

```
enum ceType
```

An enumeration defining the property types.

Value	Meaning
ckWrite	The property is a value that is simply written.
ckCommand	The property is a command that is executed.

Constructors/Destructors

Default constructors and destructors are used.

Public Member Functions

addItem

```
void addItem(ceType type, const ccCvlString& name,
   const ccCvlString& value = cmT(""));
```

Adds the supplied item to this **ccCustomPropertyBag**. A **ccCustomPropertyBag** may contain multiple items with the same name; any existing item with the same name is retained in the collection. The new item is added as the last item of the collection.

This function does not throw any errors. If you provide an illegal or incorrectly formatted item, the acquisition system will generate an error when you attempt to acquire an image.

Parameters

type — The type of the item. *type* must be one of the following values:

ccCustomPropertyBag::ckWrite
ccCustomPropertyBag::ckCommand

name — The name of the item.

value — The value of the item. This parameter is ignored if *type* is *ccCustomPropertyBag::ckCommand*.

getItemCount

```
c_Int32 getItemCount() const;
```

Returns the number of items in the collection.

getName

```
ccCvlString getName(c_Int32 n) const;
```

Returns the name of the specified item.

Parameters

n — The index of the item. The first item has an index of 0.

Throws

ccCustomPropertyBag::BadParams
n is greater than or equal to the number of items returned by **getItemCount()**.

getValue

```
ccCvlString getValue(c_Int32 n) const;
```

Returns the value of the specified item.

Parameters

n — The index of the item. The first item has an index of 0.

Throws

ccCustomPropertyBag::BadParams

n is greater than or equal to the number of items returned by **getItemCount()**.

getType

```
eCustomPropertyType getType(c_Int32 n) const;
```

Returns the type of the specified item. The returned value is one of

ccCustomPropertyBag::ckWrite
ccCustomPropertyBag::ckCommand

Parameters

n The index of the item. The first item has an index of 0.

Throws

ccCustomPropertyBag::BadParams

n is greater than or equal to the number of items returned by **getItemCount()**.

toString

```
ccCvlString toString() const;
```

Returns a single string containing the entire contents of this **ccCustomPropertyBag**. Multiple items are separated by newline characters, and each item is formatted as follows:

type\t*name*\t*value*\n\r

where

type is “Command” or “Write”

name is the property name

value is the property value (not present for commands)

fromString

```
void fromString(ccCvlString source);
```

Replaces the current contents of this **ccCustomPropertyBag** with the values in the supplied **ccCvlString**.

If the supplied **ccCvlString** contains multiple items, they must be separated with newline characters. Individual items must be formatted as follows:

type\t*name*\t*value*\n\r

where

type is “Command” or “Write”

name is the property name

value is the property value (not present for commands)

The following is an example of a valid string:

```
Write   TestPatternSelect 1024
Write   TestPatternEnable 762
Command AutoFocus
```

Parameters

source The items to set, formatted as described above.

Throws

ccCustomPropertyBag::BadParams

string does not conform to the formatting rules described above.

Notes

You must use a DOS-style newline composed of a carriage return followed by a line feed character when formatting the string.

ccDeBoorSpline

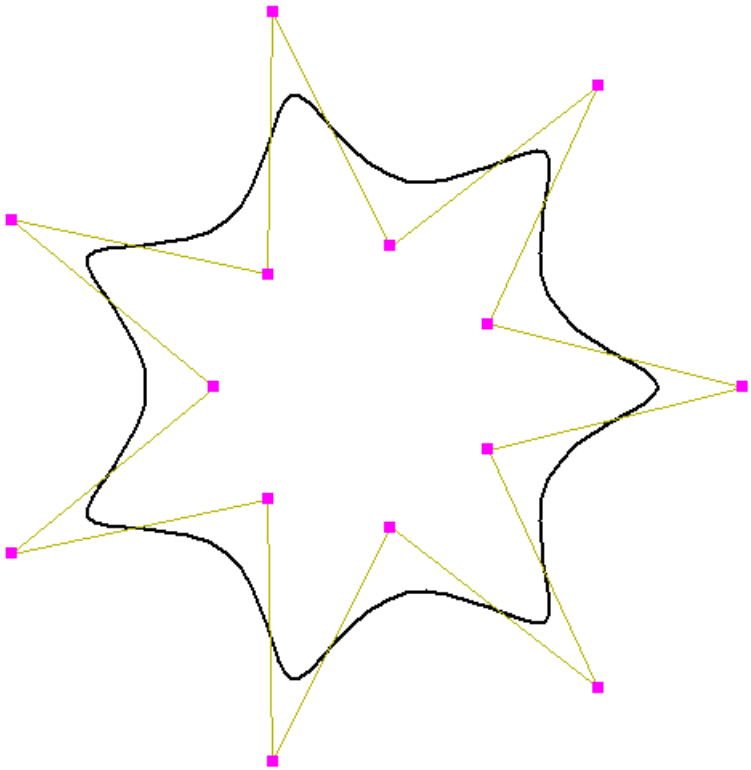
```
#include <ch_cvl/spline.h>

class ccDeBoorSpline : public ccCubicSpline;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccDeBoorSpline** class is an implementation of 2D cubic de Boor splines, a type of cubic B-Spline in which the spline control points are used to generate the Bezier control points according to the de Boor algorithm.



The above figure shows an example of a de Boor spline with control points in the shape of a star. The spline does not interpolate any of the control points.

Properties of de Boor Splines

The following properties apply to all de Boor splines:

- The curve lies within the convex hull of the spline control points.
- Moving a spline control point affects only a limited number of component Bezier curves (four if the parameterization is independent of control point geometry, six if it is not).
- Any assignment of non-negative weights to the spline control points produces a valid de Boor Spline.

The spline curve does not generally interpolate (pass through) the spline control points except for the first and last control point of an open spline.

The minimum number of spline control points needed to specify a non-empty **ccDeBoorSpline** is four for an open spline, and three for a closed spline. In other words, an open **ccDeBoorSpline** is empty if it has fewer than four control points; a closed **ccDeBoorSpline** is empty if it has fewer than three control points.

Weights

As implemented in CVL, de Boor spline control points have associated positive scalar weights, which default to unity (1.0). Increasing the weight of any control point pulls the spline curve toward that point; decreasing the weight reduces the effect of that point on the curve. Weights are relative quantities; multiplying all control point weights by a common factor has no effect on the curve. When the weights of the control points are not all equal, a de Boor spline is a form of *rational* spline. Because the parameterization may also be non-uniform, the type of de Boor splines implemented in CVL are sometimes called NURBS (Non-Uniform, Rational B-splines).

Note For in-depth information on the theory and use of 2D cubic Bezier curves and splines, see any textbook on the subject, such as *Curves and Surfaces for Computer Aided Geometric Design* by Gerald Farin, Second Edition, Academic Press, 1990, ISBN 0-12-249051-7.

Note All methods defined for this class leave the **ccDeBoorSpline** object unchanged when they throw an error.

Operators

operator==

```
bool operator==(const ccDeBoorSpline &rhs) const;
```

Returns true if and only if this **ccDeBoorSpline** is equal to *rhs*. Two splines are equal if all of their defining parameters are identical (no tolerance is used).

Parameters

rhs The other **ccDeBoorSpline**.

Notes

Splines that describe identical curves are not necessarily equal.

operator!=

```
bool operator!=(const ccDeBoorSpline &rhs) const;
```

Returns the opposite truth value to **operator==()**.

Parameters

rhs	The other **ccDeBoorSpline**.

Constructors/Destructors

ccDeBoorSpline

```
explicit
ccDeBoorSpline(bool isClosed = false,
  IntervalMode intervalMode = eUniform);

explicit
ccDeBoorSpline(const cmStd vector<cc2Vect> &ctrlPts,
  bool isClosed = false,
  IntervalMode intervalMode = eUniform);

ccDeBoorSpline(const cmStd vector<cc2Vect> &points,
  const cmStd vector<double> &weights,
  bool isClosed = false,
  IntervalMode intervalMode = eUniform);

explicit
ccDeBoorSpline(const ccBezierCurve &bezierCurve);
```

-
```
explicit
ccDeBoorSpline(bool isClosed = false,
  IntervalMode intervalMode = eUniform);
```

Constructs a de Boor spline with the given open/closed state and interval mode. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

isClosed	The open/closed state (default = open).
intervalMode	The interval mode. Must be one of the following: *ccCubicSpline::eUniform (default)* *ccCubicSpline:eChordLength* *ccCubicSpline::eCentripetal* *ccCubicSpline::eFixed*

- ```
  explicit
  ccDeBoorSpline(const cmStd vector<cc2Vect> &ctrlPts,
    bool isClosed = false,
    IntervalMode intervalMode = eUniform);
  ```

  Constructs a **ccDeBoorSpline** with the given control points, open/closed state, and interval mode. The weights of all control points are initialized to 1.0.

  Parameters

  ctrlPts — The vector of control points.

  isClosed — The open/closed state (default = open).

  intervalMode — The interval mode. Must be one of the following:
  ccCubicSpline::eUniform (default)
  ccCubicSpline:eChordLength
  ccCubicSpline::eCentripetal
  ccCubicSpline::eFixed

- ```
  ccDeBoorSpline(const cmStd vector<cc2Vect> &points,
    const cmStd vector<double> &weights,
    bool isClosed = false,
    IntervalMode intervalMode = eUniform);
  ```

  Constructs a **ccDeBoorSpline** with the given control points, weights, open/closed state, and interval mode.

  Parameters

  points — The vector of control points.

  weights — The vector of control point weights.

  isClosed — The open/closed state (default = open).

  intervalMode — The interval mode. Must be one of the following:
  ccCubicSpline::eUniform (default)
  ccCubicSpline:eChordLength
  ccCubicSpline::eCentripetal
  ccCubicSpline::eFixed

  Throws

  ccShapesError::BadParams
  points and *weights* vectors have different sizes.

  ccShapesError::NonpositiveWeight
  Any weight is non-positive.

- `explicit ccDeBoorSpline(const ccBezierCurve &bezierCurve);`

  Constructs a de Boor spline that describes the same geometry as the specified Bezier curve.

  Parameters

  bezierCurve The Bezier curve.

  Notes

  The constructed spline is open, has four control points, has a single Bezier curve that is equal to the supplied Bezier curve, and has a **maxParam()** value of 1.0.

Public Member Functions

weight

```
double weight(c_Int32 idx) const;

void weight(c_Int32 idx, double newWeight);
```

- `double weight(c_Int32 idx) const;`

  Gets the weight of the control point with the given index.

  Parameters

  idx The index.

  Throws

  ccShapesError::BadIndex

  idx is less than 0, or greater than or equal to **numControlPoints()**.

- `void weight(c_Int32 idx, double newWeight);`

  Sets the weight of the control point with given index.

  Parameters

  idx The index.

  newWeight The new weight.

  Throws

  ccShapesError::BadIndex

  idx is less than 0, or greater than or equal to **numControlPoints()**.

ccShapesError::NonpositiveWeight
newWeight is non-positive.

weights

```
const cmStd vector<double> &weights() const;

void weights(const cmStd vector<double> &wghts);
```

- `const cmStd vector<double> &weights() const;`

  Gets the vector of control point weights.

- `void weights(const cmStd vector<double> &wghts);`

  Sets the vector of control point weights.

  Parameters
  wghts The vector of control point weights.

  Throws
  ccShapesError::BadParams
  The size of *wghts* is not equal to **numControlPoints()**.

  ccShapesError::NonpositiveWeight
  Any element of *wghts* is non-positive.

insertControlPoint

```
void insertControlPoint(c_Int32 idx, const cc2Vect &point,
 double weight);

virtual void insertControlPoint(c_Int32 idx,
 const cc2Vect &point);
```

- `void insertControlPoint(c_Int32 idx, const cc2Vect &point, double weight);`

  Identical to **ccCubicSpline::insertControlPoint()**, except that the new control point is assigned the given weight rather than the default weight of 1.0.

  Parameters
  idx The index.

  weight The weight.

Throws

ccShapesError::BadIndex
idx is less than 0, or greater than **numControlPoints()** before the insertion.

ccShapesError::NonpositiveWeight
weight is non-positive.

See **ccCubicSpline::insertControlPoint()** for more information.

- ```
  virtual void insertControlPoint(c_Int32 idx,
    const cc2Vect &point);
  ```

Inserts a new control point before the point with the given index.

Parameters

idx The index.

point The control point.

Throws

ccShapesError::BadIndex
idx is less than 0, or greater than **numControlPoints()** before the insertion.

Notes

The new control point is assigned a weight of 1.0.

See **ccCubicSpline::insertControlPoint()** for more information.

addControlPoint

```
void addControlPoint(const cc2Vect &point,
  double weight = 1.0);
```

Convenience function. Appends a control point at the end of the sequence of control points. Equivalent to **ccCubicSpline::insertControlPoint(numControlPoints(), point, weight)**.

Parameters

point The control point.

weight The weight (default = 1.0).

Throws

ccShapesError::NonpositiveWeight
weight is non-positive.

See **ccCubicSpline::addControlPoint()** for more information.
```

removeControlPoint

```
virtual void removeControlPoint(c_Int32 idx);
```

Removes the control point with the given index.

Parameters

idx The index.

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than **numControlPoints()** before the insertion.

See **ccCubicSpline:removeControlPoint()** for more information.

map

```
ccDeBoorSpline map(const cc2Xform& X) const;
```

Returns this **ccDeBoorSpline** mapped by *X*.

Parameters

X The transformation object.

Notes

This function maps only control point positions by *X* while leaving weights and intervals unchanged. It may be desirable to invoke **reparameterize()** on the returned spline. See *Mapping Splines* and *Reparameterizing Splines* on page 1112 for more information.

Note Several of **ccCubicSpline**'s setter/getter pairs have a virtual setter and a non-virtual getter. The getters must be explicitly exposed in derived classes, or they will be hidden by the setter overrides.

isClosed

```
bool isClosed() const;

virtual void isClosed(bool);
```

- `bool isClosed() const;`

  Gets the open/closed state of this **ccDeBoorSpline** (true = closed, false = open).

- `virtual void isClosed(bool);`

  Sets the open/closed state of this **ccDeBoorSpline**.

  Parameters

  bool True sets this spline to closed, false sets it to open.

See **ccControlPoint::isClosed()** for more information.

controlPoint

```
cc2Vect controlPoint(c_Int32 idx) const;

virtual void controlPoint(c_Int32 idx,
  const cc2Vect &ctrlPt);
```

- `cc2Vect controlPoint(c_Int32 idx) const;`

  Gets the control point with the given index.

  Parameters

  idx The index.

- `virtual void controlPoint(c_Int32 idx, const cc2Vect &ctrlPt);`

  Sets the control point with the given index.

  Parameters

  idx The index.

  ctrlPt The control point.

  Notes

  This function leaves the weight of the control point unchanged.

  See **ccCubicSpline::controlPoint()** for more information.

controlPoints

```
const cmStd vector<cc2Vect> &controlPoints() const;

virtual void controlPoints(
  const cmStd vector<cc2Vect> &ctrlPts);
```

- `const cmStd vector<cc2Vect> &controlPoints() const;`

  Gets the entire vector of control points.

- `virtual void controlPoints( const cmStd vector<cc2Vect> &ctrlPts);`

  Sets the entire vector of control points.

  Parameters

  ctrlPts The vector of control points.

Notes

This function leaves the weights of existing control points unchanged. If *ctrlPts* has size *n*, the weights of the first *n* existing control points are used for the new points. If there are fewer than *n* existing control points, the surplus points in *ctrlPts* receive weights of 1.0.

See **ccCubicSpline::controlPoints()** for more information.

reparameterize

```
virtual void reparameterize();
```

Recomputes all intervals based on the current control points and interval mode. See **ccCubicSpline::reparameterize()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this de Boor spline.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this de Boor spline. See **ccShape::reverse()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this **ccDeBoorSpline** mapped by *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

ccDegree

```
#include <ch_cvl/units.h>

class ccDegree;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes an angle in degrees.

Note that you can use the constructors to convert from one angle representation to another. For example, to specify π radians in degrees, you could write:

```
 // ckPI is defined in <ch_cvl/math.h>
ccDegree deg(ccRadian(ckPI));
```

Constructors/Destructors

ccDegree

```
ccDegree();

ccDegree(ccRadian a);

ccDegree(ccAngle8 a);

ccDegree(ccAngle16 a);

explicit ccDegree(double a);
```

- `ccDegree();`

  Creates an uninitialized **ccDegree** object.

- `ccDegree(ccRadian a);`

  Creates a **ccDegree** object from the given **ccRadian** object.

  Parameters

a	The **ccRadian** object to convert to degrees.

- `ccDegree(ccAngle8 a);`

  Creates a **ccDegree** object from the given **ccAngle8** object.

  Parameters

  a The **ccAngle8** object to convert to degrees.

- `ccDegree(ccAngle16 a);`

  Creates a **ccDegree** object from the given **ccAngle16** object.

  Parameters

  a The **ccAngle16** object to convert to degrees.

- `explicit ccDegree(double a);`

  Creates a **ccDegree** object with the specified value.

  Parameters

  a The angle in degrees.

Operators

operator+

```
ccDegree operator+(ccDegree a) const;
```

Returns the result of adding the angle *a* in degrees to this angle.

Parameters

a The angle to add to this angle.

operator-

```
ccDegree operator-(ccDegree a) const;
ccDegree operator-() const;
```

- `ccDegree operator-(ccDegree a) const;`

  Returns the result of subtracting the angle *a* in degrees from this angle.

  Parameters

  a The angle to subtract from this angle.

- `ccDegree operator-() const;`

  Returns the negative of this angle. The unary minus operator.

operator*

```
ccDegree operator*(double a) const;
double operator*(ccDegree a) const;
friend ccDegree operator*(double a, ccDegree b);
```

- `ccDegree operator*(double a) const;`

  Returns the result of multiplying this angle by *a*.

  Parameters

  a The amount to multiply by.

- `double operator*(ccDegree a) const;`

  Returns the result of multiplying this angle by the angle *a* in degrees.

  Parameters

  a The angle to multiply by.

- `friend ccDegree operator*(double a, ccDegree b);`

  Returns the result of multiplying the angle *b* by *a*.

  Parameters

  a The amount to multiply by.

  b The angle to multiply.

operator/

```
ccDegree operator/(double a) const;
double operator/(ccDegree a) const;
```

- `ccDegree operator/(double a) const;`

  Returns the result of dividing this angle by *a*.

  Parameters

  a The amount to divide by.

- `double operator/(ccDegree a) const;`

  Returns the result of dividing this angle by the angle *a* in degrees.

  Parameters

  a The angle to divide by.

operator=

```
ccDegree& operator=(double a);
```

Assigns the value *a* to this angle.

Parameters

a The value to assign.

---

operator*=

```
ccDegree& operator*=(double a);
ccDegree& operator*=(ccDegree a);
```

- ```
  ccDegree& operator*=(double a);
  ```

  Multiplies this angle by *a* and returns the result.

  Parameters

  a The value to multiply by.

- ```
  ccDegree& operator*=(ccDegree a);
  ```

  Multiplies this angle by the angle *a* and returns the result.

  Parameters

  a The angle to multiply by.

---

operator/=

```
ccDegree& operator/=(double a);
ccDegree& operator/=(ccDegree a);
```

- ```
  ccDegree& operator/=(double a);
  ```

  Divides this angle by the value *a* and returns the result.

  Parameters

  a The value to divide by.

- ```
  ccDegree& operator/=(ccDegree a);
  ```

  Divides this angle by the angle *a* and returns the result.

  Parameters

  a The angle to divide by.

operator+= `ccDegree& operator+=(ccDegree a);`

Adds the angle *a* to this angle and returns the result.

Parameters

a	The angle to add.

operator-= `ccDegree& operator-=(ccDegree a);`

Subtracts the angle *a* from this angle and returns the result.

Parameters

a	The angle to subtract.

operator== `bool operator!=(ccDegree a) const;`

Returns true if this angle is exactly equal to the angle *a*.

Parameters

a	The other angle.

operator!= `bool operator!=(ccDegree a) const;`

Returns true if this angle is not equal to the angle *a*.

Parameters

a	The other angle.

operator< `bool operator<(ccDegree a) const;`

Returns true if this angle is less than angle *a*.

Parameters

a	The other angle.

operator<= `bool operator<=(ccDegree a) const;`

Returns true if this angle is less than or equal to angle *a*.

Parameters

a	The other angle.

operator> `bool operator>(ccDegree a) const;`

Returns true if this angle is greater than angle *a*.

Parameters

a The other angle.

operator>= `bool operator>(ccDegree a) const;`

Returns true if this angle is greater than or equal to angle *a*.

Parameters

a The other angle.

Public Member Functions

toDouble `double toDouble() const;`

Returns this angle as a **double** value.

plain `double plain() const;`

Returns this angle as a **double**.

norm `ccDegree norm() const;`

Returns this angle normalized to the range from 0 up to (but not including) 360.0.

signedNorm `ccDegree signedNorm() const;`

Returns this angle normalized to the range from -180.0 up to (but not including) 180.0.

ccDiagDefs

```
#include <ch_cvl/diagobj.h>
```

```
class ccDiagDefs;
```

A name space class that holds enumerations used with tool diagnostics.

Enumerations

What

```
enum What;
```

What tool operations to record.

Value	Meaning
eInputs	Record tool inputs.
eIntermediate	Record tool intermediate results.
eResults	Record tool final results.

When

```
enum When;
```

Flag to record tool operations.

Value	Meaning
eRecordOn	Recording enabled
eRecordOff	Recording disabled

```
enum {eShallowCopy = 0x400000};
```

Value	Meaning
eShallowCopy	Record all handled data with shallow copies. The default is to record tool results with deep copies.

```
enum {eRecordDefault = eInputs | eResults | eRecordOn};
```

Value	Meaning
eRecordDefault	Record inputs and results.

ccDiagDefs

ccDiagIncrementLevel

```
#include <ch_cvl/diagobj.h>

class ccDiagIncrementLevel;
```

This is a helper class for vision tool implementers.

Constructors/Destructors

ccDiagIncrementLevel

```
ccDiagIncrementLevel(ccDiagObject* obj);

~ccDiagIncrementLevel();
```

- `ccDiagIncrementLevel(ccDiagObject* obj);`

  Increments the level of the given diagnostic object.

  Parameters

  obj The diagnostic object.

  Notes

  When *obj* is 0, the object has no effect. *obj* must not be deleted until *this* object has been destroyed.

`~ccDiagIncrementLevel();`

Decrements the level of the given diagnostic object.

ccDiagIncrementLevel

ccDiagObject

```
#include <ch_cvl/diagobj.h>

class ccDiagObject;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This is a container class to hold **ccDiagRecord** objects.

Constructors/Destructors

ccDiagObject

```
ccDiagObject();
```

Creates a diagnostic object with a level of zero and no diagnostic records. See **level()** on page 1155.

Public Member Functions

level

```
c_Int32 level() const;

void level(c_Int32 lvl);
```

- `c_Int32 level() const;`

  Gets the current level for new record creation.

- `void level(c_Int32 lvl);`

  Sets the level for new record creation. The level of the record is the nested depth of the tool which created it. The top-level tool adds records with a level of zero. As each tool calls sub-tools, the sub-tools create records with increasing level values.

  Parameters

  lvl The level to be used for new record creation.

  Throws

  ccDiagDefs::InvalidLevel The given level is less than zero.

newDiagRecord

```
ccDiagRecord& newDiagRecord();
```

Allocates a new diagnostic record and returns a reference to the newly created record. The new record has its level set to **level()**. The returned reference should not be cached for later use. See also **reset()** on page 1156.

Notes

All references to records in this object previously returned by **newDiagRecord()** or **diagRecord()** are invalid after calling this function.

numRecords

```
c_Int32 numRecords() const;
```

Returns the total number of records in this object.

diagRecord

```
ccDiagRecord& diagRecord(c_Int32 num);
```

Retrieves a previously allocated record. This reference should not be cached. See also **newDiagRecord()** on page 1156 and **reset()** on page 1156.

Parameters

num	The number of the record to retrieve. Records are numbered from 0 to **numRecords()** - 1.

Throws

ccDiagDefs::InvalidRecordNumber The number is not a valid record.

reset

```
void reset();
```

Resets the diagnostic object to initialized state. All records associated with this diagnostic object are released.

Notes

All references to records in this object previously returned by **newDiagRecord()** or **diagRecord()** are invalid after calling this function.

Static Functions

setThreadRecording

```
static void setThreadRecording(ccDiagObject* obj,
  c_UInt32 flags);
```

Sets the diagnostic object used for recording all tools executed by this thread.

Parameters

obj — The diagnostic object to use for recording. If *obj* is zero, thread recording is disabled for this thread.

flags — Recording flags. Flags can be the OR of any of the **ccDiagDefs::What** values ORed with one of the **ccDiagDefs::When** values.
What values:
ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

When values:
ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

getThreadRecording

```
static ccDiagObject* getThreadRecording(c_UInt32& flags);
```

Gets the diagnostic object used for recording all tools executed by this thread.

Parameters

flags — Recording flags. Flags can be the OR of any of the **ccDiagDefs::What** values ORed with one of the **ccDiagDefs::When** values.
What values:
ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

When values:
ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

shouldRecord

```
static bool shouldRecord(c_UInt32 diagFlags,
  ccDiagDefs::What what);
```

Returns true if the given type of diagnostic data should be recorded to this diagnostic object. This function is generally only called by vision tool implementors.

Parameters

diagFlags — Current value of diagnostic recording flags.

what — Recording flag. Must be one or more of the following:
ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

getRecordingDestination

```
static ccDiagObject* getRecordingDestination(
  ccDiagObject* obj, c_UInt32& flags);
```

Takes the diagnostic object and flags passed to a vision tool run function and returns the diagnostic object and flags to be used for recording, either zero, the one passed in, or the thread recording settings. This function is generally only called by vision tool implementors.

Parameters

obj — The current diag object. If *obj* is non-zero, it overrides any thread recording object. If *obj* is zero, the thread recording diagnostic object is returned (this defaults to a null pointer).

flags — Recording flags. If *flags* is zero, the thread recording flags are returned (these default to zero). If non-zero *flags* are passed to a vision tool run function, they override any thread recording settings.
Flags can be the OR of any of the **ccDiagDefs::What** values ORed with one of the **ccDiagDefs::When** values.
What values:
ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

When values:
ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

When a given tool has data to record, it should use this function to determine which diagnostic object to record to and what flags to use.

ccDiagRecord

```
#include <ch_cvl/diagobj.h>

class ccDiagRecord;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This class holds diagnostic record objects.

Enumerations

ItemType

```
enum ItemType;
```

This enumeration defines the type of an item in the **ccDiagRecord**.

Value	Meaning
eGraphics	Item is a graphic object.
eText	Item is a text object.
eData	Item is a data object.
eSketch	Item is a sketch object.

Notes

eSketch is provided for backward compatibility only. *eGraphics* should be used for all new application code.

Constructors/Destructors

ccDiagRecord

```
ccDiagRecord(c_Int32 level=0);
```

Constructs a diagnostic record with a level of 0 and no items. See comments for member function **level()** on page 1160.

Parameters

level The level of the record.

Throws
ccDiagDefs::InvalidLevel
If *level* is < 0.

Public Member Functions

level

```
c_Int32 level() const;
void level(c_Int32 lvl);
```

- `c_Int32 level() const;`

  Gets the level of the record

- `void level(c_Int32 lvl);`

  Sets the level of this record. The level of a record reflects the nested depth of the tool which created it. The top-level tool adds records with a level of zero. As each tool calls sub-tools, the sub-tools create records with increasing level values.

  Parameters
  lvl The level of the record

  Throws
  ccDiagDefs::InvalidLevel
  If given level is < 0.

recordAnnotation

```
ccCvlString recordAnnotation() const;
void recordAnnotation(const ccCvlString& annot);
```

- `ccCvlString recordAnnotation() const;`

  Gets the annotation string for this record.

- `void recordAnnotation(const ccCvlString& annot);`

  Sets the annotation string for this record.

  Parameters
  annot The annotation string.

Notes

Each record has an annotation string, and each item in a record has its own annotation string.

---

image

```
ccPelBuffer_const<c_UInt8>& image() const;

void image(const ccPelBuffer_const<c_UInt8>& pb,
  bool allowOverwrite = false);
```

- `ccPelBuffer_const<c_UInt8>& image() const;`

Returns the image for this record. If no image has been set, returns an unbound pel buffer.

- `void image(const ccPelBuffer_const<c_UInt8>& pb, bool allowOverwrite = false);`

Adds an image to the current record.

Parameters

pb The image.

allowOverwrite If *allowOverwrite* is true, the given pel buffer will replace the current pel buffer. If *allowOverwrite* is false, attempting to add more than one pel buffer to a record will result in a throw.

Throws

ccDiagDefs::ImageItemNotAvailable
When attempting to add more than one image and *allowOverwrite* == **true**.

Notes

A record can have only one image. The pel buffer image must not be modified until the **ccDiagObject** is no longer using it.

numItems

```
c_Int32 numItems() const;
```

Returns the number of items in this record.

itemType

```
ItemType itemType(c_Int32 num) const;
```

Gets the type of the given item. Items are numbered from 0 to **numItems()** - 1.

Parameters

num The number of the item.

Throws

ccDiagDefs::InvalidItemNumber
If *num* is < 0 or >= **numItems()**

graphics

```
void graphics(c_Int32 num, ccGraphicList& graphics,
 ccDisplay::CoordinateSystem& coord,
 ccCvlString& itemAnnot) const;

void graphics(const ccGraphicList& graphics,
 ccDisplay::CoordinateSystem coord,
 const ccCvlString& itemAnnot);
```

- ```
  void graphics(c_Int32 num, ccGraphicList& graphics,
   ccDisplay::CoordinateSystem& coord,
   ccCvlString& itemAnnot) const;
  ```

  Returns the data associated with the given *eGraphics* item.

  Parameters

num	The item number to be retrieved.
graphics	The graphics list for the given item.
coord	The graphics list coordinate system for the given item.
itemAnnot	The annotation string for the given item.

  Throws

  ccDiagDefs::InvalidItemNumber
  If *num* < 0 or >= **numItems().**

  ccDiagDefs::InvalidItemType
  If the given item is not of type *eGraphics.*

- ```
  void graphics(const ccGraphicList& graphics,
   ccDisplay::CoordinateSystem coord,
   const ccCvlString& itemAnnot);
  ```

  Appends a new *eGraphics* item with the given data to the current list of items.

  Parameters

graphics	The graphics list for the new item.
coord	The graphics coordinate system for the new item.
itemAnnot	The annotation string for the new item.

text

```
void text(c_Int32 num, ccCvlString& text,
 ccCvlString& itemAnnot) const;

void text(const ccCvlString& text,
 const ccCvlString& itemAnnot);
```

- ```
  void text(c_Int32 num, ccCvlString& text,
   ccCvlString& itemAnnot) const;
  ```

  Returns the data associated with the given *eText* item.

  Parameters

  num The item number to be retrieved.

  text The text for the given item.

  itemAnnot The annotation string for the given item.

  Throws

  ccDiagDefs::InvalidItemNumber
  If *num* < 0 or >= **numItems().**

  ccDiagDefs::InvalidItemType
  If the given item is not of type *eText*.

- ```
  void text(const ccCvlString& text,
   const ccCvlString& itemAnnot);
  ```

  Appends a new *eText* item with the given data to the current list of items.

  Parameters

  text The text string for the new item.

  itemAnnot The annotation string for the new item.

reset

```
void reset();
```

Reset the record. Clears all images, text, graphics, and data, and resets the record annotation and level.

Deprecated Members

sketch

```
void sketch(c_Int32 num, ccUISketch& sketch,
 ccDisplay::CoordinateSystem& coord,
 ccCvlString& itemAnnot) const;

void sketch(const ccUISketch& graphics,
 ccDisplay::CoordinateSystem coord,
 const ccCvlString& itemAnnot);
```

- ```
  void sketch(c_Int32 num, ccUISketch& sketch,
   ccDisplay::CoordinateSystem& coord,
   ccCvlString& itemAnnot) const;
  ```

  Returns the data associated with the given *eSketch* item.

  Parameters

  num Item number to be retrieved.

  sketch Sketch for the given item.

  coord Sketch coordinate system for the given item.

  itemAnnot Annotation string for the given item.

  Throws

  *ccDiagDefs::*InvalidItemNumber
  If num < 0 or >= **numItems().**

  *ccDiagDefs::*InvalidItemType
  Given item is not of type *eSketch.*

- ```
  void sketch(const ccUISketch& sketch,
  ccDisplay::CoordinateSystem coord, const ccCvlString&
  itemAnnot);
  ```

  Appends a new *eSketch* item with the given data to the current list of items.

  Parameters

  sketch Sketch for the given item.

  coord Sketch coordinate system for the given item.

  itemAnnot Annotation string for the given item.

ccDiagServer

```
#include <ch_cvl/diagsrv.h>

class ccDiagServer;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is a server for **ccDiagObject** objects.

Constructors/Destructors

Constructors and destructors are automatically called by the program for this class.

Static Functions

init

```
static void init();
```

Initializes the diagnostics server. This function must be called before trying to show any diagnostic objects using **ccDiagServer:: showDiagObject()**. If this function is called, do not call **ccRPC::init()**, since this is done within this function.

The host application must call **ccDiagServer::init()** at system initialization and **ccDiagServer::exit()** at system shutdown if diagnostic objects are going to be displayed on the host, whether the call to**ccDiagServer:: showDiagObject()** is executed on the host or on the embedded side. If an embedded application is going to call **ccDiagServer::showDiagObject()** during its lifetime, it also must call the **ccDiagServer::init()** and **ccDiagServer::exit()** function pair.

Notes

ccDiagServer::init() must be called only once at system startup. Attempting to call this function more than once will result in an error.

exit

```
static void exit();
```

Shuts down all threads and releases all resources used by the display server for all accelerators.

Notes

ccDiagServer::exit() must be called only once at system shutdown. Attempting to call this function more than once will result in an error.

showDiagObject

```
static void showDiagObject(ccAccelerator* acc,
  const c_Int32 channel, ccDiagObject& diagObject);
```

Displays a diagnostic object to the specified channel (window) associated with the specified accelerator.

Parameters

acc	The accelerator, 0 specifies the host.
channel	The channel number (window) on the host.
diagObject	The diagnostic object to be displayed.

ccDIB

```
#include <ch_cvl/dib.h>

class ccDIB;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Not applicable

The **ccDIB** class lets you convert Windows DIB (Device-Independent Bitmap) files into CVL **ccPelBuffer**s and CVL **ccPelBuffer**s into Windows DIB files.

Constructors/Destructors

ccDIB

```
ccDIB();
```

Constructs an uninitialized **ccDIB** object with no image pixel or palette data. Member functions that require an initialized **ccDIB** object will throw if it is uninitialized.

Public Member Functions

init

```
void init(const ccCvlString& filename);
void init(ccCvlIStream& stream);
void init(const ccPelBuffer_const<c_UInt8>& pelBuf);
void init(const c_UInt8* dib, c_UInt32 len);
```

- `void init(const ccCvlString& filename);`

Reads a DIB from the supplied file and initializes this object with pixel and palette data.

Parameters

filename The file from which to read the DIB.

Throws

ccDIB::ReadError
The supplied file cannot be opened or read.

ccDIB::BadFormat
The supplied file is not in the proper DIB format.

- `void init(ccCvlIStream& stream);`

Reads a DIB from the supplied **ccCvlIStream** and initializes this object with pixel and palette data.

Parameters
stream The **ccCvlIStream** from which to read the DIB.

Throws
ccDIB::BadFormat
The supplied **ccCvlIStream** is not in the proper DIB format.

- `void init(const ccPelBuffer_const<c_UInt8>& pelBuf);`

Given a **ccPelBuffer**, initializes this object with pixel data from the **ccPelBuffer** and a 256 color grey-scale palette.

Parameters
pelBuf The pixel data used to initialize this object.

- `void init(const c_UInt8* dib, c_UInt32 len);`

Given a DIB in packed-memory DIB format, initializes this **ccDIB** with pixel and palette data from the DIB.

Parameters
dib A pointer to a DIB in packed-memory format.

len The number of bytes pointed to by *dib*.

Throws
ccDIB::BadFormat
dib does not point to a valid packed-memory format DIB.

---

write

```
void write(const ccCvlString& filename) const;
void write(ccCvlOStream& stream) const;
```

- `void write(const ccCvlString& filename) const;`

Writes this **ccDIB** object out to the specified file in DIB format.

Parameters

filename The file to which to write the DIB.

Throws

ccDIB::WriteError

file cannot be written.

ccDIB::NoDibData

This **ccDIB** was default constructed.

- `void write(ccCvlOStream& stream) const;`

Writes this **ccDIB** object out to the supplied **ccCvlOstream** in DIB format.

Parameters

stream The **ccCvlOstream** to which to write the DIB.

Throws

ccDIB::WriteError

The supplied **ccCvlOstream** cannot be written.

ccDIB::NoDibData

This **ccDIB** was default constructed.

pelBuffer `ccPelBuffer<c_UInt8> pelBuffer() const;`

Returns a **ccPelBuffer** representation of this **ccDIB** object. A color DIB is converted to a grey-scale **ccPelBuffer**. The algorithm used for converting color DIBs to 8 bit images is as follows:

$$p = (R + G + B) / 3$$

where

p is the pixel value in the grey-scale **ccPelBuffer**

R is the red value of the corresponding DIB pixel

G is the green value of the corresponding DIB pixel

B is the blue value of the corresponding DIB pixel

Throws

ccDIB::NoDibData

This **ccDIB** was default constructed.

clipboardDibSize

```
c_UInt32 clipboardDibSize() const;
```

Returns the number of bytes required to store the current contents of this **ccDIB** in packed-memory DIB format.

renderClipboardDib

```
void renderClipboardDib(c_UInt8* dest) const;
```

Copies the current contents of this **ccDIB** in packed-memory DIB format to the supplied block of memory.

Parameters

dest — The memory to which the packed-memory format DIB is copied. Note that you must allocate *dest* to point to at least the number of bytes returned by **clipboardDibSize()**.

Throws

ccDIB::NoDibData — This **ccDIB** was default constructed.

ccDigitalCameraControlProp

```
#include <ch_cvl/prop.h>

class ccDigitalCameraControlProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class allows you to control properties of certain digital cameras on platforms that support this property.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccDigitalCameraControlProp

```
ccDigitalCameraControlProp();
```

Creates a digital camera property not associated with any acquisition FIFO. By default, high gain is off.

Constants

defaultMasterClockFrequency

```
static const double defaultMasterClockFrequency;
```

The default master clock frequency: 32.0 MHz.

Public Member Functions

selectHighGain

```
void selectHighGain(bool isHigh);

bool selectHighGain() const;
```

- `void selectHighGain(bool isHigh);`

  Sets the digital camera's analog-to-digital (A/D) gain either high (true) or low (false).

  Some digital cameras provide only manual gain control by means of a physical switch or a dial in the camera. However, some digital cameras, such as the Dalsa Spyder line scan cameras, support gain selection by means of a control line.

  Parameters

  isHigh — True to set the A/D gain adjustment high; false to set it low.

- `bool selectHighGain() const;`

  Returns whether the digital camera's analog-to-digital (A/D) gain is set high (true) or low (false). Not all digital cameras support this feature.

masterClockFrequency

```
void masterClockFrequency(double frequency);

double masterClockFrequency() const;
```

- `void masterClockFrequency(double frequency);`

  Sets the master clock frequency in megahertz.

  Parameters

  frequency — The master clock frequency in MHz.

  Throws

  ccDigitalCameraControlProp::BadParams — The frequency is not in the range 5.0 to 40.0.

- `double masterClockFrequency() const;`

  Returns the master clock frequency in megahertz.

ccDimTol

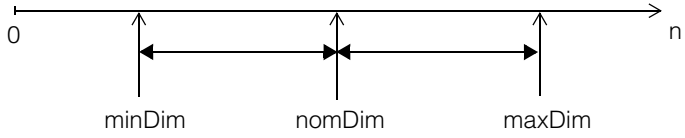
```
#include <ch_cvl/dimtol.h>

class ccDimTol;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	Simple

This class embodies information about dimension tolerances. Specifically, a nominal dimension, and its minimum and maximum values.



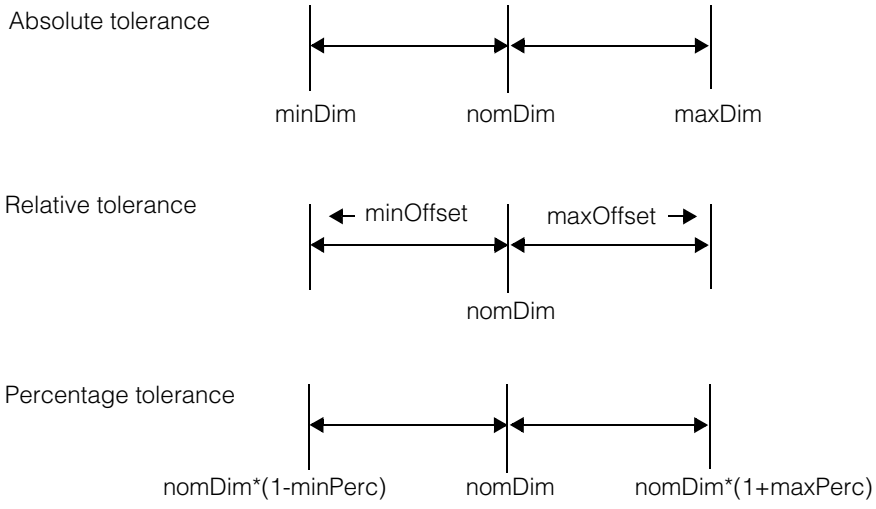
The class allows a dimension minimum and maximum tolerance to be specified using one of three measurement types:

- As percentages of the nominal dimension
- As relative offsets from the nominal dimension
- As absolute limits on the dimension.

In this manner, it is possible to store tolerances without explicit knowledge of the nominal dimension. If the nominal dimension is known, however, the class provides methods for converting tolerance information from one measurement type to another.

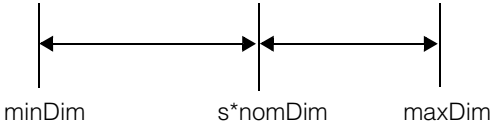
Note that both minimum and maximum tolerances are always specified as positive numbers (relative offsets and percentages add and subtract from the nominal). Furthermore, the minimum tolerance is constrained such that the absolute minimum dimension can never be less than zero. However, either the maximum or minimum tolerances can be specified as *undefined* using a value of -1, which is the default.

The three measurement types are illustrated below:

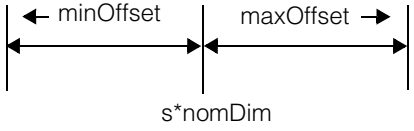


When you apply a scale factor to a **ccDimTol** object, the effect depends on the tolerance type as illustrated below. (scale factor = s)

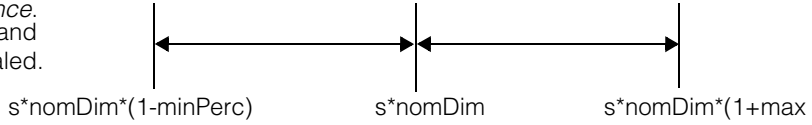
Absolute tolerance.
nomDim scales but the min and max limits stay fixed.



Relative tolerance.
nomDim, minDim, and maxDim scale, but the offsets remain fixed



Percentage tolerance.
nomDim, minDim, and maxDim are all scaled.



Constructors/Destructors

ccDimTol

```
ccDimTol(
  double nomDim = -1,
  double minTol = -1,
  double maxTol = -1,
  TolType type = eAbsolute);
```

Constructs an object with the specified absolute dimension tolerances, and the tolerance type *eAbsolute*. The tolerance type dictates how the *minTol* and *maxTol* values you specify are interpreted. See the reference page introductory information.

Parameters

nomDim	The nominal dimension.
minTol	The minimum tolerance.
maxTol	The maximum tolerance.
type	The tolerance type.

If your constructor specifies *type=eAbsolute*, the following throws apply.

Throws

ccShapesError::BadGeom
If *minDim* < 0 and not -1,
or if *maxDim* < 0 and not -1,
or if *minDim* and *maxDim* are defined and *minDim* > **maxTol()**,
or if *minDim* and *nomDim* are defined and *minDim* > *nomDim*,
or if *maxDim* and *nomDim* are defined and *maxDim* < *nomDim*.

If your constructor specifies *type=eRelative*, the following throws apply.

Throws

ccShapesError::BadGeom
If *minOffset* < 0 and not -1,
or if *maxOffset* < 0 and not -1,
or if *minOffset* and *nomDim* are defined and *minOffset* > *nomDim*.

If your constructor specifies *type=ePercentage*, the following throws apply.

Throws

ccShapesError::BadGeom
If *minPerc* < 0 and not -1,
or if *minPerc* > 1 and not -1,
or if *maxPerc* < 0 and not -1.

Enumerations

TolType

```
enum TolType
```

Value	Meaning
eAbsolute	Keep absolute tolerance limits constant.
eRelative	Keep relative tolerance offsets constants.
ePercentage	Keep tolerance percentages constant.

Operators

operator*

```
friend ccDimTol operator* (
  double scale,
  const ccDimTol& dim);
```

Scales the dimensional tolerance object *dim*. The effect of scaling on the dimension tolerances depends on the *dim* tolerance type. See the introductory information for this reference page.

Parameters

scale	Scale factor.
dim	Object to be scaled.

operator==

```
bool operator== (const ccDimTol& tol) const;
```

This operator allows you to compare two **ccDimTol** objects. For example,

```
if(dim1 == dim2) {.....}
```

The equality expression evaluates to *true* if the objects are equal. It is *false* if they are not equal.

Parameters

tol	The right-hand **ccDimTol** object. For example, ***dim2***.

operator!=

```
bool operator!= (const ccDimTol& tol) const;
```

This operator allows you to compare two **ccDimTol** objects. For example,

```
if(dim1 != dim2) {.....}
```

The inequality expression evaluates to *true* if the objects are not equal. It is *false* if they are equal.

Parameters

tol The right-hand **ccDimTol** object. For example, *dim2*.

Public Member Functions

nomDim

```
void nomDim(double d);
```

```
double nomDim() const;
```

The nominal dimension value in physical units. A -1 indicates the dimension is undefined.

- `void nomDim(double d);`

  Sets a new nominal dimension value.

  Parameters

  d The new nominal dimension value.

- `double nomDim() const;`

  Returns the nominal dimension.

  Throws

  ccShapesError::BadGeom

  If *d* <= 0 and not -1,
  or if **tolType()** = *eRelative* and **minOffset()** and *d* are defined and **minOffset()** > *d*.
  or if **tolType()** = *eAbsolute* and one of the following is true:
  minDim() and *d* are defined and *d* < **minDim()**,
  or **maxDim()** and *d* are defined and *d* > **maxDim()**.

minTol

```
double minTol() const;
```

Returns the minimum dimension tolerance. You will need to know the **tolType()** value to interpret this result.

maxTol

```
double maxTol() const;
```

Returns the maximum dimension tolerance. You will need to know the **tolType()** value to interpret this result.

tolType

```
TolType tolType() const;
void tolType(TolType type);
```

- `TolType tolType() const;`

  Returns the tolerance type.

- `void tolType(TolType type);`

  Sets a new tolerance type. Must be *eAbsolute*, *eRelative*, or *ePercentage*.

  Parameters

  type The new tolerance type.

  Throws

  ccShapesError::BadGeom
  If *type* != **tolType()** and **nomDim()** = -1. (Measurement conversion is impossible).

minDim

```
double minDim() const;
```

Returns the absolute minimum dimension tolerance. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom
If the minimum dimension value is defined and **nomDim()** is not defined. (Measurement conversion is impossible).

maxDim

```
double maxDim() const;
```

Returns the absolute maximum dimension tolerance. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom
If the maximum dimension value is defined and **nomDim()** is not defined. (Measurement conversion is impossible).

minOffset

```
double minOffset() const;
```

Returns the relative minimum dimension tolerance. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom

If **tolType()** != *eAbsolute*, the minimum dimension is defined, and **nomDim()** is not defined. (Measurement conversion is impossible).

maxOffset

```
double maxOffset() const;
```

Returns the relative maximum dimension tolerance. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom

If **tolType()** != *eAbsolute*, the maximum dimension is defined, and **nomDim()** is not defined. (Measurement conversion is impossible).

minPerc

```
double minPerc() const;
```

Returns the minimum dimension tolerance percentage. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom

If **tolType()** != *eAbsolute*, the minimum dimension is defined, and **nomDim()** is not defined. (Measurement conversion is impossible).

maxPerc

```
double maxPerc() const;
```

Returns the maximum dimension tolerance percentage. A tolerance value of -1 indicates the tolerance value is undefined.

Throws

ccShapesError::BadGeom

If **tolType()** != *eAbsolute*, the maximum dimension is defined, and **nomDim()** is not defined. (Measurement conversion is impossible).

limits

```
void limits(double minDim, double maxDim);
void limits(double nomDim, double minDim, double maxDim);
```

- `void limits(double minDim, double maxDim);`

Sets the absolute minimum and maximum dimension tolerances, and sets the tolerance type to *eAbsolute*. A tolerance value of -1 indicates the tolerance value is undefined. The nominal dimension is unchanged.

Parameters

minDim The absolute minimum dimension tolerance.

maxDim The absolute maximum dimension tolerance.

Throws

ccShapesError::BadGeom
If *minDim* < 0 and not -1,
or if *maxDim* < 0 and not -1,
or if *minDim* and *maxDim* are defined and *minDim* > **maxTol()**,
or if *minDim* and *nomDim* are defined and *minDim* > *nomDim*,
or if *maxDim* and *nomDim* are defined and *maxDim* < *nomDim*.

- `void limits(double nomDim, double minDim, double maxDim);`

Sets the nominal dimension, and the absolute minimum and maximum dimension tolerances. Sets the tolerance type to *eAbsolute*. A tolerance value of -1 indicates the tolerance value is undefined.

Parameters

nomDim The nominal dimension value.

minDim The absolute minimum dimension tolerance.

maxDim The absolute maximum dimension tolerance.

Throws

ccShapesError::BadGeom
If *minDim* < 0 and not -1,
or if *maxDim* < 0 and not -1,
or if *minDim* and *maxDim* are defined and *minDim* > **maxTol()**,
or if *minDim* and *nomDim* are defined and *minDim* > *nomDim*,
or if *maxDim* and *nomDim* are defined and *maxDim* < *nomDim*.

offsets

```
void offsets(double minOffset, double maxOffset);

void offsets(
  double nomDim,
  double minOffset,
  double maxOffset);
```

- `void offsets(double minOffset, double maxOffset);`

  Sets the relative minimum and maximum dimension offset tolerances, and sets the tolerance type to *eRelative*. The nominal dimension is unchanged. A tolerance value of -1 indicates the tolerance value is undefined.

  Parameters

  minOffset The relative minimum dimension offset tolerance.

  maxOffset The relative minimum dimension offset tolerance.

  Throws

  ccShapesError::BadGeom
  If *minOffset* < 0 and not -1,
  or if *maxOffset* < 0 and not -1,
  or if *minOffset* and *nomDim* are defined and *minOffset* > *nomDim*.

- ```
  void offsets(
    double nomDim,
    double minOffset,
    double maxOffset);
  ```

  Sets the nominal dimension and the relative minimum and maximum dimension tolerances. Sets the tolerance type to *eRelative*. A tolerance value of -1 indicates the tolerance value is undefined.

  Parameters

  nomDim The nominal dimension.

  minOffset The relative minimum dimension offset tolerance.

  maxOffset The relative minimum dimension offset tolerance.

  Throws

  ccShapesError::BadGeom
  If *minOffset* < 0 and not -1,
  or if *maxOffset* < 0 and not -1,
  or if *minOffset* and *nomDim* are defined and *minOffset* > *nomDim*.
  ```

percentages

```
void percentages(double minPerc, double maxPerc);

void percentages(
  double nomDim,
  double minPerc,
  double maxPerc);
```

Sets the minimum and maximum dimension tolerance percentages, and sets the tolerance type to *ePercentage*. The nominal dimension is unchanged. A tolerance value of -1 indicates the tolerance value is undefined.

- `void percentages(double minPerc, double maxPerc);`

Parameters

minPerc The minimum dimension tolerance percentage.

maxPerc The maximum dimension tolerance percentage.

Throws

ccShapesError::BadGeom
If *minPerc* < 0 and not -1,
or if *minPerc* > 1 and not -1,
or if *maxPerc* < 0 and not -1.

- ```
  void percentages(
    double nomDim,
    double minPerc,
    double maxPerc);
  ```

Sets the nominal dimension and the minimum and maximum dimension tolerance percentages. Sets the tolerance type to *ePercentage*. A tolerance value of -1 indicates the tolerance value is undefined.

Parameters

nomDim The nominal dimension.

minPerc The minimum dimension tolerance percentage.

maxPerc The maximum dimension tolerance percentage.

Throws

ccShapesError::BadGeom
If *minPerc* < 0 and not -1,
or if *minPerc* > 1 and not -1,
or if *maxPerc* < 0 and not -1.
  ```

isWithin

```
bool isWithin(double measurement) const;
```

Returns true if *measurement* is within the absolute minimum and absolute maximum dimension tolerances. More precisely, the function returns true if the following two conditions are both true:

1. **minDim()** == -1 OR *measurement* >= **minDim()**
2. **maxDim()** == -1 OR *measurement* <= **maxDim()**

Parameters

measurement The dimension to be tested.

Throws

ccShapesError::BadGeom
Both nominal dimensions are undefined and **tolType()** != *eAbsolute*.

ccDiscretePelRootPool

```
#include <ch_cvl/discpool.h>

class ccDiscretePelRootPool : public ccPelRootPool;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This class manages an image root pool with a fixed number of same-sized root images. See **ccPelRoot** on page 2391 to learn more about root images.

Constructors/Destructors

ccDiscretePelRootPool

```
ccDiscretePelRootPool(c_Int32 sizeOfEachPelArray,
  void** pelArrays, c_Int32 numArrays = 1,
  c_Int32 minRowUpdate = 0, c_Int32 alignModulus = 32);

ccDiscretePelRootPool(c_Int32 sizeOfEachPelArray,
  const cmStd vector<void*>& pelArrays,
  c_Int32 minRowUpdate = 0, c_Int32 alignModulus = 32);

~ccDiscretePelRootPool();
```

- ```
  ccDiscretePelRootPool(c_Int32 sizeOfEachPelArray,
    void** pelArrays, c_Int32 numArrays = 1,
    c_Int32 minRowUpdate = 0, c_Int32 alignModulus = 32);
  ```

  Constructs a pool of pixel arrays for constructing pel root objects.

  Parameters

  sizeOfEachPelArray
  The size of each root image in the pool.

  pelArrays An array of pointers to the memory allocated for each root image pool. Each *perlArrays[i]* points to a block of *sizeOfEachPelArray* bytes.

  numArrays The number of root images.
  ```

minRowUpdate The minimum row update value to use in bytes. See **cc_PelRoot::rowUpdate()** on page 3473.

alignModulus The alignment modulus value to use in bytes. See **cc_PelRoot::alignModulus()** on page 3474**.**

Notes

The actual row update value used for root images will be no less than *minRowUpdate*, and, if necessary, will be rounded up to be multiple of *alignModulus*.

- ```
  ccDiscretePelRootPool(c_Int32 sizeOfEachPelArray,
    const cmStd vector<void*>& pelArrays,
    c_Int32 minRowUpdate = 0, c_Int32 alignModulus = 32);
  ```

Constructs a pool of pixel arrays for constructing pel root objects. This constructor uses vectors instead of an array of pixel arrays.

Parameters

sizeOfEachPelArray
The size of each root image in the pool.

pelArrays A vector of pointers to the memory allocated for each root image pool. Each *perlArrays[i]* points to a block of *sizeOfEachPelArray* bytes.

minRowUpdate The minimum row update value to use in bytes. See **cc_PelRoot::rowUpdate()** on page 3473.

alignModulus The alignment modulus value to use in bytes. See **cc_PelRoot::alignModulus()** on page 3474**.**

Notes

The actual row update value used for root images will be no less than *minRowUpdate*, and, if necessary, will be rounded up to be multiple of *alignModulus*.

- ```
  ~ccDiscretePelRootPool();
  ```

Destroys the pixel root pool.

Public Member Functions

size

```
virtual void size();

virtual size_t size(size_t bytes) const;
```

- `virtual void size();`

  Returns the number of bytes occupied by the root image pool. This value is equal to the size of each root image multiplied by the number of root images.

- `virtual size_t size(size_t bytes) const;`

  Throws

  ccPelRootPool::NotSupported
  This root image pool does not support resizing.

Typedefs

ccPelRootPoolPtrh_const

```
typedef ccPtrHandle_const<ccPelRootPool>
ccPelRootPoolPtrh_const;
```

A **const** pointer handle to a **ccPelRootPool** object.

ccDiscretePelRootPoolPtrh

```
typedef ccPtrHandle<ccDiscretePelRootPool,
  ccPelRootPoolPtrh, ccPelRootPoolPtrh_const>
  ccDiscretePelRootPoolPtrh;
```

A pointer handle to this class.

ccDiscretePelRootPoolPtrh_const

```
typedef ccPtrHandle_const<ccDiscretePelRootPool,
  ccPelRootPoolPtrh_const>
  ccDiscretePelRootPoolPtrh_const;
```

A **const** pointer handle to this class.

ccDiscretePelRootPool

ccDisplay

```
#include <ch_cvl/display.h>

class ccDisplay : public ccUIControlFrame, public ccRepBase;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is one of the platform-independent interfaces for displaying images and graphics. **ccDisplay** is one of the base classes for the overall display class hierarchy. It serves as the base class for other derived classes that create platform-independent display interfaces, such as **ccWin32Display**. See the following derivation hierarchy:

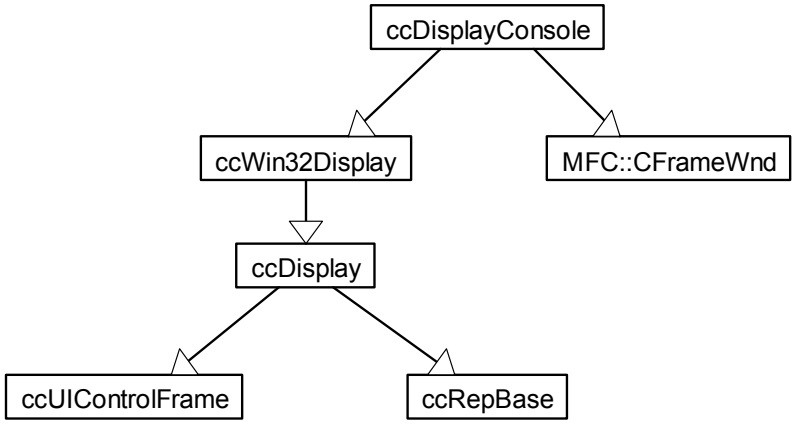


Figure 1. ccDisplay class inheritance hierarchy

Creating your own platform-independent interfaces through direct derivation from **ccDisplay** is not supported. When designing your own display classes, make them subclasses of one of the existing CVL classes that are derived from **ccDisplay**, such as **ccWin32Display** or **ccDisplayConsole**, and overload the existing virtual methods that you class will inherit by this means.

For the majority of CVL applications, including all those that use a Cognex frame grabber, use either the **ccDisplayConsole** or **ccWin32Display** class, as follows:

- **ccWin32Display**: For display classes based on the Microsoft Win32 API for execution on a Windows host computer.
- **ccDisplayConsole**: For applications that use Microsoft MFC and execute on a Windows host computer. **ccDisplayConsole** also inherits from the MFC class **CFrameWnd**.

Note CVL display is not multi-thread safe. Always mutex or semaphore protect any code that accesses a **ccDisplay**-based object and its methods from multiple threads.

Display Features

The **ccDisplay** class contains interfaces that provide the following capabilities:

- Display of different types of pel buffers, such as grey-scale and color. Not all derived implementations support the display of all types of pel buffers. Only one image can be displayed at a time.
- Adding static graphics to the display. Static graphics are added through the **ccUISketch** interface. Once static graphics have been added, the display automatically handles redrawing and refreshing them whenever the system is modified.
- Adding interactive graphics to the display. Interactive graphics are those classes that derive from **ccUIShapes**. Once interactive graphics have been added, the display automatically handles redrawing and refreshing them whenever the system is modified.
- Managing three separate coordinate spaces of the display: client, image, and display coordinates.
- Managing the viewport into the display by providing methods to pan, fit, and scale the image and graphics.
- Scaling the viewport with integer or floating-point precision. The **ccUITablet** interface provides the ability to interpolate images.
- Adding pixel and subpixel grids.
- Application of a user-defined color map that can be used to map image pixel values to color values.
- Control of the shape of the cursor.
- Control of the blinking of graphics colors. Not all derived implementations support the blinking of graphics colors.
- Selection of a region of interest.

- Control of the live display of an acquisition FIFO within the display window.
- Control of synchronization with the monitor refresh rate. Not all derived implementations support this feature.
- Retrieval of a copy of the image and all graphics as they are seen on the screen.

Graphics

Two different types of graphics can be displayed in a **ccDisplay**-derived window:

- **Interactive graphics:** these are **ccUIShapes**-derived objects that are passed into the **addShape()** method, specifying the coordinate system in which they are to be displayed. The *ccUIObject::drawLayer* argument specifies the layer to which the graphic is to be added. These graphics contain handles for manipulating size, rotation, and position.
- **Static graphics:** these are non-interactive graphics. They are created in a **ccUISketch** and passed into the **drawSketch()** method, specifying the coordinate system in which they are to be displayed. A sketch is a list of drawing commands that are recorded into a **ccUITablet** when recording is turned on. See the **ccUITablet** reference page for more information.

The static representation of a graphic generally renders faster and uses fewer resources than its interactive counterpart (for example, **ccCircle** is faster than **ccUICircle**).

Coordinate Systems

Three different coordinate systems are available within CVL display:

- **Display coordinates:** used to draw graphics in the display coordinate system. The display coordinate system is relative to the upper left corner of the display window.
- **Image coordinates:** used to draw graphics in the image coordinate system. The image coordinate system is relative to the upper left corner of the image. Mapping from image to display coordinates is based on translation and scale, and depends on whether the image is panned or zoomed, and whether it has an offset. When there is no image in the display, the image coordinate space is the same as the display coordinate space.
- **Client coordinates:** used to draw graphics in the client coordinate system. The transform contained within the pel buffer that is passed to the **image()** method specifies how image coordinates are to be translated to client coordinates.

Constructors/Destructors

The constructors and destructors of **ccDisplay** are used exclusively by derived classes. Do not instantiate **ccDisplay** objects directly in your own applications.

Enumerations

DisplayFormat `enum DisplayFormat`

This enumeration specifies the display format of the display. For **ccWin32Display** and **ccDisplayConsole**, the **displayFormat()** method returns the desktop format. For all other classes derived from **ccDisplay**, **displayFormat()** returns *e8Bit*.

Value	Meaning
e8Bit	The image is an 8-bit grey scale image (8 bits per pixel).
eRGB15	The image is a 15-bit RGB image (15 bits per pixel, encoded as `0rrr rrgg gggb bbbb`). This format is also known as packed 5-5-5 RGB.
eRGB16	The image is a 16-bit RGB image (16 bits per pixel, encoded as `rrrr rggg gggb bbbb`). This format is also known as packed 5-6-5 RGB.
eRGB24	The image is a 24-bit RGB image (24 bits per pixel, the bytes encoded as `0rgb`). This format is also known as 8-8-8 RGB.
eRGB32	The image is a 32-bit RGB image (32 bits per pixel, the bytes encoded as `argb`, where a is an alphabetic byte). This format is also known as packed 0-8-8-8 ARGB.

CoordinateSystem

```
enum CoordinateSystem
```

This enumeration lets you specify the coordinate system to use for display operations.

Value	Meaning
eDisplayCoords	Display coordinate space. This coordinate system is relative to the upper left corner of the display window, irrespective of panning or zooming.
eImageCoords	Image coordinate space. This coordinate system is relative to the upper left corner of the image when the transform of the pel buffer is the identity transform. The mapping from image to display coordinates can include translation and scale information, depending on whether the image is panned or zoomed, or both, and whether it has an offset. When there is no image in the display, the image coordinate space is the same as the display coordinate space.
eClientCoords	Client coordinate space. The image-to-client coordinate system transformation is specified by the transform object associated with the pel buffer. When this is the identity transform, the client coordinate space is the same as the image coordinate space.

ColorMapIndex

```
enum ColorMapIndex
```

This enumeration defines the minimum and maximum indices into the entire color map over which you have control. You cannot change the color map setting for indices less than *eMinUserColor* or greater than *eMaxUserColor*. Note that the default value of 0 for the *mapStart* argument to the **colorMap()** setter causes the input map to be used starting at index *eMinUserColor*, or [10].

Value	Meaning
eMinUserColor = 10	Minimum index into the area of the color map that is user-accessible (10).
eMaxUserColor =240	Maximum index into the area of the color map that is user-accessible (240).

MouseMode `enum MouseMode`

This enumeration specifies the mouse mode.

Value		Meaning
ePointer		Sets the cursor to a pointer arrow shape. Graphics can be selected, panned, and so on. The image cannot be panned. Switches to *ePan* mode when the *<Ctrl>* key or the *<Shift>* key is pressed.
ePan		Sets the cursor to a hand shape. Graphics cannot be selected or panned. The image can be panned. Switches to *ePointer* mode when the *<Ctrl>* key or the *<Shift>* key is pressed.
eZoomIn		Sets the cursor to a plus magnifying glass shape. Graphics cannot be selected or panned. The image cannot be panned. Left mouse click zooms in, right mouse click zooms out. Switches to *ePan* mode when the *<Ctrl>* key or the *<Shift>* key is pressed.
eZoomOut		Sets the cursor to a minus magnifying glass shape. Graphics cannot be selected or panned. The image cannot be panned. Left mouse click zooms out, right mouse click zooms in. Switches to *ePan* mode when the *<Ctrl>* key or the *<Shift>* key is pressed.

overlayState `enum overlayState;`

This enumeration enables or disable the overlay layer of the drawing tablet (*ccUITablet::eOverlayLayer*).

Value	Meaning
eOverlayPlane	Enables the overlay layer. This is a complementary value to *eDisableOverlayPlane*.
eChromaKeying	Chromakeying is deprecated. Do not use this value in new code.

Value	Meaning
eDisableOverlayPlane	Disables the overlay layer. This is a complementary value to *eOverlayPlane*. When the overlay layer is disabled, any sketches and interactive shapes added to the overlay layer are discarded. This value applies only to host-based displays (**ccDisplayConsole** and **ccWin32Display**).
eDisableChromaKeying	Chromakeying is deprecated. Do not use this value in new code.
eNone	The overlay layer is not supported. Never pass this value as an argument to the **enableOverlay()** setter. The **enableOverlay()** getter returns this value when both the overlay layer and chromakeying are disabled.

Notes

overlayState values cannot be OR'ed together.

Public Member Functions

image

```
void image(const ccPelBuffer_const<c_UInt8>& pb,
  bool displayRaw = true);

void image(const ccPelBuffer_const<ccPackedRGB16Pel>& pb);

void image(const ccPelBuffer_const<ccPackedRGB32Pel>& pb);

bool image(const ccAcqImagePtrh, cc2Xform* img2client=0);
```

Displays the image in the supplied pel buffer.

On 8-bit desktops, pixel values in the range [10,240] are displayed as grey values and pixel values in the ranges [0,9] and [241,255] are displayed as colors by default. See also **colorMap()**.

On non 8-bit desktops, all pixel values are displayed as grey values by default. See also **colorMapEx()**.

This method uses the image from client coordinate transform, produced by **imageFromClientXform()** and stored in the pel buffer, to convert client coordinates to image coordinates. Call **image()** again to redisplay the image if the transform changes.

The base map of the drawing tablet, retrieved with **ccUITablet::baseMap()**, is automatically updated to reflect the current state of the image-from-client-coordinate transform of the image. When the transform is the identify matrix, the image is automatically centered within the display.

Whenever the image size (width or height) or transform differs from that of the current displayed image, all graphics are automatically redrawn on all layers.

Each time you call **image()**, the current image in the display is replaced with the supplied image, and all static and interactive graphics on the image layer are re-rendered. Graphics on the overlay layer are not redrawn, unless the transform has changed.

If the supplied pel buffer contains a non-linear transform, the display linearizes the transform using a first order polynomial fit over the entire area of the image. Any client coordinate graphics already contained in the display then use this linear approximation.

Notes

This method triggers an **imageChanged()** event to notify that a new image is about to be displayed. It also triggers an **updatePanRanges()** event when **defaultPan()** is true. See *Protected Member Functions* of **ccDisplay** for more information.

- `void image(const ccPelBuffer_const<c_UInt8>& pb, bool displayRaw = true);`

  Displays the supplied 8-bit pel buffer. This overload provides an option to clip pixel values.

  Parameters

  pb The 8-bit pel buffer.

  displayRaw If true, the pel buffer is not clipped. All pixel values are displayed as is with no mapping of pixel values. This is the default behavior.

  If false, the pel buffer is clipped. Values are mapped as follows:
  Pixel values in the range [0,9] are mapped to 10.
  Pixel values in the range [241,255] are mapped to 240.
  All other pixel values remain unchanged.

  Notes

  The *displayRaw* parameter is applicable to all desktop depths.

  An 8-bit pel buffer can be displayed on any desktop depth. If the physical display device has a non-8-bit pixel format, the pel buffer is converted automatically, with a corresponding increase in execution time.

- `void image(const ccPelBuffer_const<ccPackedRGB16Pel>& pb);`

  Displays the supplied 16-bit RGB pel buffer. Uses the transform stored in *pb*. This method must be called again if the transform changes.

  Parameters

  pb The 16-bit RGB pel buffer.

  Notes

  The image must be in packed 5-6-5 RGB format (that is, **displayFormat()** must return *eRGB16* for this image). The desktop depth of the physical display device must also be set to 16-bit to use this overload.

  The color map has no effect on the image displayed by this function.

- `void image(const ccPelBuffer_const<ccPackedRGB32Pel>& pb);`

  Displays the supplied 32-bit RGB pel buffer. Uses the transform stored in *pb*. This method must be called again if the transform changes.

  Parameters

  pb The 32-bit RGB pel buffer.

Notes

The image format must be in 32-bit RGB (that is, **displayFormat()** must return *eRGB32* for this image). The desktop depth of the physical display device must also be set to 32-bit to use this overload.

The color map has no effect on the image displayed by this function.

- `bool image(const ccAcqImagePtrh, cc2Xform* img2client=0);`

Displays an acquired image. The image is first converted to the proper pel buffer type for the current display settings. The transform in img2client, if specified, is then applied to the pel buffer. Finally, the pel buffer is displayed using the other other overloads of the image() function, as described above.

Returns true if the image was successfully displayed. Returns false if the image cannot be converted to a format suitable for display.

Notes

Color images will be displayed in color, if possible.

displayFormat `virtual DisplayFormat displayFormat() const;`

Retrieves the display format of this display.

hasImage `virtual bool hasImage() const;`

Returns true if the display has an image and it is currently visible.

hasImage8 `virtual bool hasImage8() const;`

Returns true if the display has an 8-bit image that it will manage. The image need not be currently visible.

Notes

Only one of the **hasImage*()** methods can be true at a time, as the CVL display framework can display and manage only a single image at a time.

hasImage16 `virtual bool hasImage16() const;`

Returns true if the display has a 16-bit image that it will manage. The image need not be currently visible.

Notes

Only one of the **hasImage*()** methods can be true at a time, as the CVL display framework can display and manage only a single image at a time.

hasImage32 `virtual bool hasImage32() const;`

Returns true if the display has a 32-bit image that it will manage. The image need not be currently visible.

Notes

Only one of the **hasImage*()** methods can be true at a time, as the CVL display framework can display and manage only a single image at a time.

removeImage `void removeImage();`

Removes the image from the display and resets the display to show the background only. All graphics in the display are automatically redrawn.

Notes

All of the **hasImage*()** methods return false after this method has been called.

imageSize `virtual ccIPair imageSize() const;`

This method returns the size of the image as a (width, height) pair if **hasImage()** is true. If **hasImage()** is false, this method returns (0,0).

Notes

The image size may be larger, smaller, or equal to the client area of the display.

imageOffset `virtual ccIPair imageOffset() const;`

This method returns the offset of the image if **hasImage()** is true. If **hasImage()** is false, this method returns (0,0).

clientArea `virtual ccIPair clientArea() const;`

Returns the current size of the client area of the display.

Notes

The size is returned as an integer pair (width, height). This size represents only the client drawing area and does not include any window decorations such as borders and scroll bars. This size may not necessarily match the size of the image currently in the display.

addShape

```
void addShape(ccUIShapes* shape, CoordinateSystem cs);
```

Adds the specified shape to the display. The shape is drawn in the specified coordinate system. Use this method with interactive shapes.

The drawing layer is specified in the shape itself (default = the image layer). You can change the layer by calling the shape's **ccUIObject::drawLayer()** method before calling this method.

Parameters

shape The interactive shape to add to the display.

cs The coordinate system to use to draw the shape. Must be one of the following values:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

See *CoordinateSystem* on page 1193 for more information.

Notes

In CVL, there are two ways to display graphics:

- Create UI shapes derived from **ccUIShapes** and pass them to **addShape()**, specifying the coordinate system in which to display the shape.
- Create a sketch and pass it to **drawSketch()**, again specifying the coordinate system. A sketch is a list of recorded drawing commands, recorded by drawing into a **ccUITablet** with recording turned on. You can either call the tablet's draw methods directly, or call the **ccUIShape**-derived objects' **draw()** methods by passing in a reference to the tablet.

Use **removeShape()** to remove interactive shapes from the display. You can add a shape to a different display without calling **removeShape()**. You can add a UI shape to only one display at a time.

If the UI shape's *ccUIObject::autoDelete* flag is set to true, then this display object takes ownership of the shape when it is added. Upon termination, the display automatically deletes any shapes it owns that were not previously removed using **removeShape()**. Therefore, UI shapes for which the *ccUIObject::autoDelete* flag is true must be allocated on the heap (with **new**) and must not be destroyed (with **delete**) in user code. You must explicitly delete only those UI shapes for which the *ccUIObject::autoDelete* flag is set to false.

The display automatically redraws interactive shapes as needed, re-rendering all other shapes in the display each time a new shape is added. Therefore, when adding a large number of shapes, call **disableDrawing()** before adding the first

shape, and call **enableDrawing()** after all the shapes have been added. This will improve performance, as the shapes will not be rendered until **enableDrawing()** has been called.

See **drawSketch()** for information on adding static graphics.

removeShape

```
bool removeShape(ccUIShapes* shape);
```

Removes the specified shape from the display. Returns true if the operation is successful, and false if the shape does not belong to this display. Use this method with interactive shapes.

Parameters

shape The interactive shape to remove from the display. This parameter must not be a NULL pointer.

Notes

You may have to call either **root()->globalUpdate()** or **ccUITablet::fullDraw()** after calling this function to redraw any overlapping shapes. If you remove a shape that overlaps other shapes, those other shapes may be partially erased. Calling one of these methods after each invocation of **removeShape()** will ensure that the display is correct. However, be aware that this will add overhead to your application.

When removing a large number of shapes, call **disableDrawing()** before calling **removeShape()**. Call **enableDrawing()** after all the shapes have been removed. This will improve performance, as the shapes will not be erased until **enableDrawing()** is called.

See **eraseSketch()** for information on removing static graphics.

drawSketch

```
void drawSketch(const ccUISketch& sketch,
 CoordinateSystem cs);

void drawSketch(const ccUISketch& sketch,
 CoordinateSystem cs, const ccRect& clipRect);
```

Draws the sketch in the specified coordinate system, and appends it to any other sketches that have already been added to the display for that coordinate space. A cliprect can be specified to restrict the rendering of the given sketch to within the rectangular clipping region.

Use this method with static graphics.

Parameters

sketch The sketch to draw.

cs — The coordinate system to use to draw the sketch. Must be one of the following values:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

See *CoordinateSystem* on page 1193 for more information.

clipRect — Specifies a restricted bounding box into which the given sketch will be rendered. The units of the *clipRect* should be in the same units as the graphics and whose reference point will be based on the coordinate system specified. The clipping region is always axis-aligned, and as such, the *clipRect* can be represented as an axis-aligned bounding box. fi the *clipRect* is the null rect (**ccRect**(0,0,0,0)), then no clipping is performed.

The *clipRect* must not degenerate. See **ccRect::degen()**.

Notes

The *clipRect* only applies to the specified *sketch* and not any other sketches that may already be added to the display system.

The *clipRect* applies to all graphics contained within the given *sketch*. The *clipRect* does not depend on the layer the graphic is associated with. The *clipRect* is applied to both the image layer and the overlay layer when viewing the display window.

By default, the display system only renders sketch graphics that are contained within the visible viewing area of the display window. By specifying a *clipRect*, you can alter this default behavior and restrict the rendering of sketch graphics to the

bounding box specified by *clipRect*. In cases where the *clipRect* intersects the display viewing area, the clipping region consists of the intersection of the *clipRect* and the display viewable area.

The graphics contained within the sketch are drawn using the current zoom and scroll settings, and will be automatically redrawn as needed whenever the zoom, scroll, or other part of the display mechanism requires a redraw.

All graphics in the sketch specified in the **ccUITablet::eImageLayer** and **ccUITablet::eOverlayLayer** are immediately rendered to the display. On some platforms, you must enable the overlay layer in order to see graphics on that layer, otherwise graphics on the **ccUITablet::eOverlayer** may not be visible. See **ccDisplay::enableOverlay**.

If drawingDisabled() == false, then the sketch is immediately rendered into the display.

Not all platforms support clipping of sketches. For those platforms that do not support clipping, the clipRect argument is ignored and rendering proceeds as if no clipping rectangle was present.

See **addShape()** for information on adding interactive graphics.

eraseSketch

```
void eraseSketch(CoordinateSystem cs);
```

Erases the sketch currently displayed in the specified coordinate system. Use this method with static graphics.

Parameters

cs The coordinate system to use when erasing the sketch. Must be one of the following:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

See *CoordinateSystem* on page 1193 for more information.

Notes

Calling this method may cause a complete refresh of other parts of the display, including redrawing any interactive graphics in the display.

See **removeShape()** for information on removing interactive graphics.

getSketch

```
ccUISketch& getSketch(CoordinateSystem cs);
```

Returns a reference to the sketch in the specified coordinate system.

Parameters

cs The coordinate system to use when getting the sketch. Must be one of the following values:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

See *CoordinateSystem* on page 1193 for more information.

Notes

Use extreme caution when calling this method. The return value is a non-**const** reference, which will allow you to change the internal sketch separately from the display. Changing a sketch while the display is using it may cause unexpected behavior.

If the returned sketch is passed into the **drawSketch()** method that takes a clipping rectangle, then the clipping of graphics to the clipping region may not apply if the sketch already contains a clipping region.

Be sure to mutex/semaphore protect any code using **getSketch()**, or any other CVL display methods, when using display from multiple threads.

disableDrawing `void disableDrawing();`

Disables drawing and prevents screen updates, including all static and interactive graphics on all coordinate systems. Call **disableDrawing()** and then **enableDrawing()** to refresh the entire display.

For every call to **disableDrawing()**, there must be a corresponding call to **enableDrawing()** to re-enable drawing. These two methods must be called in pairs, with **disableDrawing()** always being called before **enableDrawing()**. Nesting of these paired methods is allowed, but the nesting cannot exceed 32 levels.

Throws

ccUIError::FlagStackOverflow
disableDrawing() was called more than 32 times without **enableDrawing()** having being called.

Notes

Call **disableDrawing()** to prevent multiple redraws when making multiple changes to the display, such as changing the image and then inserting a sketch, or changing the pan and then the magnification setting.

enableDrawing `void enableDrawing (bool redraw = true);`

Cancels the effect of one call to **disableDrawing()**. See **disableDrawing()** above.

Parameters

redraw If true, the display is redrawn by calling **ccUITablet::fullDraw()**.

Throws

ccUIError::FlagStackUnderflow
No matching call to **disableDrawing()** was made.

drawingDisabled

```
bool drawingDisabled() const;
```

Returns true if drawing is disabled, false otherwise.

Notes

The **disableDrawing()** and **enableDrawing()** methods control the drawing state.

---

pan

```
void pan(const cc2Vect& offset);

const cc2Vect& pan() const;
```

- `void pan(const cc2Vect& offset);`

  Sets the pan value. Positive values for **panOffset.x()** and **panOffset.y()** shift the image down and to the right. The pan offset is the distance from the center of the display to the center of the image in image coordinates.

  Parameters

  offset The amount by which to pan in image coordinates.

  Notes

  Setting *offset* to (0,0) centers the image in the display.

  This setter triggers a **panChanged()** event to notify that a new pan setting has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

- `const cc2Vect& pan() const;`

  Returns the current pan setting.

---

maxPan

```
ccDPair maxPan() const;

void maxPan(const ccDPair& xy);
```

- `ccDPair maxPan() const;`

  Returns the maximum pan value.

- `void maxPan(const ccDPair& xy);`

  Sets the maximum pan value.

  Parameters

  xy The maximum pan value.

  Notes

  This setter triggers an **updatePanRanges()** event to notify that a new maximum pan setting has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

minPan

```
ccDPair minPan() const;
void minPan(const ccDPair&);
```

- `ccDPair minPan() const;`

  Returns the minimum pan value.

- `void minPan(const ccDPair& xy);`

  Sets the minimum pan value.

  Parameters

  xy The minimum pan value.

  Notes

  This setter triggers an **updatePanRanges()** event to notify that a new minimum pan setting has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

defaultPan

```
bool defaultPan() const;
void defaultPan(bool defaultToImageSize);
```

- `bool defaultPan() const;`

  Returns true if panning is limited to the image size.

- `void defaultPan(bool defaultToImageSize);`

  Sets panning behavior.

Parameters

defaultToImageSize

If true, the minimum and maximum pan values are limited to the image size. If true, the pan ranges are automatically updated whenever a new image is added to the display. If false, the pan ranges are not automatically updated.

Notes

To adjust the minimum and maximum pan ranges, use **minPan()** and **maxPan()**, respectively.

panDelta

```
void panDelta(const ccIPair& delta);
```

Pans the image by the specified amount in display coordinates.

Parameters

delta The amount by which to pan the image in the x and y directions in display coordinates.

mag

```
void mag(c_Int32 m);

c_Int32 mag() const;
```

- `void mag(c_Int32 m);`

Sets the magnification (zoom) value. The display is completely refreshed, and all graphics are re-rendered at the new magnification level.

Parameters

m An integer-based magnification value. Positive values zoom in, negative values zoom out. Thus, a value of 2 means 2x magnification and a value of -2 means 1/2x magnification.

Notes

This setter triggers a **magChanged()** event to notify that a new magnification setting has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

- `c_Int32 mag() const;`

Retrieves the current magnification (zoom) value.

magExact

```
void magExact(double m);
double magExact() const;
```

- `void magExact(double m);`

  Sets the magnification (zoom). This method allows you to specify a **double** as the scale value. The display is completely refreshed, and all graphics are re-rendered at the new magnification level.

  Parameters

  m — A floating-point magnification value. A value of 1.52 means 152% of the actual size. A value of 0.5 means 50% of the actual size. This value must be non-negative.

  Notes

  The image is scaled as close to the specified value as possible. Non-integer scale values force sampling of the image, which can significantly decrease performance when panning and in live display. To restore performance, use the **mag()** method.

  This setter triggers a **magChanged()** event to notify that a new magnification setting has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

- `double magExact() const;`

  Gets the current magnification scale.

fit

```
void fit();
```

Centers the image and changes the magnification to the integer scale value that best fits the current display window size.

fitExact

```
void fitExact();
```

Centers the image in the display and changes the magnification to best fit the current display window size.

Notes

One dimension of the image, either x or y, will fit exactly.The other will fit as close as possible so that the aspect ratio is preserved and the entire image is viewable.

grid

```
void grid(c_Int32 spacing);
c_Int32 grid() const;
```

- `void grid(c_Int32 spacing);`

  Sets the grid spacing, in pixels.

  Parameters

  spacing — The number of pixels per grid lines. A value of 1 places a grid line at every pixel boundary. A value of 2 places a grid line at every other pixel, and so on. Must be a positive value for grid lines to be displayed.

  Notes

  No grid lines are drawn if spacing is less than or equal to 0, or if the image is not sufficiently magnified.

- `c_Int32 grid() const;`

  Returns the current grid spacing, in pixels.

gridColor

```
void gridColor(const ccColor& c);
const ccColor& gridColor() const;
```

- `void gridColor(const ccColor& c);`

  Sets the color of the pixel grid lines.

  Parameters

  c — The color of the grid lines.

- `const ccColor& gridColor() const;`

  Returns the current color of the pixel grid lines.

subpixelGrid

```
void subpixelGrid(c_Int32 spacing);
c_Int32 subpixelGrid() const;
```

- `void subpixelGrid(c_Int32 spacing);`

  Sets the sub-pixel grid spacing.

Parameters

spacing A spacing of *n* means draw *n-1* grid lines within each pixel. A value less than 2 means no grid lines.

Notes

No grid lines are drawn if the image is not magnified enough.

- `c_Int32 subpixelGrid() const;`

Returns the current sub-pixel grid spacing.

subpixelGridColor

```
void subpixelGridColor(const ccColor& c);

const ccColor& subpixelGridColor() const;
```

- `void subpixelGridColor(const ccColor& c);`

Sets the color of the sub-pixel grid lines.

Parameters

c The color of the grid lines.

- `const ccColor& subpixelGridColor() const;`

Returns the current color of the sub-pixel grid lines.

colorMap

```
cmStd vector<ccRGB> colorMap() const;

void colorMap(const cmStd vector<ccRGB>& map,
  c_Int32 mapStart = 0);
```

- `cmStd vector<ccRGB> colorMap() const;`

Returns the color map. The color map is a 256-entry lookup table that controls image pixel mapping, and graphics color mapping in the reserved ranges, on 8-bit desktops. This method returns the entire lookup table, including both the reserved and user-accessible ranges.

Notes

This method does not return the lookup table used for pixel mapping image pel buffers on non-8-bit desktops. Cognex therefore recommends using this method only for 8-bit desktops.

See the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information.

- ```
  void colorMap(const cmStd vector<ccRGB>& map,
    c_Int32 mapStart = 0);
  ```

Sets the lookup table used for mapping graphics and images. Maps from 8-bit pseudo color to RGB. The lookup table has 256 entries, of which entries [0,9] and [241,255] are fixed and cannot be changed. You can modify entries [10,240].

Parameters

map — The pseudo color to RGB map, specifying the new RGB values to insert into the table.

mapStart — The location in *map* to be used as the starting point for copying into the 256-entry lookup table starting at index [10].

Notes

This method is supported for all desktop depths. However, Cognex recommends using this method only for 8-bit desktops. To set the lookup table on non-8-bit desktops, use **colorMapEx()** instead.

This setter triggers a **colorMapChanged()** event to notify that a new color map for 8-bit desktops has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

See the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information on color maps.

colorMapEx

```
cmStd vector<ccRGB> colorMapEx() const;

void colorMapEx(const cmStd vector<ccRGB>& map);
```

- ```
  cmStd vector<ccRGB> colorMapEx() const;
  ```

Returns the image color map used with non-8-bit desktops. This function returns the entire lookup table.

See the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information.

- ```
  void colorMapEx(const cmStd vector<ccRGB>& map);
  ```

Sets the image color map used with non-8-bit desktops. This function sets the entire 256-element range of the color map. This function is supported only for non-8-bit desktops.
  ```

Parameters

map Vector of RGB colors to map to the look-up table. Must contain 256 elements.

Throws

ccUIError::InvalidColorMapSize
The size of *map* is not 256.

Notes

This method is supported only for non-8-bit desktops. It is not supported for 8-bit desktops.

This setter triggers an **imageMapChanged()** event to notify that a new color map for non-8-bit desktops has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

See also the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information on color maps.

clearColorMap `void clearColorMap();`

Sets all values in the user-accessible range of the graphics color map (that is, the range [10, 240]) to their default, index-based, grey-scale RGB values:

```
for(i = eMinUserColor; i <= eMaxUserColor; i++)
  colorMap[i] = ccRGB(i, i, i);
```

For example, colorMap[10] is set to the RGB values 10, 10, 10, or very dark grey; and colorMap[240] is set to the RGB values 240, 240, 240, or very light grey.

Notes

This method applies only to the lookup table used for graphics mapping. To set the lookup table used for image mapping, use **colorMap()**.

overlayColorMap

```
cmStd vector<ccRGB> overlayColorMap() const;
```

Returns the overlay color map. The overlay color map is a lookup table that maps between pixel values in an overlay display buffer and **ccRGB** values. (See the **ccRGB** reference page for information about **ccRGB** values).

The size of the returned vector is both platform and hardware-configuration dependent. There is a one-to-one correspondence between the returned vector index and pixel values in the overlay layers display buffer. For example, pixel values of 0 map to the **ccRGB** value found at vector index 0, pixel values of 1 map to the **ccRGB** value found at vector index 1, and so on.

The length of the returned vector is one more than the maximum pixel value that can exist in the overlay display buffer. Use **ccDisplay::getDisplayedImage()** to retrieve the overlay display buffer.

See also the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information on color maps.

Throws

ccUIError::NotAvailable

This display does not support overlay buffers. Use **ccUITablet::overlaySupported()** to test for overlay buffer support.

ccUIError::NotEnabled

This display supports overlay buffers, but the overlay layer is not currently enabled. Some classes derived from **ccDisplay** require the overlay display buffer to be explicitly enabled.

getPassThroughValue

```
virtual void getPassThroughValue(c_UInt8& v) const;

virtual void getPassThroughValue(ccPackedRGB16Pel& v)
 const;

virtual void getPassThroughValue(ccPackedRGB32Pel& v)
 const;
```

The pass through value is the value used when the overlay display buffer is combined with the image display buffer such that any pixel value in the overlay display buffer that is equal to the pass through value will show through, revealing the corresponding image display buffer pixel underneath. For example, if your overlay display buffer contains no

pass through values, you will display only the overlay buffer and none of the image buffer. If your overlay display buffer contains all pass through values, you will display only the image buffer and none of the overlay buffer.

All overlay display buffers are initialized with a pass through value depending on the current desktop depth.

Notes

Some **ccDisplay** subclasses may require the overlay display buffer to be explicitly enabled. However, the overlay display buffer does not need to be enabled for this function to perform properly.

- `virtual void getPassThroughValue(c_UInt8 & v) const;`

Returns the 8-bit pass through value used with overlay display buffers.

Parameters

v Specifies the pixel depth.

Throws

ccUIError::NotImplemented
The derived class does not support this format.

- `virtual void getPassThroughValue(ccPackedRGB16Pel& v) const;`

Returns the 16-bit pass through value used with overlay display buffers.

Parameters

v Specifies the pixel depth.

Throws

ccUIError::NotImplemented
The derived class does not support this format.

- `virtual void getPassThroughValue(ccPackedRGB32Pel& v) const;`

Returns the 32-bit pass through value used with overlay display buffers.

Parameters

v Specifies the pixel depth.

Throws

ccUIError::NotImplemented
The derived class does not support this format.

mouseMode

```
virtual void mouseMode(MouseMode mm);

MouseMode mouseMode() const;
```

- `virtual void mouseMode(MouseMode mm);`

  Sets the mouse mode. The mouse mode specifies the shape of the mouse cursor and the action that takes place when the user clicks in a display.

  Parameters

  mm The mouse mode. Must be one of the following values:

  ccDisplay::ePointer
  ccDisplay::ePan
  ccDisplay::eZoomIn
  ccDisplay::eZoomOut

  Notes

  This setter triggers a **mouseModeChanged()** event to notify that a new mouse mode has been applied. See *Protected Member Functions* of **ccDisplay** for more information.

  See also *MouseMode* on page 1194 for more information on this enumerated value.

- `MouseMode mouseMode() const;`

  Returns the current mouse mode.

selectAreaStart

```
virtual c_Int32 selectAreaStart(
  CoordinateSystem cs = eImageCoords,
  const ccPelRect& startLocation = ccPelRect(),
  const ccColor& c = ccColor::greenColor()) = 0;
```

Starts a rectangular area selection. Displays a manipulable rectangle that the user can size and reposition with the mouse. Returns a unique tag number indicating the selection. The tag number can be passed to **ccDisplay::selectAreaEnd()**.

Parameters

cs The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation The initial location of the selection area in the coordinate system specified by *cs*. If *startLocation* is a null rectangle, degenerate, or does not overlap the visible portion of the image, the initial

location of the manipulable rectangle is either:
- The location of the most recently selected area, or
- Centered within an area that is two-thirds the size of the client area of the display.

c — The color to use to draw the selection rectangle. Can be any of the predefined stock colors (defined in *<ch_cvl/color.h>*) or a user-construced **ccColor**. The default color is green.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

selectAreaEnd

```
virtual ccPelRect selectAreaEnd(c_Int32 tag) = 0;
```

Completes the rectangular area selection started by **ccDisplay::selectAreaStart()**. Hides the rectangle graphic. Returns the selected area in the coordinate system specified in **ccDisplay::selectAreaStart()**.

Parameters

tag — The tag identifying the selection.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

Notes

If *tag* is not a value returned by **selectAreaStart()**, this function has no effect.

selectArea

```
virtual ccPelRect selectArea(
  CoordinateSystem cs = eImageCoords,
  const ccPelRect& startLocation = ccPelRect(),
  const TCHAR* prompt = cmT("Select an Area"),
  const ccColor& c = ccColor::greenColor()) = 0;
```

Starts and ends an area selection. Displays a manipulable rectangle that the user can size and reposition with the mouse. Waits for the user to select a rectangular area on the display and to confirm the selection by pressing the OK button in a message dialog box. When the user presses OK, this method returns the selected rectangle in the specified coordinate system. The user can cancel the selection by closing the message dialog box.

Parameters

cs — The coordinate system to use for reporting the location of the selected rectangle. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation The initial location of the selection area in the coordinate system specified by *cs*.

If *startLocation* is a null rectangle, degenerate, or does not overlap the visible portion of the image, the initial location of the manipulable rectangle is either:
- The location of the most recently selected area, or
- Centered within an area that is two-thirds the size of the client area of the display.

prompt The message displayed in the message dialog box. The default prompt is "Select an Area."

c The color used to draw the selection rectangle. Can be any of the predefined stock colors (defined in *<ch_cvl/color.h>*, or a user-constructed color. The default color is green.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

Notes

This method is usually implemented as a wrapper for **selectAreaStart()** and **selectAreaEnd()**.

selectPointStart

```
virtual c_Int32 selectPointStart(
  CoordinateSystem cs = eImageCoords,
  const ccDPair& startLocation = ccDPair(-1,-1),
  const ccColor& c = ccColor::greenColor()) = 0;
```

Starts a point selection. Displays a **ccUIPointIcon** graphic that the user can reposition with the mouse.

Returns a tag number indicating the selection. The tag number can be passed to **selectPointEnd()**.

Parameters

cs The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords

startLocation The initial location of the point icon in the coordinate system specified by *cs*.

If *startLocation* is not in the visible portion of the image, the initial location of the point icon is either:
- The location of the last-selected point, if the coordinate system from the last selected point matches that specified by *cs*, or
- Centered within the client area of the display if the coordinate system of the last-selected point differs from that specified by *cs*.

c — The color to use to draw the selection cross. Can be any of the predefined stock colors (defined in <ch_cvl/*color.h*>) or a user-constructed color. The default color is green.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

selectPointEnd

```
virtual ccDPair selectPointEnd(c_Int32 tag) = 0;
```

Completes a point selection started with **selectPointStart()**. Hides the **ccUIPointIcon** graphic, and returns the center of the point icon representing the selected point in the coordinate system specified in **selectPointStart()**.

Parameters

tag — The tag that identifies the selection. If *tag* is not a value returned by **selectPointStart()**, this function has no effect.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

selectPoint

```
virtual ccDPair selectPoint(
  CoordinateSystem cs = eImageCoords,
  const ccDPair& startLocation = ccDPair(-1,-1),
  const TCHAR* prompt = cmT("Select a Point"),
  const ccColor& c = ccColor::greenColor()) = 0;
```

Starts and ends a point selection. Displays a **ccUIPointIcon** graphic and waits for the user to select a point on the display (see **selectPointStart()** above). This function does not return until the user confirms the selection by pressing the OK button in a message dialog box. The user may cancel the operation instead of selecting.

When the user presses OK, this function returns the point in the center of the point icon in the specified coordinate system.

Parameters

cs — The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation The initial location of the selection cross in the coordinate system specified by *cs*. If *startLocation* is not in the visible portion of the image, the initial location is either:
- The location of the last-selected point if the coordinate system of the last-selected point matches that specified by *cs*, or
- Centered within the client area of the display if the coordinate system of the last-selected point differs from that specified by *cs*.

prompt The title displayed in the message dialog box.

c The color used to draw the point icon. Can be any of the predefined stock colors (defined in *<ch_cvl/color.h>*), or a user-constructed color. The default color is green.

Throws

ccUIError::NotImplemented
The derived class does not support this function.

Notes

This method is usually implemented as a simple wrapper for **selectPointStart()** and **selectPointEnd()**.

image8

```
const ccPelBuffer_const<c_UInt8>& image8();
```

Returns a reference to the 8-bit grey-scale image currently in the display.

Notes

The display can manage only one image at a time. Therefore, only one image can be bound to this display at a given time.

imageRGB16

```
const ccPelBuffer_const<ccPackedRGB16Pel>& imageRGB16()
  const;
```

Returns a reference to the 16-bit color image currently in the display.

Notes

The display can manage only one image at a time. Therefore, only one image can be bound to this display at a given time.

imageRGB32

```
const ccPelBuffer_const<ccPackedRGB32Pel> imageRGB32()
  const;
```

Returns a reference to the 32-bit color image currently in the display.

Notes

The display can manage only one image at a time. Therefore, only one image can be bound to this display at a given time.

enableOverlay

```
virtual overlayState enableOverlay() const;
virtual void enableOverlay(overlayState);
```

- `virtual overlayState enableOverlay() const;`

Returns the state of the overlay layer (*eOverlayPlane* if enabled, or *eDisableOverlayPlane* if disabled). Should return *eNone* if both the overlay layer and chromakeying are disabled.

Throws

ccUIError::NotImplemented
The overlay layer is not supported in the derived class.

- `virtual void enableOverlay(overlayState state);`

Enables or disables the overlay layer of the drawing tablet (*ccUITablet::eOverlayLayer*) on host-based displays (**ccDisplayConsole** or **ccWin32Display**).

Parameters

state The state of the overlay layer. Must be one of:

ccDisplay::eOverlayPlane (for enabled),
ccDisplay::eDisableOverlayPlane (for disabled)

Notes

Never pass *ccDisplay::eNone* as an argument to this method.

Before you can draw into the overlay layer on a host-based display (**ccDisplayConsole** or **ccWin32Display**), you must enable the overlay layer by calling **enableOverlay(ccDisplay::eOverlayPlane)**.

Before enabling the overlay layer, call **ccUITablet::overlaySupported()** to check whether the overlay layer is supported on a particular platform.

Attempting to enable the overlay layer on a display that does not support it, or on an embedded display, has no effect. In the first case, the overlay layer is not supported. In the second, the overlay layer is already enabled.

Before disabling the overlay layer on a host-based display, remove any interactive shapes from the overlay layer and erase all sketches on all drawing layers.

Throws

ccUIError::NotImplemented
The overlay layer is not supported in the derived class.

canBlink

```
virtual bool canBlink() const;
```

Returns true if the derived display object supports blinking colors, false otherwise.

Notes

Blinking colors are supported only on embedded displays, and only in the overlay layer.

enableBlink

```
virtual bool enableBlink();
```

Starts the blinking of the color specified by **blinkColor()**. Returns true if blinking started successfully, false otherwise.

Notes

Blinking colors are supported only on embedded displays, and only in the overlay layer.

disableBlink

```
virtual bool disableBlink();
```

Stops the blinking started by **enableBlink()**. Returns true if blinking was successfully halted, false if blinking was not enabled or could not be halted.

Notes

Blinking colors are supported only on embedded displays, and only in the overlay layer.

blinkRate

```
virtual void blinkRate(double seconds);

virtual double blinkRate() const;
```

Notes

Blinking colors are supported only on embedded displays, and only in the overlay layer.

- `virtual void blinkRate(double seconds);`

Sets the blink rate. The blink rate must be set prior to calling **enableBlink()**, otherwise the previous blink rate is used.

Parameters

seconds The blink rate in seconds. Must be greater than zero.

- `virtual double blinkRate() const;`

  Returns the current blink rate.

blinkColor

```
virtual void blinkColor(
  const cmStd vector<ccColor>& blink);

virtual const cmStd vector<ccColor>& blinkColor();
```

Notes

Blinking colors are supported only on embedded displays, and only in the overlay layer.

- ```
  virtual void blinkColor(
    const cmStd vector<ccColor>& blink);
  ```

  Specifies the colors that blink in the overlay plane when **enableBlink()** is called.

  Parameters

  blink A vector of colors. See *color.h* for a list of predefined colors.

  Notes

  Once blinking is enabled, objects drawn in the colors specified in the *blink* parameter blink against a black background.

- `virtual const cmStd vector<ccColor>& blinkColor();`

  Returns a vector of the colors that blink when **enableBlink()** is called.
  ```

startLiveDisplay

```
virtual bool startLiveDisplay(ccAcqFifo* fifo,
 ccLiveDisplayProps* p = 0);

virtual bool startLiveDisplay(ccAcqFifoPtrh fifo,
 ccLiveDisplayProps* p = 0);
```

Starts continuous live display of images acquired through the specified acquisition FIFO. While live display is in progress, **startLiveDisplay()** owns the FIFO. Your application should not make changes to the FIFO until you stop live display.

All overloads return true if live display is able to start successfully, false otherwise.

You can set live display properties, such as whether to use a different transform than the transform associated with each pel buffer acquired for live display, by assigning them to a **ccLiveDisplayProps** object. You can pass this object as the optional second argument to **startLiveDisplay()**. See **ccLiveDisplayProps** for details.

Some derived classes do not support live display.

Notes

Repeated calls to **startLiveDisplay()**, even with a different FIFO, have no effect once live display has already started. Before you can start live display on a different FIFO, you must first call **stopLiveDisplay()**.

On most frame grabbers, the acquisition rate is maximized for the supplied acquisition FIFO and the current frame grabber. On some frame grabbers, you can reduce the acquisition frame rate to account for hardware limitations that may affect the refresh rate. To control the acquisition and display frame rate, call **ccLiveDisplayProps::restartDelay()**, passing a delay amount as an argument.

Call **fifo->prepare(0.0)** before calling **startLiveDisplay()** to reduce the delay between when the first image is acquired and when it appears in the display.

There is a finite amount of time between when **startLiveDisplay()** returns and when the live display actually starts.

-
```
virtual bool startLiveDisplay(ccAcqFifo* fifo,
 ccLiveDisplayProps* p = 0);
```

Starts continuous live display of images acquired through the supplied FIFO.

Parameters

fifo	Pointer to the acquisition FIFO to use for live display. The FIFO must be configured to use the manual trigger model.
p	The live display properties. See **ccLiveDisplayProps** for more information.

Throws

ccDisplay::BadFifo
The input FIFO is not valid.

- `bool startLiveDisplay(ccAcqFifoPtrh fifo, ccLiveDisplayProps* p = 0);`

Starts continuous live display of images acquired through the supplied FIFO.

Parameters

fifo Pointer handle to the acquisition FIFO to use for live display. The FIFO must be configured to use the manual trigger model.

p The live display properties. See **ccLiveDisplayProps** for more information.

Throws

ccDisplay::BadFifo
The input FIFO is not valid.

stopLiveDisplay

```
virtual void stopLiveDisplay();
```

Stops live display.

Notes

You must call **stopLiveDisplay()** before modifying any FIFO properties, or switching the FIFO that is supplying the images.

Repeated calls to **stopLiveDisplay()** have no effect once live display is inactive.

isLiveEnabled

```
virtual bool isLiveEnabled() const;
```

Returns true if live display has started and is active, false otherwise.

waitForVerticalBlank

```
virtual void waitForVerticalBlank(bool set);
```

Sets the *waitForVerticalBlank* flag. If this flag is true, the display is synchronized to the vertical blank refresh of the monitor. If false, the display is not synchronized.

Parameters

set The new value for the *waitForVerticalBlank* flag.

Notes

Be aware that not all display drivers support this synchronization feature. For those that do, execution time may increase when *waitForVerticalBlank* is true.

getDisplayedImage

```
virtual void getDisplayedImage(
  ccPelBuffer<c_UInt8>& buf,
  ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
    = 0;

virtual void getDisplayedImage(
  ccPelBuffer<ccPackedRGB16Pel>& buf,
  ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
    = 0;

virtual void getDisplayedImage(
  ccPelBuffer<ccPackedRGB32Pel>& buf,
  ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
    = 0;
```

Returns the image, graphics, and background as currently displayed on the specified layer in the viewable client area of the display window. If no layer is specified, the returned pel buffer contains the combined pixel data from the image and overlay layers.

The return pel buffer must be allocated and sized to the current size of the client area of the display window. This can be done, for example, as follows:

```
ccPelBuffer<c_UInt8> buf(display.clientArea().x(),
                         display.clientArea().y());
display.getDisplayedImage(buf);
```

Notes

Always use display coordinates (*eDisplayCoords*) to allocate and size the pel buffer used with this method.

To achieve best performance, use the overload that matches the current desktop depth. If the desktop depth differs from the destination pel buffer, data conversion will occur with possible loss of data.

Retrieval of the displayed image always starts from the top left corner of the display window, and does not take into account any offset that may be set in the *buf* return parameter. To obtain a smaller portion of the displayed window, capture the entire window and then use subwindowing.

- ```
  virtual void getDisplayedImage(
    ccPelBuffer<c_UInt8>& buf,
    ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
     = 0;
  ```

  Parameters

  buf — The 8-bit pel buffer in which pixel data are returned.

  layer — The layer (default = unspecified). If no layer is specified, the returned pel buffer contains the combined pixel data from the image and overlay layers.

- ```
  virtual void getDisplayedImage(
    ccPelBuffer<ccPackedRGB16Pel>& buf,
    ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
     = 0;
  ```

  Parameters

  buf — The 16-bit packed RGB pel buffer in which pixel data are returned.

  layer — The layer (default = unspecified). If no layer is specified, the returned pel buffer contains the combined pixel data from the image and overlay layers.

- ```
  virtual void getDisplayedImage(
    ccPelBuffer<ccPackedRGB32Pel>& buf,
    ccUITablet::Layers layer = ccUITablet::eUnspecifiedLayer)
     = 0;
  ```

  Parameters

  buf — The 32-bit packed RGB pel buffer in which pixel data from the specified layer are returned.

  layer — The layer (default = unspecified). If no layer is specified, the returned pel buffer contains the combined pixel data from the image and overlay layers.

liveFrameRate

```
virtual double liveFrameRate() const;
```

Returns the live display frame rate in frames per second.
```

Protected Member Functions

panChanged

```
virtual void panChanged();
```

Called by **pan()** to notify that a new pan setting has been applied to the display.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the image pan changes. Unless overridden, this function performs no action and simply returns.

magChanged

```
virtual void magChanged();
```

Called by **mag()** to notify that a new magnification setting has been applied to the display.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the magnification changes. Unless overridden, this function performs no action and simply returns.

imageChanged

```
virtual void imageChanged();
```

Called by **image()** to notify that a new image has been displayed.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the image changes. Unless overridden, this function performs no action and simply returns.

mouseModeChanged

```
virtual void mouseModeChanged();
```

Called by **mouseMode()** to notify that a new mouse mode has been applied to the display.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the mouse mode changes. Unless overridden, this function performs no action and simply returns.

colorMapChanged

```
virtual void colorMapChanged();
```

Called by **colorMap()** to notify that a new color map for the 8-bit desktop depth has been applied to the display.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the color map changes. Unless overridden, this function performs no action and simply returns.

imageMapChanged

```
virtual void imageMapChanged();
```

Called by **colorMapEx()** to notify that a new color map for non-8-bit desktop depths has been applied to the display.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when the color map for non-8-bit desktops changes. Unless overridden, this function performs no action and simply returns.

redraw_

```
virtual void redraw_();
```

Implements drawing of the image and all static graphics.

Notes

Overrides the virtual method inherited from the **ccUITablet** base class.

dragStart_

```
virtual void dragStart_ (const ccIPair& startPos);
```

Implements panning of the image. Called at the start of a pan operation.

Parameters

startPos The mouse starting position for the drag.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

dragAnimate_

```
virtual void dragAnimate_(const ccIPair&, const ccIPair&);
```

Implements panning of the image. Called repeatedly during a pan operation to implement visual dragging of the image on the screen. Graphics are not animated during a pan operation, but they are repositioned when dragging stops.

Parameters

ccIPair The starting image position, in screen coordinates.

ccIPair The new image position in screen coordinates.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

dragStop_ `virtual void dragStop_ (const ccIPair&, const ccIPair&);`

Implements panning of the image. Called at the end of a pan operation.

Parameters

ccIPair The starting image position, in screen coordinates.

ccIPair The ending image position in screen coordinates.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

resize_ `virtual void resize_();`

Implements resizing of the display window. Adjusts the child frame scope rectangles and maintains the pan.

Notes

Overrides the virtual method inherited from the **ccUITablet** base class.

This method triggers an **updatePanRanges()** event to notify that the window has been resized and **defaultPan()** is true.

click_ `virtual void click_();`

Implements mouse mode behavior when the user clicks with the mouse on an image.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

dblClick_ `virtual void dblClick_();`

Called when a double click occurs while the mouse pointer is in the image. Scrolls the double-clicked point to the center of the display if the display is draggable.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

keyboard_ `virtual void keyboard_(const ccKeyboardEvent &ev);`

Changes the mouse mode if a <Ctrl> key is pressed or released.

Parameters

ev The keyboard event.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

mouseEnter_ `virtual void mouseEnter_();`

Sets the mouse mode. Called when the mouse pointer enters the image with the left mouse button depressed.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

idleMouseEnter_

`virtual void idleMouseEnter_();`

Sets the mouse mode. Called when the mouse pointer enters the image with no mouse button depressed.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

mouseLeave_ `virtual void mouseLeave_();`

Restores the cursor to the state it was in before entering the image. Called when the mouse pointer leaves the image.

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

mouseRight_

```
virtual void mouseRight_(const ccIPair& p, MouseAction m,
  c_UInt32 keys);
```

Called when the right-hand mouse button is depressed while the mouse pointer is in the image. Implements right-click for *eZoomIn* and *eZoomOut* modes.

Parameters

p	The last mouse position, in screen coordinates.
m	Type of mouse event that caused this call. Must be one of the **ccMouseEvent::Event** enums (*eNone, eMovement, eDownClick, eDoubleClick, eUpClick, eDwell*).
keys	Modifier keys depressed when the mouse action occurred. Must be one of the **ccMouseEvent::Key** enums (*eNoKey*, *eAlt*, *eControl*, *eShift*).

Notes

Overrides the virtual method inherited from the **ccUIObject** base class.

updateDisplay

```
void updateDisplay(Layers lyr = eNumLayers);
```

Updates the display by calling **ccUITablet::update()** on the specified layer.

Parameters

lyr The layer to update.

Notes

If **drawingDisabled()** is true, no update occurs.

updatePanRanges

```
virtual void updatePanRanges();
```

Called when the minimum or maximum pan range changes. This can result from calls to **image()**, **minPan()**, **maxPan()**, **image()**, or **resize_()**.

Notes

You can override this callback function in a derived class of your own to take application-specific actions when either of the pan ranges changes. Unless overridden, this function performs no action and simply returns.

Deprecated Members

selectArea

```
ccPelRect selectArea(
  CoordinateSystem cs,
  const TCHAR* prompt,
  const ccColor &c = ccColor::greenColor());
```

For new development, use the overload on page 1216.

selectPoint

```
ccDPair selectPoint(CoordinateSystem cs,
  const TCHAR* prompt,
  const ccColor& c = ccColor::greenColor());
```

For new development, use the overload on page 1218.

ccDisplay

ccDisplayConsole

```
#include <ch_cvl/windisp.h>

class ccDisplayConsole : public CFrameWnd, public ccWin32Display;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	No

The **ccDisplayConsole** class is based on the Microsoft Foundation Class (MFC) frame window. Besides a frame, it contains a client window and optionally displays a tool bar, status bar, and scroll bars. The image is displayed in the client area of the window, which is resized within the frame window. The status bar displays image coordinates, pixel values, and an optional status message. The tool bar contains buttons that zoom in and out, fit, or pan the image, and enable or disable grid lines.

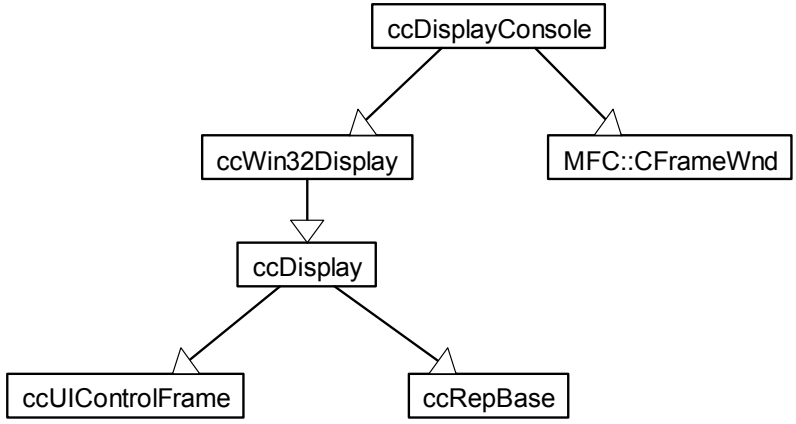

Figure 1. ccDisplayConsole class inheritance hierarchy

This class is derivable. In other words, you can create your own subclass that derives directly from **ccDisplayConsole**, implementing the virtual methods it inherits from the **ccDisplay** class hierarchy. You can also derive your own class to add more Windows MFC message map methods from the MFC class hierarchy.

This class must not be constructed at static initialization time (STI). It may be allocated either on the heap or on the stack as a local variable. Cognex recommends that a **ccDisplayConsole** be allocated on the heap when the close window action is set to *ccDisplayConsole::eCloseDelete*. If the display console contains an image pel buffer that was acquired from an acquisition FIFO, first delete the FIFO before deleting the display console. See **closeAction()** for more information.

ccDisplayConsole uses resources contained within the DLL (*cogdisp*.dll*) distributed with CVL. These resources are automatically loaded either upon construction, or as needed. If the distributed DLL is repackaged inside of another regular (non-ActiveX) MFC DLL, you must call **cfInitializeDisplayResources()** before constructing a **ccDisplayConsole** object to tell it where to find the display resources it needs.

If you are not programming under MFC, use the **ccWin32Display** class instead. This class uses the Microsoft Win32 API.

The **ccDisplayConsole** display class has the following capabilities:

- Displaying images (pel buffers)
- Displaying live images from Cognex frame grabbers
- Adding static graphics to the display
- Adding interactive graphics to the display
- GUI with mouse support

Constructors/Destructors

ccDisplayConsole

```
ccDisplayConsole(const ccIPair& windowSize,
  const TCHAR* title = cmT("Display Console"),
  CWnd* parentWnd = NULL);

ccDisplayConsole(const TCHAR* title, const ccIPair& ul,
  const ccIPair& windowSize,
  bool makeVisible = true, bool minimized = false,
  CWnd* parentWnd = NULL);

virtual ~ccDisplayConsole();
```

Both constructors construct fully-functional, MFC-based, framed windows that can display images (pel buffers) and CVL static and interactive graphics.

The **ccDisplayConsole** constructors are not available at static initialization time.

Only static and interactive graphics from the CVL API can be added to a **ccDisplayConsole**. This object cannot manage user-created graphics from Win32/GDI or any other graphics package.

A **ccDisplayConsole** manages refresh updates of the display window automatically whenever the image or graphics change.

Construct **ccDisplayConsole** objects only in a thread or application that contains a Windows message handler so that window events, such as mouse movement, are properly retrieved and dispatched. For an example of how to do this, see the display sample code.

- ```
  ccDisplayConsole(const ccIPair& windowSize,
    const TCHAR* title = cmT("Display Console"),
    CWnd* parentWnd = NULL);
  ```

  This constructor sets the client area size to the specified size, and centers the framed window on the desktop. This is the simplest way to create a display console.

  Parameters

windowSize	The size of the client area of the display window in pixels. The actual framed window is larger than *windowSize*, as it includes the scroll bars, status bar, and title bar.
title	The title of the window (default = “Display Console”).
parentWnd	The parent window, if any. This window is passed on to **CFrameWnd::Create()** during construction of the frame window.
  ```

Throws

ccUIError::InitFailed

The object failed to construct. This may indicate a failure to properly load the MFC display resource file, or a conflict with other resource files.

- ```
  ccDisplayConsole(const TCHAR* title,
    const ccIPair& ul, const ccIPair& windowSize,
    bool makeVisible = true, bool minimized = false,
    CWnd* parentWnd = NULL);
  ```

  This constructor gives you more control over window placement and appearance, allowing you to specify its location, whether the window is visible or hidden, and whether it is minimized or full size.

  Parameters

  title — The title of the window (default = “Display Console”).

  ul — The location of the upper left corner of the window in screen coordinates.

  windowSize — The size of the client area of the display window in pixels. The actual framed window is larger than *windowSize*, as it includes the scroll bars, status bar, and title bar.

  makeVisible — True makes the window initially visible upon construction. You can also use the MFC method **CWnd::ShowWindow()** to control the visibility of the window.

  minimized — True makes the window initially minimized upon construction. You can also use the MFC method **CWnd::ShowWindow()** to control the active state of the window.

  parentWnd — The parent window, if any. This window is passed on to **CFrameWnd::Create()** during construction of the frame window.

  Throws

  ccUIError::InitFailed

  The object failed to construct. This may indicate a failure to properly load the MFC display resource file, or a conflict with other resource files.

- ```
  virtual ~ccDisplayConsole();
  ```

  Destroys the display console.

Notes

Live display is automatically stopped before the window is destroyed.

Enumerations

CloseAction

```
enum CloseAction;
```

This enumeration specifies the action to be performed when a **ccDisplayConsole** window is closed, using either the **Close** (X) box or the menu item.

Value	Meaning
eCloseDisabled	Disables the close option of the display console. In other words, this option disables the **Close** button (or menu item) so that nothing happens when the user tries to select it.
eCloseHide	Hides the display console when the **Close** button (or menu item) is selected, but does not delete the **ccDisplay** object. To make a **ccDisplayConsole** window visible again after it has been hidden, call the MFC function **ShowWindow()** as follows: `display->ShowWindow(SW_SHOWNOACTIVATE);`
eCloseDelete	Deletes the **ccDisplayConsole** object when the window is closed. This has the effect of both disabling and hiding the display console. The **ccDisplayConsole** must be created on the heap to use the *eCloseDelete* option.

Operators

operator new

```
void* operator new(size_t sz);
```

Allocates storage on the heap for a new **ccDisplayConsole**, initializes it, and returns a pointer to it. Disambiguates the **new()** operator.

Parameters

sz — A non-negative, integral value representing the number of bytes to allocate. If 0, this operator returns a NULL pointer.

Notes

Both the **ccUIObject** class, defined in *<ch_cvl/uifrmwrk.h>*, and the **CObject** class, defined in MFC, override **new()**. This operator forces the call to the MFC **CObject** version. This avoids the use of the CVL **ccUIObject** version, which sets **ccUIObject::autoDelete()** to true.

operator delete

```
void operator delete(void* ptr);
```

Deallocates the storage for the **ccDisplayConsole** pointed to by *ptr*.

Public Member Functions

showStatusBar

```
void showStatusBar(bool vis);
```

Shows or hides the display console's status bar.

Parameters

vis	True shows the status bar, false hides it.

showToolBar

```
void showToolBar(bool vis);
```

Shows or hides the display console's tool bar.

Parameters

vis	True shows the tool bar, false hides it.

statusBarText

```
void statusBarText(const ccCvlString &text,
     bool resize=true);
```

Set the text displayed in the status bar. By default, the status bar is resized to fit the supplied text.

Parameters

text	The text of the status bar.
resize	If true, the bar is resized to fit the supplied text.

Notes

The status bar can be changed only from the thread that created this object. Attempting to set the status bar text from another thread has no effect.

closeAction

```
void closeAction (CloseAction action);
CloseAction closeAction() const;
```

- `void closeAction (CloseAction action);`

  Sets the action to perform when the user clicks on the window's **Close** (X) button or selects the **Close** menu item.

  Parameters

  action — The close action to perform. Must be one of the following:

  ccDisplayConsole::eCloseDisabled (default)
  ccDisplayConsole::eCloseHide
  ccDisplayConsole::eCloseDelete

  Notes

  The standard **CFrameWnd** behavior is *ccDisplayConsole::eCloseDelete*. Select this action if the **ccDisplayConsole** window is the application's main frame window. The **ccDisplayConsole** must be created on the heap to use this option.

- `CloseAction closeAction() const;`

  Returns the current close action.

RecalcLayout

```
virtual void RecalcLayout(BOOL bNotify = TRUE);
```

This function is the CVL implementation of the MFC **CFrameWnd::RecalcLayout()** method. If you add additional panes (such as status bars) to a class that you derive from **ccDisplayConsole**, you should override this function to position your pane after a window has been resized. See the MFC documentation for more information.

ccDisplayConsole

ccEdgelet

```
#include <ch_cvl/edge.h>

class ccEdgelet: public ccEdgeletBase;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class describes a single sub-pixel edge in an image. You should not construct **ccEdgelet** objects, nor should you attempt to modify them.

A **ccEdgelet** object stores the whole-pixel location of the edge using a pair of 16-bit integer values. For this reason, a **ccEdgelet** object cannot represent an edge that has an image offset of greater than +32767 or less than -32768. If you are working with extremely large images, you can specify the use of the **ccEdgelet2** class, described on page 1245, to represent edges, or you can specify that the tool use multiple blocks of memory with offset specifiers, as described in the function **ccEdgeletParams::**edgeTypeRequest() on page 1279

For information on using the edge tool with very large images, see the description of the class **ccEdgeletSet** on page 1281.

Constructors/Destructors

ccEdgelet

```
ccEdgelet();

ccEdgelet(const cc2Vect& position, c_UInt16 magnitude,
  const ccAngle8& angle);
```

- `ccEdgelet();`

- `ccEdgelet(const cc2Vect& position, c_UInt16 magnitude, const ccAngle8& angle);`

  Constructs a **ccEdgelet** with the specified position, magnitude and angle.

  Parameters

position	The sub-pixel location
magnitude	The magnitude, expressed as a grey-level change.

angle The angle.

Notes

The constructed **ccEdgelet** will store the position as a one-dimensional offset from a pixel center along a line drawn through the pixel center at the edge angle.

Public Member Functions

position

```
cc2Vect position() const;
void position(const cc2Vect& pos);
```

- `cc2Vect position() const;`

Returns the sub-pixel location of this **ccEdgelet**.

- `void position(const cc2Vect& pos);`

Sets the sub-pixel location of this **ccEdgelet**.

Parameters

pos The position to set.

Notes

The **ccEdgelet** stores the position as a one-dimensional offset from a pixel center along a line drawn through the pixel center at the edge angle. The value returned by **position()** may not be exactly the same as the position specified upon construction or that passed as an argument to **position()**.

posQuickX

```
double posQuickX(void) const;
```

Returns the whole-pixel x-axis location of this **ccEdgelet** with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickY

```
double posQuickY(void) const;
```

Returns the whole-pixel y-axis location of this **ccEdgelet** with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickR

```
double posQuickR(void) const;
```

Returns the sub-pixel offset of this **ccEdgelet** with the lowest possible overhead, assuming that the edge location has been determined.

This is the distance, in image coordinate system units, from the pixel center to the sub-pixel edge, measured along a line drawn through the pixel center in the direction of the edge.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

magnitude

```
c_UInt16 magnitude() const;
void magnitude(c_UInt16 mag);
```

- `c_UInt16 magnitude() const;`

  Returns the magnitude of this **ccEdgelet**.

- `void magnitude(c_UInt16 mag);`

  Sets the magnitude of this **ccEdgelet**.

  Parameters

  mag The edge magnitude to set

angle

```
ccAngle8 angle() const;
void angle(const ccAngle8& ang);
```

- `ccAngle8 angle() const;`

  Returns the angle of this **ccEdgelet**, relative to the image coordinate system x-axis.

- `void angle(const ccAngle8& ang);`

  Sets the angle of this **ccEdgelet**, relative to the image coordinate system x-axis.

Parameters

ang The angle to set

gradient

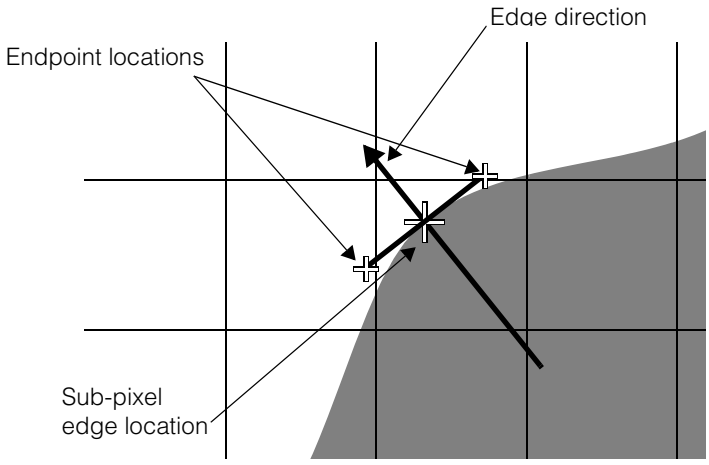
```
cc2Vect gradient() const;
```

Returns a unit vector in positive gradient direction (dark-to-light) that describes this **ccEdgelet**.

endpoints

```
void endpoints(cc2Vect& left, cc2Vect& right,
  bool useSubpixel = true) const;
```

Returns the location of a one-pixel-long line perpendicular to this **ccEdgelet**'s edge direction and drawn through the sub-pixel edge location, as shown in the following figure:



Parameters

left A reference to the left endpoint of the line

right A reference to the right endpoint of the line

useSubpixel If true, locate the line with sub-pixel accuracy; if false, locate the line through the pixel center.

Notes

This function is intended to support the graphic display of **ccEdgelet**s.

ccEdgelet2

```
#include <ch_cvl/edge.h>

class ccEdgelet2;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class describes a single sub-pixel edge in an image. You should not construct **ccEdgelet2** objects, nor should you attempt to modify them.

A **ccEdgelet2** object stores the whole-pixel location of the edge using a pair of 32-bit integer values. Unlike a **ccEdgelet** object, a **ccEdgelet2** object can represent edges in images of any size or offset.

For information on using the edge tool with very large images, see the description of the class **ccEdgeletSet** on page 1281.

Constructors/Destructors

ccEdgelet2

```
ccEdgelet2();

ccEdgelet2(const cc2Vect& position, c_UInt16 magnitude,
   const ccAngle8& angle);
```

- `ccEdgelet2() {}`

- `ccEdgelet2(const cc2Vect& position, c_UInt16 magnitude, const ccAngle8& angle);`

  Constructs a **ccEdgelet2** with the specified position, magnitude and angle.

  Parameters

position	The sub-pixel location
magnitude	The magnitude, expressed as a grey-level change.
angle	The angle.

Notes

The constructed **ccEdgelet2** will store the position as a one-dimensional offset from a pixel center along a line drawn through the pixel center at the edge angle.

Public Member Functions

position

```
cc2Vect position() const;
void position(const cc2Vect& pos);
```

- `cc2Vect position() const;`

Returns the sub-pixel location of this **ccEdgelet2**.

- `void position(const cc2Vect& pos);`

Sets the sub-pixel location of this **ccEdgelet2**.

Parameters

pos The position to set.

Notes

The **ccEdgelet2** stores the position as a one-dimensional offset from a pixel center along a line drawn through the pixel center at the edge angle. The value returned by **position()** may not be exactly the same as the position specified upon construction or that passed as an argument to **position()**.

posQuickX

```
double posQuickX(void) const;
```

Returns the whole-pixel x-axis location of this **ccEdgelet2** with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickY

```
double posQuickY(void) const;
```

Returns the whole-pixel y-axis location of this **ccEdgelet2** with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickR

```
double posQuickR(void) const;
```

Returns the sub-pixel offset of this **ccEdgelet2** with the lowest possible overhead, assuming that the edge location has been determined.

This is the distance, in image coordinate system units, from the pixel center to the sub-pixel edge, measured along a line drawn through the pixel center in the direction of the edge.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

---

magnitude

```
c_UInt16 magnitude() const;
```

```
void magnitude(c_UInt16 mag);
```

- ```
  c_UInt16 magnitude() const;
  ```

  Returns the magnitude of this **ccEdgelet2**.

- ```
  void magnitude(c_UInt16 mag);
  ```

  Sets the magnitude of this **ccEdgelet2**.

  Parameters

  mag The edge magnitude to set

---

angle

```
ccAngle8 angle() const;
```

```
void angle(const ccAngle8& ang);
```

- ```
  ccAngle8 angle() const;
  ```

  Returns the angle of this **ccEdgelet2**, relative to the image coordinate system x-axis.

- ```
  void angle(const ccAngle8& ang);
  ```

  Sets the angle of this **ccEdgelet2**, relative to the image coordinate system x-axis.

  Parameters

  ang The angle to set

gradient

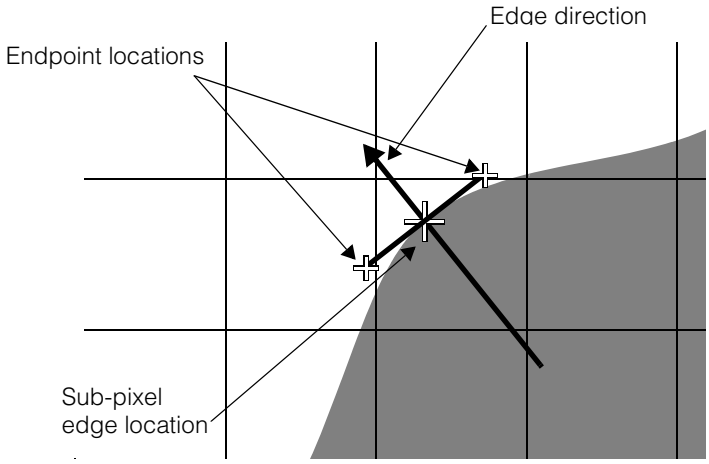
```
cc2Vect gradient() const;
```

Returns a unit vector in positive gradient direction (dark-to-light) that describes this **ccEdgelet2**.

endpoints

```
void endpoints(cc2Vect& left, cc2Vect& right,
  bool useSubpixel = true) const;
```

Returns the location of a one-pixel-long line perpendicular to this **ccEdgelet2**'s edge direction and drawn through the sub-pixel edge location, as shown in the following figure:



Parameters

left	A reference to the left endpoint of the line
right	A reference to the right endpoint of the line
useSubpixel	If true, locate the line with sub-pixel accuracy; if false, locate the line through the pixel center.

Notes

This function is intended to support the graphic display of **ccEdgelet2**s.

ccEdgeletChainFilter

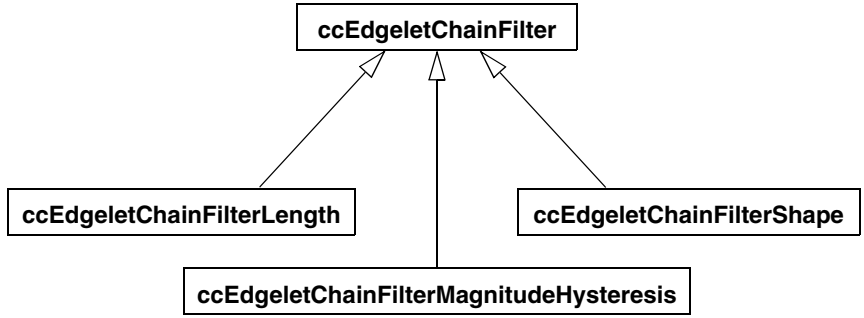
```
#include <ch_cvl/edgefilt.h>

class ccEdgeletChainFilter: public virtual ccPersistent,
                            public virtual ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This is the abstract base class for derived edgelet chain filter classes. Derived classes should override the virtual member function **filter()** and should implement a particular filtering algorithm. The three filters provided by Cognex are shown below.



Edgelet chain filters are designed to filter edgelet chains produced by the edge detection tool (**cfEdgeDetect()**). You first run the edge detection tool to find a set of edgelets in an image, and then run a filter tool on the detected edgelets to eliminate edgelets you do not want to consider in your application.

The edge detection tool produces a vector of edgelets, and an index chain list that describes how these edgelets are grouped as chains. The edgelet filter tool creates a new edgelet chain list that eliminates unwanted edgelets but still refers to the input edgelet vector. The input edgelet vector is not modified. After running the filter the edgelet vector is unchanged and contains both wanted and unwanted edgelets, however only the wanted edgelets are described in the output filtered chain list.

Constructors/Destructors

ccEdgeletChainFilter

```
ccEdgeletChainFilter();

virtual ~ccEdgeletChainFilter();
```

- `ccEdgeletChainFilter();`

  Default constructor.

- `virtual ~ccEdgeletChainFilter();`

  Destructor.

Public Member Functions

filter

```
virtual void filter(
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains) const = 0;
```

This function must be overridden in a derived class.

Filters the given edgelets based on the criteria implemented in derived classes. The filtering algorithm analyzes the input edgelets and applies the filtering criteria specified in the derived class. Edgelets that meet the filter criteria are saved and the other edgelets are discarded (filtered out). The surviving edgelets are described by *filteredChains* which contains chains of surviving edgelets in the *inputEdgelets* vector.

A new **ccIndexChainList** is created using the surviving edgelets by eliminating chains, trimming chains by eliminating edgelets at either end, or by breaking chains into multiple chains. If a chain is broken by eliminating an interior edgelet, the two resulting chains cannot be joined.

Parameters

inputEdgelets	A vector of edgelets to be filtered.
inputChains	The input index chain list for *inputEdgelets*.
filteredChains	The new index chain list produced when you execute this function.

Throws

ccEdgeletChainFilterDefs::OutOfBounds

If the input chains have any out of bounds pointers to edgelets or edgelet indices.

Notes

The filtering will be performed correctly even if *inputChains* and *filteredChains* are references to the same vector. The output chain list overwrites the input chain list.

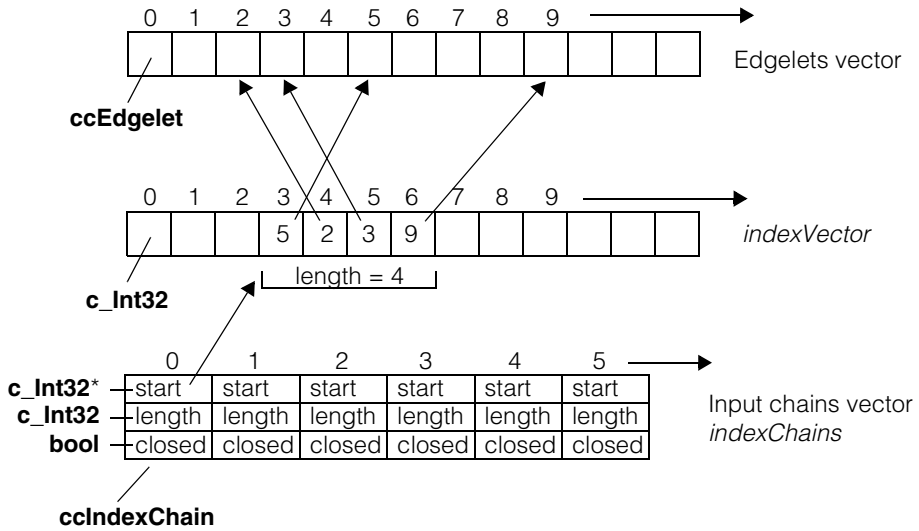
Any existing elements in *filteredChains* will be discarded before the filtering starts.

Any derived class overriding this function should replicate the behavior described in these notes.

makeChainList

```
static void makeChainList(
  const cmStd vector<ccIndexChain> &indexChains,
  const cmStd vector<c_Int32> &indexVector,
  ccIndexChainList &chainList);
```

Convert a vector of **ccIndexChain** objects to a **ccIndexChainList** representation. *indexChains* is a vector **ccIndexChain** objects, each representing a chain of **ccEdgelets**. Each **ccIndexChain** object contains a pointer into *indexVector* which holds indices into a vector of **ccEdgelets**. See the following diagram. The resulting *chainList* can be used as an input to a filtering operation along with the vector of **ccEdgelets**.



The *indexChains* vector is converted into an equivalent **ccIndexChainList** object.

Parameters

indexChains A vector of input chains to be converted.

indexVector The index vector associated with *indexChains*.

chainList The index chain list created.

Throws

ccEdgeletChainFilterDefs::OutOfBounds
If *indexChains* or *chainList* has any out of bounds pointers to *indexVector*.

Notes

chainList holds a deep copy of *indexVector* and *indexChains*.

makeChainVect

```
static void makeChainVect(
  const ccIndexChainList &chainList,
  cmStd vector<c_Int32> &indexVector,
  cmStd vector<ccIndexChain> &indexChains);
```

Convert a **ccIndexChainList** object into a vector of **ccIndexChain** objects. *chainList* contains **ccIndexChain** objects, each representing a chain of **ccEdgelets**. Each **ccIndexChain** object contains a pointer into *indexVector* which holds indices into a vector of **ccEdgelets**.

This function performs the inverse of **makeChainList()** above. *chainList* is converted into an equivalent vector of **ccIndexChain** objects. See the above diagram.

Parameters

chainList The chain list to be converted.

indexVector The index vector associated with *chainList*.

indexChains The index chains vector created.

Throws

ccEdgeletChainFilterDefs::OutOfBounds
If *indexChains* or *chainList* has any out of bounds pointers to *indexVector*.

Typedefs

ccEdgeletChainFilterPtrh

```
typedef ccPtrHandle<ccEdgeletChainFilter>
                                        ccEdgeletChainFilterPtrh;
```

ccEdgeletChainFilterPtrh_const

```
typedef ccPtrHandle_const<ccEdgeletChainFilter>
                                  ccEdgeletChainFilterPtrh_const;
```

ccEdgeletChainFilter

ccEdgeletChainFilterLength

```
#include <ch_cvl/edgefilt.h>

class ccEdgeletChainFilterLength: public ccEdgeletChainFilter;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This is a filter class derived from **ccEdgeletChainFilter**. This filter provides functionality for filtering **ccEdgelet** chains based on their length, regardless of the open or closed status of the chains.

Please see the **ccEdgeletChainFilter** base class reference page for additional information about using this class.

Constructors/Destructors

ccEdgeletChainFilterLength

```
explicit ccEdgeletChainFilterLength(
  c_Int32 minChainLength = 1);
```

Constructor.

Parameters

minChainLength

The minimum chain length. Must be at least 1.

Throws

ccEdgeletChainFilterDefs::BadParams

If *minChainLength* < 1.

Operators

operator==

```
bool operator== (
  const ccEdgeletChainFilterLength &that) const;
```

Returns true if the internal data members of this object are exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that The **ccEdgeletChainFilterLength** object to compare with this object.

operator!=

```
bool operator!= (
  const ccEdgeletChainFilterLength &that) const;
```

Returns true if the internal data members of this object are not exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that The **ccEdgeletChainFilterLength** object to compare with this object.

Public Member Functions

minChainLength

```
c_Int32 minChainLength() const;
```

Returns the minimum chain length.

filter

```
virtual void filter(
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains) const;
```

An override.

Performs a filtering operation on the given chains based on the chain length. A new **ccIndexChainList** will be formed by eliminating the chains from *inputChains* whose length is less than **minChainLength()**.

Parameters

inputEdgelets The vector of edgelets referenced by *inputChains*.

inputChains The input chains to be filtered.

filteredChains The filtered chains created when you execute this function.

ccEdgeletChainFilterMagnitudeHysteresis

```
#include <ch_cvl/edgefilt.h>

class ccEdgeletChainFilterMagnitudeHysteresis:
                                        public ccEdgeletChainFilter;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This is a filter class derived from **ccEdgeletChainFilter**. It provides functionality for filtering **ccEdgelet** chains based on the hysteresis magnitude of the **ccEdgelet**s and their chains. This filter can also be used as a simple **ccEdgelet** magnitude filter by using the same high and low threshold values.

Please see the **ccEdgeletChainFilter** base class reference page for additional information about using this class.

Constructors/Destructors

ccEdgeletChainFilterMagnitudeHysteresis

```
ccEdgeletChainFilterMagnitudeHysteresis(
  c_Int32 lowMagThresh = 1,
  c_Int32 highMagThresh = 1);
```

Constructs an object with the given low and high magnitude threshold values.

Parameters

lowMagThresh The low hysteresis magnitude threshold.

highMagThresh The high hysteresis magnitude threshold.

Throws

ccEdgeletChainFilterDefs::BadParams
If *highMagThresh* < *lowMagThresh*,
or if *lowMagThresh* < 1,
or if *highMagThresh* < 1.

Operators

operator==

```
bool operator== (const
  ccEdgeletChainFilterMagnitudeHysteresis &that) const;
```

Returns true if the internal data members of this object are exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that — The **ccEdgeletChainFilterMagnitudeHysteresis** object to compare with this object.

operator!=

```
bool operator!= (const
  ccEdgeletChainFilterMagnitudeHysteresis &that) const;
```

Returns true if the internal data members of this object are not exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that — The **ccEdgeletChainFilterMagnitudeHysteresis** object to compare with this object.

Public Member Functions

lowMagThresh

```
c_Int32 lowMagThresh() const;
```

Returns the low hysteresis magnitude threshold.

highMagThresh

```
c_Int32 highMagThresh() const;
```

Returns the high hysteresis magnitude threshold.

filter

```
virtual void filter(
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains) const;
```

An override.

This function performs a hysteresis threshold filtering operation on the given edgelets and chains. The following rules apply:

1. Edgelets with a magnitude less than **lowMagThresh()** are filtered out.
2. Edgelets with a magnitude greater than, or equal to **lowMagThresh()** are retained if they are in a chain that includes at least one edgelet with a magnitude greater than, or equal to **highMagThresh()**.

   Note that chains without at least one edgelet magnitude greater than, or equal to **highMagThresh()** are completely eliminated.
3. A new **ccIndexChainList** is created using the surviving edgelets by eliminating chains, trimming chains by eliminating edgelets at either end, or by breaking chains into multiple chains. If a chain is broken by eliminating an interior edgelet, the two resulting chains cannot be joined.

Parameters

inputEdgelets	The input edgelets associated with *inputChains*.
inputChains	The input chains to be filtered.
filteredChains	The filtered chains created when you execute this function.

ccEdgeletChainFilterMagnitudeHysteresis

ccEdgeletChainFilterShape

```
#include <ch_cvl/edgefilt.h>

class ccEdgeletChainFilterShape: public ccEdgeletChainFilter
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This is a filter class derived from **ccEdgeletChainFilter**. This filter provides functionality for filtering **ccEdgelet**s that are aligned with, and are within a specified distance from, any of the contours described by a supplied shape. Note that the shape model information (implicit or explicit) is used when doing this filtering operation. Weights are not used, but if you specify that the polarity should be used, the gradient direction of the edge must match the polarity of the specified shape for it to be filtered. One application of this filtering tool is to remove edge chains that are too close to a border of a region that is to be inspected. This avoids picking up normal variations near the border as defects.

Please see the **ccEdgeletChainFilter** base class reference page for additional information about using this class.

Constructors/Destructors

ccEdgeletChainFilterShape

```
ccEdgeletChainFilterShape(
  const ccShape &shape = cc2Point(),
  double distanceTol = HUGE_VAL,
  const ccRadian &angleTol = ccRadian(ckPI),
  bool ignorePolarity = true,
  const ccShape::ccSampleParams &samplingParams =
            ccShape::ccSampleParams(0.0, 0.1, ckMaxInt32,
                                                true, false));
```

Constructs a filter object using the given shape, distance and angle tolerance values, an edgelet polarity ignore flag, and sampling parameters.

Parameters

shape	The shape to use for filtering.
distanceTol	Edgelets that are not within this distance tolerance to a shape edge will be filtered out.

angleTol Edgelet tangent angles not within this angular tolerance to the nearest shape edge tangent angle are filtered out.

ignorePolarity When set to true, edge polarity is ignored. When set false, the edge polarity must be the same as the edgelet polarity or the edgelet is filtered out.

samplingParams The shape sampling parameters.

Throws

ccEdgeletChainFilterDefs::BadParams
If *distanceTol* < 0,
or if *angleTol* < **ccRadian(0.0)**,
or if *ignorePolarity* is false and the effective ignore polarity flag for any portion of *shape* is true.

Notes

Please see the **ccShapeModel** class for information on how to specify the shape polarity.

Operators

operator==

```
bool operator== (
  const ccEdgeletChainFilterShape &that) const;
```

Returns true if the internal data members of this object are exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that The **ccEdgeletChainFilterShape** object to compare with this object.

operator!=

```
bool operator!= (
  const ccEdgeletChainFilterShape &that) const;
```

Returns true if the internal data members of this object are not exactly equal to the corresponding data members of *that*. Returns false otherwise.

Parameters

that The **ccEdgeletChainFilterShape** object to compare with this object.

Public Member Functions

shape

```
ccShapePtrh_const shape() const;
```

Returns the shape object specified in the constructor.

distanceTol

```
double distanceTol() const;
```

Returns the distance tolerance specified in the constructor.

angleTol

```
ccRadian angleTol() const;
```

Returns the angle tolerance specified in the constructor.

ignorePolarity

```
bool ignorePolarity() const;
```

Returns the ignore polarity flag specified in the constructor.

samplingParams

```
const ccShape::ccSampleParams &samplingParams() const;
```

Returns the sampling parameters specified in the constructor.

filter

```
virtual void filter(
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains) const;
```

An override.

This function is an override. It performs a filtering operation on the input edgelets using the shape, distance tolerance, and angle tolerance provided in the constructor. The filter analyzes the input edgelets and edgelet chains.

First, the shape is sampled by calling the static member function **ccShapeModel::sampleWithPolarity()** and passing it the *samplingParams* provided in the **ccEdgeletChainFilterShape** constructor. For each input edgelet, the sampled points within a distance of <= *distanceTol* to the edgelet are found. If there are no such points, the edgelet is not filtered out and it survives. If there are such points, the angular differences between the tangents of these points and the edgelet tangent angle is measured. If any of these angular differences is <= angleTol, the edgelet is filtered out. Otherwise, the edgelet survives.

The angular differences are taken in the ccRadian(0.0) to ccRadian(ckPI) range if *ignorePolarity* is true. Otherwise, the angular differences will be taken in the ccRadian(0.0) to ccRadian(ck2PI) range to take the shape and edgelet polarity into

consideration. If angleTol is >= ccRadian(ckPI), filtering based on angle tolerance will not be performed by turning off the *computeTangents* flag of samplingParams. No filtering will be done for shapes if there are no tangent angles produced by sampling and angleTol is not >= ccRadian(ckPI). A new ccIndexChainList will be formed using the surviving edgelets by eliminating, trimming or breaking the input chains.

Parameters

inputEdgelets	The edgelets associated with *inputChains*.
inputChains	The chains to be filtered.
filteredChains	The filtered result chains.

Throws

Any errors thrown by **ccShapeModel::sampleWithPolarity()** will be caught here.

ccEdgeletDefs

```
#include <ch_cvl/edge.h>

class ccEdgeletDefs;
```

A name space that holds enumerations and constants used with the Edge tool.

Enumerations

EdgeType

```
enum EdgeType;
```

This enumeration defines the types of edgelet representations that may be used to store a collection of edgelets within a **ccEdgletSet**.

Value	Meaning
eEdges	A vector of **ccEdgelet** objects that use 16-bit integers to store the whole-pixel location of the edge.
eEdges2	A vector of **ccEdgelet2** objects that use 32-bit integers to store the whole-pixel location of the edge.
eEdgesAndOffsets	One or more blocks of memory, where each block includes a 32-bit image offset specifier as well as a vector of **ccEdgelet** objects. This representation is more efficient and requires less memory when using very large images.

EdgeTypeRequest

```
enum EdgeTypeRequest;
```

This enumeration defines the types of edgelet representations that you may request that the tool use when storing edges within a **ccEdgletSet**. The actual representation used is returned by the tool.

Value	Meaning
eRequestContiguous	Request that edgelets be stored in a contiguous block of **ccEdgelet** objects. The resulting storage type may be *eEdges* or *eEdges2*.
eRequestEdges2	Request that edgelets be stored in a contiguous block of **ccEdgelet2** objects. The resulting storage type will be *eEdges2*.
eRequestEdgesAndOffsets	Request that edgelets be multiple blocks of **ccEdgelet** objects with an offset specifier for each block. The resulting storage type may be *eEdgesAndOffsets* or *eEdges* (if all the edges have whole-pixel image coordinates within the range -32768 to +32767.

ccEdgeletIterator

```
#include <ch_cvl/edge.h>

class ccEdgeletIterator: public ccEdgeletIterator_const;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	None

This class represents a single edgelet in a **ccEdgeletSet**. Unlike **ccEdgelet** and **ccEdgelet2**, this class can represent an edgelet regardless of the underlying storage method used by the **ccEdgeletSet**.

ccEdgeletIterator provides the same public accessor methods as **ccEdgelet** and **ccEdgelet2**. It also implements the standard STL iterator methods and operators for accessing edgelets within the **ccEdgeletSet**.

Note This class is derived from **ccEdgeletIterator_const**, which provides the most commonly-used methods for accessing edgelets. For more information, see the description of that class on page 1271.

Constructors/Destructors

ccEdgeletIterator

```
ccEdgeletIterator();

ccEdgeletIterator(c_Int32 edgeletIndex,
   ccEdgeletSet* set);
```

- `ccEdgeletIterator();`

  Constructs a null **ccEdgeletIterator**. The constructed object cannot be used.

- ```
  ccEdgeletIterator(c_Int32 edgeletIndex,
     ccEdgeletSet* set);
  ```

  Constructs a **ccEdgeletIterator** that points to the specified edgelet within the supplied **ccEdgeletSet**.
  ```

Parameters

edgeletIndex The index of the edgelet.

set The **ccEdgeletSet** to iterate upon.

Notes

The default copy constructor, assignment operator, and destructor are used.

The copy constructor and assignment operator are shallow, and the iterator will have the same edgelet set lifetime constraints as the iterator being copied or assigned from.

Operators

operator-

```
c_Int32 operator-(const ccEdgeletIterator& rhs) const;
```

Returns the difference between two iterators. Both iterators must refer to the same **ccEdgeletSet**.

Parameters

rhs The iterator to subtract from this one.

Standard STL Iterator Operators

The operators in this section implement the standard iterator increment, decrement, addition, subtraction, and comparison operators.

Notes

The comparison operators require that the *rhs* argument be an iterator that refers to the same **ccEdgeletSet**.

operator++

```
ccEdgeletIterator& operator++();
ccEdgeletIterator operator++(int);
```

operator--

```
ccEdgeletIterator& operator--();
ccEdgeletIterator operator--(int);
```

operator+=

```
ccEdgeletIterator& operator+=(c_Int32 offset);
```

operator+

```
ccEdgeletIterator operator+(c_Int32 offset) const;
```

operator-

```
ccEdgeletIterator operator-(c_Int32 offset) const;
```

operator-=

```
ccEdgeletIterator& operator-=(c_Int32 offset);
```

Public Member Functions

magnitude

```
void magnitude(c_UInt16 m);
```

Sets the gradient magnitude for this edgelet.

Parameters

m	The magnitude to set.

angle

```
void angle(const ccAngle8& a);
```

Sets the positive gradient angle for this edgelet.

Parameters

a	The angle to set.

ccEdgeletIterator

ccEdgeletIterator_const

```
#include <ch_cvl/edge.h>

class ccEdgeletIterator_const;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	None

This class represents a single edgelet in a **ccEdgeletSet**. Unlike **ccEdgelet** and **ccEdgelet2**, this class can represent an edgelet regardless of the underlying storage method used by the **ccEdgeletSet**.

ccEdgeletIterator_const provides the same public accessor methods as **ccEdgelet** and **ccEdgelet2**. It also implements the standard STL iterator methods and operators for accessing edgelets within the **ccEdgeletSet**.

Note This class provides const access to the **ccEdgeletSet**; for non-const access, use **ccEdgeletIterator**.

Constructors/Destructors

ccEdgeletIterator_const

```
ccEdgeletIterator_const();

ccEdgeletIterator_const(c_Int32 edgeletIndex,
   const ccEdgeletSet* set);
```

- `ccEdgeletIterator_const();`

  Constructs a null **ccEdgeletIterator_const**. The constructed object cannot be used.

- `ccEdgeletIterator_const(c_Int32 edgeletIndex, const ccEdgeletSet* set);`

  Constructs a **ccEdgeletIterator_const** that points to the specified edgelet within the supplied **ccEdgeletSet**.

  Parameters

  edgeletIndex The index of the edgelet.

set The **ccEdgeletSet** to iterate upon.

Notes

The default copy constructor, assignment operator, and destructor are used.

The copy constructor and assignment operator are shallow, and the iterator will have the same edgelet set lifetime constraints as the iterator being copied or assigned from.

Public Member Functions

isEnd `bool isEnd() const;`

Returns whether this iterator is done forward iterating, i.e. whether it has reached the end of the edgelet set.

Notes

Using this function may be significantly more efficient than using the more STL-like syntax

```
if (iter != end) ...
```

isRend `bool isRend() const;`

Returns whether this iterator is done reverse iterating, that is whether it has reached the reverse end of the edgelet set (one edgelet before the beginning).

Notes

Using this function may be significantly more efficient that using the more STL like syntax

```
if (iter != eend) ...
```

isDone `bool isDone() const;`

Returns whether this iterator is done iterating, that is whether it has reached either the forward or reverse end of the edgelet set.

index `c_Int32 index() const;`

Returns the index of the edgelet within the **ccEdgeletSet**. The returned value will be in the range 0 through **ccEdgeletSet::nEdges()** -1.

Notes

A newly constructed iterator returned by **ccEdgeletSet::begin()** will have an **index()** of 0.

setIndex `void setIndex(c_Int32 edgeletIndex);`

Set this iterator to refer to the specified edgelet index.

Parameters

edgeletIndex The index. *edgeletIndex* must be in the range 0 through **ccEdgeletSet::nEdges()** -1.

position `cc2Vect position() const;`

Returns the sub-pixel location of this edgelet.

posQuickX `double posQuickX(void) const;`

Returns the whole-pixel x-axis location of this edgelet with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickY `double posQuickY(void) const;`

Returns the whole-pixel y-axis location of this edgelet with the lowest possible overhead, assuming that the edge location has been determined.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

posQuickR `double posQuickR(void) const;`

Returns the sub-pixel offset of this edgelet with the lowest possible overhead, assuming that the edge location has been determined.

This is the distance, in image coordinate system units, from the pixel center to the sub-pixel edge, measured along a line drawn through the pixel center in the direction of the edge.

Notes

If the sub-pixel peak location has not been determined by a previous call to **ccEdgeletSet::doEdgeInterp()**, then this function will not be particularly efficient.

magnitude

```
c_UInt16 magnitude() const;
```

Returns the magnitude of this edgelet.

angle

```
ccAngle8 angle() const;
```

Returns the angle of this edgelet, relative to the image coordinate system x-axis.

gradient

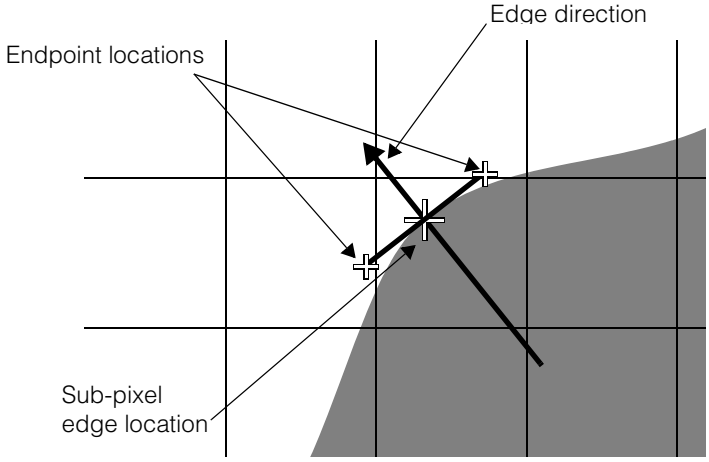
```
cc2Vect gradient() const;
```

Returns a unit vector in positive gradient direction (dark-to-light) that describes this edgelet.

endpoints

```
void endpoints(cc2Vect& left, cc2Vect& right, bool
useSubpixel = true) const;
```

Returns the location of a one-pixel-long line perpendicular to this edgelet's edge direction and drawn through the sub-pixel edge location, as shown in the following figure:



Parameters

left	A reference to the left endpoint of the line
right	A reference to the right endpoint of the line
useSubpixel	If true, locate the line with sub-pixel accuracy; if false, locate the line through the pixel center.

Notes

This function is intended to support the graphic display of edgelets.

Operators

operator-

```
c_Int32 operator-(
   const ccEdgeletIterator_const& rhs) const;
```

Returns the difference between two iterators. Both iterators must refer to the same **ccEdgeletSet**.

Parameters

rhs	The iterator to subtract from this one.

Standard STL Iterator Operators

The operators in this section implement the standard iterator increment, decrement, addition, subtraction, and comparison operators.

Notes

The comparison operators require that the *rhs* argument be an iterator that refers to the same **ccEdgeletSet**.

operator++

```
ccEdgeletIterator_const& operator++();
ccEdgeletIterator_const operator++(int);
```

operator--

```
ccEdgeletIterator_const& operator--();
ccEdgeletIterator_const operator--(int);
```

operator+=

```
ccEdgeletIterator_const& operator+=(c_Int32 offset);
```

operator+

```
ccEdgeletIterator_const operator+(c_Int32 offset) const;
```

operator-=

```
ccEdgeletIterator_const& operator-=(c_Int32 offset);
```

operator-

```
ccEdgeletIterator_const operator-(c_Int32 offset) const;
```

operator==

```
bool operator==(const ccEdgeletIterator_const& rhs) const;
```

operator!=

```
bool operator!=(const ccEdgeletIterator_const& rhs) const;
```

operator<

```
bool operator<(const ccEdgeletIterator_const& rhs) const;
```

operator>

```
bool operator>(const ccEdgeletIterator_const& rhs) const;
```

operator<=

```
bool operator<=(const ccEdgeletIterator_const& rhs) const;
```

operator>=

```
bool operator>=(const ccEdgeletIterator_const& rhs) const;
```

ccEdgeletParams

```
#include <ch_cvl/edge.h>

class ccEdgeletParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the parameters you use to control the generation of edge angle images, edge magnitude images, and **ccEdgeletSet**s.

Constructors/Destructors

ccEdgeletParams

```
ccEdgeletParams(double magScale = 1.0,
  double magThresh = 20.0, ccEdgeletDefs::EdgeTypeRequest
  edgeTypeRequest = ccEdgeletDefs::kDefaultRequest);
```

Constructs a **ccEdgeletParams** using the supplied parameters

Parameters

magScale The magnitude scaling factor. The computed edge magnitude for each pixel is multiplied by *magScale* before being placed in the edge magnitude image.

magThresh The magnitude threshold. **ccEdgelet**s are only constructed for edges with a magnitude greater than *magThresh* (after having been multiplied by *magScale*).

edgeTypeRequest
The requested storage method for edgelets. The supplied value must be one of the following:

ccEdgeletDefs::eRequestContiguous
ccEdgeletDefs::eRequestEdges2
ccEdgeletDefs::eRequestEdgesAndOffsets

Throws

ccEdgeletDefs::BadParams
magScale or *magThresh* is less than 0 or *edgeTypeRequest* is not a member of **ccEdgeletDefs::EdgeTypeRequest**.

Public Member Functions

magScale

```
double magScale() const;
void magScale(double scale);
```

- `double magScale() const;`

  Returns the magnitude scaling factor of this **ccEdgeletParams**.

- `void magScale(double scale);`

  Sets this **ccEdgeletParams**'s magnitude scaling factor. The edge magnitude computed for each pixel in the input image is multiplied by this factor before being placed in the edge magnitude image.

  Parameters

  scale The magnitude scaling factor to set

  Notes

  A magnitude scaling factor of 0.89 guarantees a maximum magnitude equal to the maximum pixel value.

  For a 16-bit input image and a 8-bit output magnitude image, *scale* should be divided by 256. For an 8-bit input image and a 16-bit output magnitude image, *scale* must be greater than 1.0 in order to capture the full range of edge magnitudes in the input image.

  On some platforms, the magnitude may silently overflow the maximum magnitude image pixel value; on others, it may be clipped to the maximum pixel value.

magThresh

```
double magThresh() const;
void magThresh(double thresh);
```

- `double magThresh() const;`

  Returns the magnitude threshold value for this **ccEdgeletSet**.

- `void magThresh(double thresh);`

  Sets the magnitude threshold value for this **ccEdgeletSet**, expressed as the change in pixel values across the edge. Only edges with magnitudes greater than *thresh* will have **ccEdgelet**s created for them.

Parameters

thresh The threshold to set

Notes

This value does not affect the magnitude or angle images.

edgeTypeRequest

```
ccEdgeletDefs::EdgeTypeRequest edgeTypeRequest() const;

void edgeTypeRequest(ccEdgeletDefs::EdgeTypeRequest e);
```

- `ccEdgeletDefs::EdgeTypeRequest edgeTypeRequest() const;`

  Returns the storage form specified for this **ccEdgeletParams** object. The returned value is one of the following

  ccEdgeletDefs::eRequestContiguous
  ccEdgeletDefs::eRequestEdges2
  ccEdgeletDefs::eRequestEdgesAndOffsets

- `void edgeTypeRequest(ccEdgeletDefs::EdgeTypeRequest e);`

  Sets the requested storage method for edgelets. The supported edge types are:

  - If the requested value is *ccEdgeletDefs::eRequestContiguous*, the edgelets will be stored in a single contiguous block. If no edgelet has a whole-pixel location with an image X- or Y-coordinate outside the range -32768 through +32767, the edgelets are stored in a vector of **ccEdgelet** and accessed through **ccEdgeletSet::edges()**. If any edgelet has a whole pixel location with an image X- or Y-coordinate that is outside the range outside the range -32768 through +32767, the edgelets are stored in a vector of **ccEdgelet2** and accessed through **ccEdgeletSet::edges2()**. In both cases, the edges can be accessed using the **ccEdgeletIterator** or **ccEdgeletIterator_const** classes obtained by calling **ccEdgeletSet::begin()**.
  - If the requested value is ccEdgeletDefs::eRequestEdges2, the edgelets are stored in a vector of **ccEdgelet2** and accessed through **ccEdgeletSet::edges2()** or by using the **ccEdgeletIterator** or **ccEdgeletIterator_const** classes obtained by calling **ccEdgeletSet::begin()**.
  - If the requested value is *ccEdgeletDefs::eRequestEdgesAndOffsets*, the edgelets are stored in one or more separate blocks of memory, where each block contains an array of **ccEdgelet** objects and a pair of 32-bit offset specifiers. Edgelets are accessed using the **ccEdgeletIterator** or **ccEdgeletIterator_const** classes. You obtain one of these objects by calling **ccEdgeletSet::begin()**.

Multiple blocks are only used when at least one edgelet has a whole pixel location with an image X- or Y-coordinate that is outside the range outside the range -32768 through +32767. If only a single block is created, you can use both **ccEdgeletSet::edges()** and the **ccEdgeletIterator()** methods for accessing the set's edgelets.

ccEdgeletSet::edgeTypes() indicates the actual edgelet storage method for a given **ccEdgeletSet** (which may not be the same as the requested method). While the **ccEdgeletSet::edges()** and **ccEdgeletSet::edges2()** edgelet accessors may only be used if the corresponding storage type was used, The **ccEdgeletIterator()** and **ccEdgeletIterator_const()** methods may always be used.

The default requested storage method is *ccEdgeletDefs::eRequestContiguous*.

Parameters

e — The requested storage type. *e* must be one of the following values:

ccEdgletDefs::eRequestContiguous
ccEdgletDefs::eRequestEdges2
ccEdgletDefs::eRequestEdgesAndOffsets

Notes

In general, *eRequestEdgesAndOffsets* is the most efficient form in terms of speed and memory usage of edgelet generation, as the other forms may require copying the edgelets. However, if the edgelets will need to be accessed in random order (such as when processing chains with a **ccIndexChainList**), the overall processing may be more efficient if the edgelets are copied into contiguous storage, since random access using **ccEdgeletIterator()** into discontiguous storage is less efficient that random access into contiguous storage.

ccEdgeletSet

```
#include <ch_cvl/edge.h>

class ccEdgeletSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all the edgelets located in the input image.

The edgelets in this object may be stored in one of three ways, depending on the storage method that you requested with **ccEdgeletParams::edgeTypeRequest** and on whether or not any edgelet has a whole pixel location with an image X- or Y-coordinate that is outside the range -32768 through +32767.

ccEdgeletSet provides a single method, **ccEdgeletSet::begin()** that allows you to use a **ccEdgeletIterator** or **ccEdgeletIterator_const** object to access all of the **ccEdgeletSet**'s edgelets, regardless of how they are stored.

Cognex recommends the use of **ccEdgeletSet::begin()** rather than the storage-type specific **edges()** and **edges2()** accessors.

For more information, see the function **ccEdgeletParams::edgeTypeRequest()** on page 1279 and the function **ccEdgeletSet::edgeTypes()** on page 1287.

Constructors/Destructors

ccEdgeletSet

```
ccEdgeletSet();

ccEdgeletSet(const cmStd vector<ccEdgelet>& set,
  double magScale = 1.0);
```

- `ccEdgeletSet();`

  Constructs an unbound **ccEdgeletSet**.

- `ccEdgeletSet(const cmStd vector<ccEdgelet>& edgelets,
  double magScale = 1.0);`

  Constructs a **ccEdgeletSet** from the supplied vector of **ccEdgelet**s.

Parameters

edgelets	The **ccEdgelet**s for this **ccEdgeletSet**
magScale	The edge magnitude scaling factor that was used to construct the **ccEdgelet**s in *edgelets*

Public Member Functions

setUnbound

```
void setUnbound();
```

Deletes all of the **ccEdgelet**s in this **ccEdgeletSet** but does not affect the **cc2Xform** or magnitude scaling factor associated with this **ccEdgeletSet**.

isBound

```
bool isBound() const;
```

Returns true if this **ccEdgeletSet** contains at least one **ccEdgelet**.

copyXforms

```
void copyXforms(const ccEdgeletSet& other);
```

Efficiently sets this **ccEdgeletSet** object's **imageFromClientXformBase** and **ClientFromImageXformBase** transforms to be the same as the supplied **ccEdgeletSet** object's transforms.

Parameters

other	The object containing the transforms to set.

Notes

This function is the most efficient way (in both speed and memory) to make two **ccEdgeletSet** objects use the same transform; it is much more efficient than calling the two objects' setters and getters. Also, this method avoids any potential loss of accuracy caused by inverting a transform twice.

The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

clientFromImageXformBase

```
const cc2XformBasePtrh_const&
   clientFromImageXformBase() const;

void clientFromImageXformBase(
   const cc2XformBasePtrh_const& xform, bool copy = true);

void clientFromImageXformBase(const cc2XformBase& xform);
```

- ```
  const cc2XformBasePtrh_const&
     clientFromImageXformBase() const;
  ```

  Returns a **cc2XformBase** that describes the transformation between the coordinate system in which the edgelet positions are given and the client coordinate system of the input image used to create this **ccEdgeletSet**.

  Notes

  The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

- ```
  void clientFromImageXformBase(
     const cc2XformBasePtrh_const& xform, bool copy = true);
  ```

  Sets the **cc2XformBase** that describes the transformation between the coordinate system in which the edgelet positions are given and the client coordinate system of the input image used to create this **ccEdgeletSet**.

  Parameters

xform	The transformation.
copy	If true, a deep copy is made of *xform*; if false, a reference is stored. If *copy* is false, the supplied transform must not be modified during the lifetime of this **ccEdgeletSet**.

  Notes

  The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

- ```
  void clientFromImageXformBase(const cc2XformBase& xform);
  ```

  Sets the **cc2XformBase** that describes the transformation between the coordinate system in which the edgelet positions are given and the client coordinate system of the input image used to create this **ccEdgeletSet**.
  ```

Parameters

xform The transformation.

Notes

This overload makes a deep copy of the supplied transformation.

The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

imageFromClientXformBase

```
const cc2XformBasePtrh_const&
   imageFromClientXformBase() const;

void imageFromClientXformBase(
   const cc2XformBasePtrh_const& xform, bool copy = true);

void imageFromClientXformBase(const cc2XformBase& xform);
```

- ```
  const cc2XformBasePtrh_const&
     imageFromClientXformBase() const;
  ```

  Returns a **cc2XformBase** that describes the transformation between the client coordinate system of the input image used to create this **ccEdgeletSet** and the coordinate system in which the edgelet positions are given.

  Notes

  The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

- ```
  void imageFromClientXformBase(
     const cc2XformBasePtrh_const& xform, bool copy = true);
  ```

  Sets the **cc2XformBase** that describes the transformation between the client coordinate system of the input image used to create this **ccEdgeletSet** and the coordinate system in which the edgelet positions are given.

  Parameters

  xform The transformation.

  copy If true, a deep copy is made of *xform*; if false, a reference is stored. If *copy* is false, the supplied transform must not be modified during the lifetime of this **ccEdgeletSet**.

Notes

The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

- `void imageFromClientXformBase(const cc2XformBase& xform);`

Sets the **cc2XformBase** that describes the transformation between the client coordinate system of the input image used to create this **ccEdgeletSet** and the coordinate system in which the edgelet positions are given.

Parameters

xform The transformation.

Notes

This overload makes a deep copy of the supplied transformation.

The **imageFromClientXformBase** and **ClientFromImageXformBase** methods both refer to the same underlying object (as do the deprecated **imageFromClientXform** and **ClientFromImageXform** methods).

nEdges `c_Int32 nEdges() const;`

Returns the number of edgelets in this **ccEdgeletSet**.

magScale `double magScale() const;`

Returns magnitude scaling factor used to compute the magnitudes associated with the edgelets in this **ccEdgeletSet**.

doEdgeInterp `void doEdgeInterp();`

Forces the computation of sub-pixel offsets for each edgelet in this **ccEdgeletSet**.

begin

```
ccEdgeletIterator begin();

ccEdgeletIterator_const begin() const;
```

- `ccEdgeletIterator begin();`

  Gets a **ccEdgeletIterator** object that you can use to access the edgelets in this **ccEdgeletSet**. This is the recommended method for accessing edgelets, as it is valid regardless of the storage method used by this **ccEdgeletSet**.

  You can use several methods to iterate using a **ccEdgeletIterator** object:

  - You can use the **ccEdgeletIterator::isEnd()**:

    ```
    for (ccEdgeletIterator_const iter = edgeletSet.begin();
         !iter.isEnd());
         ++iter)
         {
         cc2Vect pos = iter.position();
         }
    ```

  - You can use **ccEdgeletSet::nEdges()** to determine the extent of the edgelet set:

    ```
    c_Int32 nEdges = edgeletSet.nEdges();
    ccEdgeletIterator_const iter = edgeletSet.begin();
    for (c_Int32 i = 0; i < nEdges; ++i, ++iter)
         {
         cc2Vect pos = iter.position();
         }
    ```

  - You can also use the iterator to obtain random access to an edgelet, instead of the sequential access shown above, by using the **ccEdgeletIterator::setIndex()** or the slightly less efficient **ccEdgeletIterator::operator+** overload:

    ```
    ccEdgeletIterator_const iter = edgeletSet.begin();
    const ccIndexChain& chain = chainList.chain[chainIndex];
    const c_Int32* start = chain.start();
    c_Int32 n = chain.length();
    for (c_Int32 i = 0; i < n; i++)
       {
       c_Int32 edgeletIndex = start[i];
       iter.setIndex(edgeletIndex);
       cc2Vect pos = iter.position();
       }
    ```

- `ccEdgeletIterator_const begin() const;`

  This method provides const access to the edgelets. For more information see the class **ccEdgeletIterator_const** on page 1271.

edgeTypes `c_UInt32 edgeTypes() const;`

Returns the storage methods used in this **ccEdgeletSet** to store edgelets. The returned value is formed by ORing together one or more of the following values:

ccEdgeletDefs::eEdges
ccEdgeletDefs::eEdges2
ccEdgeletDefs::eEdgesAndOffsets

Notes

An empty edgelet set will return *ccEdgeletDefs::eEdges* | *ccEdgeletDefs::eEdges2*. All other cases will return only a single bit.

If *ccEdgeLetDefs::eRequestEdgesAndOffsets* was specified for the requested edge type and all of the edgelets had whole-pixel locations with X- and Y-coordinates in the range -32768 through +32767, **edgeTypes** will return *ccEdgeletDefs::eEdges*.

hasEdges `bool hasEdges() const`

Returns true if this **ccEdgeletSet** stores edgelets as a vector of **ccEdgelet**, accessible by calling **ccEdgeletSet::edges()**.

This function returns true in two cases:

- *ccEdgeLetDefs::eRequestContiguous* was specified for the requested edge type and all of the edgelets had whole-pixel locations with X- and Y-coordinates in the range -32768 through +32767.
- *ccEdgeLetDefs::eRequestEdgesAndOffsets* was specified for the requested edge type and all of the edgelets had whole-pixel locations with X- and Y-coordinates in the range -32768 through +32767.

hasEdges2

```
bool hasEdges2() const;
```

Returns true if this **ccEdgeletSet** stores edgelets as a vector of **ccEdgelet2**, accessible by calling **ccEdgeletSet::edges2()**.

This function returns true in two cases:

- *ccEdgeLetDefs::eRequestContiguous* was specified for the requested edge type and at least one of the edgelets had whole-pixel locations with X- and Y-coordinates outside of the range -32768 through +32767.
- *ccEdgeLetDefs::eRequestEdges2* was specified for the requested edge type.

hasEdgesAndOffsets

```
bool hasEdgesAndOffsets() const;
```

Returns true if this **ccEdgeletSet** stores edgelets in two or more possibly non-contiguous blocks of memory along with 32-bit offsets for each block. If this function returns true, you must use the **ccEdgeletIterator** or **ccEdgletIterator_const** returned by **begin()** to access the edgelets in this set.

This function returns true in one case:

- *ccEdgeLetDefs::eRequestEdgesAndOffsets* was specified for the requested edge type and at least one of the edgelets had whole-pixel locations with X- and Y-coordinates outside of the range -32768 through +32767.

edges

```
const cmStd vector<ccEdgelet>& edges() const;

void edges(const cmStd vector<ccEdgelet>& edges);
```

- ```
  const cmStd vector<ccEdgelet>& edges() const;
  ```

  Returns a reference to a vector containing all of the **ccEdgelet**s in this **ccEdgeletSet**.

  Notes

  This function may only be called if **hasEdges()** returns true. By using the **begin()** function instead of this one, you can be assured that your code will work correctly regardless of how the edgelets in this **ccEdgeletSet** are stored.

- ```
  void edges(const cmStd vector<ccEdgelet>& edges);
  ```

  Replaces all the **ccEdgelet**s in this **ccEdgeletSet** with the supplied vector of **ccEdgelet**s.

Parameters

edges The **ccEdgelet**s to set

Notes

If *edges* contains no **ccEdgelet**s, the effect is equivalent to calling **setUnbound()**.

This function also sets the **edges2()** vector to an empty vector and clears any edgelets stored in multiple storage blocks.

---

edges2

```
const cmStd vector<ccEdgelet2>& edges2() const;
void edges2(const cmStd vector<ccEdgelet2>&);
```

- `const cmStd vector<ccEdgelet2>& edges2() const;`

Returns a reference to a vector containing all of the **ccEdgelet2**s in this **ccEdgeletSet**.

Notes

This function may only be called if **hasEdges2()** returns true. By using the **begin()** function instead of this one, you can be assured that your code will work correctly regardless of how the edgelets in this **ccEdgeletSet** are stored.

- `void edges2(const cmStd vector<ccEdgelet2>&);`

Replaces all the **ccEdgelet2**s in this **ccEdgeletSet** with the supplied vector of **ccEdgelet2**s.

Notes

This function also sets the **edges()** vector to an empty vector and clears any edgelets stored in multiple storage blocks.

boundingBox

```
ccPelRect boundingBox() const;
```

Returns the minimum enclosing rectangle of the whole pixel positions in this **ccEdgeletSet**. The rectangle is in image coordinates. If there are no **ccEdgelet**s in this **ccEdgeletSet**, then a null **ccPelRect** is returned.

centerOfMass

```
cc2Vect centerOfMass() const;
```

Returns the center of mass of the **ccEdgelet**s in this **ccEdgeletSet** in image coordinates.

Throws

ccMathError::Singular

This **ccEdgeletSet** contains no **ccEdgelet**s.

centerOfProjection

```
cc2Vect centerOfProjection() const;
```

Returns the point that minimizes the RMS distance to all the **ccEdgelet**s in this **ccEdgeletSet**, where **ccEdgelet**s are considered to have only 1 degree of freedom. (The point returned by **centerOfMass()** considers **ccEdgelet**s to have 2 degrees of freedom).

For many figures, the center of projection has a useful meaning. For example, for a corner of any size, the center of projection is at the corner point.

Throws

ccMathError::Singular
This **ccEdgeletSet** contains no **ccEdgelet**s or the center of projection is undefined.

Operators

operator=

```
ccEdgeletSet& operator=(const ccEdgeletSet& rhs);
```

Assignment operator.

Parameters

rhs The object to assign to this one.

Deprecated Members

clientFromImageXform

```
cc2Xform clientFromImageXform() const;

void clientFromImageXform(
  const cc2Xform& clientFromImage);
```

This function is deprecated. Use **clientFromImageXformBase()** instead.

- `cc2Xform clientFromImageXform() const;`

  Returns the **cc2Xform** that describes the transformation between the client coordinate system of the input image used to create this **ccEdgeletSet** and the coordinate system in which the **ccEdgelet** positions are given.

- ```
  void clientFromImageXform(
    const cc2Xform& clientFromImage);
  ```

  Sets the **cc2Xform** that describes the transformation between the client coordinate system of the input image used to create this **ccEdgeletSet** and the coordinate system in which the **ccEdgelet** positions are given.

  Parameters
  clientFromImage The transformation to set

imageFromClientXform

```
cc2Xform imageFromClientXform() const;

void imageFromClientXform(
  const cc2Xform& imageFromClient);
```

This function is deprecated. Use **imageFromClientXformBase()** instead.

- ```
  cc2Xform imageFromClientXform() const;
  ```

  Returns the **cc2Xform** that describes the transformation between the coordinate system in which the **ccEdgelet** positions are given and the client coordinate system of the input image used to create this **ccEdgeletSet**.

- ```
  void imageFromClientXform(
    const cc2Xform& imageFromClient);
  ```

  Sets the **cc2Xform** that describes the transformation between the coordinate system in which the **ccEdgelet** positions are given and the client coordinate system of the input image used to create this **ccEdgeletSet**.

  Parameters
  imageFromClient

  The transformation to set
  ```

ccEdgeletSet

ccEllipse

```
#include <ch_cvl/oldshape.h>

class ccEllipse;
```

This class is deprecated. Use the **ccEllipse2** class instead.

ccEllipse

ccEllipse2

```
#include <ch_cvl/ellipse.h>

class ccEllipse2 : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccEllipse2** class represents arbitrary 2D ellipses. The ellipses may be degenerate, that is, one or both of the radii may vanish. (The term *radii* refers to the half-lengths of the major and minor axes of an ellipse.) More precisely, **ccEllipse2** represents an arbitrary 2D affine transformation of the unit circle. This definition is more general than defining an ellipse simply as a locus of points. The affine transformation definition allows you to parameterize the ellipse by an angle in a well-defined way, and either in a right-handed or left-handed fashion.

Degrees of Freedom

When considered simply as a locus of points, an ellipse has five degrees of freedom (DOF): a center point, two radii, and an orientation. (The center point is a vector (x,y), so it has two DOF.)

An alternative view is to consider an ellipse to be an arbitrary affine transformation of the unit circle, that is, as the set of points (*x*, *y*) generated by the mapping:

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \times \begin{bmatrix} \cos\Phi \\ \sin\Phi \end{bmatrix} + \begin{bmatrix} e \\ f \end{bmatrix}$$

where *a*, *b*, *c*, *d*, *e*, and *f* are constant real values, and ϕ is an angle varying from 0 to 2π radians. The vector ($cos\phi$, $sin\phi$) parameterizes points on the unit circle in the standard way. The matrix multiplication and vector addition map these points to the ellipse.

The six DOF in the affine transformation do not contradict the fact that ellipses have but five DOF when viewed as loci of points. The paradox is resolved by noting that for any ellipse in the plane, viewed as a locus of points, there are an infinite number of mappings of the unit circle to that ellipse. For one particular point on the unit circle, such as the point (1, 0), one can arbitrarily choose to where that point is mapped on the ellipse.

Once this correspondence has been established, the affine transformation is completely determined, and all of the other points on the unit circle are mapped to the ellipse in a continuous fashion. The freedom to choose the mapped destination of the point (1, 0) accounts for the extra degree of freedom in the affine transformation representation. In **ccEllipse2**, this extra degree of freedom is called the *phase* of the ellipse.

To completely determine the affine transformation of the unit circle, you must also specify in which direction the mapped unit circle points proceed around the ellipse. This direction is called the *handedness* of the ellipse, and corresponds to the sign of the determinant of the 2 x 2 matrix of the affine transformation.

If an application treats ellipses purely as geometric objects, and never requires nor refers to a parameterization of points along the ellipse, then the phase and handedness of the ellipse are irrelevant and can be ignored. On the other hand, if you want to define arcs of the ellipse based on ranges of an angular parameter, or if you want to know the parameter value (not simply the 2D coordinates) of, for example, the closest point on the ellipse, then phase and handedness play a role.

Ellipse Parameterization

The **ccEllipse2** class can map an angle ϕ to a point on the ellipse. For example, if *X* is a **cc2XformLinear** object that maps points on the unit circle to points on the ellipse, then ϕ is mapped to the point **X.mapPoint(cc2Vect(1, ϕ))**.

In terms of the individual DOF, the mapping proceeds as follows:

1. $\phi' = \phi$ + *phase()*
2. if (!*isRightHanded()*)
   $\phi' = -\phi'$
3. *p = cc2Vect(1, ϕ')*
4. *p.x() *= radii().x()*;
   *p.y() *= radii().y()*
5. Rotate *p* by *angle()*
6. Translate *p* by *center()*

After the above sequence, *p* is the point on the ellipse corresponding to ϕ. The transformation from the ellipse to the unit circle, if it exists, is achieved by negating the sense of each of the above steps and performing them in reverse order.

DOF versus Transform Representations

The **ccEllipse2** class provides two representations of an ellipse: the DOF representation and the transform representation. The DOF representation includes a constructor plus setters and getters for all of the individual DOFs (center, radii, orientation, phase) as well as handedness. The transform representation includes a constructor, setter, and getter that take or return the full **cc2XformLinear** object that maps the unit circle to the ellipse.

Within a single representation, all of the values are exactly consistent. The DOF getters return the exact values passed to the corresponding DOF setters or the DOF constructor. Likewise, the transform getter returns the exact value passed to the transform setter or the transform constructor.

Mixing representations is legal, but has some consistency issues. When using a DOF constructor or setter, the transform representation is recomputed from the values of the DOF. Conversely, when using the transform constructor or setter, the entire DOF representation is recomputed from the transform. The decomposition of the transform into individual DOFs is almost unique, but not completely. **ccEllipse2** uses a heuristic that attempts to pick the *least surprising* DOF representation when the transform is modified: it minimizes the change in phase. This tends to prevent swapping of the radii, and to reflect changes in rotation of the transform in the angle DOF. For example, premultiplying the transform by a pure rotation by θ will adjust the angle by θ but leave the phase unchanged. There is still a possibility of unexpected changes in the individual DOF when modifying the transform.

Mapping Functions

Mapping of ellipses using **map()** is based on the transform representation. The transform of the mapped ellipse is the composition of the mapping transform with the transform of the original ellipse. This invariant holds for any **ccEllipse2** *e* and **cc2XformLinear** *X*:

```
e.map(X).ellFromUnitCirc() == X * e.ellFromUnitCirc();
```

where == denotes exact equality. The DOF representation of the mapped ellipse must be recomputed from the new transform. This representation is not completely unique, so the values of the individual DOF may be different than expected after a map.

Consider an ellipse that is mapped by a transform that produces a new ellipse, centered at the origin, with x-intercepts of ±3 and y-intercepts of ±2. The mapped ellipse can be viewed as an ellipse with an x-radius of 3, a y-radius of 2, and an orientation of 0; or it can be viewed as an ellipse with an x-radius of 2, a y-radius of 3, and an orientation of $\pi/2$ radians. There are other variations that involve adjusting the orientation and the phase in tandem. The representation you ultimately choose depends on the values of the individual DOFs in the original ellipse.

The process of mapping ellipses may also introduce slight imprecision in DOF values as a result of floating point error. For example, mapping an ellipse by a rigid transform should leave the radii unchanged. However, this process may cause the radii values to change slightly, as they are recomputed from the mapped transform. Because of floating point error, even mapping by the identity transform can cause slight changes in the DOF values since they are recomputed from the transform in the mapped ellipse, whereas the transform may have been computed from the DOF in the original.

Because of issues associated with mapping ellipses, the **ccEllipse2** also provides three auxiliary mapping functions: **translate()**, **rotate()**, and **scale()**. Unlike **map()**, which operates on the transform representation, these operations operate on the DOF representation. For instance, **rotate()** adjusts the orientation DOF and leaves the other DOF unchanged; the transform is then recomputed from the DOF. These DOF-based mapping functions have some advantages over the transform-based **map()**. For simple mappings, such as a pure rotation or scaling, they are simpler to call and also faster than **map()**. They can easily be composed, as in:

```
e.rotate(theta).translate(offset);
```

Finally, they are guaranteed to leave certain DOFs unchanged. For example, rotating an ellipse via **rotate()** produces a new ellipse with exactly the same radii, whereas calling **map()** with a pure rotation transform may perturb the radii as a result of floating point error. In the first case, the transform of the mapped ellipse is recomputed from the DOF, while in the second case, the DOFs are recomputed from the transform.

Constructors/Destructors

ccEllipse2

```
ccEllipse2();

ccEllipse2(const cc2Vect &radii,
  const ccRadian &angle = ccRadian(0.0),
  const cc2Vect &center = cc2Vect(0.0, 0.0),
  bool isRightHanded = true,
  const ccRadian &phase = ccRadian(0.0));

ccEllipse2(const cc2XformLinear &ellFromUnitCirc);

ccEllipse2(double a, double b, double c, double d,
  double e, double f);

explicit ccEllipse2(const ccEllipse &ell);
```

- `ccEllipse2();`

  Default constructor. Constructs a right-handed unit circle, centered at the origin, with zero angle and phase.

- ```
  ccEllipse2(const cc2Vect &radii,
    const ccRadian &angle = ccRadian(0.0),
    const cc2Vect &center = cc2Vect(0.0, 0.0),
    bool isRightHanded = true,
    const ccRadian &phase = ccRadian(0.0));
  ```

  Constructs an ellipse with given values for the individual degrees of freedom and handedness.
  ```

Parameters

radii	The radii.
angle	The angle in radians.
center	The center.
isRightHanded	Whether the ellipse is right-handed (default = true)
phase	The phase.

Notes

The *angle* and *phase* degrees of freedom are internally normalized to lie within the range $-\pi$ through $+\pi$.

Throws

ccShapesError::BadParams
Either component of *radii* is negative.

- `ccEllipse2(const cc2XformLinear &ellFromUnitCirc);`

Conversion constructor. Constructs an ellipse by mapping the unit circle by the given affine transform.

Parameters

ellFromUnitCirc	The affine transform.

Notes

If *ellFromUnitCirc* specifies a circular ellipse, the initial phase is zero.

- `ccEllipse2(double a, double b, double c, double d, double e, double f);`

Constructs an ellipse that satisfies the equation:

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

The x values of the radii of the constructed ellipse are greater than or equal to the y values, the ellipse has zero phase, and is right-handed.

Parameters

a	A constant coefficient.
b	A constant coefficient.
c	A constant coefficient.

d A constant coefficient.

e A constant coefficient.

f A constant coefficient.

Throws

ccShapesError::BadParams
The combination of coefficients does not produce a valid ellipse.

Notes

Not all combinations of coefficients specify ellipses. Some specify other conic sections (for example, hyperbolas), lines, empty sets, or the entire 2D plane. Only combinations that specify ellipses are valid.

- `explicit ccEllipse2(const ccEllipse &ell);`

Conversion constructor. Constructs a **ccEllipse2** from a deprecated **ccEllipse**. The constructed **ccEllipse2** will have zero phase. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

ell The old-style ellipse.

Notes

This constructor is provided to support legacy code that might need to convert an old-style **ccEllipse** to a new-style **ccEllipse2**. It is not recommended as a way of constructing a **ccEllipse2** in new code.

Operators

operator== `bool operator==(const ccEllipse2 &rhs) const;`

Returns true if and only if this ellipse equals *rhs*. This method tests for exact equality of all internal data members.

Parameters

rhs The other ellipse.

operator!= `bool operator!=(const ccEllipse2 &rhs) const;`

Returns true if and only if this ellipse is not equal to *rhs*.

Parameters

rhs The other ellipse.

Public Member Functions

radii

```
const cc2Vect &radii() const;
void radii(const cc2Vect &r);
```

- `const cc2Vect &radii() const;`

  Gets the radii of this ellipse.

- `void radii(const cc2Vect &r);`

  Sets the radii of this ellipse.

  Parameters

  r — The radii. Both components of the **cc2Vect** must be greater than or equal to zero.

  Throws

  ccShapesError::BadParams — Either component of *r* is negative.

  Notes

  The radii are the half-lengths of the axes of symmetry. Both values are non-negative. Either may be the larger of the two (that is, either the x-component or the y-component of the radii vector may represent the major axis of the ellipse.

center

```
const cc2Vect &center() const;
void center(const cc2Vect &c);
```

- `const cc2Vect &center() const;`

  Gets the center of this ellipse.

- `void center(const cc2Vect &c);`

  Sets the center point of this ellipse.

  Parameters

  c — The center.

angle

```
ccRadian angle() const;
void angle(const ccRadian &a);
```

- `ccRadian angle() const;`

  Gets the orientation of this ellipse.

- `void angle(const ccRadian &a);`

  Sets the orientation of this ellipse.

  Parameters

  a The orientation as an angle in radians.

  Notes

  The orientation is the angle that the x-axis of symmetry (that is, the axis corresponding to **radii.x()**) makes with the positive x-axis. In determining the mapping from the unit circle to the ellipse, this value has significance over the full range of 2π radians. However, in determining the locus of points on the ellipse, the value is only significant modulo π radians.

phase

```
ccRadian phase() const;
void phase(const ccRadian &p);
```

- `ccRadian phase() const;`

  Gets the phase of the ellipse.

- `void phase(const ccRadian &p);`

  Sets the phase of this ellipse.

  Parameters

  p The phase in radians.

  Notes

  With handedness, the phase establishes the precise parameterization (correspondence) between angles and points on the ellipse. If the ellipse is right-handed, then the angle -phase (or if it is left-handed, the angle +phase) maps to the point:

```
center() + cc2Vect(radius().x(), angle())
```

Phase has no effect in determining the locus of points that lie on the ellipse. It is the sixth degree of freedom, absent in the geometric representation of an ellipse but present in the affine transformation representation. Changing the phase does not change the locus of points that lie on the ellipse. Setting the phase to zero is often a convenient way to establish a simple parameterization of the ellipse, where the zero angle maps to a point on the x axis of symmetry.

isRightHanded

```
bool isRightHanded() const;
void isRightHanded(bool isRtHanded);
```

- `bool isRightHanded() const;`

Returns true if this ellipse is right-handed. See **ccShape::isRightHanded()** for more information.

- `void isRightHanded(bool isRtHanded);`

Sets the handedness of this ellipse.

Parameters

isRtHanded True sets this ellipse to right-handed, false to left-handed.

Notes

With phase, the handedness establishes the precise correspondence between angles and points on the ellipse. See **phase()** on page 1302 for details. In a right-handed ellipse, as the angle increases the mapped points travel around the ellipse in the sense of the x-axis rotating into the y-axis. In a left-handed ellipse, the direction is reversed. Changing the handedness does not change the locus of points that lie on the ellipse.

ellFromUnitCirc

```
const cc2XformLinear &ellFromUnitCirc() const;
void ellFromUnitCirc(const cc2XformLinear &X);
```

- `const cc2XformLinear &ellFromUnitCirc() const;`

Gets the full affine transformation from the unit circle to this ellipse.

- `void ellFromUnitCirc(const cc2XformLinear &X);`

  Sets the full affine transformation from the unit circle to this ellipse. This transformation includes the effects of phase and handedness. See the constructor **ccEllipse2(const cc2XformLinear &ellFromUnitCirc);** on page 1299 for details.

  Parameters

  X The affine transformation object that transforms a unit circle to this ellipse.

  Notes

  A singular transform corresponds to a degenerate ellipse, in which at least one of the two radii is zero.

map

```
ccEllipse2 map(const cc2XformLinear &X) const;
```

Returns this ellipse mapped by the transformation object *X*.

Parameters

X The transformation object.

Notes

This method recomputes the radii, center, angle, phase, and handedness values for the mapped ellipse. These values may differ for the mapped ellipse from those of the original ellipse in ways not expected. See *Mapping Functions* on page 1297 for details. The **translate()**, **rotate()**, and **scale()** methods offer more controlled mappings that are guaranteed to leave certain DOFs completely unchanged.

translate

```
ccEllipse2 translate(const cc2Vect &offset) const;
```

Returns this ellipse translated by the vector *offset*.

Parameters

offset The vector containing the offset value.

Notes

The *radii*, *angle*, *phase*, and *handedness* values of the translated ellipse are identical to those of the original ellipse. Only the *center* is translated by *offset*.

This method is functionally equivalent to copy constructing a new ellipse *e* from this one, and then executing the sequence:

```
e.center(e.center() + offset);
```

rotate

```
ccEllipse2 rotate(const ccRadian &theta) const;
```

Returns this ellipse rotated about its center by the angle *theta*.

Parameters

theta The angle.

Notes

The *radii*, *center*, *phase*, and *handedness* values of the rotated ellipse are identical to those of the original ellipse. Only the *angle* is adjusted by *theta*.

This method is functionally equivalent to copy constructing a new ellipse *e* from this one, and then executing the sequence:

```
e.angle(e.angle() + theta);
```

scale

```
ccEllipse2 scale(const cc2Vect &mag) const;
```

Returns this ellipse scaled by the vector *mag* about its center and along the directions of its axes of symmetry.

Parameters

mag The vector containing the magnification value.

Notes

The *center*, *angle*, *phase*, and *handedness* values of the translated ellipse are identical to those of the original ellipse. The **radii().x()** value is scaled by **mag().x()**, and the **radii().y()** value is scaled by **mag.y()**.

Notes

This method is functionally equivalent to copy constructing a new ellipse *e* from this one, and then executing the sequence:

```
e.radii(cc2Vect(e.radii().x() * mag.x(),
                e.radii().y() * mag.y()));
```

Throws

ccShapesError::BadParams
Either component of *mag* is negative.

point

```
cc2Vect point(const ccRadian &phi) const;
```

Returns the point at parameter value ϕ along the ellipse.

Notes

The *phase* and *handedness* of the ellipse both affect this value.

tangent

```
ccRadian tangent(const ccRadian &phi) const;
```

Returns the tangent direction at parameter value ϕ along the ellipse.

Notes

The *phase* and *handedness* of the ellipse both affect this value.

Throws

ccShapesError::NoTangent

hasTangent() is false for this ellipse. This occurs if and only if both radii are zero.

phi

```
ccRadian phi(const cc2Vect &p) const;
```

Returns the value of the parameter ϕ corresponding to a given point on this ellipse.

Parameters

p The point.

Notes

This method assumes *p* is a point on (or very near) the ellipse, such as a point computed by **nearestPoint()**. The result returned for other points is undefined.

coeffs

```
void coeffs(double &a, double &b, double &c, double &d,
  double &e, double &f) const;
```

Returns a set of coefficients defining an equation satisfied by all points that lie on this ellipse:

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

Parameters

a A constant coefficient.

b A constant coefficient.

c A constant coefficient.

d A constant coefficient.

e A constant coefficient.

f A constant coefficient.

Notes

Not all ellipses have such an algebraic representation. Specifically, there is no algebraic representation for an ellipse with one zero radius and one nonzero radius.

Throws

ccShapesError::DegenerateShape

This ellipse has exactly one zero radius. (A fully degenerate point ellipse with both radii equal to zero will not cause a throw.)

isDegenerate `bool isDegenerate() const;`

Returns true if and only if at least one of the radii of this ellipse is zero.

clone `virtual ccShapePtrh clone() const;`

Returns a pointer to a copy of this ellipse.

isOpenContour `virtual bool isOpenContour() const;`

Returns true if this shape is an open contour. For ellipses, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion `virtual bool isRegion() const;`

Returns true if this shape is a region. For ellipses, this function always returns true, including ellipses that are degenerate. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

For ellipses, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For ellipses, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

For ellipses, this function returns true if either of the radii is nonzero. It returns false if both radii are zero. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For ellipses, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For ellipses, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this ellipse. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this ellipse to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

sample

```
void sample(const ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this ellipse.

Parameters

params	Parameters object specifying details of how the sampling should be done.
result	Result object to which position and tangent chains are stored.

Notes

If **params.computeTangents()** is true, this function ignores ellipses for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the given point is within this ellipse.

Parameters

p	The point.

Notes

This function always returns false for ellipses that are degenerate.

See **ccShape::within()** for more information. See also **isDegenerate()** on page 1307.

perimeter

```
virtual double perimeter() const;
```

Returns the length of the perimeter of this ellipse. See **ccShape::perimeter()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform &X) const;
```

Returns this ellipse mapped by the transformation object *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this ellipse. See **ccShape::reverse()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccEllipseArc2**s. See **ccShape::decompose()** for more information.

ccEllipse2

ccEllipseAnnulus

```
#include <ch_cvl/shapes.h>

class ccEllipseAnnulus : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes an ellipse annulus, a ring shape made up of two ellipses.

Constructors/Destructors

ccEllipseAnnulus

```
ccEllipseAnnulus();

ccEllipseAnnulus(const cc2Vect& c, double r1, double r2);

ccEllipseAnnulus(const ccEllipse2& inner,
  const ccEllipse2& inner);

ccEllipseAnnulus(const ccCircle& inner,
  const ccCircle& outer);
```

- `ccEllipseAnnulus();`

  Default constructor. Constructs a degenerate ellipse annulus.

- `ccEllipseAnnulus(const cc2Vect& c, double r1, double r2);`

  Constructs an ellipse annulus with the specified center and radii.

  Parameters

c	The center of the radius.
r1	The inner radius.
r2	The outer radius.

- `ccEllipseAnnulus(const ccEllipse2& inner, const ccEllipse2& outer);`

  Creates an ellipse annulus from two concentric ellipses.

  Parameters

  inner The inner ellipse.

  outer The outer ellipse.

  Throws

  ccShapesError::BadGeom
  inner and *outer* do not have the same orientation and aspect ration (that is, the ratio of the x to y radii).

  ccShapesError::NotConcentric
  inner and *outer* are not concentric.

  Notes

  This constructor ignores and discards the phase of the *inner* and *outer* ellipses.

- `ccEllipseAnnulus(const ccCircle& inner, const ccCircle& outer);`

  Creates an ellipse annulus from two concentric circles.

  Parameters

  inner The inner circle.

  outer The outer circle.

  Throws

  ccShapesError::NotConcentric
  inner and *outer* are not concentric.

Operators

operator== `bool operator==(const ccEllipseAnnulus& other) const;`

Returns true if this ellipse annulus is equal to another ellipse annulus: it has the same center, inner radius, and outer radius as the other ellipse annulus.

Parameters

other The other ellipse annulus.

operator!=

```
bool operator!=(const ccEllipseAnnulus&) const;
```

Returns true if this ellipse annulus is not equal to another ellipse annulus.

Parameters

other The other ellipse annulus.

Public Member Functions

inner

```
ccEllipse2 inner() const;
```

Returns the inner ellipse.

outer

```
ccEllipse2 outer() const;
```

Returns the outer ellipse.

center

```
const ccPoint& center() const;
```

Returns the center of the ellipse annulus.

innerRadii

```
cc2Vect innerRadii() const;
```

Returns the radii of the inner ellipse.

outerRadii

```
cc2Vect outerRadii() const;
```

Returns the radii of the outer ellipse.

map

```
ccEllipseAnnulus map(const cc2Xform& c) const;
```

Returns an ellipse annulus that is the result of mapping this ellipse annulus with the transformation object *c*.

Parameters

c The transformation object.

Notes

The transform *c* must be nonsingular, and the outer radii of both ellipses must be strictly positive. If both of these conditions are false, use **mapshape()** instead.

ccEllipseAnnulus

degen

```
bool degen() const;
```

Returns true if the ellipse annulus is degenerate, that is if any of the radii of either ellipse is less than or equal to zero.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this ellipse annulus.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For ellipse annuli, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For ellipse annuli, this function always returns true, even for ellipse annuli that are degenerate. See **ccShape::isRegion()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if this ellipse annulus is right-handed. See **ccShape::isRightHanded()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For ellipse annuli, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For ellipse annuli, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

This function returns true if **hasTangent()** is true for the inner or outer ellipse. It returns false if **hasTangent()** is false for both ellipses. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For ellipse annuli, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For ellipse annuli, this function always returns false. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this ellipse annulus. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this ellipse annulus to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this ellipse annulus to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this ellipse annulus.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.

result Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores ellipse annuli for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this ellipse annulus mapped by *X*.

Parameters

X The transformation object.

Notes

If the transform *X* is singular or either of the outer radii is zero, this function returns a **ccRegionTree**. If both of these conditions are false, this function returns a **ccEllipseAnnulus**.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccEllipseArc2**s. See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the given point is within this ellipse annulus.

Parameters

p The point.

Notes

This function returns false if either of the underlying ellipses is degenerate.

See **ccShape::within()** for more information.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this ellipse annulus over the given perimeter range.

Parameters

info	Shape information for this ellipse annulus.
range	The perimeter range.

See **ccShape::subShape()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccEllipseAnnulus

```
ccEllipseAnnulus(const ccEllipse& inner,
  const ccEllipse& outer);
```

Use the constructor that constructs an ellipse annulus from a **ccEllipse2** instead of this version.

innerEllipse

```
const ccEllipse& innerEllipse() const;
```

Use **inner()** instead of this function.

outerEllipse

```
const ccEllipse& outerEllipse() const;
```

Use **outer()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

ccEllipseAnnulus

ccEllipseAnnulusSection

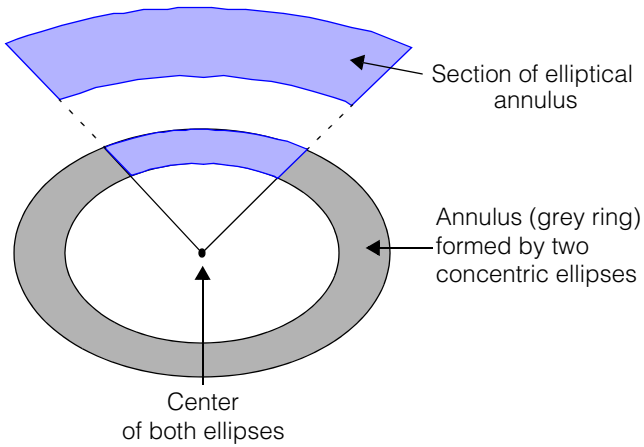
```
#include <ch_cvl/shapes.h>

class ccEllipseAnnulusSection : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a section of an elliptical annulus, as shown in the following diagram.



An elliptical annulus might be used, for example, to draw boundaries around a bar code, serial number, or other mark etched in a curve around the inner ring of a music CD or around the outer ring of a chip wafer. You could then use **cfPolarTransformImage** and **ccPolarSamplingParams** to transform the pixels in the elliptical annulus section image into a rectangular image for easier interpretation by OCR or OCV vision tools.

Constructors/Destructors

ccEllipseAnnulusSection

```
ccEllipseAnnulusSection();

ccEllipseAnnulusSection(const cc2Vect& c, double r1,
  double r2, const ccRadian& phi1, const ccRadian& phi2,
  bool increasingAngle = true, bool centrifugal = true,
  bool normalizePhi2 = true);

ccEllipseAnnulusSection(const ccCircle& c1,
  const ccCircle& c2, const ccRadian& phi1,
  const ccRadian& phi2, bool increasingAngle = true,
  bool centrifugal = true, bool normalizePhi2 = true);

ccEllipseAnnulusSection(const ccEllipse2& c1,
  const ccEllipse2& c2, const ccRadian& phi1,
  const ccRadian& phi2, bool increasingAngle = true,
  bool centrifugal = true, bool normalizePhi2 = true);

ccEllipseAnnulusSection(const ccEllipseAnnulus& ann,
  const ccRadian& phi1, const ccRadian& phi2,
  bool increasingAngle = true, bool centrifugal = true,
  bool normalizePhi2 = true);

ccEllipseAnnulusSection(const ccAnnulus& ann,
  const ccRadian& phi1, const ccRadian& phi2,
  bool increasingAngle = true, bool centrifugal = true,
  bool normalizePhi2 = true);
```

- `ccEllipseAnnulusSection();`

  The default constructor creates a degenerate elliptical annulus section.

- `ccEllipseAnnulusSection(const cc2Vect& c, double r1, double r2, const ccRadian& phi1, const ccRadian& phi2, bool increasingAngle = true, bool centrifugal = true, bool normalizePhi2 = true);`

  Creates an elliptical annulus section given a center, radii, start and end angles.

  Parameters

c	The center of the ellipse annulus section.
r1	The inner radius.
r2	The outer radius.

phi1 The starting angle of the ellipse annulus section.

phi2 The ending angle of the ellipse annulus section.

increasingAngle True if the angle increases. Used for polar unwrapping.

centrifugal True if unwrapping from the center to the outer edge. Used for polar unwrapping.

normalizePhi2 True to ensure that *phi2* is greater than *phi1*.

Throws

ccShapesError::DegenerateShape
phi2 < *phi1* and *normalizePhi2* is false.

Notes

See *Notes* on page 1324 for a discussion of measuring the *phi1* and *phi2* angles.
See *Notes* on page 1329 for illustrations of the effects of the *increasingAngle* and *centrifugal* arguments.

- ```
  ccEllipseAnnulusSection(const ccCircle& c1,
    const ccCircle& c2, const ccRadian& phi1,
    const ccRadian& phi2, bool increasingAngle = true,
    bool centrifugal = true, bool normalizePhi2 = true);
  ```

  Creates an ellipse annulus section from two concentric circles.

  Parameters

  c1 The inner circle.

  c2 The outer circle.

  phi1 The starting angle of the ellipse annulus section.

  phi2 The ending angle of the ellipse annulus section.

  increasingAngle True if the angle increases. Used for polar unwrapping.

  centrifugal True if unwrapping from the center to the outer edge. Used for polar unwrapping.

  normalizePhi2 True to ensure that *phi2* is greater than *phi1*.

  Throws

  ccShapesError::DegenerateShape
  phi2 < *phi1* and *normalizePhi2* is false.

  ccShapesError::NotConcentric
  c1 and *c2* are not concentric
  ```

Notes

See *Notes* on page 1324 for a discussion of measuring the *phi1* and *phi2* angles. See *Notes* on page 1329 for illustrations of the effects of the *increasingAngle* and *centrifugal* arguments.

- ```
  ccEllipseAnnulusSection(const ccEllipse2& c1,
    const ccEllipse2& c2, const ccRadian& phi1,
    const ccRadian& phi2, bool increasingAngle = true,
    bool centrifugal = true, bool normalizePhi2 = true);
  ```

  Creates an ellipse annulus section from two concentric ellipses.

  Parameters

c1	The inner ellipse.
c2	The outer ellipse.
phi1	The starting angle of the ellipse annulus section.
phi2	The ending angle of the ellipse annulus section.
increasingAngle	True if the angle increases. Used for polar unwrapping.
centrifugal	True if unwrapping from the center to the outer edge. Used for polar unwrapping.
normalizePhi2	True to ensure that *phi2* is greater than *phi1*.

  Throws

  ccShapesError::NotConcentric
  The two ellipses, *c1* and *c2*, do not have the same center, ratio of *x* and *y* radii, and orientation.

  ccShapesError::DegenerateShape
  phi2 is less than *phi1* and *normalizePhi2* is false.

  Notes

  This constructor ignores and discards the phase of the inner and outer ellipses.

  See *Notes* on page 1324 for a discussion of measuring the *phi1* and *phi2* angles. See *Notes* on page 1329 for illustrations of the effects of the *increasingAngle* and *centrifugal* arguments.
  ```

- ```
  ccEllipseAnnulusSection(const ccEllipseAnnulus& ann,
    const ccRadian& phi1, const ccRadian& phi2,
    bool increasingAngle = true, bool centrifugal = true,
    bool normalizePhi2 = true);
  ```

  Creates an ellipse annulus section from an ellipse annulus.

  Parameters

ann	The ellipse annulus.
phi1	The starting angle of the ellipse annulus section.
phi2	The ending angle of the ellipse annulus section.
increasingAngle	True if the angle increases. Used for polar unwrapping.
centrifugal	True if unwrapping from the center to the outer edge. Used for polar unwrapping.
normalizePhi2	True to ensure that *phi2* is greater than *phi1*.

  Throws

  ccShapesError::DegenerateShape
  phi2 < *phi1* and *normalizePhi2* is false.

  Notes

  See *Notes* on page 1324 for a discussion of measuring the *phi1* and *phi2* angles.
  See *Notes* on page 1329 for illustrations of the effects of the *increasingAngle* and *centrifugal* arguments.

- ```
  ccEllipseAnnulusSection(const ccAnnulus& ann,
    const ccRadian& phi1, const ccRadian& phi2,
    bool increasingAngle = true, bool centrifugal = true,
    bool normalizePhi2 = true);
  ```

  Creates an ellipse annulus section from an annulus.

  Parameters

ann	The annulus.
phi1	The starting angle of the ellipse annulus section.
phi2	The ending angle of the ellipse annulus section.
increasingAngle	True if the angle increases. Used for polar unwrapping.
centrifugal	True if unwrapping from the center to the outer edge. Used for polar unwrapping.
normalizePhi2	True to ensure that *phi2* is greater than *phi1*.

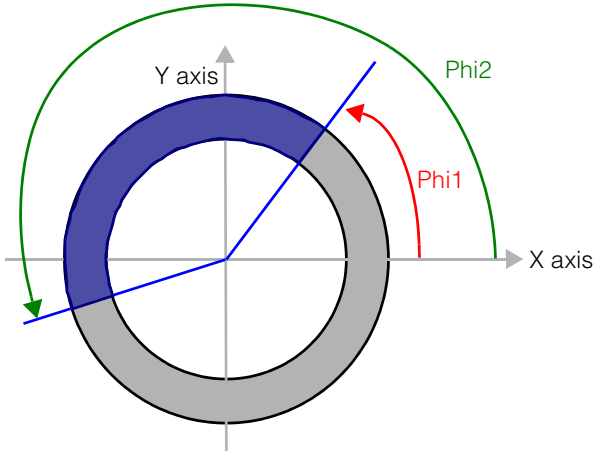
Throws

ccShapesError::DegenerateShape
phi2 < *phi1* and *normalizePhi2* is false.

Notes

The starting angle *phi1* of the section, and the ending angle *phi2,* are measured with respect to the section projected onto a unit circle. Angles are measured from the X axis of the unit circle.

In the case of an annular section of two concentric circles, the starting angle is simply the angle from the X axis to the circle radius that marks the beginning of the section. Likewise, the ending angle *phi2* is the angle from the X axis to the radius that marks the end of the section. This case is shown in the following figure.



In the general case of an annular section of two concentric ellipses, the **ccEllipse** object that represents the outer ellipse includes a **ccEllipseUnit** structure. This structure defines the transformation from ellipse coordinates to unit circle coordinates. You can use this transformation to calculate the starting and ending angle values. For a given point *p* on the section's outer ellipse, its angle *phi* in the unit coordinate system is computed by the following expression:

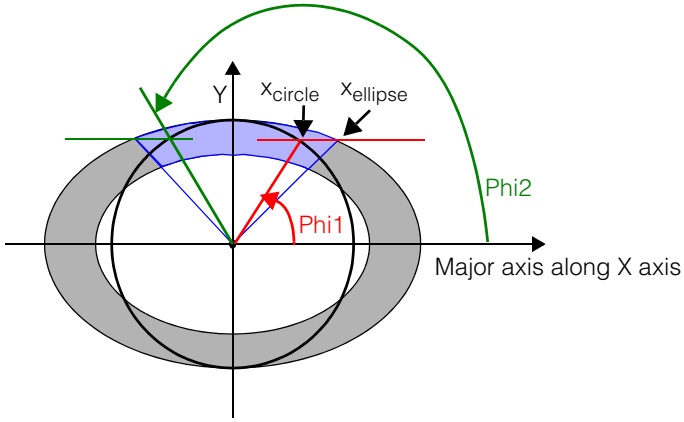
```
ccEllipse2  outerEllipse;
cc2Vect     center; // default constructor creates as (0,0)
ccPoint     p;

(outerEllipse.unit().U_ * (p - center)).angle();
```

Apply the above expression in turn to each endpoint *p* of the outer elliptical arc of the section to yield the values of *phi1* and *phi2* for the section.

If you do not have a **ccEllipse2** object to start from, you can obtain approximate *phi1* and *phi2* angles from the projection method illustrated in the following diagram. Draw a unit reference circle whose radius is one-half of the minor axis of the outer ellipse; this reference circle fits just inside the outer ellipse. Draw a line parallel to the major axis, and passing through the endpoint, $x_{ellipse}$, of the outer elliptical arc of the section. The point where this line intersects the inner reference circle, x_{circle}, is the projection of $x_{ellipse}$ onto the circle. The section's starting angle *phi1* is measured from the major axis to the line between the center and x_{circle}.

Likewise the ending angle *phi2* is measured from the major axis to the line formed between the center and the projection of the other outer arc endpoint onto the reference circle.



This projection method and the diagram above assume that the transformation of the outer ellipse onto the unit reference circle is not reflected (that is, it presumes that **outerEllipse.geom().reverseAngleDir_** is false, the default condition).

Operators

operator==

```
bool operator==(const ccEllipseAnnulusSection& e) const;
```

Returns true if this ellipse annulus section is equal to another ellipse annulus section: it has the same center, inner radius, outer radius, start angle, and end angle as the other ellipse annulus.

Parameters

e	The other ellipse annulus section.

operator!=

```
bool operator!=(const ccEllipseAnnulusSection& e) const;
```

Returns true if this ellipse annulus section is not equal to another ellipse annulus section.

Parameters

e	The other ellipse annulus section.

Public Member Functions

ellipseAnnulus

```
const ccEllipseAnnulus& ellipseAnnulus() const;
```

Returns the complete ellipse annulus that this object is a section of.

center

```
const ccPoint& center() const;
```

Returns the center of the ellipse annulus section.

phi1

```
const ccRadian &phi1() const;
void phi1(const ccRadian &phi1);
```

- `const ccRadian &phi1() const;`

  Returns the starting angle of the ellipse annulus section.

- `void phi1(const ccRadian &phi1);`

  Sets the starting angle of the ellipse annulus section.

  Parameters

phi1	The starting angle.

  Notes

  See *Notes* on page 1324 for a discussion of how starting angles are measured.

phi2

```
const ccRadian &phi2() const;
void phi2(const ccRadian &phi2);
```

- `const ccRadian &phi2() const;`

  Returns the ending angle of the ellipse annulus section.

- `void phi2(const ccRadian &phi2);`

  Sets the ending angle of the ellipse annulus section.

  Parameters
  phi2 The ending angle.

  Notes
  See *Notes* on page 1324 for a discussion of how ending angles are measured.

increasingAngle

```
bool increasingAngle() const;
void increasingAngle(bool increasingAngle);
```

- `bool increasingAngle() const;`

  Return true if the angle is increasing. This information is used by the polar unwrapping functions.

- `void increasingAngle(bool increasingAngle);`

  Sets whether the angle is increasing.

  Parameters
  increasingAngle True if the angle increases. Used for polar unwrapping.

  Notes
  See *Notes* on page 1329 for illustrations of the effect of *increasingAngle*.

centrifugal

```
bool centrifugal() const;
void centrifugal(bool centrifugal);
```

- `bool centrifugal() const;`

  Returns true if unwrapping from the center to the outer edge. Used for polar unwrapping.

- `void centrifugal(bool centrifugal);`

Sets whether unwrapping from the center to the outer edge. Used for polar unwrapping.

Parameters

centrifugal True if unwrapping from the center to the outer edge. Used for polar unwrapping.

Notes

See *Notes* on page 1329 for illustrations of the effect of *centrifugal*.

inner `ccEllipse2 inner() const;`

Returns the inner ellipse.

outer `ccEllipse2 outer() const;`

Returns the outer ellipse.

map `ccEllipseAnnulusSection map(const cc2Xform& c) const;`

Returns an ellipse annulus section that is the result of mapping this ellipse annulus section with the transformation object *c*.

Parameters

c The transformation object.

Throws

ccShapesError::BadCoeff
The mapping is not a pure rotation, translation, and scale mapping.

Notes

Avoid using this method with transforms that have a negative determinant. With these kind of transforms, this method does *not* correctly maintain the correspondence between points of the ellipse annulus section. For example, if *X* is a transofrm with a negative determinant and *eas* is an ellipse annulus section, it will *not* necessarily be the case that **eas.map(X).cornerPo()** approximately equals **X.mapPoint(eas.cornerPo())**, as might be expected. Use **mapShape()** instead of this function where possible, as it does not exhibit this problem.

degen `bool degen() const;`

Returns true if the ellipse annulus section is degenerate, that is if any of the radii of either ellipse is less than or equal to zero.

cornerPo `ccPoint cornerPo() const;`

Returns the corner point P_o of the ellipse annulus section. Refer to the illustrations below.

cornerPx `ccPoint cornerPx() const;`

Returns the corner point P_x of the ellipse annulus section.

cornerPy `ccPoint cornerPy() const;`

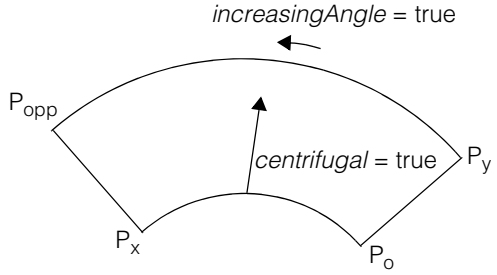
Returns the corner point P_y of the ellipse annulus section.

cornerPopp `ccPoint cornerPopp() const;`

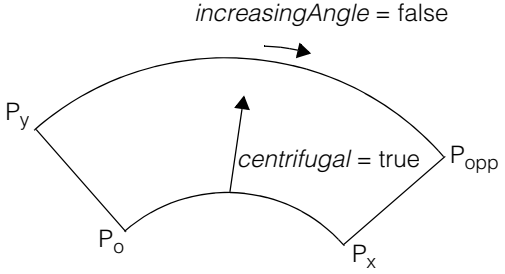
Gets the corner point P_{opp} of the ellipse annulus section.

Notes

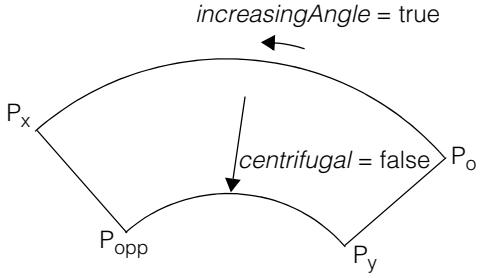
The **corner*** functions refer to the points shown in the following figures. The first figure shows the default case, where *increasingAngle* and *centrifugal* are true:



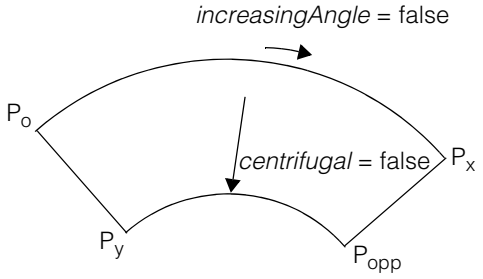
The points are reversed left-to-right if *increasingAngle* is false:



The points are reversed up-to-down if *centrifugal* is false:



Finally, the points are reversed both ways if both *increasingAngle* and *centrifugal* are false:



mapFromUnitSq `ccPoint mapFromUnitSq(const ccPoint &pt) const;`

Maps the given point from the unit square to the ellipse annulus section.

Parameters

pt The point.

mapToUnitSq `ccPoint mapToUnitSq(const ccPoint &pt) const;`

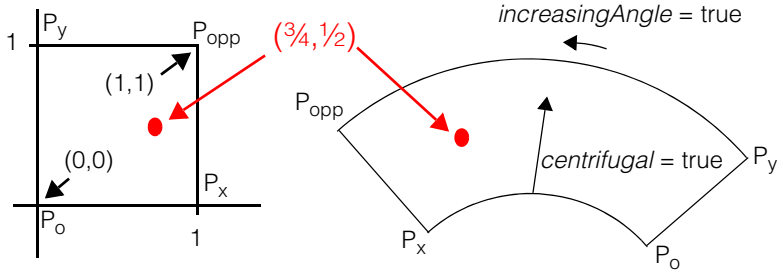
Maps the given point to the unit square from the ellipse annulus section.

Parameters

pt The point.

Notes

The **map*UnitSq** functions map a point to and from anywhere on or within an ellipse annulus section to a reference unit square with height and width equal to 1. A section and unit square are shown in the following figure:



In the unit square projection, the X axis corresponds to the angle from *phi1* at which a point in the annular section is found. The Y axis corresponds to the radius of the point. Thus, a point, illustrated in red in the figure, about 3/4 of the way over in the direction of the *increasingAngle* vector, and about 1/2 way into the section in the direction of the *centrifugal* vector, would be mapped as shown in the reference unit square.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this ellipse annulus section.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For ellipse annulus sections, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For ellipse annulus sections, this function always returns true, even for ellipse annulus sections that are degenerate. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For ellipse annulus sections, this function always returns true. See **ccShape::isFinite()** for more information.

ccEllipseAnnulusSection

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For ellipse annulus sections, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

This function returns true if the perimeter of this ellipse annulus section is positive. It returns false if the perimeter is zero. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For ellipse annulus sections, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For ellipse annulus sections, this function always returns false. See **ccShape::reverse()** for more information.

isRightHanded `virtual bool isRightHanded() const;`

Returns true if this ellipse annulus section is right-handed. See **ccShape::isRightHanded()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the smallest rectangle that encloses this ellipse annulus section. See **ccShape::boundingBox()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns the nearest point on the boundary of this ellipse annulus section to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

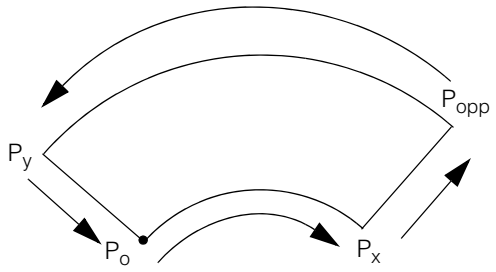
See **ccShape::nearestPoint()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape. The corner points of the ellipse annulus section are traversed in the following order:

1. P_o
2. P_x
3. P_{opp}
4. P_y
5. P_o



Sampling Starts and Ends at P_o

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores ellipse annulus sections for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this ellipse annulus section mapped by *X*.

Parameters

X	The transformation object.

Notes

If the transform *X* is singular, this function returns a closed **ccContourTree**. Otherwise, it returns a **ccEllipseAnnulusSection**.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Decomposes this **ccEllipseAnnulusSection** into a closed **ccContourTree** with four children in the following order:

1. An arc from P_o to P_x
2. A line segment from P_x to P_{opp}
3. An arc from P_{opp} to P_y
4. A line segment from P_y to P_o

See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the given point is within this ellipse annulus section.

Parameters

p The point.

Notes

This function returns false if either of the underlying ellipses is degenerate.

See **ccShape::within()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccEllipseAnnulusSection

```
ccEllipseAnnulusSection(const ccEllipse& c1,
  const ccEllipse2& c2, const ccRadian& phi1,
  const ccRadian& phi2, bool increasingAngle = true,
  bool centrifugal = true, bool normalizePhi2 = true);
```

Use the constructor that uses **ccEllipse2** references as its first two arguments instead of this version.

innerEllipse

```
const ccEllipse &innerEllipse() const;
```

Use **inner()** instead of this function.

outerEllipse `const ccEllipse &outerEllipse() const;`

Use **outer()** instead of this function.

distToPoint `double distToPoint(const cc2Vect& v) const;`

Use **distanceToPoint()** instead of this function.

encloseRect `ccRect encloseRect() const;`

Use **boundingBox()** instead of this function.

ccEllipseAnnulusSection

ccEllipseArc

```
#include <ch_cvl/oldshape.h>

class ccEllipseArc : public ccEllipse;
```

This class is deprecated. Use the **ccEllipseArc2** class instead.

ccEllipseArc2

```
#include <ch_cvl/ellipse.h>

class ccEllipseArc2 : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccEllipseArc2** class represents arbitrary 2D elliptical arcs. An elliptical arc is represented as an underlying ellipse plus a parameter range that specifies that portion of the ellipse included in the arc. The parameter range is specified by a starting angle and an angular span. Together, these values specify the range of *phi* values of the underlying ellipse that lie on the elliptical arc.

Note The *phase* and *handedness* of the underlying ellipse of an ellipse arc affect the range of *phi* values of the underlying ellipse that are on the elliptical arc. See **ccEllipse2** for more information.

The angular span may be positive or negative. Changing the sign of the angle range changes the direction along the ellipse in which the ellipse arc lies relative to the starting point. Flipping the *isRightHanded* flag of the underlying ellipse has the same effect. The angular span may have a magnitude greater than 2π radians, so it is possible to specify multiple revolutions around the ellipse. The **ccEllipse2** class provides methods for manipulating the underlying ellipse as well as the angle range of the arc.

Tangents

The tangent direction along an ellipse arc is always in the direction from the start point, at parameter value **phiStart()**, toward the end point, at parameter value **phiEnd()**. This means that if **phiSpan()** is positive, the tangent directions are aligned with the tangent directions of the underlying ellipse, and if **phiSpan()** is negative, the tangent directions are opposite those of the underlying ellipse.

Constructors/Destructors

ccEllipseArc2

```
ccEllipseArc2(const ccEllipse2 &ell = ccEllipse2());

ccEllipseArc2(const ccEllipse2 &ell,
  const ccRadian &phiStart, const ccRadian &phiSpan);

explicit ccEllipseArc2(const ccEllipseArc &ellArc);
```

- `ccEllipseArc2(const ccEllipse2 &ell = ccEllipse2());`

  Conversion constructor. Constructs an ellipse arc with the given underlying ellipse and an angle range of 0 through $\pi/2$ radians.

  Parameters

  ell — The underlying ellipse. The default **ccEllipse2** is a right-handed unit circle, centered at the origin, with zero angle and phase.

- `ccEllipseArc2(const ccEllipse2 &ell, const ccRadian &phiStart, const ccRadian &phiSpan);`

  Constructs an ellipse arc with the given underlying ellipse, starting angle, and angular span.

  Parameters

  ell — The underlying ellipse.

  phiStart — The starting angle. This parameter is only significant modulo 2π radians.

  phiSpan — The angular span. his parameter is significant over all values, positive and negative. Values of *phiSpan* with a magnitude exceeding 2π radians specify arcs comprising more than one revolution around the underlying ellipse.

- `explicit ccEllipseArc2(const ccEllipseArc &ellArc);`

  Conversion constructor. Constructs a **ccEllipseArc2** from a deprecated **ccEllipseArc**. The underlying ellipse of the constructed **ccEllipseArc2** will have zero phase. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  ellArc — The old-style ellipse arc.

Notes

This constructor is provided to support legacy code that might need to convert an old-style **ccEllipseArc** to a new-style **ccEllipseArc2**. It is not recommended as a way of constructing a **ccEllipseArc2** in new code.

Operators

operator==

```
bool operator==(const ccEllipseArc2 &rhs) const;
```

Returns true if an only if this ellipse arc is equal to *rhs*. This method tests for exact equality of all internal data members.

Parameters

rhs The other ellipse arc.

operator!=

```
bool operator!=(const ccEllipseArc2 &rhs) const;
```

Returns true if this ellipse arc is not equal to *rhs*.

Parameters

rhs The other ellipse arc.

Public Member Functions

ellipse

```
const ccEllipse2 &ellipse() const;
void ellipse(const ccEllipse2 &ell);
```

- ```
  const ccEllipse2 &ellipse() const;
  ```

  Gets the underlying ellipse of this ellipse arc.

- ```
  void ellipse(const ccEllipse2 &ell);
  ```

  Sets the underlying ellipse of this ellipse arc.

  Parameters

  ell The underlying ellipse.

phiStart

```
ccRadian phiStart() const;
void phiStart(const ccRadian &s);
```

- `ccRadian phiStart() const;`

  Gets the starting angle of this ellipse arc.

- `void phiStart(const ccRadian &s);`

  Sets the starting angle of this ellipse arc.

  Parameters

  s The starting angle.

  Notes

  The starting angle is only significant modulo 2π radians, although neither the getter nor the setter force its value to lie in this range.

phiSpan

```
ccRadian phiSpan() const;
void phiSpan(const ccRadian &s);
```

- `ccRadian phiSpan() const;`

  Gets the angular span of this ellipse arc.

- `void phiSpan(const ccRadian &s);`

  Sets the angular span of this ellipse arc.

  Parameters

  s The angular span.

  Notes

  The angle span is significant over all values, positive and negative. Values of *phiSpan* with magnitude exceeding 2π radians specify arcs comprising more than one revolution around the underlying ellipse.

phiEnd

```
ccRadian phiEnd() const;
```

Gets the ending angle of this ellipse arc, equal to *phiStart()* + *phiSpan()*.

map

```
ccEllipseArc2 map(const cc2XformLinear &X) const;
```

Parameters

Returns this ellipse arc mapped by the transformation object *X*.

Parameters

X	The transformation object.

Notes

This method operates by calling the corresponding method on the underlying ellipse and leaving the arc angle range unchanged.

See **ccEllipse2::map()** for details.

translate

```
ccEllipseArc2 translate(const cc2Vect &offset) const;
```

Returns this ellipse arc translated by the vector *offset*.

Parameters

offset	The vector containing the offset value.

Notes

This method operates by calling the corresponding method on the underlying ellipse and leaving the arc angle range unchanged.

See **ccEllipse2::translate()** for details.

rotate

```
ccEllipseArc2 rotate(const ccRadian &theta) const;
```

Returns this ellipse arc rotated about its center by the angle *theta*.

Parameters

theta	The angle.

Notes

This method operates by calling the corresponding method on the underlying ellipse and leaving the arc angle range unchanged.

See **ccEllipse2::rotate()** for details.

scale

```
ccEllipseArc2 scale(const cc2Vect &mag) const;
```

Returns this ellipse arc scaled by the vector *mag* about its center and along the directions of its axes of symmetry.

Parameters

mag The vector containing the magnification value.

Throws

ccShapesError::BadParams
Either component of *mag* is negative.

Notes

This method operates by calling the corresponding method on the underlying ellipse and leaving the arc angle range unchanged.

See **ccEllipse2::scale()** for details.

isInSpan

```
bool isInSpan(const ccRadian &phi) const;
```

Returns true if and only if *phi* corresponds to a point on this ellipse arc.

Parameters

phi An angle that specifies a point that may or may not be on this ellipse arc.

Notes

The values **phiStart()** and **phiEnd()** together specify a half-open range if **phiSpan()** is positive. In other words, for a positive angle span, **isInSpan()** is true for the starting angle, returned by **phiStart()**, and false for the ending angle, returned by **phiEnd()**.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this ellipse arc.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For ellipse arcs, this function always returns true. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For ellipse arcs, this function always returns false. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For ellipse arcs, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For ellipse arcs, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

For ellipse arcs, this function returns true if **hasTangent()** is true for the underlying ellipse and **phiSpan()** is not zero. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For ellipse arcs, this function always returns true. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For ellipse arcs, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this ellipse arc. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on this ellipse arc to the given point. See **ccShape::nearestPoint()** for more information.

Parameters

p	The point.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this ellipse arc. See **ccShape::perimeter()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this ellipse arc to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this ellipse arc.

point The point.

Notes

The returned position always corresponds to an angular position within 2π radians from the start angle, even when the magnitude of **phiSpan()** exceeds 2π.

See **ccShape::nearestPerimPos()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns the net signed angle through which the tangent vector rotates along this ellipse arc from the start point to the end point.

Throws

ccShapesError::NoTangent
hasTangent() is false for this ellipse arc.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

Parameters

p A point.

See **ccShape::windingAngle()** for more information.

startPoint

```
virtual cc2Vect startPoint() const;
```

Returns the starting point of this ellipse arc. See **ccShape::startPoint()** for more information.

endPoint

```
virtual cc2Vect endPoint() const;
```

Returns the ending point of this ellipse arc. See **ccShape::endPoint()** for more information.

startAngle

```
virtual ccRadian startAngle() const;
```

Returns the starting angle of this ellipse arc.

Throws

ccShapesError::NoTangent
hasTangent() is false for this ellipse arc.

See **ccShape::startAngle()** for more information.

endAngle

```
virtual ccRadian endAngle() const;
```

Returns the ending angle of this ellipse arc.

Throws

ccShapesError::NoTangent
hasTangent() is false for this ellipse arc.

See **ccShape::endAngle()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this ellipse arc. See **ccShape::reverse()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this ellipse arc.

Parameters

params	Parameters object specifying details of how the sampling should be done.
result	Result object to which position and tangent chains are stored.

Notes

If **params.computeTangents()** is true, this function ignores ellipse arcs for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform &X) const;
```

Returns this ellipse arc mapped by the transformation object *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a clone of this ellipse arc. As an ellipse arc is already a decomposed shape, this method is equivalent to **clone()** for ellipse arcs. See **ccShape::decompose()** for more information.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape on the perimeter of this ellipse arc within the given range.

Parameters

info	Shape information for this ellipse arc.
range	The perimeter range.

See **ccShape::subShape()** for more information.

ccEllipseFitDefs

```
#include <ch_cvl/fit.h>

class ccEllipseFitDefs;
```

A name space that holds enumerations and constants used with the Ellipse Fitting tool.

Enumerations

fit_mode

```
enum fit_mode
```

This enumeration defines types of fitting supported by the Ellipse Fitting tool.

Value	Meaning
eLeastSquares = 0	Fits an ellipse by minimizing the least squares error.
eLeastSquaresUseExpectedOrientation = 1	Fits an ellipse whose orientation you specify by minimizing the least squares error.
eLeastSquaresUseAccurateRMSError = 2	Fits an ellipse by minimizing the least squares error and subtracting the accurate RMS measurement error.
eLeastSquaresUseExpectedOrientationAndAccurateRMSError = 3	Fits an ellipse whose orientation you specify by minimizing the least squares error and subtracting the accurate RMS measurement error.
kDefaultFitMode = eLeastSquares	

ccEllipseFitDefs

ccEllipseFitParams

```
#include <ch_cvl/fit.h>

class ccEllipseFitParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the Ellipse Fitting tool parameters. See **cfEllipseFit()**.

Constructors/Destructors

ccEllipseFitParams

```
ccEllipseFitParams(
  enum ccEllipseFitDefs::fit_mode fitMode =
                          ccEllipseFitDefs::kDefaultFitMode,
  const ccRadian &orientation = ccRadian(0),
  c_UInt32 numIgnore=0,
  double threshold=HUGE_VAL);
```

Constructs an ellipse fit parameters object

Parameters

fitMode — The ellipse fit mode. Must be one of the following:

eLeastSquares; the tool finds the ellipse axes.

eLeastSquaresUseExpectedOrientation; you provide the ellipse orientation (see *orientation* below). Can cause the tool to run faster but may produce a less accurate found position

orientation — The expected orientation of the ellipse. You can specify either the ellipse major axis orientation or the minor axis orientation. The fitter will work with either axis.

This parameter is only used when *fitMode = eLeastSquaresUseExpectedOrientation*.

numIgnore — The number of outlying points to ignore. The tool always discards this number of points from the point set used to find the ellipse.

threshold The maximum RMS error for a valid fit. If the fitted ellipse has an RMS error greater than *threshold*, it is not considered a valid fit.

Throws

ccEllipseFitDefs::BadParams
If *threshold* < 0

Operators

operator==

```
bool operator== (const ccEllipseFitParams& that) const;
```

True if **this* equals *that*; false otherwise.

Two **ccEllipseFitParams** objects are considered equal if and only if their fitMode, radius, numIgnore, and threshold values are each equal.

Parameters

that The **ccEllipseFitParams** object to compare with this object.

Public Member Functions

fitMode

```
enum ccEllipseFitDefs::fit_mode fitMode();

void fitMode(enum ccEllipseFitDefs::fit_mode fitMode);
```

See the CTOR description.

- `enum ccEllipseFitDefs::fit_mode fitMode();`

  Returns the ellipse fitting mode.

- `void fitMode(enum ccEllipseFitDefs::fit_mode fitMode);`

  Sets a new ellipse fit mode.

  Parameters

  fitMode The new ellipse fit mode. Must be one of the *ccEllipseFitDefs::fit_mode* enums.

orientation

```
ccRadian orientation() const;

void orientation(const ccRadian &orientation);
```

See *orientation* in the CTOR description.

- `ccRadian orientation() const;`

  Returns the current ellipse orientation angle specification.

- `void orientation(const ccRadian &orientation);`

  Sets a new ellipse orientation angle specification. This expected orientation may correspond to the major axis or the minor axis of the ellipse.

  Parameters
  orientation The new orientation angle.

numIgnore

```
c_UInt32 numIgnore() const;
void numIgnore(c_UInt32 numIgnore);
```

The number of outlying points to ignore. The tool always discards this number of points from the point set used to find the ellipse.

- `c_UInt32 numIgnore() const;`

  Returns the current number specified.

- `void numIgnore(c_UInt32 numIgnore);`

  Sets a new number of outlying points to ignore.

  Parameters
  numIgnore The number of points to ignore.

threshold

```
double threshold() const;
void threshold(double threshold);
```

The maximum RMS error for a valid fit. If the fitted ellipse has an RMS error greater than *threshold*, it is not considered a valid fit.

- `double threshold() const;`

  Returns the current threshold value.

- `void threshold(double threshold);`

  Sets a new threshold value.

Parameters

threshold The new threshold value.

Throws

ccEllipseFitDefs::BadParams
If *threshold* < 0.

ccEllipseFitResults

```
#include <ch_cvl/fit.h>

class ccEllipseFitResults;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the results from the Ellipse Fitting tool. See **cfEllipseFit()**.

Constructors/Destructors

ccEllipseFitResults

```
ccEllipseFitResults()
```

Default constructor. **found()** = false, **error()** = 0, **time()** = 0.

Operators

operator==

```
bool operator== (const ccEllipseFitResults& that) const;
```

True if **this* equals *that*; false otherwise

Two **ccEllipseFitResults** objects are considered equal if and only if their found, ellipse, error, runParams, outliers, and time values are equal.

Parameters

that The **ccEllipseFitResults** object to compare with this object.

Public Member Functions

found

```
bool found() const;
```

Returns true if an ellipse was found when this object was used by the Ellipse Fitting tool. Returns false otherwise.

reset `void reset();`

Reset this result object to its default-constructed state (unfound).

ellipse2 `const ccEllipse2 &ellipse2() const;`

Returns the fitted ellipse.

error `double error() const;`

Returns the measured RMS error between the input points and the fitted ellipse when the Ellipse Fitting tool was run using this result object. The default value is 0

runParams `const ccEllipseFitParams &runParams() const;`

Returns the run parameters used when the Ellipse Fitting tool was run using this results object.

outliers `const cmStd vector<c_UInt32> &outliers() const;`

Returns the Indices of the ignored data points when the Ellipse Fitting tool was run using this results object. The number of ignored points equals **ccEllipseFitParams::numIgnore()** in the run parameters used.

time `double time() const;`

Returns the time (in milliseconds) used to compute this result. This is the **cfEllipseFit()** run time.

Deprecated Members

The following functions are deprecated and are provided for backward compatibility only.

ellipse `const ccEllipse &ellipse() const;`

Returns the fitted ellipse.

ccEncoderControlProp

```
#include <ch_cvl/prop.h>

class ccEncoderControlProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class provides functions to control a specified encoder connected to a Cognex frame grabber.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccEncoderControlProp

```
ccEncoderControlProp();
```

Creates a new encoder control property not associated with any FIFO.

Public Member Functions

zeroCounter

```
void zeroCounter();
```

If this property is associated with a FIFO that uses an encoder, the encoder's absolute position counter is reset to zero. A subsequent call to **currentEncoderCount()** will return zero.

Notes

If the encoder is currently in use for an acquisition, this function waits for the acquisition to complete before resetting the counter.

Notes

On the MVS-8600 platform, there is no absolute encoder position counter available. There is however, a counter that stores the count of any backward encoder pulses detected by the hardware when the encoder is moving in the opposite direction to the one expected for acquisition. If there are stored backward count pulses, new acquisition will not begin until the backward motion is compensated by forward motion. Calling **zeroCounter()** will clear this backward encoder pulse counter and make acquisition begin immediately without waiting for encoder compensation

zeroCounterWhenTriggered

```
void zeroCounterWhenTriggered(bool zeroWhenTriggered);

bool zeroCounterWhenTriggered() const;
```

- `void zeroCounterWhenTriggered(bool zeroWhenTriggered);`

  Sets whether the absolute position counter is reset to zero when the FIFO associated with this property receives an external trigger. The default setting is false.

  This functionality is not supported by all line scan platforms.

  Parameters

  zeroWhenTriggered

  True if the counter should be reset on a trigger; false otherwise.

- `bool zeroCounterWhenTriggered() const;`

  Returns true if the absolute position counter is reset to zero when the FIFO associated with this property receives an external trigger; false otherwise.

currentEncoderCount

```
c_Int32 currentEncoderCount();
```

Returns the current encoder count if this property is associated with a FIFO that has an encoder.

Notes

On the MVS-8600 platform, there is no absolute encoder position counter available. Therefore, this function returns the product of the currently acquiring line number and the steps per line encoder setting.

The value returned may not be accurate if the encoder travels backward during the acquisition. Also, when a test encoder is being used the steps per line setting is ignored, so the currently acquiring line number will be returned.

Calling **currentEncoderCount()** with no acquisition in progress returns a 0.

ccEncoderControlProp

ccEncoderProp

```
#include <ch_cvl/prop.h>

class ccEncoderProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class controls frame grabber-specific devices for interfacing to an external encoder on hardware that supports an encoder interface such as the CVM11. In most cases, you will want to use this class to set the steps-per-line property for a line scan camera (see **stepsPerLine()** on page 1208).

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccEncoderProp

```
ccEncoderProp();
```

Creates a new encoder property not associated with any FIFO.

Enumerations

ceEncoderResolution

```
enum ceEncoderResolution;
```

This enumeration specifies the choices for the number of counts to expect from the encoder you are using in your application.

Notes

See **encoderResolution** on page 1371 for a detailed description of how encoder pulses are derived.

Value	Meaning
e1xEncoderResolution = 0	The encoder pulse from a full clock cycle produces one count. The default.
e2xEncoderResolution = 1	The encoder pulse from a full clock cycle produces two counts.
e4xEncoderResolution = 2	The encoder pulse from a full clock cycle produces four counts.

Public Member Functions

useTestEncoder

```
void useTestEncoder(bool use);
bool useTestEncoder() const;
```

- `void useTestEncoder(bool use);`

Specifies whether to use signals from the test encoder on the CVM or the actual encoder that this property is associated with. The default value is false.

Parameters

use If true, use the test encoder; if false, use the actual encoder.

Notes

This property affects only the encoder that corresponds to the camera port of the FIFO that this property object is associated with.

On the MVS-8120/CVM11 platform, when using the test encoder, be sure to use **stepsPerLine()** on page 1208 appropriately. If you are acquiring 2048-pixel wide images, the minimum value to use is 34 (for 1024-pixel wide images, the value is 18). Any value smaller than that will result in **isTooFastEncoder()** failures.

On the MVS-8600 and MVS-8600e platforms, there is no test encoder available. When this property is enabled, the hardware free runs and acquires lines as fast as possible without using an encoder input. The **stepsPerLine()** setting is ignored. To introduce a delay between acquisitions of successive lines, you can specify a positive trigger delay value. See the **ccTriggerFilterProp** reference page.

- `bool useTestEncoder() const;`

  Returns true if using the test encoder on the CVM; false if using the actual encoder.

positiveTestEncoderDirection

```
void positiveTestEncoderDirection(bool isPositive);

bool positiveTestEncoderDirection() const;
```

- `void positiveTestEncoderDirection(bool isPositive);`

  Sets whether the test encoder increments or decrements its position counter. The default value is true: the test encoder increments.

  Parameters

  isPositive — If true, the test encoder increments the position counter; if false, the test encoder decrements the position counter.

- `bool positiveTestEncoderDirection() const;`

  Returns true if the test encoder increments the position counter; false if it decrements the position counter.

encoderTriggerEnabled

```
void encoderTriggerEnabled(bool useXEncoder,
  bool useYEncoder=false);

bool encoderTriggerEnabled() const;
```

- `void encoderTriggerEnabled(bool useXEncoder, bool useYEncoder=false);`

  Specifies whether to use an encoder instead of an external input line as an acquisition trigger. Encoder-triggering is valid only for auto and semi trigger models. (See **ccTriggerProp** on page 2229 and **ccTriggerModel** on page 2221.) This value is ignored if manual triggering is used.

  For platforms that support only single encoder triggering, either the *useXEncoder* or the *useYEncoder* argument can be true, but not both. In these cases, the camera port and encoder port combination will determine which argument must be set true.

Parameters

useXEncoder True to use a single or dual encoder. False to use external triggering or only the y-encoder (which is a second independent encoder).

useYEncoder True to use the y-encoder. False to use external triggering or only the x-encoder.

- `bool encoderTriggerEnabled() const;`

  Returns true if the acquisition uses an encoder instead of an external input line as an acquisition trigger.

xEncoderTriggerEnabled

```
bool xEncoderTriggerEnabled() const;
```

Returns true if the acquisition uses the x-encoder as an acquisition trigger

yEncoderTriggerEnabled

```
bool yEncoderTriggerEnabled() const;
```

Returns true if the acquisition uses the y-encoder as an acquisition trigger

stepsPerLine

```
void stepsPerLine(c_Int32 stepsPerLine,
  c_Int32 step16thsPerLine = 0);

c_Int32 stepsPerLine() const;
```

- `void stepsPerLine(c_Int32 stepsPerLine, c_Int32 step16thsPerLine = 0);`

  Sets the number of encoder steps and fractional steps per line that correspond to a single line of an image. The valid range for *stepsPerLine* depends on the encoder and on the hardware that interfaces with the encoder.

  Parameters

  stepsPerLine The number of encoder steps per line

  step16thsPerLine The number fractional steps per line as 1/16th steps that can be added to the *stepsPerLine* value to make up a single line.

Throws

ccEncoderProp::BadParams

stepsPerLine is not in the range 1 through *maxStepsPerLine*, inclusive. This is the range allowed by the hardware.
step16thsPerLine is not in the range 0 through 15, inclusive.

- `c_Int32 stepsPerLine() const;`

Returns the number of encoder steps that correspond to a single line of an image.

Example

How to calculate the *stepsPerLine* that produce square pixels in the resulting image.

This example uses the following assumptions:

- Encoder resolution is 10 pulses per micrometer or 40 encoder counts per micrometer since one encoder pulse produces four encoder counts.
- The encoder is moving at 10 millimeters per second or 10 micrometers per millisecond.
- The optical magnification is such that 0.5 micrometers in object height maps to the pixel height of the sensor (one image line).

Calculate *stepsPerLine* as follows:

$$stepsPerLine = pixelHeight \times (encoderCounts)/(micrometer) = 0.5 \times 40 = 20$$

So, to obtain square pixels, set *stepsPerLine* = 20 for this example.

Example

Determining maximum speed.

A common enhancement is to speed up an application by increasing the speed of the objects passing under the line scan camera. The objective is to calculate the maximum speed that will still produce square pixels and not cause acquisition failures.

We start with the minimum *stepsPerLine* formula as follows:

$$minStepsPerLine = (encoderCountsPerSecond \times effectiveSensorScanTime)$$

Where *effectiveSensorScanTime* is the greater of the sensor scan time or the exposure time. Sensor scan time and exposure time are covered in the following paragraphs.

Sensor Scan Time

Sensor scan time is the time required to read out the line sensor in the camera. Sensor scan time depends on the sensor width and the camera clock speed. The camera speed is adjustable from 20 MHz to 40 MHz. See **ccDigitalCameraControlProp::masterClockFrequency()**.

The following table shows the minima and maxima of the sensor scan time range. There is a linear relationship between the camera speed settings and the sensor scan time.

Sensor width	Minimum sensor scan time, camera speed = 40 MHz	Maximum sensor scan time, camera speed = 20 MHz
1K pixels	27 microseconds	54 microseconds
2K pixels	54 microseconds	108 microseconds

For a 1K sensor, the sensor scan time can be in the range from 27 to 54 microseconds. For a 2K sensor the range is 54 to 108 microseconds.

Exposure Time

Some line scan camera and platform combinations support adjustable exposure. For these systems exposure time can be set in a range from 0 to a maximum value depending on the camera speed setting as follows:

- 204.8 microseconds at 40 MHz
- 409.6 microseconds at 20 MHz

For line scan camera-platform combinations that do not support adjustable exposure, the exposure time is the time to move the object under the camera one line.

Calculation

For this example we assume an exposure time of 30 microseconds and a 27 microsecond scan time. Therefore, we use an *effectiveSensorScanTime* = 30 microseconds and the assumptions from the previous example in the *minStepsPerLine* formula below. We constrain the *minStepsPerLine* = 20 to ensure square pixels and specify the encoder speed as an unknown:

$$minStepsPerLine = (encoderCountsPerSecond \times effectiveSensorScanTime) + 1$$

$$20 = \left(\left(\frac{40counts}{\mu m} \times \frac{Xmm}{Sec}\right) \times 30\mu Sec\right) + 1$$

Solving for X, X = 16 mm/sec.

So, whereas in the original example assumptions we used a speed of 10 mm/sec, we have shown that for this application the speed could be increased to 16 mm/sec while still maintaining square pixels.

For speeds faster than 16 mm/sec you will get **ccAcqFailure::isTooFastEncoder()** errors.

Test Encoder

When using the test encoder (see **useTestEncoder()** on page 1205), the encoder pulses are applied to the acquisition circuitry at the rate:

encoderCountsPerSecond = ccDigitalCameraProp::masterClockFrequency() * 1e6 / *64*

The minimum steps per line you can use without getting **isTooFastEncoder()** errors is, in the general case:

*minStepsPerLine = encoderCountsPerSecond * effectiveSensorScanTime* + 1

For example, using the table in *Sensor Scan Time* on page 1366, the minimum steps per line for a 1024 pixel wide sensor operating at a 40 MHz master clock frequency is:

(40 * 1e6 / 64) * (27 μs) + 1 = 18

If the test encoder is used for acquiring images of a moving object, the number of steps per line is calculated as:

*stepsPerLine = encoderCountsPerSecond * distancePerLine / speed*

where *distancePerLine* is the physical distance, line to line. The time per line (*distancePerLine / speed)* must be greater than the minimum sensor scan time.

The test encoder can also be used for acquiring images from the test line scan camera (see **cfLSTest_2048()** on page 2169). You can choose to use a portion of the image generated by the test line scan camera, in which case the minimum steps per line you can use without getting **isTooFastEncoder()** errors is:

$$minStepsPerLine = \frac{width + xOffset}{64} + 2$$

where *width* is the width of the region of interest and *xOffset* is the x-offset of the region of interest (see **ccRoiProp** on page 1999). If you are not using an x-offset, the smallest value you can use with the test encoder without getting **isTooFastEncoder()** failures is 34 for 2048 pixel-wide images and 18 for 1024 pixel-wide images.

step16thsPerLine

```
c_Int32 step16thsPerLine() const;
```

Retrieves the number fractional steps per line as 1/16th steps that can be added to the *stepsPerLine* value to make up a single line:

$$EncoderStepsPerLine = stepsPerLine + \frac{step16thsPerLi}{16}$$

Notes

This function is not supported on MVS-8600 and MVS-8600e platforms.

encoderPort

```
void encoderPort(c_Int32 encoderPort);

c_Int32 encoderPort() const;
```

- `void encoderPort(c_Int32 encoderPort);`

Sets the encoder port to use with the FIFO associated with this property. The default value is zero.

Parameters

encoderPort The encoder port.

Notes

This property is used only for encoder-triggered acquires. See **encoderTriggerEnabled()** on page 1207.

On some platforms the association between a camera port and an encoder port is fixed: each encoder can trigger an acquisition to a subset of all the available camera ports on each frame grabber. This means that the encoder port you specify

must be consistent with the camera port of the FIFO that this property is associated with. Unsupported encoder port settings are ignored. See the documentation for the Cognex Video Module (CVM) that you are using for the correspondence between encoder ports and camera ports for your CVM.

Throws

ccEncoderProp::BadParams

i is not in the range zero to **numEncoderPort()** - 1.

- `c_Int32 encoderPort() const;`

Returns the encoder port used with the FIFO associated with this property.

numEncoderPort

`c_Int32 numEncoderPort() const;`

Returns the number of encoder ports that the frame grabber used by the FIFO associated with this property.

Throws

ccEncoderProp::NoFrameGrabber

This property is not associated with a FIFO.

encoderOffset

`void encoderOffset(c_Int32 encoderOffset);`

`c_Int32 encoderOffset() const;`

- `void encoderOffset(c_Int32 encoderOffset);`

Sets the encoder position at which line zero of the region of interest occurs.

The *encoderOffset* value is only part of the calculation of the encoder position where acquisition will start when using encoder-triggered acquisition. The parameters included in the calculation are the **ccRoiProp::roi().ul().y()** line number, the steps per line, and this offset. For positive direction acquisitions, the starting encoder count is:

```
// For this example, y0 means ccRoiProp::roi().ul().y()
startCount = (y0 * stepsPerLine) + encoderOffset.
```

For negative direction acquires the starting encoder count is:

```
startCount = (-y0 * stepsPerLine) + encoderOffset.
```

Region of interest values that exceed the maximum width, height, or size of the camera format result in a **ccAcqFailure::isInvalidRoi()** error.

Parameters

encoderOffset The ROI offset in encoder counts.

- `c_Int32 encoderOffset() const;`

  Gets the encoder position at which line zero of the region of interest occurs.

positiveAcquireDirection

```
void positiveAcquireDirection(bool isPositive);

bool positiveAcquireDirection() const;
```

- `void positiveAcquireDirection(bool isPositive);`

  Specifies whether encoder values increase or decrease during image acquisition. The default value is true.

  Parameters

  isPositive If true, encoder values increase during image acquisition; if false, encoder values decrease during image acquisition.

- `bool positiveAcquireDirection() const;`

  Returns true if encoder values increase during image acquisition; false if encoder values decrease during image acquisition.

encoderTriggerLatency

```
c_Int32 encoderTriggerLatency() const;
```

Returns the latency between the encoder offset to trigger acquisitions and the start of the acquisition in encoder counts based on the most recent encoder-triggered acquisition. If this property is not associated with a FIFO, this function returns zero.

useSingleChannel

```
void useSingleChannel(bool isSingleChannel);

bool useSingleChannel() const;
```

Specifies whether only one channel, or two channels of the encoder signal are used for acquisition.

- `void useSingleChannel(bool isSingleChannel);`

  Set to *true* to use a single channel. Set to *false* to use both channels.

  Parameters
  isSingleChannel True or false.

- `bool useSingleChannel() const;`

  Returns true if set for single channel. Returns false if set for two channels.

  Notes
  The default value is false indicating both encoder channels A and B are used for acquisition on platforms supporting this functionality.

  If **useSingleChannel()** is set to true, it might be possible to connect only a single encoder channel as the encoder input instead of using a quadrature dual channel type encoder. The channel that is used depends upon the setting of **positiveAcquireDirection()**. If **positiveAcquireDirection()** is true, channel A is used. If false, channel B is used.

  An advantage of using a single channel encoder input is that in some cases it allows you to acquire without considering the motion direction of the encoder.

  The MVS-8600 and MVS-8600e are the only platforms that support this function.

encoderResolution

```
void encoderResolution(ceEncoderResolution encRes);
ceEncoderResolution encoderResolution() const;
```

Specifies the encoder resolution.

- `void encoderResolution(ceEncoderResolution encRes);`

  Sets the encoder resolution. Must be one of the **ceEncoderResolution** enums.

  Parameters
  encRes Encoder resolution.

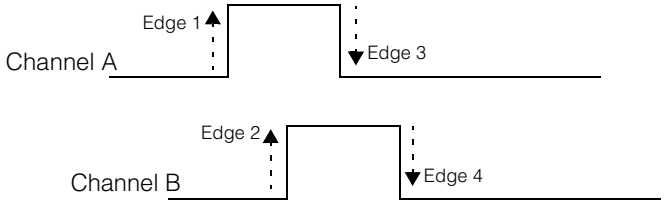
- `ceEncoderResolution encoderResolution() const;`

  Returns the currently specified encoder resolution.

Notes

The default value is *e1xEncoderResolution* indicating that the encoder pulse from a full clock cycle produces one count.

On a quadrature encoder input, by counting half or all transition edges on both channel A and channel B it is possible to get either 2x or 4x encoder input resolution. See the following diagram.



e1xEncoderResolution = 1 count from edge 1
e2xEncoderResolution = 2 counts from edges 1 and 2
e4xEncoderResolution = 4 counts from edges 1, 2, 3 and 4

The 4x encoder resolution setting is recommended, if available, and is the only setting available on the MVS-8120 with a CVM11.

For historical reasons, the MVS-8600 and MVS-8600e default to 1x.

The 4x setting with *StepsPerLine* = 4, is equivalent to the 1x setting with *StepsPerLine* = 1.

The 4x setting with *StepsPerLine* = 2 (acquires every other edge) is not equivalent to the 2x setting with *StepsPerLine* = 1 (acquires for two edges, skips two edges). See non-doc comment above.

The MVS-8600e is the only platform that fully implements this function. Refer to the MVS-8600 and MVS-8600e Hardware Manual for more information.

startAcqOnEncoderCount

```
void startAcqOnEncoderCount(c_Int32 encoderCount);

c_Int32 startAcqOnEncoderCount() const;
```

Specifies the number of encoder counts the hardware waits before beginning an acquisition. The default value is 0 which means the acquisition starts without waiting for any encoder counts. The encoder count value can be any value in the range 0 through 65535.

Also, If there are any stored backward counts, new acquisitions will not begin until the backward count is compensated by forward encoder counts.

- `void startAcqOnEncoderCount(c_Int32 encoderCount);`

  Sets the encoder count.

  Parameters

  encoderCount The number of encoder counts to wait.

- `c_Int32 startAcqOnEncoderCount() const;`

  Returns the current encoder count setting.

  Notes

  The *encoderCount* value affects acquisitions using all trigger models.

  When using trigger models that require a hardware trigger to start an acquisition, the acquisition will only start when the hardware trigger occurs and after *encoderCount* encoder counts are generated.

  For MVS-8600e frame grabbers there is no absolute encoder position counter available. There is however, a counter that stores the count of any backward encoder pulses detected by the hardware when the encoder is moving in the opposite direction to the one expected for acquisition. If there are any stored backward counts, new acquisitions will not begin until the backward motion is compensated by forward motion. Setting a non-default *encoderCount* value using this function will set the backward encoder pulse counter to this value.

  The MVS-8600e is the only platform that fully implements this function.

ignoreBackwardEncoderCountsBetweenAcquires

```
void ignoreBackwardEncoderCountsBetweenAcquires(
                                                    bool ignore);

bool ignoreBackwardEncoderCountsBetweenAcquires() const;
```

This function allows you to ignore the backward encoder counts described in **startAcqOnEncoderCount** above. When set *true*, backward encoder counts are ignored. When set false backward encoder counts are treated as described above.

- `void ignoreBackwardEncoderCountsBetweenAcquires(`
  `bool ignore);`

  Parameters

  ignore Sets the ignore flag to this value; true or false.

- `bool ignoreBackwardEncoderCountsBetweenAcquires() const;`

  Returns the current state of the *ignore* flag.

  Notes

  The default value is false which means that the backward encoder motion is tracked between acquisitions. This setting can be useful if there is unexpected backward motion between acquires and acquisition should not start until that unexpected backward motion is compensated.

  Setting a value of true will make the hardware ignore any backward encoder motion between acquisitions. This setting can be useful if between acquisitions there is deliberate backward motion that you wish to ignore when the next acquisition starts.

  The MVS-8600e is the only platform that supports this function.

ignoreTooFastEncoder

```
void ignoreTooFastEncoder(bool ignore);

bool ignoreTooFastEncoder() const;
```

Specifies whether or not to ignore the acquisition failure *isTooFastEncoder*. See **ccAcqFailure::isTooFastEncoder()**.

- `void ignoreTooFastEncoder(bool ignore);`

  Sets the ignore flag to true or false.

Parameters

ignore The ignore flag, true or false.

- `bool ignoreTooFastEncoder() const;`

  Returns the current value of the ignore flag, true or false.

  Notes

  The default value is true which means line overrun conditions will not generate an *isTooFastEncoder* acquisition failure. This setting may be useful in cases where an occasional line overrun condition can occur and the application can still handle the image.

  Setting a value of false will make the hardware report an *IsTooFastEncoder* acquisition failure when a line overrun condition occurs. See **ccAcqFailure::isTooFastEncoder()** for more information about this error.

  The MVS-8600e is the only platform that supports this function.

Constants

defaultStepsPerLine

```
static const c_Int32 defaultStepsPerLine;
```

The default steps per line value: 3.

maxStepsPerLine

```
static const c_Int32 maxStepsPerLine;
```

The maximum steps per line: 4095.

defaultStep16thsPerLine

```
static const c_Int32 defaultStep16thsPerLine;
```

The default fractional steps per line value: 0.

defaultEncoderResolution

```
static const ceEncoderResolution defaultEncoderResolution;
```

The default value is *e1xEncoderResolution*.

defaultStartAcqOnEncoderCount

```
static const c_Int32 defaultStartAcqOnEncoderCount;
```

The default value is 0.

ccEvent

```
#include <ch_cvl/threads.h>

class ccEvent: public cc_Resource;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A class that describes an event. An event can have two states, set and reset. A thread can change the state of an event, and it can block waiting for an event's state to change from reset to set.

Constructors/Destructors

ccEvent

```
ccEvent(bool manualReset=true,
  bool initiallySignaled=false,
  ccCvlString name = cmT(""));
```

Construct a **ccEvent** with the specified name, state, and auto-reset behavior.

All **ccEvent**s constructed with the same name refer to the same global event.

Parameters

manualReset — If true, whenever any thread changes the state of this **ccEvent** to set, then all threads that had locked this **ccEvent** are unblocked. If *manualReset* is false, then only the first thread that locked this **ccEvent** is unblocked and the **ccEvent** is automatically reset to the reset state.

initiallySignaled — If true, this **ccEvent** is constructed in the set state. If false, this **ccEvent** is constructed in the reset state.

name — The name of this **ccEvent**. Whenever any thread constructs a **ccEvent**, if another **ccEvent** exists with the same name, the two **ccEvent**s refer to the same global event.

If you specify a zero-length string for *name* (the default value for the argument), an unnamed **ccEvent** is constructed. Unnamed events are always separate instances.

Throws

cc_Resource::NamedObjectExists
: An underlying system mutex or semaphore with the specified name already exists.

setEvent

```
bool setEvent();
```

Changes the state of this **ccEvent** to set. If *manualReset* was set to true on construction, then all threads waiting for this event are unlocked until **resetEvent()** is called. If *manualReset* was set to false on construction, then the first thread that locked this event is unlocked and this **ccEvent**'s state is changed to reset.

This function returns true if the operation was successful, false if it failed.

resetEvent

```
bool resetEvent();
```

Changes the state of the event to reset.

This function returns true if the operation was successful, false if it failed.

lock

```
bool lock(double timeout=HUGE_VAL);
```

The current thread is blocked until this **ccEvent**'s state is becomes set. This function returns true if this **ccEvent**'s state became set, false if the timeout expired.

Parameters

timeout
: The number of seconds to block. If you specify *HUGE_VAL* for *timeout*, the thread will wait forever.

Throws

cc_Resource::BrokenLock
: The **cc_Resource::breakLocks()** static function was invoked on this thread.

unlock

```
void unlock();
```

Changes the state of the event to set. If *manualReset* was set to true on construction, then all threads waiting for this event are unlocked. If *manualReset* was set to false on construction, then the first thread that locked this event is unlocked and this **ccEvent**'s state is changed to reset. This function has the same effect as **setEvent()**.

ccException

```
#include <ch_cvl/except.h>

class ccException: public ccPersistent;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	Complex

This is a base class from which are derived all CVL exceptions.

Constructors/Destructors

You cannot construct a **ccException** directly.

Public Member Functions

message

```
ccCvlString message(bool includeClass=true) const;

void message( ccCvlOStream& str) const;
```

- `ccCvlString message(bool includeClass=true) const;`

  Returns a message describing this exception.

  If *includeClass* is true, the message consists of a type name, followed by a colon, followed by the results of a call to **message_()**. Otherwise, the message consists of the results of a call to **message_()**.

  Parameters

  includeClass — If true, the message returned by this function is prepended with the type name and a colon.

- `void message( ccCvlOStream& str) const;`

  Prints a message describing this exception to the supplied output stream. This function calls the first overload of **message()** to obtain the string.

  Parameters

  str — The stream to which to print the message.

errorNumber

```
virtual c_Int32 errorNumber() const=0;
```

This function returns a unique 32-bit value associated with this exception. The error numbers for CVL exceptions are contained in the files in *ch_err*.

You must override this function in any non-abstract class you derive from **ccException**. This function is called by the exception handling mechanism to obtain the unique 32-bit error number associated with an exception.

Cognex-supplied exceptions use values of 0x10000000 and greater; your override of this function should return a unique value in the range 0x00000001 through 0x0FFFFFFF. Values less than 0x00000001 are reserved. A value of 0x00000000 can be used to indicate “no error”.

Notes

Overrides of this member function should return a unique error number for each derived class. No mechanism is provided to automatically ensure uniqueness.

Protected Member Functions

message_

```
virtual void message_( ccCvlOStream& str) const;
```

This function is called by the exception handling mechanism to obtain a human-readable error string. You should override this function in each class that you derive from **ccException**.

The implementation of **message_()** in **ccException** prints "no further information provided" (with no newline character).

Parameters

str	The stream to which to print the message

Related Classes

```
class ccBadPointer : public ccException;

class ccBadUnicodeChar : public ccException;

class ccInvariantFailure : public ccException;

class ccUnsupportedHW : public ccException;

class ccSecurityViolation : public ccExceptionWithString;
```

These global exceptions are derived directly from **ccException**. In most cases, the causes of these exceptions are self-explanatory. It is unlikely that you will want to catch these exceptions explicitly.

- `class ccBadPointer : public ccException;`

  An attempt was made to reference memory using an invalid pointer.

- `class ccBadUnicodeChar : public ccException;`

  An invalid Unicode character was encountered.

- `class ccInvariantFailure : public ccException;`

  An internal consistency check failed; the state of some CVL object is invalid.

- `class ccUnsupportedHW : public ccException;`

  A call was made to a software tool or subsystem which does not work with the Cognex hardware device installed in this system, or with the host computer system's CPU.

- `class ccSecurityViolation : public ccExceptionWithString;`

  A license key was not available. Contact Cognex Technical Support for assistance.

ccException

ccExceptionWithString

```
#include <ch_cvl/except.h>

class ccExceptionWithString: public ccException;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	Complex

This is a base class from which you can derive exceptions for which you can specify multiple messages. Exceptions which are derived from **ccException** must have their messages defined in their override of **ccException::message_()**.

For information on how to derive classes from **ccExceptionWithString**, consult the chapter *Exception Handling* in the *CVL Users Guide*.

Constructors/Destructors

You cannot construct a **ccExceptionWithString** directly.

Protected Member Functions

ccExceptionWithString

```
ccExceptionWithString();

ccExceptionWithString(const ccCvlString& info);

ccExceptionWithString(const TCHAR* info);
```

You can only call these constructors as part of the construction of an object derived from **ccExceptionWithString**. The supplied string will be returned by calls to the derived object's **message()** function.

- `ccExceptionWithString();`

  Constructs a **ccExceptionWithString** that returns "no further information provided".

ccExceptionWithString

- `ccExceptionWithString(const ccCvlString& info);`

  Constructs a **ccExceptionWithString** that returns the supplied string as its message.

  Parameters

  info The message to return.

- `ccExceptionWithString(const TCHAR* info);`

  Constructs a **ccExceptionWithString** that returns the supplied string as its message.

  Parameters

  info The message to return.

ccExposureProp

```
#include <ch_cvl/prop.h>

class ccExposureProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class allows you to set the exposure property of an acquisition FIFO. The exposure property is used for shuttered and strobed acquisitions. For shuttered acquisitions, the exposure property specifies how long the camera shutter is open. For strobed acquisitions, you use the exposure property to report the duration of the strobe flash to the acquisition software.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccExposureProp

```
ccExposureProp();

explicit ccExposureProp(double);
```

- `ccExposureProp();`

  Creates a new exposure property not associated with any FIFO. The exposure duration is set to *ccExposureProp::defaultExposure*.

- `explicit ccExposureProp(double seconds);`

  Set the exposure duration to *seconds*. For shuttered acquisitions, this value is the amount of time to leave the shutter open. For strobed acquisitions, this value is the duration of the strobe flash.

Parameters

seconds The exposure duration in seconds. A value of zero means to use the shortest supported exposure time.

Throws

ccExposureProp::BadParams
seconds was less than zero.

Public Member Functions

exposure

```
void exposure(double seconds);
double exposure();
```

- `void exposure(double seconds);`

For shuttered acquisitions, sets the exposure duration to *seconds*.

For strobed acquisitions, this value is the duration of the strobe flash. To find the flash duration of your strobe, see the strobe light's specifications. Note that this function is used to let the acquisition software know the duration of the strobe flash, not to set the duration of the strobe flash.

Parameters

seconds The exposure duration in seconds. A value of zero means to use the shortest supported exposure time.

Notes

On most platforms, *seconds* has a granularity of 1 millisecond to 1 microsecond.

Throws

ccExposureProp::BadParams
seconds was less than zero.

- `double exposure() const;`

Return the exposure time in seconds.

Constants

defaultExposure `static const double defaultExposure;`

The default exposure value: 20e–6. This value is appropriate for strobed acquisition. If you use ambient lighting with a shuttered camera such as the Sony XC-55, you may need to increase the exposure time.

ccFeaturelet

```
#include <ch_cvl/feature.h>

class ccFeaturelet
```

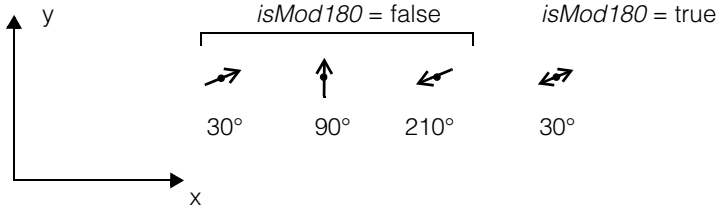
Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

The Featurelet class characterizes features which have optional weights and magnitudes. Each featurelet has the following characteristics:

Characteristic	Default value	Description
position	(0, 0)	The x,y location of the featurelet
angle	0°	The featurelet orientation
weight	1	An importance factor you can assign
magnitude	0	A relative size factor you can assign
isMod180	false	When true, the orientation is only valid mod 180° rather than the normal mod 360°

Featurelets are typically shown as a dot indicating the position, with an overlaid arrow to indicate the featurelet orientation.



The *position* is the point in x,y space where the featurelet is located. The featurelet angle is shown by the orientation of the arrow. A featurelet with an arrowhead on both ends indicates that isMod180 = true. This means that if you rotate the featurelet 180° its description does not change.

Constructors/Destructors

ccFeaturelet

```
explicit ccFeaturelet(
  const cc2Vect &position = cc2Vect(),
  const ccRadian &angle = ccRadian(0),
  double Magnitude = 0,
  double weight = 1,
  bool isMod180 = false);
```

Constructor; sets the parameters to the specified values.

Parameters

position	The (x,y) position of the featurelet.
angle	The featurelet angle, in radians.
Magnitude	The featurelet magnitude.
weight	The featurelet weight.
isMod180	True if the featurelet angle is mod 180°. False otherwise.

Throws

ccFeatureletDefs::BadParams
If *magnitude* < 0.

Operators

operator==

```
bool operator==(const ccFeaturelet& rhs) const;
```

Comparison operator. Compares this **ccFeaturelet** object to another **ccFeaturelet** object. Returns true if they are equal, and false if they are not equal.

Two **ccFeaturelet** objects are considered equal if, and only if, all their members are exactly equal.

Parameters

rhs	The **ccFeaturelet** object to compare to this one.

Public Member Functions

position

```
const cc2Vect &position() const;
void position(const cc2Vect &position);
```

- `const cc2Vect &position() const;`

  Returns the featurelet (x,y) position.

- `void position(const cc2Vect &position);`

  Sets a new featurelet (x,y) position.

  Parameters

  position The new position.

angle

```
ccRadian angle() const;
void angle(ccRadian angle);
```

The featurelet angle expressed in radians.

- `ccRadian angle() const;`

  Returns the featurelet angle.

- `void angle(ccRadian angle);`

  Sets the featurelet *angle* to the specified number of radians.

  Parameters

  angle The new angle in radians.

magnitude

```
double magnitude() const;
void magnitude(double magnitude);
```

A featurelet can be assigned a magnitude value expressed as zero or a positive number.

- `double magnitude() const;`

  Returns the magnitude value.

- `void magnitude(double magnitude);`

  Sets a new magnitude value.

  Parameters
  magnitude The new value.

  Throws
  ccFeatureletDefs::BadParams
  If *magnitude* < 0.

weight

```
double weight() const;
void weight(double weight);
```

A featurelet can be assigned a weight expressed as double.

- `double weight() const;`

  Returns the currently assigned weight.

- `void weight(double weight);`

  Sets a new weight.

  Parameters
  weight The new weight.

isMod180

```
bool isMod180() const;
void isMod180(bool isMod180);
```

If the featurelet angle is mod 180° it means the orientation information is only valid mod 180° rather than the normal mod 360°. Featurelet orientation normally indicates the gradient direction from dark to light. When a featurelet has **isMod180()** set true it generally means the gradient polarity is not known or cannot be determined.

- `bool isMod180() const;`

  Returns true if the featurelet angle is mod 180°. Returns false otherwise.

- `void isMod180(bool isMod180);`

  Sets the featurelet mod 180 state, true or false.

Parameters

isMod180 The new mod 180° state.

map

```
ccFeaturelet map(
  const cc2XformBase &xform) const;
```

Return a new featurelet corresponding to this featurelet mapped by the given transform.

Parameters

xform The mapping transform.

Notes

The new featurelet's *position* and *angle* are the original featurelet's *position* and *angle* mapped by the linearized transform at the original featurelet's position. The new featurelet's *magnitude*, *weight*, and *isMod180* are equal to the original featurelet's *magnitude*, *weight*, and *isMod180*.

This function maps angles in a non intuitive way. For example, the computed angle is not simply **xform.mapAngle(angle)**. If you want the featurelet angle computed as **xform.mapAngle(angle)**, you must write your own map function to do this.

The featurelet angle corresponds to the gradient which is normal to the featurelet tangent. The function maps the featurelet angle by first subtracting 90° to obtain the tangent angle. Then, mapping the tangent angle and adding the 90° back to the mapped angle. (For a handedness flip, 90° is subtracted from the mapped angle instead of added to the mapped angle).

ccFeaturelet

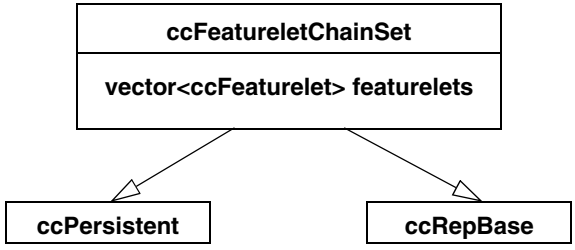
ccFeatureletChainSet

```
#include <ch_cvl/feature.h>

class ccFeatureletChainSet : public virtual ccPersistent,
                             public virtual ccRepBase
```

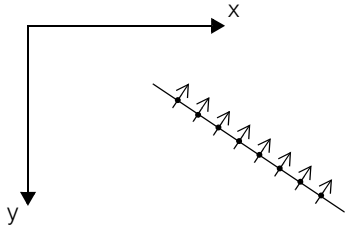
Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex



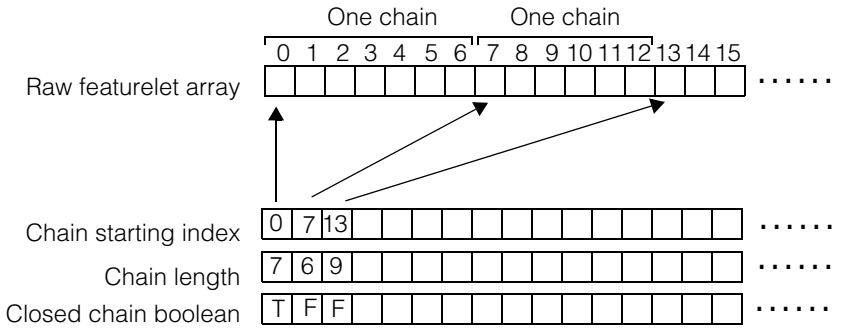
The Featurelet Chain Set class characterizes a set of chains of featurelets. (See the **ccFeaturelet** class reference page for a description of featurelets). There is an abstract notion of a single featurelet chain, but there is no class characterizing a single featurelet chain. A featurelet chain can be either open or closed. Note that open and closed featurelet chains can have any number of featurelets, including zero. There is no limit on the number of featurelets in any chain.

The example below shows a chain of featurelets along a line.



The Featurelet Chain Set class includes a vector of raw featurelets. Each chain in the set corresponds to a contiguous subset of these raw featurelets. The featurelet chain set also includes a vector of chain start indices and a vector of chain lengths. These vectors

combine to specify the contiguous featurelet subsets corresponding to each chain. The featurelet chain set also includes a vector of booleans corresponding to whether each chain is open or closed. See the following example diagram.



Note that every featurelet in the raw vector is an element of at most one chain; that is, there are no shared featurelets in the raw vector.

However, it is legal for a featurelet to belong to no chain. The most typical use cases are the following:

1. A set of featurelets where every featurelet belongs to exactly one chain, that is, there are no unchained featurelets.
2. A set of featurelets with zero chains, that is, no featurelets are chained.

However, in the most general case, some featurelets might belong to chains while other featurelets might not belong to any chain. Users who wish to iterate through all featurelets regardless of whether or not those featurelets are chained should use the featurelets() vector getter; users who wish to iterate through only chained featurelets should use the featureletChains() vector getter.

All featurelet chains are composed of a contiguous set of featurelets in the raw featurelet array.

Constructors/Destructors

ccFeatureletChainSet

```
ccFeatureletChainSet();

ccFeatureletChainSet (
  const cmStd vector<cmStd vector<ccFeaturelet>>
&chainedFeaturelets,
```

```
  const cmStd vector<bool> &isClosed,
  const cmStd vector<ccFeaturelet> &unchainedFeaturelets =
cmStd vector<ccFeaturelet>());

ccFeatureletChainSet(
  const ccFeatureletChainSet &chainSet);

virtual ~ccFeatureletChainSet();
```

- `ccFeatureletChainSet();`

  Default constructor. Constructs a featurelet chain set with no chains.

- ```
  ccFeatureletChainSet (
    const cmStd vector<cmStd vector<ccFeaturelet>>
  &chainedFeaturelets,
    const cmStd vector<bool> &isClosed,
    const cmStd vector<ccFeaturelet> &unchainedFeaturelets =
  cmStd vector<ccFeaturelet>());
  ```

  Constructor. Initializes the chain set with the given chained featurelets and *isClosed* vectors, and optionally also with the given unchained featurelets.

  Parameters

  chainedFeaturelets
  A vector of vectors holding chained featurelets. Each interior vector is a chain of featurelets. The next level vector is a vector of chains, a chain set.

  isClosed A corresponding vector of booleans, one for each chain.

  unchainedFeaturelets
  A vector holding unchained featurelets.

  Throws

  ccFeatureletDefs::BadParams
  If **chainedFeaturelets.size()** != **isClosed.size()**

- ```
  ccFeatureletChainSet(
    const ccFeatureletChainSet &chainSet);
  ```

  Copy constructor; makes a deep copy.

- `virtual ~ccFeatureletChainSet();`

  Destructor.

Operators

operator=

```
ccFeatureletChainSet& operator=(
  const ccFeatureletChainSet &chainSet);
```

Assignment operator; makes deep copy.

operator==

```
bool operator==(const ccFeatureletChainSet& rhs) const;
```

Comparison operator. Returns true if *rhs* is equal to this object. Returns false otherwise.

Two **ccFeatureletChainSet** objects are considered equal if and only if all their members are exactly equal.

Parameters

rhs The comparison object.

Public Member Functions

reset

```
void reset();
```

Reset this featurelet chain set object to its default constructed state.

replaceChain

```
void replaceChain (
  c_Int32 chainIndex,
  const cmStd vector<ccFeaturelet> &featurelets,
  bool isClosed);
```

Replace a chain in this object with the chain provided.

This may require repositioning featurelets in raw featurelet array with chain indices > *chainIndex*.

Parameters

chainIndex The index of the chain in this object that is to be replaced.

featurelets The new chain of featurelets.

isClosed True if the new chain is closed, false otherwise.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

Notes

The initial featurelet chain set remains unchanged if there is a throw.

insertChain

```
void insertChain (
  c_Int32 chainIndex,
  const cmStd vector<ccFeaturelet> &featurelets,
  bool isClosed);
```

Insert the given chain into the chain set contained in this object. The chain is inserted at index position *chainIndex*. which becomes its index in the modified chain. Indices for all chains after the inserted chain will be incremented by 1.

This will require repositioning featurelets in raw featurelet array with chain indices > *chainIndex*.

Parameters

chainIndex	The index where that new chain is inserted.
featurelets	The new chain.
isClosed	True if the new chain is closed, false otherwise.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* > **numChains()**.

Notes

The initial featurelet chain set remains unchanged if there is a throw.

addChain

```
void addChain (
  const cmStd vector<ccFeaturelet> &featurelets,
  bool isClosed);
```

Add a chain to the chain set contained in this object. The chain is appended and becomes the last chain.

Parameters

featurelets	The added chain.
isClosed	True if the new chain is closed, false otherwise.

deleteChain

```
void deleteChain(c_Int32 chainIndex);
```

Delete the specified chain from the chain set contained is this object.

This will require repositioning featurelets in raw featurelet array with chain indices > *chainIndex*.

Parameters

chainIndex The index of the chain to be deleted.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

Notes

The initial featurelet chain set remains unchanged if there is a throw.

append

```
void append(
  const ccFeatureletChainSet &featureletChainSet);
```

Append the provided featurelet chain set to the chain set contained in this object.

Parameters

featureletChainSet
The chain set to append.

numChains

```
c_Int32 numChains() const;
```

Returns the number of chains in the chain set contained in this object.

Notes

The featurelet chain set may include unchained featurelets, and thus even a chain set with zero numChains() may still contain featurelets. Use the featurelets() vector getter to access the featurelets.

numFeaturelets

```
c_Int32 numFeaturelets() const;
```

Returns the number of featurelets in the raw featurelet array contained in his object, regardless of whether a featurelet is contained by a chain or not.

reserve

```
void reserve(
  c_Int32 numChains,
  c_Int32 numFeaturelets) const;
```

Reserve the specified number of chains and featurelets for this chain set. This reserves array space for chains you anticipate adding.

Parameters

numChains The number of chains to reserve.

numFeaturelets The number of featurelets to reserve.

Throws
ccFeatureletDefs::BadParams
If *numChains* < 0,
or if *numFeaturelets* < 0.

isClosed

```
bool isClosed(c_Int32 chainIndex) const;
cmStd vector<bool> isClosed() const;
```

- `bool isClosed(c_Int32 chainIndex) const;`

Returns true if the chain specified by *chainIndex* is closed. Returns false otherwise.

Parameters
chainIndex The index of the chain to query.

Throws
ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

- `cmStd vector<bool> isClosed() const;`

Returns the vector of booleans that indicate which chains are closed and which are open. See the introductory description and the diagram.

chainLength

```
c_Int32 chainLength(c_Int32 chainIndex) const;
```

Returns the number of featurelets in the chain specified by *chainIndex*.

Parameters
chainIndex The index of the chain to query.

Throws
ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

startFeatureIndex

```
c_Int32 startFeatureIndex(c_Int32 chainIndex) const;
```

Return the index into the raw featurelet array of the start of the chain specified by *chainIndex*.

Parameters

chainIndex The index of the chain to query.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

---

featurelets

```
const cmStd vector<ccFeaturelet> &featurelets() const;

cmStd vector<ccFeaturelet> featurelets(c_Int32 chainIndex)
const;
```

- `const cmStd vector<ccFeaturelet> &featurelets() const;`

Returns the vector of all featurelets contained in this chain set, regardless of whether or not those featurelets are chained.

Notes

The returned const reference becomes invalid if and when the featurelet chain set is modified. Use the returned vector immediately following this call and then do not use it again.

- `cmStd vector<ccFeaturelet> featurelets(`
  `c_Int32 chainIndex) const;`

Returns the array of featurelets for the chain specified by *chainIndex*.

Parameters

chainIndex The index of the chain to query.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

featureletChains

```
cmStd vector<cmStd vector<ccFeaturelet>>
                                    featureletChains() const;
```

Returns the entire raw featurelets array contained in this object. These are all of the featurelets for all the chains, unchained featurelets are not included.

Notes

If you wish to iterate through all of the featurelets, regardless of whether or not those featurelets are chained, you should use the featurelets() vector getter instead.

featurelet

```
const ccFeaturelet &featurelet(
  c_Int32 chainIndex,
  c_Int32 featureletIndex) const;
```

Returns a reference to a specific featurelet. *chainIndex* specifies the chain and *featureletIndex* specifies the featurelet within the chain.

Notes

The returned const reference becomes invalid if and when the featurelet chain set is modified. Use the returned reference immediately following this call and then do not use it again.

Parameters

chainIndex The specified chain.

featureletIndex The index of the featurelet within the chain.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**,
or if *featureletIndex* < 0,
or if *featureletIndex* >= **chainLength(***chainIndex***)**.

map

```
ccFeatureletChainSetPtrh map(
  const cc2XformBase &xform) const;
```

Return a new featurelet chain set corresponding to the featurelet chain set contained in this object, mapped by the given transform.

Parameters

xform The mapping transform.

Notes

Each new featurelet's position and angle are the original featurelet's position and angle mapped by the linearized transform at each original featurelet's position. The new featurelet's *magnitude*, *weight*, and *isMod180* is equal to the original featurelet's *magnitude*, *weight*, and *isMod180*.

This function maps angles in a non intuitive way. For example, the computed angle is not simply **xform.mapAngle(angle)**. If you want the featurelet angle computed as **xform.mapAngle(angle)**, you must write your own map function to do this.

The featurelet angle corresponds to the gradient which is normal to the featurelet tangent. The function maps the featurelet angle by first subtracting 90° to obtain the tangent angle. Then, mapping the tangent angle and adding the 90° back to the mapped angle. (For a handedness flip, 90° is subtracted from the mapped angle instead of added to the mapped angle).

boundingBox

```
ccRect boundingBox(c_Int32 chainIndex) const;
ccRect boundingBox() const;
```

- `ccRect boundingBox(c_Int32 chainIndex) const;`

  Return an enclosing rectangle of the chain specified by *chainIndex*.

  Parameters

  chainIndex The index of the target chain.

  Throws

  ccFeatureletDefs::BadIndex
  If *chainIndex* < 0,
  or if *chainIndex* >= **numChains()**.

  ccFeatureletDefs::EmptyChain
  If the specified chain is empty.

- `ccRect boundingBox() const;`

  Return the enclosing rectangle of all the chains contained in this object.

  Throws

  ccFeatureletDefs::EmptyChainSet
  If the chain set is empty.

isRightHanded

```
bool isRightHanded(c_Int32 chainIndex) const;
```

Returns true if the specified chain is right-handed. Returns false if it is not. The chain must be closed.

A chain is right-handed when its signed area corresponding to the region specified by the featurelet positions is 0 or positive. The signed area is defined as the sum of all the cross products between successive featurelet positions.

Notes

A featurelet chain with a signed area of zero is defined to be right-handed.

A chain with 0, 1, or 2 featurelets is defined to be right-handed.

Parameters

chainIndex The specified chain.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

ccFeatureletDefs::NotClosedChain
If the chain is not closed.

reverseFeatureletOrder

```
void reverseFeatureletOrder(c_Int32 chainIndex);

void reverseFeatureletOrder();
```

- `void reverseFeatureletOrder(c_Int32 chainIndex);`

Reverse the order of the featurelets in the specified chain.

This has the effect of toggling the chain's handedness unless the signed area is exactly zero or unless the chain length is 0, 1, or 2, in which case the chain remains right-handed.

Reversing the order of the featurelets does not affect whether the chain is open or closed.

Parameters

chainIndex The specified chain.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

Notes

The initial featurelet chain set remains unchanged if there is a throw.

- `void reverseFeatureletOrder();`

Reverse the order of the featurelets in each chain and reverse the order of all unchained featurelets. The chains themselves remain in the same order. This has the effect of toggling the chain's handedness unless the signed area is exactly zero or unless the chain length is 0, 1, or 2, in which case the chain remains right-handed.

Reversing the order of the featurelets does not affect whether a chain is open or closed.

reverseFeatureletOrientations

```
void reverseFeatureletOrientations(c_Int32 chainIndex);
void reverseFeatureletOrientations();
```

- `void reverseFeatureletOrientations(c_Int32 chainIndex);`

  Reverse the angle of all featurelets in the specified chain by adding 180° to each featurelet angle. The new featurelet angles are computed mod 360°.

  Parameters
  chainIndex The specified chain.

  Throws
  ccFeatureletDefs::BadIndex
  If *chainIndex* < 0,
  or if *chainIndex* >= **numChains()**.

  Notes
  The initial featurelet chain set remains unchanged if there is a throw.

- `void reverseFeatureletOrientations();`

  Reverse the angle of all featurelets in the chain set by adding 180° to each featurelet angle. The new featurelet angles are computed mod 360°.

anyFeatureletIsMod180

```
bool anyFeatureletIsMod180(c_Int32 chainIndex) const;
bool anyFeatureletIsMod180() const;
```

- `bool anyFeatureletIsMod180(c_Int32 chainIndex) const;`

  Returns true if any featurelet in the specified chain has a mod 180 orientation. Returns false otherwise.

  Parameters
  chainIndex The specified chain.

  Throws
  ccFeatureletDefs::BadIndex
  If *chainIndex* < 0,
  or if *chainIndex* >= **numChains()**.

- `bool anyFeatureletIsMod180() const;`

  Returns true if any featurelet in this chain set has a mod 180 orientation. Returns false otherwise.

proportionPositiveCrossProduct

```
double proportionPositiveCrossProduct(
  c_Int32 chainIndex) const;
```

Returns the proportion of the featurelets in the specified chain that have positive cross products between both incident vectors (the vectors between successive featurelets) and the featurelet angles (assumed to be the gradient).

This is a measure of the common polarity of the featurelets in the chain. For example, in a circle if all featurelets point inwards towards the circle center, this function will return either 0 or 1.0 depending on whether the featurelet chain navigates the circle boundary in the clockwise, or counter-clockwise direction. If half of the featurelets pointed inwards, and the other half pointer outwards, the function would return 0.5. The returned result is always in the range 0 through 1.0.

For more detail see the *Featurelet Chain Polarity* section below.

Notes

This function assumes that the featurelet angles correspond to gradient orientations from negative to positive.

The proportion computation ignores any featurelets which have mod180 orientation (**isMod180()** == true).

If all of the featurelets have mod180 orientation or there are no featurelets, this function returns exactly 0.5.

When the computed value is 0, 0.5, or 1.0 the function returns exactly 0, 0.5, or 1.0 (not an approximately close floating point number). This is done so you can easily explicitly check for these cases.

Parameters

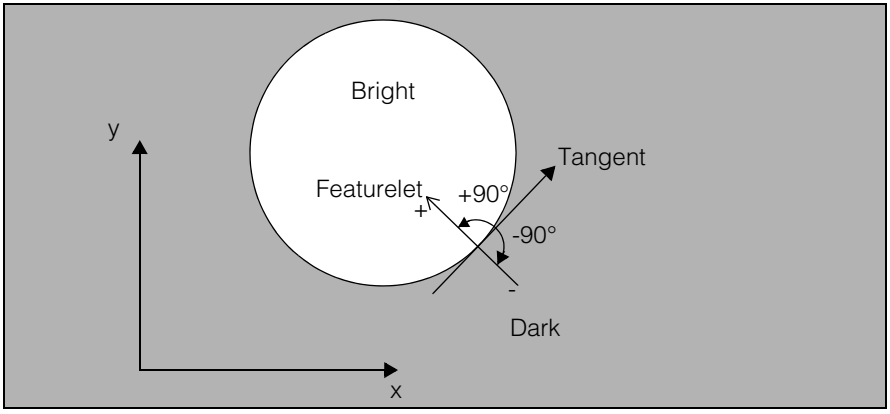
chainIndex The specified chain.

Throws

ccFeatureletDefs::BadIndex
If *chainIndex* < 0,
or if *chainIndex* >= **numChains()**.

Featurelet Chain Polarity

The CVL shapes convention defines the default polarity as *bright* in the direction of increasing angle with respect to the tangent direction along the shape boundary. The featurelet chain polarity follows this same convention assuming the featurelet angle corresponds to the gradient angle. See the following example of a circle where the featurelet positive direction is to the bright circle interior.



For closed featurelet chains, the inside/outside polarity corresponds to the combination of the **isRightHanded()** member function and the **proportionPositiveCrossProduct()** member function in the following way:

```
isNegativeOnPositive =
  ((isRightHanded() xor (proportionPositiveCrossProduct() >= 0.5)
```

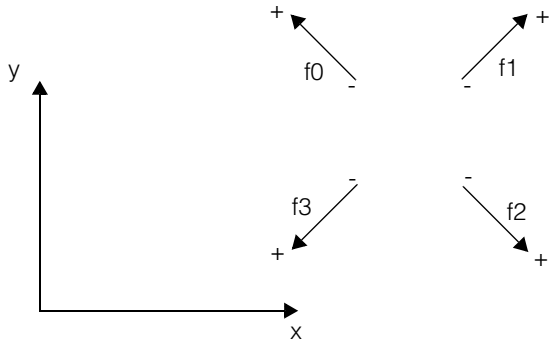
CVL provides a **ccPolylineModel** converter function which takes a featurelet chain set as its argument. (See **cfPolylineShapeModel()**). This converter computes reversed polarity using the **proportionPositiveCrossProduct()** member function in the following way:

```
isReversedPolarity == (proportionPositiveCrossProduct() < 0.5)
```

This implicitly assumes that the featurelet angles correspond to the gradient direction, from negative to positive.

The **proportionPositiveCrossProduction()** member function is used to determine polarity of a featurelet chain. This function assumes that the featurelet angles correspond to the gradient orientations from negative to positive.

Consider the closed featurelet chain (f0, f1, f2, f3) shown below where the arrows are pointing in the direction of the image gradient, from negative to positive.



For each featurelet, we compare the image gradient to both incident vectors.

Let a_i correspond to the unit vector in the direction of the angle at featurelet i, let f_i correspond to the position of featurelet i, and let isMod180_i correspond to whether featurelet i's orientation is defined modulo 180°. Let N be the number of featurelets. Then -

$$\textbf{proportionPositiveCrossProduction()} = \frac{1}{M} \times \sum_{i=0}^{N-1} \textit{if}\ (\text{isMod180\_\{i\}})\ \text{then 0,}$$

else sign((f_{i}-f{i-1}) cross a_i) + sign((f_{i+1}-f{i}) cross a_i)

Where $M = \sum_{i=0}^{N-1} \textit{if}\ (\text{isMod180\_\{i\}})\ \text{then 0, else 2,}$

and sign(x) = (+1 if x>0, 0 if x=0, or -1 if x<0).

Notes

The **proportionPositiveCrossProduction()** equation as written above is valid for closed chains only. For open chains, elements 1 and N each have only one incident vector.

Typedefs

ccFeatureletChainSetPtrh

```
typedef ccPtrHandle<ccFeatureletChainSet>
                                    ccFeatureletChainSetPtrh;
```

ccFeatureletChainSetPtrh_const

```
typedef ccPtrHandle_const<ccFeatureletChainSet>
                                  ccFeatureletChainSetPtrh_const;
```

ccFeatureletFilter

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilter: public virtual ccPersistent,
                          public virtual ccRepBase
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This is the abstract base class for featurelet filters and featurelet chain filters. Any filter class derived from this base class should behave as described in the section *Guidelines For Deriving New Filter Classes*, below.

Featurelet filtering with **ccFeatureletFilter** derived classes can be performed using the **filterFeaturelets()** member function and providing a vector of **ccFeaturelet** objects. Note that not all the filters provide featurelet filtering functionality and *ccFeatureletFilterDefs::FeatureletFilteringNotSupported* will be thrown if featurelet filtering is not supported.

Featurelet chain set filtering with **ccFeatureletFilter** derived classes can be performed using the **filterChains()** member function and providing a **ccFeatureletChainSet** object. Note that any filter derived from **ccFeatureletFilter** should provide this functionality.

Guidelines For Deriving New Filter Classes

You can design new filter classes easily by deriving from the **ccFeatureletFilter** class. To create your own filter class we suggest you copy and modify one of the standard filters provided in the *featfilt.h* header file.

The following rules are the guidelines for designing new filters.

The class constructor parameter for the *isInverted* flag (if there is one), should be passed to the base class function **isInverted()**.

The macro *cmFeatureletFilterClone* should be included in the public section of the class definition so that the **clone()** virtual member function is overridden.

The base class virtual function **filter_()** should be overridden with the desired functionality and it should assume the behavior listed under the **ccFeatureletFilter::filter_()** function.

The *survivorFlags* vector modified by the function **filter_()** should mark the filtered featurelet indices by false and its size should not be changed. For example, it should have the same size as the input vector *featurelets*.

The function **filter_()** should not perform any inversion operations based on the **isInverted()** flag. The filter inversions are done automatically by the base class member functions **filterChains()** and **filterFeaturelets()**.

Constructors/Destructors

ccFeatureletFilter

```
ccFeatureletFilter(bool isInverted = false);

virtual ~ccFeatureletFilter();
```

- `ccFeatureletFilter(bool isInverted = false);`

  Constructs a **ccFeatureletFilter** object with *isInverted* set as specified. Default is false.

  Parameters

isInverted	True or false.

- `virtual ~ccFeatureletFilter();`

  Destructor.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

operator!=

```
virtual bool operator!= (
  const ccFeatureletFilter &that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

clone

```
virtual ccFeatureletFilterPtrh clone() const = 0;
```

Returns a pointer to a new copy of this **ccFeatureletFilter**.

isInverted

```
void isInverted(bool t);

bool isInverted() const;
```

Use this function to set/get the inverted state of the featurelet filter.

- `void isInverted(bool t);`

  Sets the *isInverted* flag; true or false.

  Parameters

  t The new flag value.

- `bool isInverted() const;`

  Returns the current *isInverted* flag.

filterFeaturelets

```
void filterFeaturelets(
  const cmStd vector<ccFeaturelet>& inputFeaturelets,
  cmStd vector<ccFeaturelet>& outputFeatures) const;
```

Filters the input featurelets based on the criteria described by the derived class if **isInverted()** = false, and the inverse of the criteria if **isInverted()** = true.

Parameters

inputFeaturelets The featurelets to be filtered (input).

outputFeatures The filtered featurelets (output).

Throws

ccFeatureletFilterDefs::BadFilter
If the **filter_()** function is not properly overridden.

ccFeatureletFilterDefs::FeatureletFilteringNotSupported
If this filter does not support featurelet filtering.

Derived classes may have filter-specific throws.

Notes

The vector *outputFeatures* is resized to 0 before filtering starts.

See the protected **filter_()** function below for information on how to effectively override the behavior of this function in a derived class.

The behavior of this function is dependent on the derived filter class that calls it. Please see the documentation in the derived classes for filter-specific behavior of this function.

filterChains

```
ccFeatureletChainSetPtrh filterChains(
  const ccFeatureletChainSet& inputChainSet) const;
```

This function runs a filter on *inputChainSet* and returns the filtered result.

The function filters the featurelets in the given featurelet chain set based on the criteria described by the derived class if **isInverted()** is false, or the inverse of the criteria if **isInverted()** is true. The featurelets that remain after filtering are used to build a new chain set by eliminating, trimming or breaking the input chains. The resulting featurelet chains will be open unless the corresponding input chain is closed and none of its featurelets are eliminated.

Parameters

inputChainSet The chain set to filter.

Throws

ccFeatureletFilterDefs::BadFilter
If the **filter_()** function is not properly overridden.

Derived classes may have filter-specific throws.

Notes

See the protected **filter_()** function below for information on how to effectively override the behavior of this function in a derived class.

The behavior of this function is dependent on the derived filter class that calls it. Please see the documentation in the derived classes for filter-specific behavior of this function.

Protected Member Functions

filter_

```
virtual void filter_(
  const cmStd vector<ccFeaturelet> &featurelets,
  const cmStd vector<c_Int32> &featureletOrder,
```

```
const cmStd vector<c_Int32> &chainStartIndices,
const cmStd vector<bool> &closedFlags,
cmStd vector<bool> &survivorFlags) const = 0;
```

Notes

You should not call this function from your application code. This function is called internally by other filtering routines. If you create your own featurelet filter class by deriving from **ccFeatureletFilter** you will need to override this function in your new class. See examples of filters in the *featfilt.h* header file.

The following information is provided for those writing new filters.

Filters the featurelets in the chains for which the corresponding survivor flag is set, based on the criteria described by the derived class. Any featurelets that do not survive the filtering operation will have their corresponding survivor flags set to false. The order of featurelets is indicated by the featurelet order vector, which are indices into the featurelets. The start of each chain, i, is represented as an index, *chainStartIndices*[i], into the featureletOrder vector. For each chain, i, a closed flag is also specified by *closedFlags*[i]. Note that if this filter is performing a featurelet filtering operation (instead of featurelet chain set filtering), the vectors *featureletOrder*, *chainStartIndices*, and *closedFlags* are ignored because they provide information about the chains only. In order to be able to distinguish between two filtering types inside this function, this function assumes that the vectors *featureletOrder*, *chainStartIndices*, and *closedFlags* all have a size of 0 if it is performing a featurelet filtering operation. The following examples show how to obtain chain and featurelet information from the inputs to this function.

survivorFlags[j] is false if *featurelets*[j] is filtered out.

The following examples are valid only if this filter is performing featurelet chain set filtering.

featurelets[*featureletOrder*[*chainStartIndices*[i]+j]] accesses the jth element of the ith chain.

chainStartIndices[i+1] - *chainStartIndices*[i] returns the length of the ith chain, assuming that **chainStartIndices.size()** > i.

closedFlags[i] is true if ith chain is closed.

The following are requirements for this function:

The input vector element *survivorFlags*[j] should be true if and only if *featurelets*[j] was not filtered out previously by another filter.

The input vectors *survivorFlags* and *featurelets* should have the same size.

The vectors *featureletOrder*, *chainStartIndices*, and *closedFlags* all should have a size of 0 if this filter is performing a featurelet filtering operation.

The vectors *closedFlags* and *chainStartIndices* should have the same size.

The *chainStartIndices* all index within the bounds of the *featureletOrder* vector.

The *featureletOrder* all index within bounds of the *featurelets* vector.

featureletOrder does not contain two of any index.

Notes

Any derived class overriding this function can safely assume that all the requirements above are satisfied by the callers of this function.

Any derived class overriding this function should replicate the behavior above.

Throws

ccFeatureletFilterDefs::FeatureletFilteringNotSupported
If this filter does not support featurelet filtering and **featureletOrder.size()** is 0.

ccFeatureletFilterBoundary

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilterBoundary: public ccFeatureletFilter
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccFeatureletFilterBoundary is a filter class derived from **ccFeatureletFilter**. This filter provides functionality for filtering featurelets based on their positions, orientations, and polarities compared to a given **ccShape** boundary.

Using this filter class you can call **filterFeaturelets()** to filter featurelets, or **filterChains()** to filter featurelet chain sets. The behavior of these two functions when called from this class is described below.

Filter Featurelets

Featurelet filtering with **ccFeatureletFilterBoundary** can be performed using the **filterFeaturelets()** function by providing a vector of **ccFeaturelet** objects. First, **shape()** is sampled using the static member function **ccShapeModel::features()** with **featureParams()** in the class constructor. For each input featurelet, the sampled points within a distance less than, or equal to **distanceTol()** to the featurelet are found. If there are no such points, the featurelet is not filtered out (the featurelet survives). If there are such points, the angular differences between the tangents of these points and the featurelet tangent angle are measured. If any of these angular differences is less than, or equal to **angleTol()**, the featurelet is filtered out. Otherwise, the featurelet survives. The angular differences are taken in the range 0 through pi radians if **ignorePolarity()** is true. Otherwise, the angular differences are taken in the range 0 through 2pi to take the shape and featurelet polarity into consideration. If **angleTol()** is >= **ccRadian(**ckPI**)**, filtering based on angle tolerance will not be performed by turning off the *computeTangents* flag of *featureParams*. No filtering will be done for shapes if there are no tangent angles produced by sampling and **angleTol()** is not >= **ccRadian(**ckPI**)**.

Throws

ccFeatureletFilterDefs::BadParams
: If **ignorePolarity()** is false and **isMod180()** is true for any element of *inputFeaturelets*.

This function will not mask any throws from the static member function **ccShapeModel::features()**.

Filter Featurelet Chain Sets

Featurelet chain set filtering with **ccFeatureletFilterBoundary** can be performed using the **filterChains()** base class function by providing a **ccFeatureletChainSet** object. First, a featurelet filtering operation will be applied to the featurelets of the *inputChainSet*. The surviving featurelets from this filtering will be used to build a new **ccFeatureletChainSet**.

Throws

ccFeatureletFilterDefs::BadParams
If **ignorePolarity()** is false and **chainSet.anyFeatureletsIsMod180()** is true.

This function will not mask any throws from the static member function **ccShapeModel::features()**.

Constructors/Destructors

ccFeatureletFilterBoundary

```
explicit ccFeatureletFilterBoundary(
  const ccShape &shape = cc2Point(),
  double distanceTol = HUGE_VAL,
  const ccRadian &angleTol = ccRadian(ckPI),
  bool ignorePolarity = true,
  const ccShapeModel::ccFeatureParams &featureParams =
```

```
  ccShapeModel::ccFeatureParams (ccShape::ccSampleParams(
  0.0, 0.1, ckMaxInt32, true, false)),
bool isInverted = false);
```

Constructs a filter object with the given shape, distance and angle tolerance values, a flag to ignore featurelet polarity, and feature parameters. Default values are as follows:

Parameter	Default value
shape	**cc2Point()**
distanceTol	HUGE_VAL
angleTol	**ccRadian(**ckPI**)**
ignorePolarity	true
featureParams	sampling parameters: tolerance = 0.0 spacing = 0.1 max points = ckMaxInt32 compute tangents = true duplicate corners = false magScale = 1.0 weightScale = 1.0
isInverted	false

Please see **ccShapeModel** class for information on how to specify the shape polarity.

Parameters

shape The boundary geometric description.

distanceTol The maximum distance tolerance.

angleTol The maximum angle tolerance.

ignorePolarity If true, ignore feature chain polarity.

featureParams Shape model feature parameters.

isInverted If true filtering is inverted.

Throws

ccFeatureletFilterDefs::BadParams
If *distanceTol* < 0,
or if *angleTol* < 0,
or if *ignorePolarity* = false and the effective ignore polarity flag for any portion of the supplied shape is true.

This constructor will not mask any throws from the static member function **ccShapeModel::features()**.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Public Member Functions

clone

```
Clone(ccFeatureletFilterBoundary);
```

Creates a new copy of this **ccFeatureletFilterBoundary** object.

Overrides the **clone()** function in the **ccFeatureletFilter** base class.

shape

```
ccShapePtrh_const shape() const;
```

Returns the shape specified during construction.

distanceTol

```
double distanceTol() const;
```

Returns the distance tolerance specified during construction.

angleTol

```
ccRadian angleTol() const;
```

Returns the angle tolerance specified during construction.

ignorePolarity

```
bool ignorePolarity() const;
```

Returns the *ignorePolarity* flag specified during construction.

featureParams

```
const ccShapeModel::ccFeatureParams &featureParams()
                                                    const;
```

Returns the *featureParams* specified during construction.

ccFeatureletFilterBoundary

ccFeatureletFilterComposite

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilterComposite: public ccFeatureletFilter
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccFeatureletFilterComposite is a filter class derived from **ccFeatureletFilter**. This filter provides functionality for filtering featurelets and featurelet chain sets by composing a vector of **ccFeatureletFilter**s you provide, into a single filter.

Using this filter class you can call **filterFeaturelets()** to filter featurelets, or **filterChains()** to filter featurelet chain sets. In each case, the function is called on each filter in the filter vector, in succession. The behavior of these two functions when called from this class is described below.

Filter Featurelets

Featurelet filtering with **ccFeatureletFilterComposite** can be performed using the **filterFeaturelets()** function and providing a vector of **ccFeaturelet** objects. The filtering performed is equivalent to, but more efficient than, calling the **filterFeatures()** function of each of the filters in order, each filter operating on the result of the previous filter.

Throws

ccFeatureletFilterDefs::FeatureletFilteringNotSupported
If any filter does not support featurelet filtering.

This function will not mask throws from filters you provide.

Filter Featurelet Chain Sets

Featurelet chain set filtering with **ccFeatureletFilterComposite** can be performed using the **filterChains()** function and providing a **ccFeatureletChainSet** object. The filtering performed is equivalent to, but more efficient than, calling the **filterChains()** function of each of the filters in order, each filter operating on the result of the previous filter.

Throws

This function will not mask throws from filters you provide.

Constructors/Destructors

ccFeatureletFilterComposite

```
explicit ccFeatureletFilterComposite(
  const cmStd vector<ccFeatureletFilterPtrh_const> &filters
         = cmStd vector<ccFeatureletFilterPtrh_const>(0),
  bool isInverted = false);
```

Constructs a filter object with the given filters and isInverted flag.

Parameters

filters	A vector of featurelet filters to run.
isInverted	If true, the filtering criteria is inverted.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Public Member Functions

cmFeatureletFilterClone

```
cmFeatureletFilterClone(ccFeatureletFilterComposite);
```

A macro that creates a new copy of this **ccFeatureletFilterComposite** object.

Overrides the **clone()** function in the **ccFeatureletFilter** base class.

filters

```
const cmStd vector<ccFeatureletFilterPtrh_const>
                                          &filters() const;
```

Returns the filters specified during construction.

ccFeatureletFilterLength

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilterLength: public ccFeatureletFilter
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This filter class provides functionality for filtering featurelet chains based on their length, regardless of their open or closed status.

Using this filter class you can call **filterChains()** to filter featurelet chain sets. Calling **filterFeaturelets()** to filter featurelets is not supported by this filter. The behavior of these two functions when called from this class is described below.

Filter Featurelets

Featurelet filtering with this filter class is not allowed.

Throws

ccFeatureletFilterDefs::FeatureletFilteringNotSupported
If a featurelet filtering operation is attempted with this filter.

Filter Featurelet Chain Sets

You can perform featurelet chain set filtering with **ccFeatureletFilterLength** by calling the **filterChains()** function and providing a **ccFeatureletChainSet** object. Any chains with a length less than **minChainLength()** will not survive (they are filtered out) regardless of their open or closed status.

Constructors/Destructors

ccFeatureletFilterLength

```
explicit ccFeatureletFilterLength(
  c_Int32 minChainLength = 1,
  bool isInverted = false);
```

Constructor.

Parameters

minChainLength The minimum chain length required to survive the filter. Chains with length less than *minChainLength* are filtered out.

isInverted When set true, the filtering criteria is inverted. For example, all chain lengths less than *minChainLength* are retained, and others are filtered out.

Throws

ccFeatureletFilterDefs::BadParams
If *minChainLength* < 1.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

cmFeatureletFilterClone

```
cmFeatureletFilterClone(ccFeatureletFilterLength);
```

A macro that creates a new copy of this **ccFeatureletFilterLength** object.

Overrides the **clone()** function in the **ccFeatureletFilter** base class.

minChainLength

```
c_Int32 minChainLength() const;
```

Returns the minimum chain length specified during construction.

ccFeatureletFilterMagnitudeHysteresis

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilterMagnitudeHysteresis:
                                        public ccFeatureletFilter
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This filter class provides functionality for filtering featurelet chains based on hysteresis magnitude of the featurelets and their chains.

Using this filter class you can call **filterChains()** to filter featurelet chain sets. Calling **filterFeaturelets()** to filter featurelets is not supported by this filter. The behavior of these two functions when called from this class is described below.

Filter Featurelets

Featurelet filtering with this filter class is not allowed.

Throws

ccFeatureletFilterDefs::FeatureletFilteringNotSupported
If a featurelet filtering operation is attempted with this filter.

Filter Featurelet Chain Sets

You can perform featurelet chain set filtering with **ccFeatureletFilterMagnitudeHysteresis** by calling the **filterChains()** function and providing a **ccFeatureletChainSet** object. First, featurelets with a magnitude less than **lowMagThresh()** are filtered out and the surviving featurelets are used to build a temporary chain set. Second, the chains of this temporary set without at least one featurelet with a magnitude of greater than, or equal to **highMagThresh()** are filtered out. The remaining chains are returned as the filtered result.

Constructors/Destructors

ccFeatureletFilterMagnitudeHysteresis

```
explicit ccFeatureletFilterMagnitudeHysteresis(
  double lowMagThresh = 1,
  double highMagThresh = 1,
  bool isInverted = false);
```

Constructs an object with the given low and high magnitude threshold values.

Parameters

lowMagThresh	The featurelet low magnitude threshold.
highMagThresh	The featurelet high magnitude threshold.
isInverted	If true, filtering is inverted. Featurelets that survive when *isInverted*=false are filtered out, and the remaining featurelets survive.

Throws

ccFeatureletFilterDefs::BadParams
If *lowMagThresh* < 0.0 or *highMagThresh* < 0.0, or if *highMagThresh* < *lowMagThresh*.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Public Member Functions

cmFeatureletFilterClone

```
cmFeatureletFilterClone(
  ccFeatureletFilterMagnitudeHysteresis);
```

A macro that creates a new copy of this **ccFeatureletFilterMagnitudeHysteresis** object.

Overrides the **clone()** function in the **ccFeatureletFilter** base class.

lowMagThresh `double lowMagThresh() const;`

Returns the low magnitude threshold specified during construction.

highMagThresh `double highMagThresh() const;`

Returns the high magnitude threshold specified during construction.

ccFeatureletFilterMagnitudeHysteresis

ccFeatureletFilterRegion

```
#include <ch_cvl/featfilt.h>

class ccFeatureletFilterRegion: public ccFeatureletFilter
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This filter provides functionality for filtering featurelets based on whether they are inside or outside of a geometric region.

Using this filter class you can call **filterFeaturelets()** to filter featurelets, or **filterChains()** to filter featurelet chain sets. The behavior of these two functions when called from this class is described below.

Filter Featurelets

Featurelet filtering with **ccFeatureletFilterRegion** can be performed using the **filterFeaturelets()** function and providing a vector of **ccFeaturelet** objects. Any featurelets outside the specified geometric region are filtered out.

Filter Featurelet Chain Sets

You can perform featurelet chain set filtering with **ccFeatureletFilterRegion** by calling the **filterChains()** function and providing a **ccFeatureletChainSet** object. A featurelet filtering operation will be applied to the featurelets of the *inputChainSet*. Any featurelets outside the specified geometric region are filtered out. The surviving featurelets from this filtering are then used to build a new **ccFeatureletChainSet**.

Constructors/Destructors

ccFeatureletFilterRegion

```
explicit ccFeatureletFilterRegion(
  const ccShape &region = ccCircle(),
  bool isInverted = false);
```

Constructs an object with the given region and *isInverted* flag.

Parameters

region The geometric region containing the featurelets of interest. Featurelets outside this region are filtered out (discarded).

isInverted If true, filtering is inverted. Featurelets outside the *region* are saved, and featurelets inside the *region* are filtered out.

Throws

ccShapesError::NotRegion
If **region.isRegion()** is false.

Operators

operator==

```
virtual bool operator== (
  const ccFeatureletFilter &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

cmFeatureletFilterClone

```
cmFeatureletFilterClone(ccFeatureletFilterRegion);
```

A macro that creates a new copy of this **ccFeatureletFilterRegion** object.

Overrides the **clone()** function in the **ccFeatureletFilter** base class.

region

```
ccShapePtrh_const region() const;
```

Returns the region specified during construction.

ccFeatureParams

```
#include <ch_cvl/shapemod.h>

class ccShapeModel::ccFeatureParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class specifies the parameters used to extract features from a shape model. An instance of this class is passed as a parameter to **ccShapeModel::features()** to describe how features should be extracted from the shape. This class specifies both shape model-specific parameters and shape sampling parameters. This is a nested class defined inside of **ccShapeModel**.

See the reference pages for **ccFeaturelet** and **ccFeatureletChainSet** for more information on featurelets and featurelet chain sets.

Constructors/Destructors

ccFeatureParams

```
ccFeatureParams(
  const ccShape::ccSampleParams& sampleParams =
    ccShape::ccSampleParams(0.0, 1.0, ckMaxInt32, true,
    true),
  double magScale = 1.0,
  double weightScale = 1.0);
```

Constructs a **ccShapeModel::ccFeatureParams** object with the given parameters.

Parameters

sampleParams	The shape sampling parameters.
magScale	The magnitude scale. Magnitude must be a non-negative value (default = 1.0).
weightScale	The weight scale. Weight can be any positive or negative value, or zero (default = 1.0).

Notes

The default parameters values cause the generated features to have the same magnitude and weight as those of the original shape. This may not be appropriate for all applications. For example, to generate features from a shape with a (default) magnitude of 1.0 and subsequently compare those features to featurelets generated using Sobel edge detection, *magScale* should be set to the edge contrast of the shape's boundary.

A default-constructed **ccFeatureParams** object specifies a feature density of at least one feature per unit of perimeter. This is often appropriate when the shape is defined in a coordinate system with the same scale as image coordinates. In other cases, non-default spacing parameters may be necessary.

Throws

ccShapeModelDefs::BadParams
magScale is less than 0.0.

Operators

operator== `bool operator==(const ccFeatureParams &rhs) const;`

Returns true if and only if this feature parameters object is exactly equal to *rhs*, otherwise false.

Parameters

rhs The other **ccFeatureParams** object.

operator!= `bool operator!=(const ccFeatureParams &rhs) const;`

Returns false if and only if this feature parameters object is exactly equal to *rhs*, otherwise true.

Parameters

rhs The other **ccFeatureParams** object.

Public Member Functions

sampleParams

```
const ccShape::ccSampleParams& sampleParams() const;
void sampleParams(const ccShape::ccSampleParams& params);
```

- `const ccShape::ccSampleParams& sampleParams() const;`

  Retrieves the shape sampling parameters. The values for a default-constructed **ccShapeModel::ccFeatureParams** object are as follows:

• *tolerance*	0.0 (no tolerance)
• *spacing*	1.0
• *maxPoints*	*ckMaxInt32* (no maximum)
• *computeTangents*	true
• *duplicateCorners*	true

- `void sampleParams(const ccShape::ccSampleParams& params);`

  Sets the shape sampling parameters.

  Parameters

  params The shape sampling parameters.

magScale

```
double magScale() const;
void magScale(double val);
```

- `double magScale() const;`

  Retrieves the magnitude scale. This value is multiplied by the effective magnitude of each portion of the sampled shape model to determine the magnitudes of the respective featurelets sampled from those portions. The default magnitude scale is 1.0.

- `void magScale(double val);`

  Sets the magnitude scale. This value is multiplied by the effective magnitude of each portion of the sampled shape model to determine the magnitude of the respective featurelets sampled from those portions.

Throws

ccShapeModelDefs::BadParams
val is less than 0.0.

Notes

In order to generate features from a shape with a (default) magnitude of 1.0 and subsequently compare those features to featurelets generated using Sobel edge detection, *magScale* should be set to the edge contrast of the shape's boundary.

---

weightScale

```
double weightScale() const;
void weightScale(double val);
```

- `double weightScale() const;`

  Retrieves the weight scale. This value is multiplied by the effective weight of each portion of the sampled shape model to determine the weights of the respective featurelets sampled from those portions. The default weight scale is 1.0.

- `void weightScale(double val);`

  Sets the weight scale. This value is multiplied by the effective weight of each portion of the sampled shape model to determine the weights of the respective featurelets sampled from those portions.

ccFeatureSegment

```
#include <ch_cvl/pmifproc.h>

class ccFeatureSegment : public cc_FeatureRange;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that describes a single feature segment. A feature segment is a contiguous range of a feature where the difference in direction between neighboring feature boundary points is small.

You do not instantiate **ccFeatureSegment**s yourself. You can segment a feature into a vector of **ccFeatureSegment**s by calling **cfSegmentFeature()**.

Constructors/Destructors

ccFeatureSegment

```
ccFeatureSegment();
```

Constructs a **ccFeatureSegment**.

Public Member Functions

length

```
double length() const;
```

Return the length of this feature segment in client coordinate system units. The length of a feature is the sum of the distances between the feature's boundary points.

weight

```
double weight() const;
```

Returns the average weight of all of the feature boundary points that make up this feature segment.

matchQuality

```
double matchQuality() const;
```

Returns the average match quality of all of the feature boundary points that make up this feature segment.

ccFeatureSegment

ccFileArchive

```
#include <ch_cvl/archive.h>

class ccFileArchive : public ccArchive;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	Not applicable

The **ccFileArchive** class is a concrete class derived from **ccArchive** that implements a file archive.

Constructors/Destructors

ccFileArchive

```
ccFileArchive(const ccCvlString& fileName,
  ccArchive::Direction dir,
  ccArchive::Ordering ord = ccArchive::eLittleEndian,
  bool seekable=true, bool readOnly=false);

~ccFileArchive();
```

- ```
  ccFileArchive(const ccCvlString& fileName,
    ccArchive::Direction dir,
    ccArchive::Ordering ord = ccArchive::eLittleEndian,
    bool seekable=true, bool readOnly=false);
  ```

  Constructs a file archive associated with the specified file.

  If the archive is constructed for storing, the *readOnly* argument is ignored. If the file already exists, it is truncated.

  Parameters

fileName	The file that contains the archive.
dir	The mode of this archive (loading or storing). *dir* must be one of the following values: *ccArchive::eLoading* *ccArchive::eStoring*
  ```

ord — The endianness of this archive. *ord* must be one of the following values:

ccArchive::eBigEndian
ccArchive::eLittleEndian

seekable — If true, the seek position within this archive can be specified.

readOnly — If true, this archive cannot be stored to.

You must set *readOnly* to true if you have read-only access to the file containing the archive.

Throws

ccArchive::BadFile
The specified file could not be opened. Verify that the file exists.

ccArchive::UnknownArchiveVersion
The loading archive was stored with a later version.

Notes

Only one **ccFileArchive** may be associated with a given file at a time.

ccFilterConvolveParams

```
#include <ch_cvl/filterconv.h>

class ccFilterConvolveParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the parameters used by the variable-kernel discrete convolution tool.

Constructors/Destructors

ccFilterConvolveParams

```
ccFilterConvolveParams();
```

Public Member Functions

boundaryMode

```
ccFilterDefs::BoundaryMode boundaryMode() const ;

void boundaryMode(ccFilterDefs::BoundaryMode rhs);
```

- `ccFilterDefs::BoundaryMode boundaryMode() const;`

  Returns the current boundary mode. The returned value is one of the following:

  ccFilterDefs::eBoundaryClipped
  ccFilterDefs::eBoundaryWeighted
  ccFilterDefs::eBoundaryReflected

- `void boundaryMode(ccFilterDefs::BoundaryMode rhs);`

  Sets the boundary mode for convolution. The default mode is *ccFilterDefs::eBoundaryClipped*, where ouput pixels are only computed for locations where the kernel is fully contained within the bounds of the source image, resulting in an output image that is smaller than the input image by the size of the kernel minus 1.

Parameters

rhs The boundary mode to set. Must be *ccFilterDefs::eBoundaryClipped* or *ccFilterDefs::eBoundaryReflected*

Throws

ccFilterDefs::NotImplemented
A mode other than *ccFilterDefs::eBoundaryClipped* or *ccFilterDefs::eBoundaryReflected* was specified.

operator==

```
bool operator==(const ccFilterConvolveParams& rhs) const;
```

Return true if two objects are equal.

Parameters

rhs The object to compare to this one.

operator!=

```
bool operator!=(const ccFilterConvolveParams& rhs) const;
```

Return true if two objects are not equal.

Parameters

rhs The object to compare to this one.

ccFilterConvolveKernel

```
#include <ch_cvl/filterconv.h>

template <class P>class ccFilterConvolveKernel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encapsulates the kernel used by the variable-kernel discrete convolution tool. This object is deep copied upon copy construction or assignment.

Constructors/Destructors

ccFilterConvolveKernel

```
ccFilterConvolveKernel();
```

Construct an object with uninitialized data.

Notes

cfFilterConvolve will throw *ccFilterDefs::UnboundKernel* if uninitialized kernel is used.

Public Member Functions

kernel

```
const ccPelBuffer_const<K>& kernel() const;

void kernel(const ccPelBuffer_const<K>& rhs);
```

- ```
  const ccPelBuffer_const<K>& kernel() const;
  ```

  Returns the kernel image.

- ```
  void kernel(const ccPelBuffer_const<K>& rhs);
  ```

  Sets the kernel image. A deep copy of the supplied image is made.

  Parameters

rhs	The kernel image.

Throws

ccFilterDefs::UnboundKernel

The specified kernel is unbound.

ccFilterDefs::BadKernelSize

Either the width or height of the specified kernel is not a positive odd integer.

ccFilterDefs

```
#include <ch_cvl/filtercomm.h>

class ccFilterDefs;
```

Enumerations

BoundaryMode How the tool applies the kernel when the neighborhood is not fully contained within the source image.

Value	Meaning
eBoundaryClipped	No output pixel value is calculated if the kernel extends outside the source image. Consequently, the output image is reduced in width and height relative to the input image by the kernel width minus one and the kernel height minus 1.
eBoundaryWeighted	Only the pixel values that lie inside the source image are used to compute the output pixel value. The result of the computation is weighted to reflect the number of pixels used to compute the value relative to the total kernel size.
eBoundaryReflected	The edge of the input image is padded with pixel values generated by reflecting the values present at the boundary of the input image.

ccFilterDefs

ccFilterMaskKernel

```
#include <ch_cvl/filtercomm.h>

class ccFilterMaskKernel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class describes the kernel used by the variable-kernel median filter tool.

Constructors/Destructors

ccFilterMaskKernel

```
explicit ccFilterMaskKernel(
     const ccIPair& size = ccIPair(3, 3));

explicit ccFilterMaskKernel(
   const ccPelBuffer_const<c_UInt8>& mask);
```

- ```
  explicit ccFilterMaskKernel(
       const ccIPair& size = ccIPair(3, 3));
  ```

  Constructs a kernel of the specified size (width, height). The kernel mask is set filled with care pixels.

  Parameters

  size A **ccIPair** containing the width (*size.X*) and height (*size.Y*) of the kernel. Both the width and height must be positive odd integers.

  Notes

  The x-component denotes the width of the kernel, and y-component the height.

  Throws

  ccFilterDefs::BadKernelSize

  If either the width or height of the given size is not a positive odd integer.
  ```

- ```
  explicit ccFilterMaskKernel(
      const ccPelBuffer_const<c_UInt8>& mask);
  ```

  Construct the kernel using the supplied image. The width and height of the kernel are set to the width and height of *mask*, and the mask values are set to the pixel values of the supplied image.

  Parameters

  mask An image defining the kernel size and containing the mask values.

  Throws

  ccFilterDefs::BadKernelSize
  The width or height of *mask* is not a positive odd integer.

Public Member Functions

size

```
const ccIPair size() const;

void size(const ccIPair& rhs);
```

- ```
  const ccIPair size() const;
  ```

  Returns a **ccIPair** giving the size of this kernel. The x-component gives the width, the y-component the height.

- ```
  void size(const ccIPair& rhs);
  ```

  Sets the size of this kernel to that given by the supplied **ccIPair**. The x-component gives the width, the y-component the height. Both the width and height must be positive odd integers.

  The mask image is resized to the new kernel size. If the new size is larger in either width or height than the current size, the newly added mask pixels are set to care (255).

  Parameters

  rhs The size to set.

  Throws

  ccFilterDefs::BadKernelSize
  The width or height of *rhs* is not a positive odd integer.
  ```

mask

```
const ccPelBuffer_const<c_UInt8>& mask() const;
void mask(const ccPelBuffer_const<c_UInt8>& rhs);
```

- `const ccPelBuffer_const<c_UInt8>& mask() const;`

  Returns the kernel's mask image.

- `void mask(const ccPelBuffer_const<c_UInt8>& rhs);`

  Sets both the kernel and the mask image based on the supplied image. The kernel is reset to the height and width of the supplied image and the mask image is set to the pixel values of the supplied image.

  Parameters

  rhs The image from which to set this kernel

  Throws

  ccFilterDefs::BadKernelSize
  The width or height of the supplied image is not a positive odd integer.

  Notes

  The offset and client coordinates of the mask image are ignored. The origin of the kernel is always at the center of the kernel.

  The supplied image is deep copied.

Operators

operator=

```
const ccFilterMaskKernel& operator=(
    const ccFilterMaskKernel& rhs);
```

Assignment operator

Parameters

rhs The **ccFilterMaskKernel** to assign.

Notes

The mask image is deep copied.

operator==

```
bool operator==(const ccFilterMaskKernel& rhs) const;
```

Return true if the two kernels, including mask images, are equal. The mask images are compared by **cfPelEqual()**.

Parameters

rhs The kernel to compare to this one.

operator!=

```
bool operator!=(const ccFilterMaskKernel& rhs) const;
```

Return true if the two kernels, including mask images, are not equal. The mask images are compared by **cfPelEqual()**.

Parameters

rhs The kernel to compare to this one.

ccFilterMedianParams

```
#include <ch_cvl/filtmed.h>

class ccFilterMedianParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the parameters used by the variable-kernel median filter tool.

Constructors/Destructors

ccFilterMedianParams

```
ccFilterMedianParams();
```

Compiler-generated copy constructor and assignment operator

Public Member Functions

boundaryMode

```
ccFilterDefs::BoundaryMode boundaryMode() const;

void boundaryMode(ccFilterDefs::BoundaryMode rhs);
```

- `ccFilterDefs::BoundaryMode boundaryMode() const;`

  Returns the boundary mode used by this tool. This function always returns *ccFilterDefs::eBoundaryWeighted*.

- `void boundaryMode(ccFilterDefs::BoundaryMode rhs);`

  Sets the boundary mode.

  Parameters

  rhs The mode to set. Must be *ccFilterDefs::eBoundaryWeighted.*

  Throws

  ccFilterDefs::NotImplemented
  rhs is not *ccFilterDefs::eBoundaryWeighted*.

Operators

operator== `bool operator==(const ccFilterMedianParams& rhs) const;`

Return true if two objects are equal

Parameters

rhs The object to compare to this one.

operator!= `bool operator!=(const ccFilterMedianParams& rhs) const;`

Return true if two objects are not equal

Parameters

rhs The object to compare to this one.

ccFilterMorphologyStructuringElement

```
#include <ch_cvl/filtmrph.h>

class ccFilterMorphologyStructuringElement;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encapsulates the structuring element used by the variable-kernel grey-scale morphology tool. Both the element and the mask image are deep copied upon copy construction or assignment.

Constructors/Destructors

ccFilterMorphologyStructuringElement

```
ccFilterMorphologyStructuringElement();

ccFilterMorphologyStructuringElement(
     const ccGMorphElement& gmorphElement);

ccFilterMorphologyStructuringElement
     (const ccFilterMorphologyStructuringElement& rhs);
```

- `ccFilterMorphologyStructuringElement();`

  Construct an object with uninitialized data.

  Notes

  This tool will throw *ccFilterDefs::UnboundKernel* if an uninitialized structuring element is used

- ```
  ccFilterMorphologyStructuringElement(
       const ccGMorphElement& gmorphElement);
  ```

  Construct an equivalent structuring element to the given **ccGMorphElement** object (used by the fixed-kernel tool).
  ```

Parameters

gmorphElement The element from which to construct this **ccFilterMorphologyStructuringElement**.

Notes

If the resulting structuring element uses a kernel offset, this constructor sets *useOffsetImage* to *ceTrue*.

- `ccFilterMorphologyStructuringElement (const ccFilterMorphologyStructuringElement& rhs);`

Copy constructor.

Parameters

rhs The source of the copy.

Notes

The constructor makes a deep copy of the *rhs*'s mask and *offsetImage*.

---

mask

```
const ccPelBuffer_const<c_UInt8>& mask() const;

void mask(const ccPelBuffer_const<c_UInt8>& rhs);
```

- `const ccPelBuffer_const<c_UInt8>& mask() const;`

Returns the kernel mask image.

- `void mask(const ccPelBuffer_const<c_UInt8>& rhs);`

Sets the kernel mask image. only Structuring element pixels corresponding to care (255) mask pixels are used to compute the output image; don't care pixels (0) are ignored.

You can specify any pattern of care and don't care pixels so as as to acheive a non-rectangular element.

The supplied image is deep copied.

Parameters

rhs The mask image.

Throws

ccFilterDefs::BadKernelSize
The width or height of rhs is not a positive odd integer.

Notes

The offset and client coordinates of the mask image are ignored. The origin of the kernel is always at the center of the kernel.

The function makes a deep copy of the given image.

useOffsetImage

```
c_Bool useOffsetImage() const;
void useOffsetImage(c_Bool use);
```

- `c_Bool useOffsetImage() const;`

  Gets whether or not to use the *offsetImage*, if one is specified.

- `void useOffsetImage(c_Bool use);`

  Sets whether or not to use the *offsetImage*, if one is specified.

  The default value is *ceFalse*.

offsetImage

```
const ccPelBuffer_const<c_Int16>& offsetImage();
void offsetImage(const ccPelBuffer_const<c_Int16>& rhs);
```

- `const ccPelBuffer_const<c_Int16>& offsetImage();`

  Returns a 16-bit image containing the structuring element values.

- `void offsetImage(const ccPelBuffer_const<c_Int16>& rhs);`

  Sets the structuring element values to those in the supplied image. The pixels are deep copied.

  Parameters

  rhs The image to use.

  Throws

  ccFilterDefs::BadMask
  A pixel values in *rhs* is outside the [-255, 255] range.

Notes

If *useOffsetImage* is false, then **cfFilterMorphology()** ignores this value.

The function makes a deep copy of the given image.

The offset and client coordinates of the given image are ignored.

size

```
const ccIPair size() const;
void size(const ccIPair& size);
```

- `const ccIPair size() const;`

Returns the size of the structuring element. **size().x** is the width while **size().y** is the height.

- `void size(const ccIPair& size);`

Sets the size of the structuring element to the supplied values. size.x gives the wdith while size.y gives the height.

Parameters

size The size to set.

Throws

ccFilterDefs::BadKernelSize
Either the width or height of the given size is not a positive odd integer.

Notes

The mask is reset to the supplied size and filled with care pixels (255) while the offset image is set to unbound.

The default is (0,0).

Operators

operator==

```
bool operator==(
   const ccFilterMorphologyStructuringElement& rhs) const;
```

Return true if two objects are equal. The mask and offset images are compared using **cfPelEqual()**.

Parameters

rhs The object to compare with this one.

operator!=

```
bool operator!=(const
ccFilterMorphologyStructuringElement& rhs) const;
```

Return true if two objects are not equal. The mask and offset images are compared using **cfPelEqual()**.

Parameters

rhs The object to compare with this one.

operator=

```
const ccFilterMorphologyStructuringElement& operator
=(const ccFilterMorphologyStructuringElement& rhs);
```

Assignment operator.

Parameters

rhs The source of the assignment.

Notes

The operator makes a deep copy of the *rhs*'s mask and *offsetImage*.

ccFilterMorphologyStructuringElement

ccFilterMorphologyDefs

```
#include <ch_cvl/filtmorph.h>
```

Enumerations

Operation

The morphological operation to perform.

Value	Meaning
eDilate	Expand light areas and shrink dark areas in an image..
eErode	Shrink light areas and expand dark areas in an image.
eOpen	Erode and then dilate with the same structuring element. Eliminate extraneous light details, thin lines, and small islands. Smooth object contours while maintaining dark holes or narrow channels.
eClose	Dilate and then erode with the same structuring element. Eliminate small dark holes and gaps in light objects, and smooth edges while preserving image details.

ccFilterMorphologyDefs

ccFilterMorphologyParams

```
#include <ch_cvl/filtmorph.h>

class ccFilterMorphologyParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the parameters used by the variable-kernel grey-scale morphology tool.

Constructors/Destructors

ccFilterMorphologyParams

```
ccFilterMorphologyParams();
```

Compiler-generated copy constructor and assignment operator.

Public Member Functions

boundaryMode

```
ccFilterDefs::BoundaryMode boundaryMode() const;

void boundaryMode(ccFilterDefs::BoundaryMode rhs);
```

- ```
  ccFilterDefs::BoundaryMode boundaryMode() const;
  ```

  Returns the boundary mode used by this tool. Always returns *ccFilterDefs::eBoundaryWeighted*.

- ```
  void boundaryMode(ccFilterDefs::BoundaryMode rhs);
  ```

  Sets the boundary mode.

  Parameters

rhs	The boundary mode. Must be *ccFilterDefs::eBoundaryWeighted*.

Throws

ccFilterDefs::NotImplemented

rhs is not *ccFilterDefs::eBoundaryWeighted.*

Operators

operator==

```
bool operator==(const ccFilterMorphologyParams& rhs) const;
```

Return true if two instances are equal

Parameters

rhs	The object to compare to this one.

operator!=

```
bool operator!=(const ccFilterMorphologyParams& rhs) const;
```

Return true if two instances are not equal

Parameters

rhs	The object to compare to this one.

ccFirstPelOffsetProp

```
#include <ch_cvl/prop.h>

class ccFirstPelOffsetProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

Analog line scan cameras do not provide the acquisition software with pixel clock information, which makes it difficult to determine exactly when an acquisition should begin. In such cases, acquired images may contain black pixels at the beginning or end of an image. This is not an issue with digital line scan cameras.

This property allows you to specify the offset of the first image pixel from the value supplied by the camera's device driver.

Do not use this class to adjust the region of interest for an acquisition. To specify a region of interest use the class **ccRoiProp** on page 2763.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccFirstPelOffsetProp

```
ccFirstPelOffsetProp();

explicit ccFirstPelOffsetProp(c_Int8 offset);
```

- `ccFirstPelOffsetProp();`

  Creates a new first pixel offset property not associated with any FIFO. The default offset is used.

- `explicit ccFirstPelOffsetProp(c_Int8 offset);`

  Creates a new first pixel offset property not associated with any FIFO. The offset is specified by *offset*.

  Parameters

  offset The first pixel offset in pixels.

Public Member Functions

firstPelOffset

```
void firstPelOffset(c_Int8 offset);
c_Int8 firstPelOffset() const;
```

- `void firstPelOffset(c_Int8 offset);`

  Sets the first pixel offset.

  Parameters

  offset The first pixel offset in pixels.

  Throws

  ccFirstPelOffsetProp::BadParams
  offset was not in the range zero through *ccFirstpelOffsetProp::maxDelayOffset*.

- `c_Int8 firstPelOffset() const;`

  Gets the first pixel offset in pixels.

Constants

defaultDelayOffset

```
static const c_Int8 defaultDelayOffset;
```

The default delay offset: zero.

maxDelayOffset

```
static const c_Int8 maxDelayOffset;
```

The default maximum delay offset: 127.

ccFLine

```
#include <ch_cvl/shapes.h>

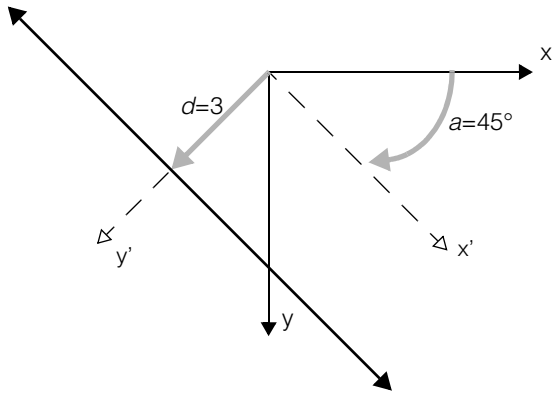
class ccFLine : public ccShape;
```

Class Properties

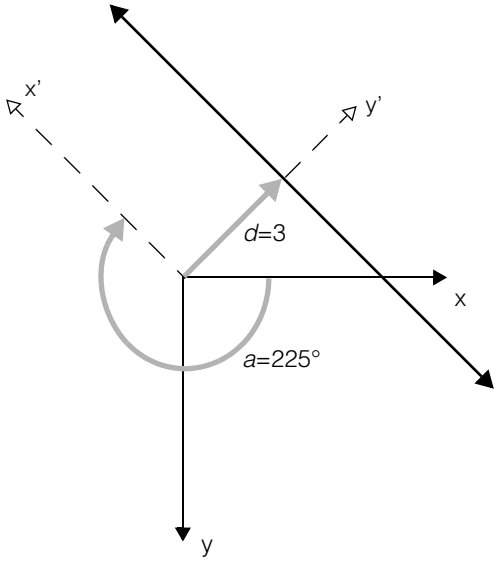
Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a line rotated by a given angle *a* relative to the x-axis and translated a specified distance *d* from the origin. *a* can be positive or negative. *d* is always positive. The line is interpreted as if it were parallel to the x-axis of a coordinate frame that is rotated *a* degrees, and translated along the rotated y-axis by *d*.

The following figure shows a line that is rotated 45° and has a distance of 3.



The following figure shows a line rotated 225° with a distance of 3.



Notes

Once created, a **ccFLine** can be modified only by the assignment operator.

Constructors/Destructors

ccFLine

```
ccFLine();
ccFLine(const ccDegree& angle, double distance);
ccFLine(const cc2Vect & point1, const cc2Vect & point2);
ccFLine(const ccDegree & angle, const cc2Vect & point);
```

- `ccFLine();`

  The default constructor creates a line whose angle and distance are both zero. The line is colinear with the x-axis.

- `ccFLine(const ccDegree& angle, double distance);`

  Creates a line rotated *angle* degrees from the x-axis and *distance* from the origin.

Parameters

angle The angle of the line.

distance The distance between the origin and the line. Must be nonnegative.

Throws

ccShapesError::DegenerateShape
distance is less than zero.

- `ccFLine(const cc2Vect & point1, const cc2Vect & point2);`

Creates the line that includes two points.

Parameters

point1 A first point in the line.

point2 A second point in the line.

Throws

ccShapesError::DegenerateShape
point1 equals *point2*.

- `ccFLine(const ccDegree & angle, const cc2Vect & point);`

Creates the line rotated *angle* degrees from the x-axis that includes *point*.

Parameters

angle The angle of the line.

point A point on the line.

Operators

operator== `int operator== (const ccFLine& line) const;`

Returns true if this line has the same angle and distance as another line.

Parameters

line The other line.

operator!= `int operator!= (const ccFLine& line) const;`

Returns true if this line is not equal to another line.

Parameters

line	The other line.

operator*

```
friend ccFLine operator* (const cc2Xform& xform,
 const ccFLine & line);

friend ccFLine operator* (const cc2Rigid& xform,
 const ccFLine & line);
```

- ```
  friend ccFLine operator* (const cc2Xform& xform,
   const ccFLine & line);
  ```

  Maps *line* by *xform* and returns a new line.

  Parameters

xform	The **cc2Xform** being applied.
line	An existing line.

- ```
  friend ccFLine operator* (const cc2Rigid& xform,
   const ccFLine & line);
  ```

  Maps *line* by *xform* and returns a new line.

  Parameters

xform	The **cc2Rigid** being applied.
line	An existing line.

operator<<

```
friend ccCvlOStream& operator<< (ccCvlOStream& out,
 const ccFLine& line);
```

Prints the supplied **ccFLine**.

Parameters

out	The stream to which to print the line.
line	The **ccFLine** to print.

Public Member Functions

angle

```
const ccDegree& angle();
```

Returns the line's angle.

distance `double distance() const;`

Returns the line's distance from the origin.

sinAngle `double sinAngle() const;`

Returns the sine of the line's angle.

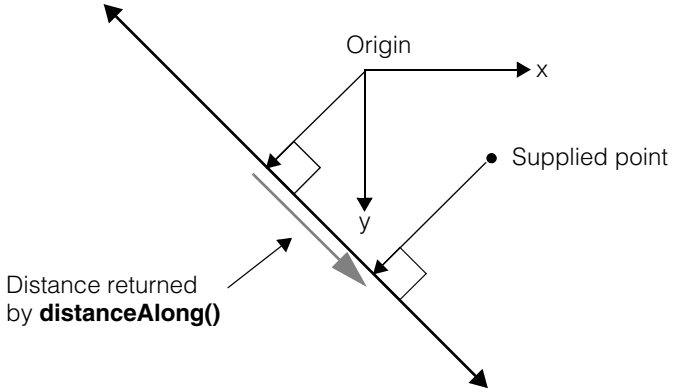
cosAngle `double cosAngle() const;`

Returns the cosine of the line's angle.

distanceAlong `double distanceAlong(const cc2Vect & point) const;`

Returns the signed distance from the projection of the origin point on the line to the projection of the supplied point on the line. The positive direction is specified by the line's angle.

The following figure shows the value returned by this function:



Parameters

point An arbitrary point.

intersection `cmStd vector<cc2Vect> intersection(const ccFLine & line) const;`

Returns the single point of intersection between this line and another line if an intersection exists, or an empty vector if no intersection exists.

Parameters

other Another line.

map `ccFLine map(const cc2Xform& c) const;`

Returns this line mapped by *c*.

Parameters

c The transformation object.

clone `virtual ccShapePtrh clone() const;`

Returns a pointer to a copy of this line.

isOpenContour `virtual bool isOpenContour() const;`

Returns true if this shape is an open contour. For lines, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion `virtual bool isRegion() const;`

Returns true if this shape is a region. For lines, this function always returns false. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

For lines, this function always returns false. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For lines, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

For lines, this function always returns true. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For lines, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For lines, this function always returns false.

Notes

ccFLines are not reversible, but **ccLine**s are.

See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccFLine**s.

See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on this line to the given point.

Parameters

p The point.

See **ccShape::nearestPoint()** for more information.

perimeter

```
virtual double perimeter() const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccFLine**s.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this line to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this line.

point The point.

See **ccShape::nearestPerimPos()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccFLine**s.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this line mapped by *X*.

Parameters

X	The transformation object.

Notes

If *X* is singular, the mapping may collapse this line to a single point.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccGeneralShapeTree** without any children. See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the line segment describing the portion of this line over the given range. The length of the final returned line segment is equal to the absolute value of the distance component of *range*.

Parameters

info	Shape information for this line.
range	The perimeter range.

See **ccShape::subShape()** for more information.

Static Functions

Xaxis

```
static ccFLine Xaxis(const cc2Rigid & xform);
static ccFLine Xaxis(const cc2Xform & xform);
```

- `static ccFLine Xaxis(const cc2Rigid & xform);`

  Returns the x-axis of a **cc2Rigid** transform as a line.

  Parameters
  xform A **cc2Rigid** transform.

- `static ccFLine Xaxis(const cc2Xform & xform);`

  Returns the x-axis of a **cc2Xform** transform as a line.

  Parameters
  xform A **cc2Xform** transform.

Yaxis

```
static ccFLine Yaxis(const cc2Rigid & xform);
static ccFLine Yaxis(const cc2Xform & xform);
```

- `static ccFLine Yaxis(const cc2Rigid & xform);`

  Returns the y-axis of a **cc2Rigid** transform as a line.

  Parameters
  xform A **cc2Rigid** transform.

- `static ccFLine Yaxis(const cc2Xform & xform);`

  Returns the y-axis of a **cc2Xform** transform as a line.

  Parameters
  xform A **cc2Xform** transform.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccFLine

closestPoint `cc2Vect closestPoint(const cc2Vect & point) const;`

Use **nearestPoint()** instead of this function.

distanceFrom `double distanceFrom(const cc2Vect & point) const;`

Use **distanceToPoint()** instead of this function.

ccFontCharMetrics

```
#include <ch_cvl/synfont.h>

class ccFontCharMetrics;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccFontCharMetrics** class contains various metrics for a single character.

Constructors/Destructors

ccFontCharMetrics

```
ccFontCharMetrics();
```

Constructs a default character metrics object.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

cellRect

```
ccRect cellRect() const;

void cellRect(const ccRect& r);
```

- ```
  ccRect cellRect() const;
  ```

  Gets cell rect.

- ```
  void cellRect(const ccRect& r);
  ```

  Sets cell rect.

  The default is **ccRect()**

  Parameters

  r The new cell rect.

isMarkRectSpecified

```
bool isMarkRectSpecified() const;
void isMarkRectSpecified(bool s);
```

- `bool isMarkRectSpecified() const;`

  Gets whether the mark rect is specified.

- `void isMarkRectSpecified(bool s);`

  Sets whether the mark rect is specified.

  The default is false.

  Parameters

  s If true, the mark rect is specified.

  Notes

  A blank character has a mark rect that is specified but degenerate.

markRect

```
ccRect markRect() const;
void markRect(const ccRect& r);
```

- `ccRect markRect() const;`

  Gets mark rect.

  Throws

  ccSynFontDefs::MarkRectNotSpecified
  isMarkRectSpecified is false.

- `void markRect(const ccRect& r);`

  Sets mark rect.

  The default is **ccRect()**

  Parameters

  r The new mark rect.

hasDetectedMarkRect

```
bool hasDetectedMarkRect() const;
void hasDetectedMarkRect(bool s);
```

- `bool hasDetectedMarkRect() const;`

  Gets whether there is a detected mark rect.

- `void hasDetectedMarkRect(bool s);`

  Sets whether there is a detected mark rect.

  The default is false.

  Parameters

  s If true, there is a detected mark rect.

  Notes

  A blank character does not have a detected mark rect.

detectedMarkRect

```
ccRect detectedMarkRect() const;
void detectedMarkRect(const ccRect& r);
```

- `ccRect detectedMarkRect() const;`

  Gets the detected mark rect.

  Throws

  ccSynFontDefs::MarkRectNotSpecified
  The **hasDetectedMarkRect()** operation returned false.

- `void detectedMarkRect(const ccRect& r);`

  Sets the detected mark rect.

  The default is **ccRect()**

  Parameters

  r The detected mark rect.

isBlank

```
bool isBlank() const;
void isBlank(bool b);
```

- `bool isBlank() const;`

  Gets whether or not the character is a blank (space).

- `void isBlank(bool b);`

  Sets whether or not the character is a blank (space).

  Setting *isBlank* to true is the same as specifying a degenerate mark rect; getter is the same as testing for a mark rect that is specified and degenerate.

  Parameters

  b — If true, the character is a blank (space).

advance

```
cc2Vect advance() const;
void advance(const cc2Vect& a);
```

- `cc2Vect advance() const;`

  Gets the advance for the character.

- `void advance(const cc2Vect& a);`

  Sets the advance for the character.

  The default is **cc2Vect(**0, 0**)**

  Parameters

  a — The new advance for the character.

ccFontKey

```
#include <ch_cvl/synfont.h>

class ccFontKey;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccFontKey** class represents a character key, which consists of a 16-bit Unicode code point and a 16-bit instance number. The instance number allows supporting fonts that have multiple representations of a given character.

Note **ccFontKey** does not support 21-bit Unicode code points.

Constructors/Destructors

ccFontKey

```
ccFontKey(c_Int32 key = 0): key_(key);

ccFontKey(TCHAR charCode, c_Int32 instance);
```

- `ccFontKey(c_Int32 key = 0): key_(key);`

  Constructs a default key with a value of 0.

  Parameters
  key

- `ccFontKey(TCHAR charCode, c_Int32 instance);`

  Constructs a key with the specified character code and instance number.

  Requires that the instance be less than or equal to *ckMaxUInt16* + 1

  Parameters

charCode	The character code.
instance	The instance.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

key

```
c_Int32 key() const;
void key(c_Int32 k);
```

- `c_Int32 key() const;`

  Gets key value.

- `void key(c_Int32 k);`

  Sets key value.

  Parameters

  k The new key value.

charCode

```
TCHAR charCode() const;
```

Gets the 16-bit Unicode code point.

instance

```
c_Int32 instance() const;
```

Gets the instance number.

c_Int32

```
operator c_Int32() const;
```

Casts the key to a c_Int32, which is the same as the value returned by **key()**.

TCHAR

```
operator TCHAR() const;
```

Casts the key to a TCHAR, which is the same as the value returned by **charCode()**.

<

```
bool operator<(const ccFontKey& rhs) const;
```

Compares *this to rhs, ordered first by character code in increasing order and then by instance in increasing order.

ccFontKey

ccFrameAverageBuffer

```
#include <ch_cvl/frameavg.h>

template <class imgPel, class accPel> class ccFrameAverageBuffer;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

ccFrameAverageBuffer is a template class that provides functionality to accumulate images with pixels of type *imgPel* into a buffer with pixels of type *accPel*, and to compute the average image. Averaged images can be cleaner images than raw camera images, and can be presented to other CVL vision tools to produce better results.

imgPel — Template parameter specifying the pel type of the images being accumulated. For example, **c_UInt8**.

accPel — Template parameter specifying the pel type of the accumulated image. For example, **c_UInt16**.

For example, if you are accumulating 8-bit images into a 16-bit accumulator, *imgPel* is **c_UInt8** and *accPel* is **c_UInt16**. If you are accumulating 12-bit images into a 16-bit accumulator, both *imgPel* and *accPel* would be **c_UInt16**.

Note The **ccFrameAverageBuffer** class is currently implemented only for the case where *imgPel* = **c_UInt8** and *accPel* = **c_UInt16**.

ccFrameAverageBuffer operates in two modes, standard and rolling average. In standard mode, you can accumulate **ccPelBuffer**s, find their average, and optionally find the standard deviation at each pixel. In rolling average mode, this class maintains a rolling average of the last N images.

Constructors/Destructors

ccFrameAverageBuffer

```
ccFrameAverageBuffer();

ccFrameAverageBuffer(const ccFrameAverageBuffer
  <imgPel, accPel> &buffer);
```

- `ccFrameAverageBuffer();`

  Default constructor. Creates a new frame average buffer in standard mode. The size of internal buffers is determined by the first image added with **add()**. **accumulateStats()** is set to false, so statistics are not accumulated.

- `ccFrameAverageBuffer(const ccFrameAverageBuffer <imgPel, accPel> &buffer);`

  Copy constructor.

Operators

operator==

```
bool operator== (ccFrameAverageBuffer<imgPel, accPel>
  &buffer);
```

Returns true if the current frame buffer average is identical to *buffer*.

operator=

```
ccFrameAverageBuffer<imgPel, accPel>& operator=
  (const ccFrameAverageBuffer &buffer);
```

Copies the accumulator and all its pixels to a new pel root.

Public Member Functions

setStandardMode

```
void setStandardMode(bool accumulateStats=false);
```

Sets the frame averaging mode to standard mode (**ccFrameAverageDefs::eStandardMode**). The current accumulation buffer is reset.

Parameters

accumulateStats

If true, statistics are accumulated that allow the computation of a standard deviation image. If false, no statistics are accumulated.

setRollingAverageMode

```
void setRollingAverageMode(c_Int32 maxNumRollingFrames);
```

Sets the frame averaging mode to rolling average mode (**ccFrameAverageDefs::eRollingAverageMode**).

Notes

Rolling average mode is currently only implemented for **ccFrameAverageBuffer** instances where the *imgPel* type is **c_UInt8** and the *accPel* type is **c_UInt16**. Any other values makes **setRollingAverageMode()** return *NotImplemented.*

Parameters

maxNumRollingFrames

The number of frames to use in the rolling average computation. Must be a power of two between 2 and 256, inclusive.

Throws

ccFrameAverageDefs::NotImplemented

If *maxNumRollingFrames* is not a power of two or is > 256.

NotImplemented is also thrown if the *imgPel* type of the current **ccFrameAverageBuffer** instance is not **c_UInt8**, or if the *accPel* type is not **c_UInt16**.

ccFrameAverageDefs::BadParams

If *maxNumRollingFrames* is <= 0.

averageMode

```
ccFrameAverageDefs::AveragingMode averageMode() const;
```

Returns the current averaging mode setting for the current frame average buffer.

reset

```
void reset();
```

Resets the current frame average buffer to have an empty accumulator, but does not alter the current frame averaging mode or statistics accumulation mode.

maxNumRollingFrames

```
c_Int32 maxNumRollingFrames() const;
```

Returns the number of images currently set for computing the rolling average when in rolling average mode.

Throws

ccFrameAverageDefs::BadParams

If the current buffer is in standard mode.

accumulateStats

```
bool accumulateStats() const;
void accumulateStats(bool);
```

- `bool accumulateStats() const;`

  Returns true if the current frame average buffer is set to accumulate standard deviation statistics; returns false if not.

- `void accumulateStats(bool);`

  Setting **accumulateStats(true)** tells the current frame average buffer to accumulate the necessary statistics to be able to compute a standard deviation image from the accumulated images. Setting **accumulateStats(false)** disables the accumulation of standard deviation statistics. Setting either true or false always calls **reset()** first, even if the current state of the buffer is the same.

  Throws

  ccFrameAverageDefs::NotImplemented
  If the current buffer is in rolling average mode.

hasStdDevImage

```
bool hasStdDevImage() const;
```

Returns true if a standard deviation image is available to be retrieved. That is, it returns true if **accumulateStats()** is true and **numFrames()** > 1.

Throws

ccFrameAverageDefs::NotImplemented
If the current buffer is in rolling average mode.

stdDevImage

```
ccPelBuffer_const<imgPel> stdDevImage() const;
```

If **hasStdDevImage()** is true, returns the standard deviation image.

Throws

ccFrameAverageDefs::NotImplemented
If the current buffer is in rolling average mode.

ccFrameAverageDefs::BadParams
If **hasStdDevImage()** is false, or if **accumulateStats()** is false.

add

```
void add (ccPelBuffer_const <imgPel> &pelbuf);
```

Adds the pixel values of *pelbuf* to the accumulator image. If the accumulator image is unbound, copies *pelbuf* to the accumulator image.

Parameters

pelbuf The pel buffer to copy to the accumulator. The template parameter *imgPel* must be the same template parameter you specifed as the first template parameter of your **ccFrameAverageBuffer** instance, probably **c_UInt8**.

Throws

ccFrameAverageDefs::ImageUnbound
If *pelbuf* is unbound.

ccFrameAverageDefs::WindowsDiffer
If *pelbuf* 's region is not identical to the region of the current frame average bufer.

ccFrameAverageDefs::NotImplemented
If in rolling average mode and the *imgPel* type of the current **ccFrameAverageBuffer** instance is not **c_UInt8**, or the *accPel* type is not **c_UInt16**.

numFrames

```
c_Int32 numFrames() const;
```

Returns the number of pel buffer frames that have been accumulated so far.

Notes

When in rolling average mode, **numFrames()** returns the number of frames included in the frame average buffer, until a maximum value equal to the number of images used in averaging is reached. This is the *maxNumRollingFrames* value set with **setRollingAverageMode()**.

average

```
ccPelBuffer<imgPel> average() const;

void average(ccPelBuffer<imgPel> &destImage) const;
```

- `ccPelBuffer<imgPel> average() const;`

  Computes the frame-averaged result by dividing all pel values in the average frame buffer by the number of frames accumulated, rounding if necessary, and returns the averaged pel buffer. *imgPel* must be the same template parameter you specifed as the first template parameter of your **ccFrameAverageBuffer** instance, probably **c_UInt8**.

- `void average(ccPelBuffer<imgPel> &destImage) const;`

  Computes the frame-averaged result as above, but places the result in *destImage. imgPel* must be the same template parameter you specifed as the first template parameter of your **ccFrameAverageBuffer** instance, probably **c_UInt8**.

Notes

If this current frame average buffer's accumulator image is unbound, the result of this function is an unbound pel buffer.

If *destImage* is specified, **average()** operates only on the intersection of the image coordinates of *destImage* and the current frame average buffer, and put the averaging result into *destImage.*

If *destImage* is unbound, **average()** sets it to have the same height, width, and origin as the current frame average buffer, and puts the results of the average operation into it.

Throws

ccFrameAverageDefs::RollingBufferNotFull

For rolling average mode, if **numFrames()** is less than the number of images you specifed to be used in computing the rolling average (*maxNumRollingFrames*).

ccFrameAverageDefs::DivideByZero

If the current frame average buffer's accumulator image is bound, but the number of images accumulated so far is zero.

ccFrameAverageDefs::NotImplemented

If in rolling average mode and the *imgPel* type of the current **ccFrameAverageBuffer** instance is not **c_UInt8**, or the *accPel* type is not **c_UInt16**.

ccFrameAverageDefs

```
#include <ch_cvl/frameavg.h>

class ccFrameAverageDefs;
```

A name space that holds enumerations used with the image averaging tools.

Enumerations

AveragingMode

```
enum AveragingMode {eStandardMode=0,
                    eRollingAverageMode};
```

ccFrameAverageDefs

ccFrameGrabber

```
#include <ch_cvl/fg.h>

class ccFrameGrabber;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This abstract class is used to describe Cognex frame grabbers. Your application will typically use a class derived from this class to specify a Cognex frame grabber.

Constructors/Destructors

Construction and destruction of derived classes is done automatically.

Enumerations

enum

```
enum {ckCvmNotPresent = -1, ckNoCvmConnector = -2};
```

Possible return values for **cvmId()**.

Value	Meaning
ckCvmNotPresent = -1	The frame grabber does support CVMs but none is currently attached.
ckNoCvmConnector = -2	The frame grabber does not support CVMs.

Public Member Functions

numChannels

```
c_Int32 numChannels() const;
```

Returns the number of video channels supported by this frame grabber. In general, this is the number of simultaneous acquisitions that this frame grabber can perform.

Throws

ccBoard::HardwareInUse

If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

numCameraPort

```
c_Int32 numCameraPort(const ccVideoFormat& fmt) const;
```

Parameters

fmt A video format.

Returns the number of camera ports that can be used with the given video format. Zero is returned if the video format is not supported on this frame grabber.

Throws

ccBoard::HardwareInUse

If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

isSupportedEx

```
bool isSupportedEx (
  const ccVideoFormat& fmt,
  ceImageFormat imgFmt=ceImageFormat_Unknown) const;
```

Returns true if the frame grabber supports the given video format. Otherwise returns false.

Parameters

ccVideoFormat A video format.

imgFmt An image format.

Notes

If a specific *imgFmt* is specified, true is returned only if images of the specified type can be acquired. If *ceImageFormat_Unknown* is specified, it is interpreted as a wildcard value, and true is returned if any image format is supported.

Throws

ccBoard::HardwareInUse

If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

isSupported

```
bool isSupported(const ccVideoFormat& fmt) const;
```

Parameters

ccVideoFormat A video format.

Returns *true* if the frame grabber supports the given video format. Otherwise returns *false*.

Notes

This is a legacy version of **isSupportedEX** (above) that will be deprecated in a future release. It returns true if a **ccGreyAcqFifo** can be constructed to acquire images using the specified video format.

Throws

ccBoard::HardwareInUse

If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

supportsCCFs

```
bool supportsCCFs() const;
```

Returns true if the frame grabber supports video formats that are formed from Cognex Configuration Files (CCFs).

Notes

The frame grabber might not necessarily support all CCF video formats. This function indicates whether the frame grabber has the ability to support *any* CCF formats.

Throws

ccBoard::HardwareInUse
If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

cvmId

```
c_Int32 cvmId() const;
```

Returns the numerical ID of the CVM attached to this frame grabber. Or, returns *ckNoCvmConnector* if the frame grabber does not support CVMs, or returns *ckCvmNotPresent* if the frame grabber does support CVMs but no CVM is currently attached.

Notes

cvmId() should be used for information purposes only and not as a substitute for other query functions, such as **ccFrameGrabber::numCameraPort()** or **ccTriggerProp::couldSlaveTo()**.

Throws

ccBoard::HardwareInUse
If the frame grabber is being used by another process. Recovery might be possible by waiting for the other process to exit, then calling this function again.

Throws other exceptions derived from **ccException** if a fatal error occurs. No recovery is possible, other than to display **ccException::message()** and exit gracefully.

Static Functions

count

```
static c_Int32 count();
```

Returns the number of frame grabbers installed.

Notes

This function is not available at static initialization time

get

```
static ccFrameGrabber& get(c_Int32 i = 0);
```

Return the *i*th frame grabber installed. Frame grabber numbering starts at 0.

Parameters

i The frame grabber number.

Throws

ccBoard::BadParams

i is not in the range 0 through **count()** - 1, or no frame grabbers are installed (**count()** returns 0).

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occurred while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from

an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

ccGaussSampleParams

```
#include <ch_cvl/gaussmpl.h>

class ccGaussSampleParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the parameters you specify to control the Gaussian Sampling tool.

Constructors/Destructors

ccGaussSampleParams

```
ccGaussSampleParams (const ccIPair& samples,
  const ccIPair& smoothnesses, double scale = 1.0,
  bool canUsePelRoot = true);

ccGaussSampleParams (c_Int32 sample = 1,
  c_Int32 smoothness = 2, double scale = 1.0,
  bool canUsePelRoot = true);
```

- ```
  ccGaussSampleParams (const ccIPair& samples,
    const ccIPair& smoothnesses, double scale = 1.0,
    bool canUsePelRoot = true);
  ```

  Constructs a **ccGaussSampleParams** using the specified values. This constructor lets you specify independent values for x-axis and y-axis smoothing and sampling values.

  Parameters

  samples — A **ccIPair** containing the x-axis and y-axis sampling factors. The output image produced by **cfGaussSample()** is reduced in size by the values specified in *samples*.

  smoothnesses — A **ccIPair** containing the x-axis and y-axis smoothing values. These values are in image coordinate system units.

  scale — The output scaling factor to apply during the smoothing operation.
  ```

canUsePelRoot If true, **cfGaussSample()** will use any available pixels present in the input image's root image when computing the smoothed image. If false, **cfGaussSample()** only uses pixels within the input image.

- ```
  ccGaussSampleParams (c_Int32 sample = 1,
    c_Int32 smoothness = 2, double scale = 1.0,
    bool canUsePelRoot = true);
  ```

  Constructs a **ccGaussSampleParams** using the specified values. This constructor accepts a single value for both x- and y-axis smoothing and a single value for both x- and y-axis sampling.

  Parameters

  sample The sampling factor. The output image produced by **cfGaussSample()** is reduced in size by the *sample*.

  smoothness The smoothing value in image coordinate system units

  scale The output scaling factor to apply during the smoothing operation

  canUsePelRoot If true, **cfGaussSample()** will use any available pixels present in the input image's root image when computing the smoothed image. If false, **cfGaussSample()** only uses pixels within the input image.

Public Member Functions

sample

```
ccIPair sample() const;

void sample(const ccIPair& samplings);

void sample(c_Int32 sampling);
```

- ```
  ccIPair sample() const;
  ```

  Returns the x- and y-axis sampling rates

- ```
  void sample(const ccIPair& samplingRates);
  ```

  Sets the x-axis and y-axis sampling rates.

  Parameters

  samplingRates The sampling values.

  Throws
  ```

ccGaussSampleParams::BadParams
samplingRates.x() or *samplingRates.y()* is less than or equal to 0.

Notes

The client coordinate system of the image produced by **cfGaussSample()** is updated to reflect the effect of the sampling rate.

- `void sample(c_Int32 sampling);`

Sets the sampling rate.

Parameters

sampling This value for both x- and y-axis sampling

Throws

ccGaussSampleParams::BadParams
sampling is less than or equal to 0.

Notes

The client coordinate system of the image produced by **cfGaussSample()** is updated to reflect the effect of the sampling rate.

smoothness

```
ccIPair smoothness () const;
void smoothness (const ccIPair& smoothnesses);
void smoothness (c_Int32 smoothness);
```

- `ccIPair smoothness () const;`

Returns the x- and y-axis smoothness values.

- `void smoothness (const ccIPair& smoothnesses);`

Sets separate smoothness values for the x- and y-axis directions. The smoothness value determines the sigma of the Gaussian curve and in turn the size of the Gaussian kernel. Specifying a smoothness value greater than *ccGaussSampleParams::kMaxSmoothness* will result in slower execution times than smaller values.

Parameters

smoothnesses The x- and y-axis smoothness values to set

Throws

ccGaussSampleParams::BadParams
Either *smoothnesses.x()* or *smoothnesses.y()* is less than 0.

- `void smoothness (c_Int32 smoothness);`

  Sets a single smoothness value for both the x- and y-axis directions. The smoothness value determines the sigma of the Gaussian curve and in turn the size of the Gaussian kernel. Specifying a smoothness value greater than *ccGaussSampleParams::kMaxSmoothness* will result in slower execution times than smaller values.

  Parameters

  smoothness The smoothing value to set

  Throws

  ccGaussSampleParams::BadParams
  smoothness is less than 0.

---

scale

`double scale () const;`

`void scale (double scale);`

- `double scale () const;`

  Returns the scaling value applied during the smoothing operation.

- `void scale (double scale);`

  Sets the scaling value applied during the smoothing operation. A scaling value of 1.0 applied to an 8-bit input image produces values in the range 0-255. A scaling value of greater than 1.0 can improve the dynamic range if the input image has low contrast, but it might cause overflow.

  Parameters

  scale The scaling factor to set.

  Throws

  ccGaussSampleParams::BadParams
  scale is 0.0 or less.

sigma

`ccDPair sigma () const;`

Returns standard deviation of the Gaussian curve in both the x- and y-axis. The standard deviation is computed using the following formula:

$$\sigma = \frac{\sqrt{s(s+2)}}{2}$$

where *s* is the smoothing value.

canUsePelRoot

```
bool canUsePelRoot () const;
void canUsePelRoot (bool useRootPels);
```

- `bool canUsePelRoot () const;`

  Returns true if this **ccGaussSampleParams** is configured to use any available pixels from the root image to compute the output image, false if only those pixels inside the input image are considered.

- `void canUsePelRoot (bool useRootPels);`

  Controls whether this **ccGaussSampleParams** uses any available pixels from the root image to compute the output image.

  Parameters

  useRootPels — If true, the **ccGaussSampleParams** uses root pixels; if false, it does not

ccGaussSampleParams

ccGenAnnulus

```
#include <ch_cvl/shapes.h>

class ccGenAnnulus : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a generalized annulus, a shape made up of two generalized rectangles (**ccGenRect**).

Constructors/Destructors

ccGenAnnulus

```
ccGenAnnulus();

ccGenAnnulus(const cc2Vect& center,
  const cc2Vect& radius1, const cc2Vect& radius2,
  const ccRadian orient, const cc2Vect& round);

ccGenAnnulus(const cc2Vect& center,
  const cc2Vect& radius1, const cc2Vect& radius2,
  const ccRadian orient,
  const cc2Vect& round1, const cc2Vect& round2);

ccGenAnnulus(const ccGenRect& r1, const ccGenRect& r2);

ccGenAnnulus(const ccAnnulus& a);
```

- `ccGenAnnulus();`

  Default constructor. Constructs a degenerate generalized annulus.

  Notes

  The default constructor is provided to support arrays and STL containers. Do not try to examine or use a default-constructed **ccGenAnnulus**.

- ```
  ccGenAnnulus(const cc2Vect& center,
    const cc2Vect& radius1,const cc2Vect& radius2,
    const ccRadian orient, const cc2Vect& round);
  ```

  Creates a generalized annulus. Both generalized rectangles have the same roundness.

  Parameters

center	The center of the annulus.
radius1	The radii of the outer generalized rectangle.
radius2	The radii of the inner generalized rectangle.
orient	The orientation of the annulus.
round	The roundness of both generalized rectangles.

  Throws

  ccShapesError::BadRadius
  One of the radii is less than zero.

  ccShapesError::NotConcentric
  radius1 and *radius2* do not have the same center.

  Notes

  The components of *round* for each **ccGenRect** are internally clipped so that they do not exceed the corresponding components of *radii* for that **ccGenRect**.

- ```
  ccGenAnnulus(const cc2Vect& center,
    const cc2Vect& radius1,const cc2Vect& radius2,
    const ccRadian orient,
    const cc2Vect& round1, const cc2Vect& round2);
  ```

  Creates a generalized annulus. Each generalized rectangle has its own roundness.

  Parameters

center	The center of the annulus.
radius1	The radii of the outer generalized rectangle.
radius2	The radii of the inner generalized rectangle.
orient	The orientation of the annulus.
round1	The roundness of the outer generalized rectangle.
round2	The roundness of the inner generalized rectangle.

Throws

ccShapesError::BadRadius
One of the radii is less than zero.

ccShapesError::NotConcentric
radius1 and *radius2* do not have the same center.

Notes

The components of *round1* and *round2* are internally clipped, if necessary, so that they do not exceed the corresponding components of *radii1* and *radii2*, respectively.

- `ccGenAnnulus(const ccGenRect& r1, const ccGenRect& r2);`

Creates a generalized annulus from two generalized rectangles.

Parameters

r1 The generalized rectangle.

r2 The generalized rectangle.

Throws

ccShapesError::BadRadius
One of the radii is less than zero.

ccShapesError::NotConcentric
r1 and *r2* do not have the same center.

- `ccGenAnnulus(const ccAnnulus& a);`

Conversion constructor. Constructs a **ccGenAnnulus** from the given **ccAnnulus**.

Parameters

a The **ccAnnulus**.

Throws

ccShapesError::BadRadius
Either of *a*'s radii is less than or equal to zero.

ccShapesError::NotConcentric
a's radii do not have the same center.

Operators

operator== `bool operator==(const ccGenAnnulus& that) const;`

Returns true if this generalized annulus is equal to that, false otherwise.

Parameters

that The other generalized annulus.

operator!=

```
bool operator!=(const ccGenAnnulus& that) const;
```

Returns true if this generalized annulus is not equal to that, false otherwise.

Parameters

that The other generalized annulus.

Public Member Functions

center

```
ccPoint center () const;
```

Returns the center of the generalized annulus.

innerRadius

```
cc2Vect innerRadius() const;
```

Returns the radii of the inner generalized rectangle.

Notes

The **innerRadius()** and **outerRadius()** of the generalized annulus are silently swapped if the **innerRadius()** is outside the **outerRadius()**.

outerRadius

```
cc2Vect outerRadius() const;
```

Returns the radii of the outer generalized rectangle.

Notes

The **innerRadius()** and **outerRadius()** of the generalized annulus are silently swapped if the **innerRadius()** is outside the **outerRadius()**.

orient

```
ccRadian orient () const;
```

Returns the orientation of the generalized annulus.

round

```
cc2Vect round () const;
```

Returns the roundness of the inner generalized rectangle.

innerRound

```
cc2Vect innerRound() const;
```

Returns the roundness of the inner generalized rectangle.

outerRound

```
cc2Vect outerRound() const;
```

Returns the roundness of the outer generalized rectangle.

innerGenRect

```
const ccGenRect& innerGenRect() const;
```

Returns the inner generalized rectangle.

outerGenRect

```
const ccGenRect& outerGenRect() const;
```

Returns the inner generalized rectangle.

map

```
ccGenAnnulus map(const cc2Xform& c) const;
```

Returns a generalized annulus that is the result of mapping this generalized annulus with the transformation object *c*.

Parameters

c	The transformation object.

Notes

The transform *c* must be singular. If it is not, use **mapShape()** instead.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this generalized annulus.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For generalized annuli, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For generalized annuli, this function always returns true, including generalized annuli that are degenerate. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For generalized annuli, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For generalized annuli, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

For generalized annuli, this function returns true if **hasTangent()** is true for either the inner or outer generalized rectangle. It returns false if **hasTangent()** is false for both the inner and outer rectangles. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For generalized annuli, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For generalized annuli, this function always returns false. See **ccShape::reverse()** for more information.

isRightHanded `virtual bool isRightHanded() const;`

Returns true if this generalized annulus is right-handed. See **ccShape::isRightHanded()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the smallest rectangle that encloses this generalized annulus. See **ccShape::boundingBox()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns the nearest point on the boundary of this generalized annulus to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this generalized annulus to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this generalized annulus.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores generalized annuli for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this generalized annulus mapped by *X*.

Parameters

X	The transformation object.

Notes

If the transform *X* is singular, this function returns a **ccRegionTree**. Otherwise it returns a **ccGenAnnulus**.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccLineSeg**s and, if the underlying **ccGenRect**s have rounded corners, **ccEllipseArcs**. See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect&) const;
```

Returns true if the given point is within this generalized annulus.

Parameters

p The point.

Notes

This function returns false if either of the underlying rectangles is degenerate.

See **ccShape::within()** for more information.

subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this generalized annulus over the given perimeter range.

Parameters

info Shape information for this shape.

range The perimeter range.

See **ccShape::subShape()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

ccGeneralShapeTree

```
#include <ch_cvl/shaptree.h>

class ccGeneralShapeTree : public ccShapeTree;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccGeneralShapeTree** class is a concrete class for maintaining arbitrary hierarchies of shapes. There are no constraints on the number or types of children any node in the hierarchy may have.

Constructors/Destructors

ccGeneralShapeTree

```
ccGeneralShapeTree();
```

Default constructor. Constructs a **ccGeneralShapeTree** containing no children.

Copies and assignments are shallow, that is, they are achieved by copying pointer handles. Hence, these operations lead to sharing of children between different **ccShapeTree**s.

Public Member Functions

connect

```
ccGeneralShapeTreePtrh connect(const double tolerance)
  const;
```

Connects the immediate children of this general shape tree into longer contours where possible. The returned tree contains the same children as this tree, with the following modifications:

- General shape tree children of this general shape tree are recursively connected.

- Any connectable open contour children of this tree are connected into contour trees, which become initial children of the result tree. These contour trees will contain as many children as can be connected into a single chain, and may be open or closed depending on the topology of the connections. Thus, the open contour children of this tree may appear either as direct children of the result tree, or within new contour trees that are direct children of the result tree.
- All non-connectable children (closed contours) of the original tree appear last among the children of the returned tree.

Two open contour shapes are connectable if the distance between two of their end points (one from each contour) is less than the specified tolerance. Each end point may be connected to at most one other end point. If end points from a number of different contours are mutually within the specified tolerance from each other, the algorithm connects the closest end points first. An open contour may be connected to itself if the distance between its start point and end point is less than the tolerance.

The connection algorithm automatically checks all combinations of end points for possible connections. For example, there are four possible ways to connect two line segments, as either the start or end point of each segment may be chosen for the connection. In constructing contour trees from the connected shapes, the component shapes are reversed when necessary to maintain the contour tree constraint that the end point of child *i* is implicitly connected to the start point of child *i*+1.

There are two choices for the direction of the final connected contour. The algorithm chooses whichever direction requires fewer reversals of individual component shapes.

Parameters

tolerance	The maximum distance between endpoints of different open contours that can be connected to each other.

Notes

The **connect()** method requires two or more open contours in order to build a connected, closed contour. It will not connect the endpoints of a single closed contour.

This method recursively processes an entire shape hierarchy. However, only open-contour shapes that have the same general shape tree parent are candidates for connection. Thus, general shape tree nodes can be used to partition the connection candidates. In some applications, it may be useful to call **flatten()** before calling **connect()**.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this general shape tree.

isOpenContour `virtual bool isOpenContour() const;`

For general shape trees, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion `virtual bool isRegion() const;`

For general shape trees, this function always returns false. See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

Returns true if all primitive shapes in the hierarchy are finite. See **ccShape::isFinite()** for more information.

isReversible `virtual bool isReversible() const;`

Returns true if and only if all descendants of this **ccGeneralShapeTree** are reversible. See **ccShape::isReversible()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns the nearest point on the boundary of this general shape tree to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p The point.

Notes

The nearest point to *p* is taken among all primitives in the hierarchy.

See **ccShape::nearestPoint()** for more information.

reverse `virtual ccShapePtrh reverse() const;`

Returns the reversed version of this general shape tree.

Notes

This method reverses the individual primitives of the hierarchy and their order within the hierarchy.

See **ccShape::reverse()** for more information.

sample

```
virtual void sample(const ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this general shape tree.

Parameters

params Parameters object specifying details of how the sampling should be done.

result Result object to which position and tangent chains are stored.

Notes

A separate chain is generated for each primitive in the hierarchy.

See **ccShape::sample()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this general shape tree over the given perimeter range.

Parameters

info Shape information for this general shape tree.

range The perimeter range.

See **ccShape::subShape()** for more information.

ccGenPoly

```
#include <ch_cvl/genpoly.h>

class ccGenPoly : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	Complex

The **ccGenPoly** class encapsulates a general polygon shape consisting of sequentially connected 2D arc and line segments connected at vertices. Each vertex is specified by a point and a rounding size. The vertex point specifies the coordinate of the vertex. The rounding size specifies the circular radius of rounding of the vertex. The general polygon object is created incrementally by adding vertices one at a time, and adjusting the curvature of the resulting segments for rounding.

See the *Shapes* chapter in the *CVL User's Guide* for more information.

Constructors/Destructors

ccGenPoly

```
ccGenPoly();
ccGenPoly(const ccLineSeg& ls);
ccGenPoly(const ccRect& rect);
ccGenPoly(const ccCircle& circle);
ccGenPoly(const ccEllipse2& ellipse);
ccGenPoly(const ccEllipseArc2& ellArc);
ccGenPoly(const ccGenRect& gr);
ccGenPoly(const ccEllipseAnnulusSection& eas);
ccGenPoly(const ccGenPoly & gp);
virtual ~ccGenPoly();
```

- `ccGenPoly();`

  Constructs a general polygon object with no vertices or segments.

- `ccGenPoly(const ccLineSeg& ls);`

  Conversion constructor. Constructs a mutable **ccGenPoly** object based on an object of type **ccLineSeg**, a straight line between two points. See the following example:

  Parameters

  ls An object of type **ccLineSeg**.

- `ccGenPoly(const ccRect& rect);`

  Conversion constructor. Constructs a mutable **ccGenPoly** object based on an object of type **ccRect**, a rectangle at point p, of width w, and length l. See the following example:

  Parameters

  rect An object of type **ccRect**.

- `ccGenPoly(const ccCircle& circle);`

  Conversion constructor. Constructs a mutable **ccGenPoly** object based on an object of type **ccCircle**, a circle at point p with a radius r. See the following example:

  Parametersh

  circle An object of type **ccCircle**.

- `ccGenPoly(const ccEllipse2& ellipse);`

  Conversion constructor. Constructs an immutable **ccGenPoly** object based on an object of type **ccEllipse2**, an ellipse as shown in the following example:

  Parameters

  ellipse An object of type **ccEllipse2**.

- `ccGenPoly(const ccEllipseArc2& ellArc);`

  Conversion constructor. Constructs an immutable **ccGenPoly** object based on an object of type **ccEllipseArc2**. An ellipse arc is a partial ellipse with the end points specified by the angles ϕ_1 and ϕ_2. See the following example:

  Parameters

  ellArc An object of type **ccEllipseArc2**.

- `ccGenPoly(const ccGenRect& gr);`

  Conversion constructor. Constructs an immutable **ccGenPoly** object based on an object of type **ccGenRect**, a general rectangle at angle θ in x,y space. The rectangle is defined by its center point (c) and r_1 and r_2 which are half the length and half the width respectively. See the following example:

  Parameters

  gr An object of type **ccGenRect**.

- `ccGenPoly(const ccEllipseAnnulusSection& eas);`

  Conversion constructor. Constructs an immutable **ccGenPoly** object based on an object of type **ccEllipseAnnulusSection**, a partial ellipse annulus with the end points specified by the angles ϕ_1 and ϕ_2. See the following example:

  Parameters

  eas An object of type **ccEllipseAnnulusSection**.

- `ccGenPoly(const ccGenPoly & gp);`

  Copy constructor. If *gp* is immutable, the constructed copy will also be immutable. If *gp* is mutable, the constructed copy will also be mutable.

Parameters

gp The **ccGenPoly** object to copy.

- `virtual ~ccGenPoly();`

  Destructor. Frees memory and deletes the object.

Operators

operator= `ccGenPoly & operator=(const ccGenPoly & gp);`

Assignment operator. If *gp* is immutable, the assigned object will also be immutable. If *gp* is mutable, the assigned object will also be mutable.

Parameters

gp The assignment source object.

operator== `bool operator==(const ccGenPoly& other) const;`

This operator allows you to compare two **ccGenPoly** objects. For example,

```
if(poly1 == poly2) {.....}
```

The equality expression evaluates to *true* if the objects are equal. It is *false* if they are not equal. Two general polygons are considered equal only if vertex and segment information is the same to within reasonable floating point precision.

Notes

Immutable general polygons that have been mapped by different sequences of linear transformations will in general not be considered equal unless they are equal before they are mapped.

Parameters

other The right-hand **ccGenPoly** object. For example, *`poly2`*.

operator!= `bool operator!=(const ccGenPoly& other) const;`

This operator allows you to compare two **ccGenPoly** objects. For example,

```
if(poly1 != poly2) {.....}
```

The inequality expression evaluates to *true* if the objects are not equal. It is *false* if they are equal. Two general polygons are considered equal only if vertex and segment information is the same to within reasonable floating point precision.

Notes

Immutable general polygons that have been mapped by different sequences of linear transformations will in general not be considered equal unless they are equal before they are mapped.

Parameters

other The right-hand **ccGenPoly** object. For example, *poly2*.

Public Member Functions

convert

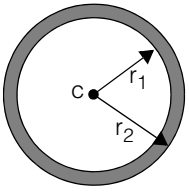
```
static cmStd vector<ccGenPoly> convert(
  const ccAnnulus& annulus);

static cmStd vector<ccGenPoly> convert(
  const ccGenAnnulus& gen_annulus);

static cmStd vector<ccGenPoly> convert(
  const ccEllipseAnnulus& ellipse_annulus);
```

- ```
  static cmStd vector<ccGenPoly> convert(
    const ccAnnulus& annulus);
  ```

Returns an equivalent pair of mutable general polygon objects for the annulus provided. The routine returns one **ccGenPoly** for the inside circle, and one for the outside circle. See the example annulus below:

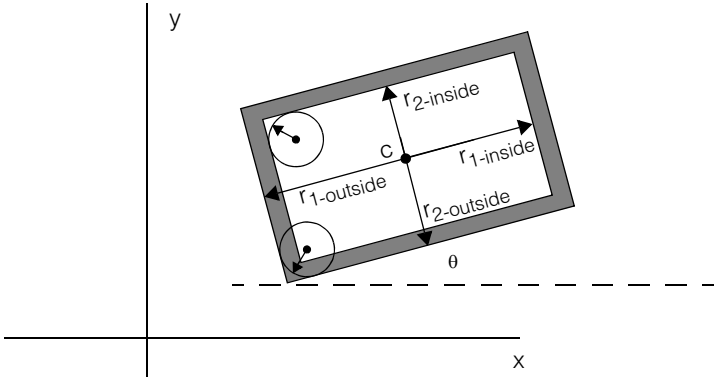


Parameters

annulus The annulus object to convert.
  ```

- `static cmStd vector<ccGenPoly> convert(`
  `const ccGenAnnulus& gen_annulus);`

  Returns an equivalent pair of mutable general polygon objects for the general annulus provided. The routine returns one **ccGenPoly** for the inside rectangle, and one for the outside rectangle. See the example below:

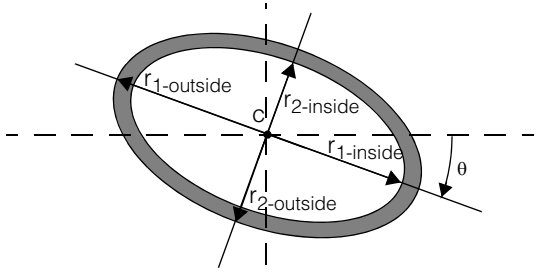


Parameters

gen_annulus The general annulus object to convert.

- `static cmStd vector<ccGenPoly> convert(`
  `const ccEllipseAnnulus& ellipse_annulus);`

  Returns an equivalent pair of mutable general polygon objects for the ellipse annulus provided. The routine returns one **ccGenPoly** for the inside ellipse, and one for the outside ellipse. See the example below:



Parameters

ellipse_annulus The ellipse annulus object to convert.

isMutable `bool isMutable() const;`

Returns *true* if this object is mutable; returns *false* otherwise.

numVertices

```
c_Int32 numVertices() const;
```

Returns the number of vertices in the general polygon contained in this object.

numSegments

```
c_Int32 numSegments() const;
```

Returns the number of segments in the general polygon contained in this object.

isOpen

```
bool isOpen() const;
```

Returns *true* if the general polygon in this object is open; returns *false* if the general polygon is closed.

degen

```
bool degen() const;
```

Returns *true* if the general polygon in this object is degenerate (contains fewer than 2 vertices). Returns *false* otherwise.

insertVertex

```
void insertVertex(
  const cc2Vect & vertexPoint,
  double roundingSize = 0.0,
  const ccRadian & previousSegmentAngleSpan =
                                              ccRadian(0.0));

void insertVertex(
  c_Int32 previousVertexIndex,
  const cc2Vect & vertexPoint,
  double roundingSize = 0.0,
  const ccRadian & previousSegmentAngleSpan =
                                              ccRadian(0.0));
```

-
```
void insertVertex(
  const cc2Vect & vertexPoint,
  double roundingSize = 0.0,
  const ccRadian & previousSegmentAngleSpan =
                                              ccRadian(0.0));
```

Inserts the specified vertex after the last vertex in the general polygon. The vertex rounding and previous segment angle span are also specified.

Parameters

vertexPoint	The x,y location of the inserted vertex.
roundingSize	The vertex rounding size.

previousSegmentAngleSpan
The previous segment angle span.

- ```
  void insertVertex(
    c_Int32 previousVertexIndex,
    const cc2Vect & vertexPoint,
    double roundingSize = 0.0,
    const ccRadian & previousSegmentAngleSpan =
                                                ccRadian(0.0));
  ```

  Inserts the specified vertex after the vertex with index *previousVertexIndex*. The vertex rounding and previous segment angle span are also specified.

  If *previousVertexIndex* = -1, the new vertex will become the first vertex.

  In all cases, vertex indices beyond the new vertex increase by 1 as a result of adding a new vertex.

  Parameters

  previousVertexIndex
  The index of the vertex prior to where the new vertex is inserted. A -1 indicates the new vertex should be the first vertex (index 0).

  vertexPoint The x,y location of the inserted vertex.

  roundingSize The vertex rounding size.

  previousSegmentAngleSpan
  The previous segment angle span.

  Throws

  ccShapesError::BadGeom
  If the resulting general polygon contains any crossing segments.

  ccShapesError::BadRadius
  If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

  ccShapesError::BadCoef
  If *previousVertexIndex* is not a valid vertex index or not -1.

  ccShapesError::BadGeom
  If **isMutable()** = *false*.

  Notes

  The general polygon is unaffected in case of any throw.
  ```

replaceVertex

```
void replaceVertex(
  c_Int32 vertexIndex,
  const cc2Vect & vertexPoint,
  double roundingSize = 0.0);

void replaceVertex(
  c_Int32 vertexIndex,
  const cc2Vect & vertexPoint,
  double roundingSize,
  const ccRadian & previousSegmentAngleSpan);
```

- ```
  void replaceVertex(
    c_Int32 vertexIndex,
    const cc2Vect & vertexPoint,
    double roundingSize = 0.0);
  ```

  Replaces the vertex with the specified index. The new segment angle span is the same as segment angle span of the replaced vertex.

  Parameters

  vertexIndex The index of the vertex to be replaced.

  vertexPoint The new vertex point.

  roundingSize The rounding size of the new vertex.

  Throws

  ccShapesError::BadGeom
  If the resulting general polygon contains any crossing segments.

  ccShapesError::BadRadius
  If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

  ccShapesError::BadCoef
  If *vertexIndex* is not a valid vertex index.

  ccShapesError::BadGeom
  If **isMutable()** = *false*.

  ccShapesError::BadGeom
  If the specified vertex is an end vertex of an open shape and the rounding size is not zero.

  Notes

  The general polygon is unaffected in case of any throw.
  ```

- ```
  void replaceVertex(
    c_Int32 vertexIndex,
    const cc2Vect & vertexPoint,
    double roundingSize,
    const ccRadian & previousSegmentAngleSpan);
  ```

  Replaces the vertex with the specified index. A new segment angle span is specified.

  Parameters

  vertexIndex The index of the vertex to be replaced.

  vertexPoint The new vertex point.

  roundingSize The rounding size of the new vertex.

  previousSegmentAngleSpan
  The angle span of the segment entering the vertex.

  Throws

  ccShapesError::BadGeom
  If the resulting general polygon contains any crossing segments.

  ccShapesError::BadRadius
  If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

  ccShapesError::BadCoef
  If *vertexIndex* is not a valid vertex index.

  ccShapesError::BadGeom
  If **isMutable()** = *false*.

  ccShapesError::BadGeom
  If the specified vertex is an end vertex of an open shape and the rounding size is not zero.

  ccShapesError::BadGeom
  If the shape is open and the *previousSegmentAngleSpan* is non-zero for the first vertex (vertex 0).

  Notes

  The general polygon is unaffected in case of any throw.
  ```

deleteVertex `void deleteVertex(c_Int32 vertexIndex);`

Removes the vertex with index *vertexIndex*. The resulting segment between the vertex with index *vertexIndex*-1 and the vertex with index *vertexIndex*+1 retains the segment angle span of the segment with index *vertexIndex*+1 modulo N (where N is the number of vertices before the delete).

The indices for all vertices with index greater than or equal to *vertexIndex* will decrease by 1 following this operation.

Parameters

vertexIndex The index of the vertex to delete.

Throws

ccShapesError::BadGeom
If **numVertices()** < 2 and the general polygon is closed.

ccShapesError::BadGeom
If the resulting general polygon contains any crossing segments.

ccShapesError::BadRadius
If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index.

ccShapesError::BadGeom
If **isMutable()** = *false*.

Notes

The general polygon is unaffected in case of any throw.

open `void open();`

Opens the general polygon. Disconnects the index 0 vertex from the vertex with the largest index. There is no effect if the general polygon is already open.

Throws

ccShapesError::BadGeom
If **isMutable()** = *false*.

close

```
void close(
  const ccRadian & segmentAngleSpan = ccDegree(0));
```

Closes the general polygon. It connects the vertex with the largest index to the vertex with the smallest index using a segment with the specified *segmentAngleSpan*. There is no effect if the general polygon is already closed.

segmentAngleSpan
The segment angle span for the segment added when the polygon is closed.

Throws

ccShapesError::BadGeom
If the resulting general polygon contains any crossing segments.

ccShapesError::BadGeom
If **isMutable()** = *false*.

Notes

The general polygon is unaffected in case of any throw.

---

vertexPoint

```
cc2Vect vertexPoint(c_Int32 vertexIndex) const;

void vertexPoint(
  c_Int32 vertexIndex,
  const cc2Vect & newVertexPoint);
```

- ```
  cc2Vect vertexPoint(c_Int32 vertexIndex) const;
  ```

  Returns the vertex point for the vertex whose index is *vertexIndex*.

  Parameters

  vertexIndex The index of the vertex you wish to retrieve.

- ```
  void vertexPoint(
    c_Int32 vertexIndex,
    const cc2Vect & newVertexPoint);
  ```

  Sets a new vertex point for the vertex whose index is *vertexIndex*. The rounding size is unaffected.

  Parameters

  vertexIndex The index of the vertex you wish to set.

  newVertexPoint The new vertex point.

Throws

ccShapesError::BadGeom
If the resulting general polygon contains any crossing segments.

ccShapesError::BadRadius
If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index.

ccShapesError::BadGeom
If **isMutable()** = *false*.

Notes

The general polygon is unaffected in case of any throw.

vertexRoundingSize

```
double vertexRoundingSize(c_Int32 vertexIndex) const;

void vertexRoundingSize(
  c_Int32 vertexIndex,
  double newVertexRoundingSize);
```

- `double vertexRoundingSize(c_Int32 vertexIndex) const;`

  Returns the vertex rounding size for the vertex specified by *vertexIndex*.

  Parameters

  vertexIndex The index of the vertex whose rounding size you want returned.

- ```
  void vertexRoundingSize(
    c_Int32 vertexIndex,
    double newVertexRoundingSize);
  ```

  Sets a new vertex rounding size for the vertex specified by *vertexIndex*.

  Parameters

  vertexIndex The index of the vertex whose rounding size you wish to set.

  newVertexRoundingSize
  The new vertex rounding size.

  Throws
  ```

ccShapesError::BadRadius
If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index.

ccShapesError::BadGeom
If the specified vertex is an end vertex of an open shape and the rounding size is not zero.

ccShapesError::BadGeom
If **isMutable()** = *false*.

Notes

The general polygon is unaffected in case of any throw.

vertexRoundingSizes

```
void vertexRoundingSizes(double newVertexRoundingSize);
```

Sets the rounding sizes for all the vertices in the general polygon.

Parameters

newVertexRoundingSize
The new rounding size.

Throws

ccShapesError::BadRadius
If any of the rounding sizes in the resulting general polygon are invalid (cause an intersection, or are too large).

ccShapesError::BadGeom
If **isMutable()** = *false*.

Notes

The general polygon is unaffected in case of any throw.

roundedVertexArc

```
ccEllipseArc2 roundedVertexArc(c_Int32 vertexIndex) const;
```

Returns the elliptical arc corresponding to the rounded portion of the vertex with the specified index.

Parameters

vertexIndex The vertex index corresponding to the elliptical arc you wish returned.

Throws

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index,
or if the specified vertex is not rounded (rounding size = 0).

segmentAngleSpan

```
ccRadian segmentAngleSpan(c_Int32 segmentIndex) const;

void segmentAngleSpan(
  c_Int32 segmentIndex,
  const ccRadian &newSegmentAngleSpan);
```

- `ccRadian segmentAngleSpan(c_Int32 segmentIndex) const;`

Returns the segment angle span for the segment specified by *segmentIndex*.

Parameters

segmentIndex The index of the segment corresponding to the segment angle span you want returned.

- `void segmentAngleSpan(`
  `c_Int32 segmentIndex,`
  `const ccRadian &newSegmentAngleSpan);`

Sets a new segment angle span for the segment specified by *segmentIndex*.

Parameters

segmentIndex The index of the segment corresponding to the segment angle span you wish to set.

newSegmentAngleSpan
The new segment angle span.

Throws

ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

ccShapesError::BadGeom
If this call causes segments to intersect.

Notest

The general polygon is unaffected in case of any throw.

isLineSegment

```
bool isLineSegment(c_Int32 segmentIndex) const;
```

Returns *true* if the segment with the specified index is a line segment (segment angle span equals 0); returns *false* otherwise. This function returns the opposite of **isArcSegment()**.

Parameters

segmentIndex The index of the segment you wish to query.

Throws

ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

isArcSegment

```
bool isArcSegment(c_Int32 segmentIndex) const;
```

Returns *true* if the segment with the specified index is an arc (has a non-zero segment angle span); returns *false* otherwise. This function returns the opposite of **isLineSegment()**.

Parameters

segmentIndex The index of the segment you wish to query.

Throws

ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

ellipseSegment

```
ccEllipseArc2 ellipseSegment(c_Int32 segmentIndex,
  bool ignoreRounding = true) const;
```

Returns the elliptical arc corresponding to the segment with the specified index. If *ignoreRounding* is true, the arc is determined as if there were no rounding at the vertices at each end of the segment. Otherwise, it is determined only by that portion of the segment which is unaffected by the rounding at the vertices at each end of the segment.

Parameters

segmentIndex The index of the segment whose arc you want returned.

ignoreRounding The ignore rounding choice; *true* or *false*.

Throws

ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

ccShapesError::BadGeom
If the specified segment is not an arc (is a line segment).

lineSegment

```
ccLineSeg lineSegment(
  c_Int32 segmentIndex,
  bool ignoreRounding = true) const;
```

Returns the line segment corresponding to the segment with the specified index. If *ignoreRounding* is true, the segment is determined as if there were no rounding at the vertices at each end of the segment. Otherwise, it is determined only by that portion of the segment which is unaffected by the rounding at the vertices at each end of the segment.

Parameters

segmentIndex The index of the segment whose line you want returned.

ignoreRounding The ignore rounding choice; *true* or *false*.

Throws

ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

ccShapesError::BadGeom
If the specified segment is not a line segment (is an arc).

---

map

```
ccGenPoly map(
  const cc2Rigid& c,
  double scale = 1.0) const;

ccGenPoly map(const cc2Xform& c) const;
```

-
```
ccGenPoly map(
  const cc2Rigid& c,
  double scale = 1.0) const;
```

Returns this general polygon scaled by *scale*, and mapped by *c*. The returned general polygon is mutable.

Parameters

c The mapping transform.

scale The scale factor.

Throws

ccMathError::Singular
If *scale* = 0.

- `ccGenPoly map(const cc2Xform& c) const;`

  Returns this general polygon mapped by *c*. The returned general polygon is immutable unless **c.isIdentity()** is *true*.

  Parameters
  c

  Throws
  ccMathError::Singular
  If *c* is singular.

pos `cc2Vect pos() const;`

Returns the position of the general polygon. If there are >0 vertices in this general polygon, the position is defined by the first vertex. Otherwise, it is simply (0,0).

center `cc2Vect center() const;`

Returns the average position of the general polygon (center of mass of all of the vertex points). Returns (0,0) if there are no vertices in this general polygon.

previousVertexIndex

```
c_Int32 previousVertexIndex(c_Int32 segmentIndex) const;
```

Returns the index of the vertex that precedes the segment with index *segmentIndex*.

Parameters
segmentIndex The segment index.

Throws
ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

nextVertexIndex

```
c_Int32 nextVertexIndex(c_Int32 segmentIndex) const;
```

Returns the index of the vertex that follows the segment with index *segmentIndex*.

Parameters
segmentIndex The segment index.

Throws
ccShapesError::BadCoef
If *segmentIndex* is not a valid segment index.

previousSegmentIndex

```
c_Int32 previousSegmentIndex(c_Int32 vertexIndex) const;
```

Returns the index of the segment that precedes the vertex with index *vertexIndex*. Returns -1 if there is no such segment.

Parameters

vertexIndex The vertex index.

Throws

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index.

nextSegmentIndex

```
c_Int32 nextSegmentIndex(c_Int32 vertexIndex) const;
```

Returns the index of the segment that follows the vertex with index vertexIndex. Returns -1 if there is no such segment.

Parameters

vertexIndex The vertex index.

Throws

ccShapesError::BadCoef
If *vertexIndex* is not a valid vertex index.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this generalized polygon.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if and only if this generalized polygon is open and has at least one vertex. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if and only if this generalized polygon is closed and has at least one vertex. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For generalized polygons and **cc2Wireframe**s (derived from **ccGenPoly**), this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if this generalized polygon has no vertices, otherwise false. See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

This function returns true for most generalized polygons. It returns false if this generalized polygon contains no line segments or arcs. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

For generalized polygons, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible `virtual bool isReversible() const;`

For generalized polygons, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the smallest rectangle that encloses this generalized polygon.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

See **ccShape::boundingBox()** for more information.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const;`

Returns the nearest point on the boundary of this generalized polygon to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p The point.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

See **ccShape::nearestPoint()** for more information.

startPoint `virtual cc2Vect startPoint() const;`

Returns the starting point of this generalized polygon if it is an open contour.

Throws

ccShapesError::NotOpenContour
This generalized polygon is not an open contour.

See **ccShape::startPoint()** for more information.

endPoint `virtual cc2Vect endPoint() const;`

Returns the ending point of this generalized polygon if it is an open contour.

Throws

ccShapesError::NotOpenContour
This generalized polygon is not an open contour.

See **ccShape::end Point()** for more information.

startAngle `virtual ccRadian startAngle() const;`

Returns the starting tangent direction of this generalized polygon if it is an open contour.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this generalized polygon.

ccShapesError::NoTangent
hasTangent() is false for this generalized polygon.

See **ccShape::startAngle()** for more information.

endAngle `virtual ccRadian endAngle() const;`

Returns the ending tangent direction of this generalized polygon if it is an open contour.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this generalized polygon.

ccShapesError::NoTangent
hasTangent() is false for this generalized polygon.

See **ccShape::endAngle()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this generalized polygon. See **ccShape::reverse()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns the net signed angle through which the tangent vector rotates from the start point to the end point.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this generalized polygon.

ccShapesError::NoTangent
hasTangent() is false for this generalized polygon.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

Parameters

p The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this generalized polygon.

See **ccShape::windingAngle()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true of the given point is within this generalized polygon.

Parameters

p The point.

See **ccShape::within()** for more information.

isRightHanded

```
bool isRightHanded() const;
```

Returns true if and only if this generalized polygon is right-handed.

Throws

ccShapesError::NotRegion
This generalized polygon is not a region.

Notes

The value returned by this function is undefined for self-intersecting polygons.

See **ccShape::isRightHanded()** for more information.

sample

```
void sample(const ccShape::ccSampleParams &params,
 ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores generalized polygons for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

Throws

ccShapesError::SampleOverflow
Supplied spacing and tolerance bounds require more than *maxPoint* samples to be generated. See **ccSampleParams** for details.

mapShape

```
ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this generalized polygon mapped by *X*.

Parameters

X	The transformation object.

Notes

The returned shape may be a **ccContourTree**.

See **ccShape::mapShape()** for more information.

decompose

```
ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccLineSeg**s and **ccEllipseArc2**s. See **ccShape::decompose()** for additional information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccGenPoly

```
ccGenPoly(const ccPolygon&);
ccGenPoly(const ccEllipse&);
ccGenPoly(const ccEllipseArc&);
```

Use conversion constructors that use references to supported shapes as arguments instead of these versions.

roundedVertex

```
ccEllipseArc roundedVertex(c_Int32 vertexIndex) const;
```

Use **roundedVertexArc()** instead of this function.

arcSegment

```
ccEllipseArc arcSegment(c_Int32 segmentIndex,
  bool ignoreRounding = true) const;
```

Use **ellipseSegment()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
ccRect encloseRect(const cc2Xform& xform) const;
```

Both overloads of this function are deprecated. Use **boundingBox()** instead.

distToPoint

```
double distToPoint(const cc2Vect & v) const;
```

Use **distanceToPoint()** instead of this function.

ccGenRect

```
#include <ch_cvl/shapes.h>

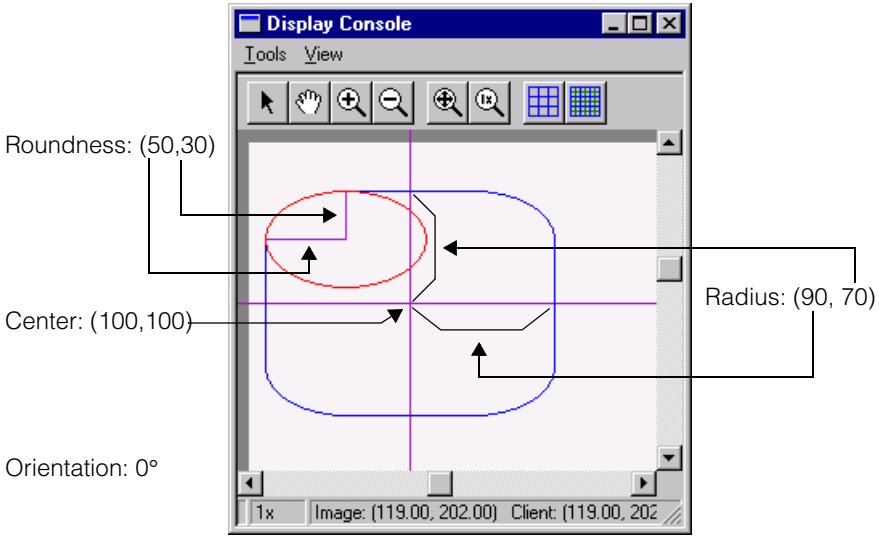
class ccGenRect : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccGenRect** class describes generalized rectangle. Unlike rectangles created by **ccRect**, generalized rectangles can be rotated. and can have rounded edges. To draw a generalized rectangle, you specify a center point, the radii of the rectangle, the roundness of the corners, and an orientation. The following figure illustrates a generalized rectangle.

```
ccGenRect(cc2Vect(100,100),cc2Vect(90,70),ccRadian(0.0),
          cc2Vect(50,30))
```



The **ccGenRect** constructors provide other ways of creating a generalized rectangle.

Note The **ccGenRect** class is immutable except for assignment. As such, it has neither setters nor any non-const members other than constructors, assignment operators, and serialization methods. Once a **ccGenRect** is constructed, the only way to change it is to assign to it or to serialize it (that is, to load to it from an archive).

Constructors/Destructors

ccGenRect

```
ccGenRect();

ccGenRect(const ccGenRect& gr);

ccGenRect(const cc2Vect& cnt, const cc2Matrix& U,
  const cc2Vect& uround);

ccGenRect(const cc2Vect& cnt, const cc2Vect& radii,
  const ccRadian& orient, const cc2Vect& round);

ccGenRect(const ccRect& r);

ccGenRect(const ccEllipse2& e);
```

- `ccGenRect();`

  The default constructor creates a degenerate rectangle.

  Notes

  The default constructor is provided to support arrays and STL containers. Do not try to examine or use a default-constructed **ccGenRect**.

- `ccGenRect(const ccGenRect& gr);`

  Copy constructor. Creates a copy of an existing generalized rectangle.

  Parameters

gr	The existing generalized rectangle, which must not be degenerate.

- ```
  ccGenRect(const cc2Vect& cnt, const cc2Matrix& U,
    const cc2Vect& uround);
  ```

  Creates a generalized rectangle by applying the matrix *U* and the unit vector *uround* (for corner roundness) to an ideal 1 x 1 rectangle.

  Let R be the constructed generalized rectangle (ignoring rounding for the moment), and let R' be a translated version of R centered at the origin. Finally, let C be a canonical 2 x 2 rectangle over the range [-1, +1] x [-1, +1]. The matrix *U* specifies the map from R' to C. Hence, the constructed generalized rectangle (without rounding) if generated by mapping the canonical rectangle *C* by **U.inverse()** and then translating by *cnt*.

  The normalized roundness vector specifies the degree of corner rounding in the x- and y-directions of the canonical rectangle *C* (not of *R*). Therefore, the components of *uround* are meaningful over the range 0 through 1. A roundness value of 0.0 specifies no corner rounding. A roundness value of 1.0 specifies complete corner rounding. For example, if **uround.x()** == 1.0, the x sides of the canonical rectangle will consist entirely of rounded corners, with no straight segment between them. The constructed generalized rectangle (with rounding) is generated by mapping the rounded canonical rectangle *C* by **U.inverse()** and then translating by *cnt*.

  Since *U* may include scaling, rotation, skew, and aspect, this is the most general constructor for generalized rectangles. It is recommended, however, that generalized rectangles with skew be avoided. Although geometric operations on such generalized rectangles will be correct, they may not display correctly.

  Parameters

cnt	The center of the rectangle.
U	A matrix that specifies the rotation and scale of the rectangle.
uround	The roundness of the rectangle's corners.

- ```
  ccGenRect(const cc2Vect& cnt, const cc2Vect& radii,
    const ccRadian& orient, const cc2Vect& round);
  ```

  Creates a generalized rectangle given a center, two radii, and orientation, and roundness as shown in the illustration at the beginning of this reference page.

  The roundness vector specifies the degree of corner rounding in the x- and y-directions of the generalized rectangle. The value **round.x()** is meaningful over the range 0 through **radii.x()**; other values are clipped to this range internally. The analogous statement holds for **round.y()** and **radii.y()**. A roundness value of 0.0 specifies no corner rounding. A roundness value equal to the corresponding radius value specifies complete corner rounding. For example, if **round.x()** == **radii.x()**, the x-sides of the generalized rectangle will consist entirely of rounded corners, with no straight segment between them.

Parameters

cnt The center of the rectangle.

radii The radii of the rectangle (half-height and half-width).

orient The orientation of the rectangle measured from the x-axis.

round The roundness of the rectangle's corners.

Throws

ccShapesError::BadRadius
If either component of radii is not positive.

- `ccGenRect(const ccRect& r);`

Construct a generalized rectangle that has the same geometry as the rectangle *r*. The rectangle *r* must not be degenerate.

Parameters

r The rectangle to copy.

- `ccGenRect(const ccEllipse2& e);`

Construct a generalized rectangle that has the same geometry as the ellipse *e*. The ellipse *e* must not be degenerate.

Parameters

e The ellipse to copy.

Throws

ccShapesError::BadRadius
One of the ellipse radii is less than zero.

Operators

operator== `bool operator==(const ccGenRect& that) const;`

Returns true if this generalized rectangle is equal to that, false otherwise.

Parameters

that The other generalized rectangle.

operator!= `bool operator!=(const ccGenRect& that) const;`

Returns true if this generalized rectangle is not equal to that, false otherwise.

Parameters

that The other generalized rectangle.

Public Member Functions

center

```
const ccPoint& center() const;
```

Returns the center of this generalized rectangle.

U

```
const cc2Matrix& U() const;
```

Returns the matrix used to transform the ideal 1x1 rectangle into a generalized rectangle.

radii

```
const cc2Vect& radii() const;
```

Returns the radii (half-height and half-width) of the generalized rectangle.

orient

```
ccRadian orient() const;
```

Returns the orientation of the generalized rectangle measured from the x-axis.

skew

```
ccRadian skew() const;
```

Returns the amount by which the generalized rectangle is skewed.

round

```
cc2Vect round() const;
```

Returns the roundness of the corners of the generalized rectangle.

uround

```
const cc2Vect& uround() const;
```

Returns the roundness of the generalized rectangle as a unit vector.

map

```
ccGenRect map(const cc2Xform& c) const;
```

Returns a generalized rectangle that is the result of mapping this generalized rectangle with the transformation object *c*.

Parameters

c The transformation object.

Notes

The transform *c* must be nonsingular. If it is not, use **mapshape()** instead.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this generalized rectangle.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For generalized rectangles, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For generalized rectangles, this function always returns true, even for generalized rectangles that are degenerate. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For generalized rectangles, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For generalized rectangles, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

This function returns true if the perimeter of this generalized rectangle is positive. It returns false if the perimeter is zero. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For generalized rectangles, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For generalized rectangles, this function always returns false. See **ccShape::reverse()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if this generalized rectangle is right-handed. See **ccShape::isRightHanded()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this generalized rectangle. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this generalized rectangle to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores generalized rectangles for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this generalized rectangle mapped by *X*.

Parameters

X	The transformation object.

Notes

If the transform *X* is singular, this function returns a closed **ccContourTree**. Otherwise this function returns a **ccGenRect**.

See **ccShape::mapShape()** for more information.

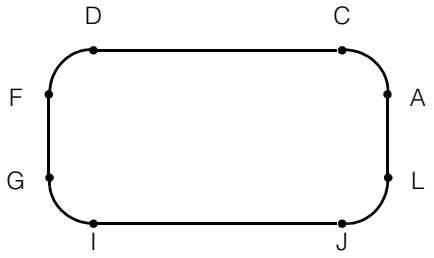
decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a closed **ccContourTree** consisting of connected **ccLineSeg**s and **ccEllipseArc2**s.

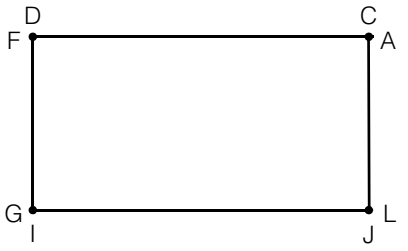
If the corners are rounded, the contour tree will have eight children in the following order:

1. Arc AC
2. Segment CD
3. Arc DF
4. Segment FG
5. Arc GI
6. Segment IJ
7. Arc JL
8. Segment LA



If the corners are not rounded, the contour tree will have four segment children in the following order:

1. Segment CD
2. Segment FG
3. Segment IJ
4. Segment LA



See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true of the given point is within this generalized polygon.

Parameters

p	The point.

See **ccShape::within()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

ccGenRect

```
ccGenRect(const ccEllipse& e);
```

Use the conversion constructor that uses a **ccEllipse2** reference instead of this version.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

ccGenRectData

```
struct ccGenRectData {
  ccPoint S;
  ccLineSeg CD, FG, IJ, LA;
  ccEllipseArc AC, DF, GI, JL;
  ccGenRectData ();
  ccGenRectData (const ccGenRect&);
  ccGenRectData (const ccGenRectData& grd,
     const cc2Xform &c);
};
```

Both the **ccGenRect::ccGenRectData** structure and the following function, which retrieves it, are deprecated.

genRectData

```
const ccGenRectData& genRectData() const;
```

ccGigEVisionCamera

```
#include <ch_cvl/vpgige.h>

class ccGigEVisionCamera : public ccUnknownFG
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes an individual GigE Vision-compliant camera connected to a computer system. There is one instance of this class for each connected camera. You use the static **get()** function to obtain a specific instance.

```
ccGigEVisionCamera& GECam = ccGigEVisionCamera::get(0);
```

Calling the **name()** function (a member of **ccBoard**, from which this class is derived) returns the name of the particular camera,

Many commonly used GigE vision camera features are supported directly through CVL image acquisition properties. For features that are not supported directly by CVL you can use the feature read/write functions such as **writeIntegerValue()** to access them directly.

In particular you should not use the feature read/write functions to modify the following GigE Vision features. If you do, the CVL acquisition system may behave erratically.

GigE Vision features used by CVL

AcquisitionMode	AcquisitionStart	AcquisitionStop
PixelFormat	TriggerMode	
ExposureTimeAbs	ExposureTimeRaw	
BlackLevelRaw	GainRaw	
OffsetX	OffsetY	
Width	Height	

Table 1.

Constructors/Destructors

A single instance of this class is created automatically for each GigE Vision camera connected to your system.

Public Member Functions

count

```
static c_Int32 count();
```

Returns the number of GigE Vision cameras found on the network.

Notes

If the cameras have not yet finished negotiating their connection with the network, this function may take up to several minutes to return.

get

```
static ccGigEVisionCamera& get(c_Int32 i = 0);
```

Returns a **ccGigEVisionCamera** object that represents the specified camera. The association between specific GigE Vision cameras and their index value is defined by the camera's IP address. You can also use the **name()** and **serialNumber()** functions to identify the camera returned by this function.

Parameters

i The index of the camera to get.

Throws

ccBoard::BadParams

i is less than zero or greater than or equal to **count()**.

Notes

For any given index value, the object returned by this function and the object returned by calling **ccBoard::get()** with the same index may not refer to the same device, since **ccBoard::get()** returns references to *all* devices, such as Cognex frame grabbers, not just GigE Vision cameras.

serialNumber

```
virtual ccCvlString serialNumber() const;
```

Returns the serial number of the GigE Vision camera. The format of the returned string is specific to the camera type.

resetTimeStamp

```
void resetTimeStamp();
```

Resets the timestamp counter in the camera to 0.

readTimeStamp

```
c_UInt64 readTimeStamp();
```

Returns the instantaneous timestamp counter value. The timestamp is an arbitrary counter. It was no relationship to clock time.

timeStampFrequency

```
c_UInt64 timeStampFrequency();
```

Returns the number timestamp counts per second.

readIntegerValue

```
c_Int32 readIntegerValue(ccCvlString nodeName);
```

Returns the integer value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name.

writeIntegerValue

```
void writeIntegerValue(ccCvlString nodeName,
   c_Int32 value);
```

Writes the integer value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

value The value to write.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name or *value* was not a valid value for this node.

readDoubleValue

```
double readDoubleValue(ccCvlString nodeName);
```

Returns the double value from associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name.

writeDoubleValue

```
void writeDoubleValue(ccCvlString nodeName, double value);
```

Writes the double value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

value The value to write.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name or *value* was not a valid value for this node.

readEnumValue

```
ccCvlString readEnumValue(ccCvlString nodeName);
```

Returns the enum value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name.

writeEnumValue

```
void writeEnumValue (ccCvlString nodeName,
                     ccCvlString value);
```

Writes the enum value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

value The value to write.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name or *value* was not a valid value for this node.

readValue

```
ccCvlString readValue(ccCvlString nodeName);
```

Returns the value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name.

writeValue

```
void writeValue (ccCvlString nodeName,
                 ccCvlString value);
```

Writes the value associated with the specified node name in the camera's definition file.

Parameters

nodeName The name of the node.

value The value to write. For nodes that describe Boolean values, the strings "1" and "0" are interpreted as True and False.

Notes

Use this function to access nodes for features that are not implemented directly in CVL. See Table 1 on page 1549 for a list of these features.

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name or *value* was not a valid value for this node.

executeCommand

```
void executeCommand(ccCvlString nodeName);
```

Executes the command specified by the *nodeName*.

Parameters

nodeName The name of the node.

Example

To save the current settings as "UserSet1", you would use the following code. (*fg* is a **ccGigEVisionCamera** object.)

```
fg.writeEnumValue(cmT("UserSetSelector"), cmT("UserSet1"));
fg.executeCommand(cmT("UserSetSave"));
```

Throws

ccGigEVisionCamera::FeatureError

nodeName was not a valid node name.

getCurrentIPAddress

```
void getCurrentIPAddress(c_Int32* addr,
                         c_Int32* subnetMask,
                         bool* isPersistent);
```

Gets the current IP address of the camera.

Parameters

addr	The IP address of the camera.
subnetMask	The subnet mask of the camera.
isPersistent	True if the address is persistent; False otherwise.

getHostIPAddress

```
void getHostIPAddress(c_Int32* addr, c_Int32* subnetMask);
```

Returns the IP address of the NIC the camera is attached to.

readTimeout

```
void readTimeout(const double seconds);

double readTimeout() const;
```

- `void readTimeout(const double seconds);`

  Sets the amount of time to wait in seconds for an Acknowledgement from the camera after a read operation is started. This includes the network communication time as well as the amount of time required by the camera to perform the requested operation.

  Throws

  ccBoard::BadParams
  The read timeout value is less than 1.0 second (1000 milliseconds).

- `double readTimeout() const;`

  Gets the amount of time to wait in seconds for an Acknowledgement from the camera after a read operation is started. This includes the network communication time as well as the amount of time required by the camera to perform the requested operation.

  Notes

  The default timeout value for reads is 1.0 second as recommended by the GigE Vision standard. This is also the minimum timeout value. There is no maximum value.

  Some cameras may require a timeout period longer than the default for some operations.

  If a camera read timeout occurs, a NetworkError exception will be thrown with the description "Receive Timeout".

writeTimeout

```
void writeTimeout(const double seconds);
double writeTimeout() const;
```

- `void writeTimeout(const double seconds);`

  Sets the amount of time to wait in seconds for an Acknowledgement from the camera after a write operation is started. This includes the network communication time as well as the amount of time required by the camera to perform the requested operation.

  Throws

  ccBoard::BadParams

  The write timeout value is less than 1.0 second (1000 milliseconds).

- `double writeTimeout() const;`

  Gets the amount of time to wait in seconds for an Acknowledgement from the camera after a write operation is started. This includes the network communication time as well as the amount of time required by the camera to perform the requested operation.

  Notes

  The default timeout value for writes is 1.0 second as recommended by the GigE Vision standard. This is also the minimum timeout value. There is no maximum value.

  Some cameras may require a timeout period longer than the default for some operations.

  If a camera write timeout occurs, a NetworkError exception will be thrown with the description "Receive Timeout".

Global Exceptions

These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareInUse

The current process tried to access a camera that is already owned by another running process. To avoid this error, a process that touches the camera must exit before another process can access the same hardware.

ccBoard::HardwareNotResponding

A camera communication error occurred.

ccGigEVisionCamers::NetworkError
: A camera on the network failed to respond. A network cable may be disconnected.

ccGigEVisionTransportProp

```
#include <ch_cvl/prop.h>

class ccGigEVisionTransportProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccGigEVisionTransportProp** class controls the transport-related properties for GigE Vision cameras.

Public Member Functions

transportTimeout

```
void transportTimeout(double val);

double transportTimeout() const;

static const double defaultTransportTimeout;
```

- `void transportTimeout(double val);`

  Sets the maximum timeout, in seconds, for the camera to transmit an image.

  Parameters

  val The timeout value to set.

  Throws

  ccGigEVisionTransportProp::BadParams
  Transport timeout < 0

  Notes

  The time interval begins when the camera sends the first data packet. This means that transportTimeout does not need to account for exposure time or for time spent waiting for a trigger signal.

  The most common use case is to adjust the transport timeout to a larger value to allow successful acquisition from cameras with a long readout time, as may occur with a linescan camera.

- `double transportTimeout() const;`

  Gets the maximum timeout.

- `static const double defaultTransportTimeout;`

  Gets the default maximum timeout, which is 2.0 seconds.

packetSize

```
void packetSize(c_Int32 val);
c_Int32 packetSize() const;
c_Int32 packetSizeMax() const;
```

- `void packetSize(c_Int32 val);`

  Sets the size of image packets transmitted by the camera.

  Parameters

  val Image packet size to set.

  Throws

  ccGigEVisionTransportProp::BadParams
  The value is less than 1 or greater than the maximum.

  Notes

  The default is the value that was automatically determined, and will vary based on the camera used and the network configuration. In most cases, the packetSize value should not be changed from the default.

  Ideally, the automatically determined value will be 8000 or larger. A smaller value may indicate that jumbo frames are disabled on the network adapter, or that a switch in the network does not support jumbo frames.

  The packetSize function controls the GevSCPSPacketSize feature of the camera.

- `c_Int32 packetSize() const;`

  Gets the size of image packets transmitted by the camera.

- `c_Int32 packetSizeMax() const;`

  Gets the maximum packet size.

latencyLevel

```
void latencyLevel(c_Int32 val);

c_Int32 latencyLevel() const;

static const c_Int32 defaultLatencyLevel;
```

- `void latencyLevel(c_Int32 val);`

  Sets the latency level of the driver.

  Parameters

  val Latency level to set.

  Throws

  ccGigEVisionTransportProp::BadParams
  The value is less than 0 or greater than 3.

  Notes

  The valid range is 0 (lowest latency) to 3 (lowest CPU).

  Smaller values reduce acquisition latency and may improve reliability at the expense of higher CPU usage.

- `c_Int32 latencyLevel() const;`

  Gets the latency level of the driver.

- `static const c_Int32 defaultLatencyLevel;`

  Gets the default latency level of the driver, which is 3.

ccGigEVisionTransportProp

ccGMorph3x3Element

```
#include <ch_cvl/gmorph.h>

class ccGMorph3x3Element;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single 3x3 pixel grey-scale morphology structuring element.

Constructors/Destructors

ccGMorph3x3Element

```
ccGMorph3x3Element(ccGMorphDefs::ElementType
  type = ccGMorphDefs::eSquare3x3);
```

Constructs a 3x3 structuring element of the specified type. All offsets in the element are set to 0.

Parameters

type The element type to create. *type* must be one of the following values:

ccGMorphDefs::eSquare3x3
ccGMorphDefs::eDiamond3x3
ccGMorphDefs::eLine1x3_0
ccGMorphDefs::eLine1x3_45
ccGMorphDefs::eLine1x3_90
ccGMorphDefs::eLine1x3_135
ccGMorphDefs::eArbitrary

Operators

operator==

```
bool operator== (const ccGMorph3x3Element& that) const;
```

Tests this **ccGMorph3x3Element** for equality with the supplied one. The function returns true if the two **ccGMorph3x3Element**s are of the same type and have the same offsets, mask, and origins.

Parameters

that The **ccGMorph3x3Element** to compare to this one

Public Member Functions

elementType

```
const ccGMorphDefs::ElementType elementType() const;
void elementType(const ccGMorphDefs::ElementType& type);
```

- `const ccGMorphDefs::ElementType elementType() const;`

  Returns the type of this **ccGMorph3x3Element**. The returned value is one of the following values:

  ccGMorphDefs::eSquare3x3
  ccGMorphDefs::eDiamond3x3
  ccGMorphDefs::eLine1x3_0
  ccGMorphDefs::eLine1x3_45
  ccGMorphDefs::eLine1x3_90
  ccGMorphDefs::eLine1x3_135
  ccGMorphDefs::eArbitrary

- `void elementType(const ccGMorphDefs::ElementType& type);`

  Sets the type of this **ccGMorph3x3Element**.

  Parameters

  type The element type to set. *type* must be one of the following values:

  ccGMorphDefs::eSquare3x3
  ccGMorphDefs::eDiamond3x3
  ccGMorphDefs::eLine1x3_0
  ccGMorphDefs::eLine1x3_45
  ccGMorphDefs::eLine1x3_90
  ccGMorphDefs::eLine1x3_135
  ccGMorphDefs::eArbitrary

offsets

```
cmStd vector<c_Int8> offsets() const;

void offsets(cmStd vector<c_Int8>& values);
```

- `cmStd vector<c_Int8> offsets() const;`

  Returns a nine-element vector of **c_Int8** containing the offsets for each pixel of this **ccGMorph3x3Element**. The offsets are returned in the following order: NW, N, NE, W,C,E, SW, S, and SE. Each offset is a signed value in the range -128 to 127. Returns a vector of zeros for all of the predefined element types.

- `void offsets(cmStd vector<c_Int8>& values);`

  Sets the offsets for each pixel of this **ccGMorph3x3Element**. The offsets must be supplied in the following order: NW, N, NE, W,C,E, SW, S, and SE. Each offset must be a signed value in the range -128 to 127.

  Parameters

  values The offsets to set.

  Throws

  ccGmorphDefs::EmptyList
  No 3x3 elements are present.

  Notes

  The setter should be used only if the *elementType* is *eArbitrary*.
  If this setter is used, the offsets are interpreted as additive offsets.

dontCareMask

```
c_UInt32 dontCareMask() const;

void dontCareMask(const c_UInt32 maskValue);
```

- `c_UInt32 dontCareMask() const;`

  Returns the don't care mask for this **ccGMorph3x3Element**. The returned value is constructed by ORing together each of the following values that corresponds to a don't care pixel:

  ccGMorphDefs::ePosNE
  ccGMorphDefs::ePosN
  ccGMorphDefs::ePosNW
  ccGMorphDefs::ePosW
  ccGMorphDefs::ePosSW
  ccGMorphDefs::ePosS

ccGMorphDefs::ePosSE
ccGMorphDefs::ePosE
ccGMorphDefs::ePosCntr

If no don't care mask has been set, this function returns 0 (all pixels are care pixels).

- `void dontCareMask(const c_UInt32 maskValue);`

Sets the don't care mask for this **ccGMorph3x3Element**. The mask is specified by ORing together each of the values defined in **ccGMorphDefs::Pos3x3** that corresponds to a don't care pixel.

Parameters

maskValue The mask to set. *maskValue* must be either 0 or a value formed by ORing together any of the following values:

ccGMorphDefs::ePosNE
ccGMorphDefs::ePosN
ccGMorphDefs::ePosNW
ccGMorphDefs::ePosW
ccGMorphDefs::ePosSW
ccGMorphDefs::ePosS
ccGMorphDefs::ePosSE
ccGMorphDefs::ePosE
ccGMorphDefs::ePosCntr

Notes

The setter should be used only if the *elementType* is *eArbitrary*.
If this setter is used, the offsets are interpreted as masking offsets.

The offsets can be modified and interpreted as listed below:

Element Type	Setter to Modify Offsets	Values Interpreted as
eArbitrary	**offsets(***values***)**	additive
eArbitrary	**dontCareMask(***mask***)**	mask
all predefined	do not modify offsets	mask (always)

origin

```
ccGMorphDefs::Pos3x3 origin() const;
void origin(const ccGMorphDefs::Pos3x3 pos);
```

- `ccGMorphDefs::Pos3x3 origin() const;`

  Returns the origin of this **ccGMorph3x3Element**. The returned value is one of the following:

  ccGMorphDefs::ePosNE
  ccGMorphDefs::ePosN
  ccGMorphDefs::ePosNW
  ccGMorphDefs::ePosW
  ccGMorphDefs::ePosSW
  ccGMorphDefs::ePosS
  ccGMorphDefs::ePosSE
  ccGMorphDefs::ePosE
  ccGMorphDefs::ePosCntr

- `void origin(const ccGMorphDefs::Pos3x3 pos);`

  Sets the origin of this **ccGMorph3x3Element**.

  Parameters

  pos The origin to set. *pos* must be one of the following values:

  ccGMorphDefs::ePosNE
  ccGMorphDefs::ePosN
  ccGMorphDefs::ePosNW
  ccGMorphDefs::ePosW
  ccGMorphDefs::ePosSW
  ccGMorphDefs::ePosS
  ccGMorphDefs::ePosSE
  ccGMorphDefs::ePosE
  ccGMorphDefs::ePosCntr

  The default origin is *ccGMorphDefs::ePosCntr*.

  Throws

  ccGMorphDefs::BadElement
  The origin is outside the structuring element.

ccGMorph3x3Element

ccGMorphDefs

```
#include <ch_cvl/gmorph.h>

class ccGMorphDefs;
```

A name space that holds enumerations and constants used with the Grey-scale Morphology tool.

Enumerations

ElementType

```
enum ElementType
```

This enumeration defines the pre-defined 3x3 structuring element types supported by the Grey-scale Morphology tool.

Value	Meaning
eSquare3x3	 3x3 square
eDiamond3x3	 3x3 diamond
eLine1x3_0	 1x3 horizontal line (0° from horizontal)
eLine1x3_45	 1x3 diagonal line (45° from horizontal)

Value	Meaning
eLine1x3_90	 1x3 vertical line (90° from horizontal)
eLine1x3_135	 1x3 diagonal line (135° from horizontal)
eArbitrary	The element is undefined.
kDefaultElementType	The default element type, as defined in *gmorph.h*

Pos3x3 `enum Pos3x3`

This enumeration defines the pixel locations within a 3x3 structuring element.

Value	Meaning
ePosNE	ePosN	
Value	Meaning
ePosNW	ePosW	ePosSW	ePosS	ePosSE	
Value	Meaning
ePosE	ePosCntr	
ccGMorphElement

```
#include <ch_cvl/gmorph.h>

class ccGMorphElement : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains a grey-scale morphology structuring element of any size. It includes members that let you compose a structuring element and members that let you apply the structuring element to an input image.

Constructors/Destructors

ccGMorphElement

```
ccGMorphElement();

ccGMorphElement(
  const cmStd vector<ccGMorph3x3Element>& elements);

virtual ~ccGMorphElement();

ccGMorphElement(const ccGMorphElement& rhs);
```

- `ccGMorphElement();`

  Constructs a **ccGMorphElement** that cannot be applied to an image.

- ```
  ccGMorphElement(
    cmStd vector<ccGMorph3x3Element>& elements);
  ```

  Composes a structuring element using the supplied list of 3x3 structuring elements. All but the first 3x3 element are reflected, then applied to the first 3x3 element using dilation.

  Parameters

  elements A vector of **ccGMorph3x3Element**.

  Throws
  ```

ccGMorphDefs::BadElement
An invalid 3x3 element is present in *elements*.

Operators

operator==

```
bool operator== (const ccGMorphElement& that) const;
```

Tests this **ccGMorphElement** for equality with the supplied one. The function returns true if the **ccGMorphElement**s have the same height, width, and offsets.

Parameters
that The **ccGMorphElement** to compare to this one

Public Member Functions

elementArray

```
cmStd vector<ccGMorph3x3Element> elementArray() const;

void elementArray(
  const cmStd vector<ccGMorph3x3Element>& elements);
```

- ```
  cmStd vector<ccGMorph3x3Element> elementArray() const;
  ```

  Returns a vector of **ccGMorph3x3Element** These 3x3 structuring elements were used to compose this **ccGMorphElement**.

  Throws
  ccGMorphDefs::EmptyList
  This **ccGMorphElement** contains no 3x3 structuring elements.

- ```
  void elementArray(
    const cmStd vector<ccGMorph3x3Element>& elements);
  ```

  Sets the 3x3 structuring elements used to compose this **ccGMorphElement**.

  Parameters
  elements A vector of **ccGMorph3x3Element**.

  Throws
  ccGMorphDefs::BadElement
  An invalid 3x3 element is present in *elements*.

num3x3Elements

```
c_Int32 num3x3Elements() const;
```

Returns the number of 3x3 elements which were used to compose this **ccGMorphElement**.

renderElement

```
ccPelBuffer_const<c_UInt8> renderElement() const;
```

Return a **ccPelBuffer_const<c_UInt8>** that contains a graphical representation of this **ccGMorphElement**.

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

origin

```
ccIPair origin() const;
```

```
void origin(const ccIPair& pos);
```

- `ccIPair origin() const;`

  Returns the origin of this **ccGMorphElement** in unreflected integer coordinates. The upper-left corner of the element is at (0,0).

- `void origin(const ccIPair& pos);`

  Sets the origin of this **ccGMorphElement** in unreflected integer coordinates. The upper-left corner of the element is at (0,0).

  Parameters

  pos The origin to set.

  Throws

  ccGMorphDefs::EmptyList
  This **ccGMorphElement** contains no 3x3 structuring elements.

  ccGMorphDefs::BadElement
  The origin is outside the structuring element.

width

```
c_Int32 width() const;
```

Returns the width of this **ccGMorphElement**.

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

height

```
c_Int32 height() const;
```

Returns the height of this **ccGMorphElement**.

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

erode

```
void erode(const ccPelBuffer_const<c_UInt8>& srcImg,
 ccPelBuffer<c_UInt8>& dstImg) const;
```

Perform an erosion by applying this **ccGMorphElement** to the supplied image.

Parameters

srcImg The input image

dstImg The output image

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

ccGMorphDefs::BadImage
srcImg is not large enough to apply the structuring element.

dilate

```
void dilate(const ccPelBuffer_const<c_UInt8>& srcImg,
 ccPelBuffer<c_UInt8>& dstImg) const;
```

Perform a dilation by applying this **ccGMorphElement** to the supplied image.

Parameters

srcImg The input image

dstImg The output image

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

ccGMorphDefs::BadImage
srcImg is not large enough to apply the structuring element.

open

```
void open(const ccPelBuffer_const<c_UInt8>& srcImg,
 ccPelBuffer<c_UInt8>& dstImg) const;
```

Perform an opening by applying this **ccGMorphElement** to the supplied image.

Parameters

srcImg The input image

dstImg The output image

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

ccGMorphDefs::BadImage
srcImg is not large enough to apply the structuring element.

close

```
void close(const ccPelBuffer_const<c_UInt8>& srcImg,
  ccPelBuffer<c_UInt8>& dstImg) const;
```

Perform a closing by applying this **ccGMorphElement** to the supplied image.

Parameters

srcImg The input image

dstImg The output image

Throws

ccGMorphDefs::EmptyList
This **ccGMorphElement** contains no 3x3 structuring elements.

ccGMorphDefs::BadImage
srcImg is not large enough to apply the structuring element.

ccGMorphElement

ccGraphic

```
#include <ch_cvl/glist.h>

class ccGraphic :  public virtual ccPersistent,
                   public virtual ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccGraphic is the base class for graphic items. It defines functions common to the derived classes **ccGraphicBuiltIn**, **ccGraphicEllipseAnnulusSection,** **ccGraphicText**, **ccGraphicPointIcon,** and **ccGraphicCross**.

ccGraphic-derived classes are wrapper classes for graphic shapes defined in *shapes.h* and are stored in a **ccGraphicList** container class to provide an iterable list of graphics.

Constructors/Destructors

ccGraphic

```
ccGraphic();

ccGraphic(const ccColor& clr);

ccGraphic(const ccGraphicProps& props);
```

- `ccGraphic();`

  Creates an empty graphic object.

- `ccGraphic(const ccColor& clr);`

  Creates an empty graphic object of the specified color.

  Parameters

  clr The color to use.

- `ccGraphic(const ccGraphicProps& props);`

  Creates an empty graphic object using the specified graphic properties.

Parameters

props The graphic properties object specifying the color and other drawing properties of the graphic.

Public Member Functions

props

```
const ccGraphicProps& props() const;
ccGraphicProps& props();
void props(const ccGraphicProps& p);
```

- `const ccGraphicProps& props() const;`

  Retrieves the drawing properties of the graphic object as a const object reference.

- `ccGraphicPropsProps& props();`

  Retrieves the drawing properties of the graphic object as a non-const object reference.

- `void props(const ccGraphicProps& p);`

  Sets the drawing properties of the graphic object.

  Parameters

  p The drawing properties.

map

```
virtual ccGraphicPtrh map(const cc2Xform& c) const = 0;
```

Returns a copy of this graphic item shape, mapped by the transformation object *c*.

Parameters

c The transformation object.

clone

```
virtual ccGraphicPtrh clone() const = 0;
```

Duplicates this object and returns a pointer to the duplicate.

encloseRect

```
virtual ccRect encloseRect() const = 0;
```

Returns the enclosing rectangle for the shape of this graphic item.

distToPoint

```
virtual double distToPoint(const cc2Vect& v) const = 0;
```

Returns the distance from the given point to this graphic line.

Parameters

v The point to measure from, as a **cc2Vect** x,y coordinate pair.

Deprecated Members

color

```
const ccColor& color() const;
void color(const ccColor& c);
```

Deprecated function, replaced with **props()**.

ccGraphicBuiltin

```
#include <ch_cvl/glist.h>

template <class T>
class ccGraphicBuiltin : public ccGraphic;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccGraphicBuiltin is a template base class for built in **ccGraphic** items that defines functions common to derived classes **ccGraphicSimple** and **ccGraphicWithFill**. All **ccGraphicBuiltin**-derived classes provide wrapper classes for shapes defined in *shapes.h*.

T Template parameter which specifies the type of the graphic item. Graphic item types are specified by a **typedef** in the derived classes **ccGraphicSimple** and **ccGraphicWithFill**.

Constructors/Destructors

ccGraphicBuiltin

```
ccGraphicBuiltin();

ccGraphicBuiltin(const T& item, const ccColor& clr);

ccGraphicBuiltin(const T& item,
  const ccGraphicProps& props);
```

- `ccGraphicBuiltin();`

  Creates a built in graphic.

- `ccGraphicBuiltin(const T& item, const ccColor& clr);`

  Creates a built in graphic of specified type and color.

  Parameters

  item The graphic item.

  clr The color of the graphic.

- `ccGraphicBuiltin(const T& item, const ccGraphicProps& props);`

  Creates a built in graphic of the specified type using the specified drawing properties.

  Parameters

item	The graphic item.
props	The drawing properties.

Public Member Functions

item

```
const T& item() const;
T& item();
```

- `const T& item() const;`

  Returns the underlying shape of this graphic item.

- `T& item();`

  Returns a non-**const** reference to the underlying shape of this graphic item.

Deprecated Members

encloseRect

```
ccRect encloseRect() const;
```

Returns the enclosing rectangle of the underlying shape of this graphic item.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Retrieves the distance from the built in graphic to the specified point.

Parameters

v	Two-dimensional vector specifying the coordinates of the point.

ccGraphicCross

```
#include <ch_cvl/glist.h>

class ccGraphicCross : public ccGraphic;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccGraphicCross is a graphic item wrapper class for the **ccCross** class defined in *shapes.h*.

Constructors/Destructors

ccGraphicCross

```
ccGraphicCross();

ccGraphicCross(const ccCross& cross, const ccColor& clr);

ccGraphicCross(const ccCross& cross,
  const ccGraphicProps& props);
```

- `ccGraphicCross();`

  Creates a cross graphic.

- `ccGraphicCross(const ccCross& cross, const ccColor& clr);`

  Creates a cross graphic of the specified color

  Parameters

cross	The cross.
clr	The color.

- ```
  ccGraphicCross(const ccCross& cross,
    const ccGraphicProps& props);
  ```

  Creates a cross graphic using the specified drawing properties.
  ```

Parameters

cross	The cross.
props	The drawing properties.

Public Member Functions

item

```
const ccCross& item() const;
ccCross& item();
```

- `const ccCross& item() const;`

  Returns this graphic item.

- `ccCross& item();`

  Returns a non-**const** reference to this graphic item.

map

```
ccGraphicPtrh map(const cc2Xform& c) const;
```

Returns a copy of this graphic item, mapped by the transformation object *c*.

Parameters

c	The transformation.

clone

```
ccGraphicPtrh clone() const;
```

Duplicates this object and returns a pointer to the duplicate.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Retrieves the distance from the point icon to the specified point.

Parameters

v	Two-dimensional vector specifying the coordinates of the point.

ccGraphicEllipseAnnulusSection

```
#include <ch_cvl/glist.h>

class ccGraphicEllipseAnnulusSection : public ccGraphic;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccGraphicEllipseAnnulusSection is a graphic item wrapper class for the **ccEllipseAnnulusSection** class defined in *shapes.h*.

Constructors/Destructors

ccGraphicEllipseAnnulusSection

```
ccGraphicEllipseAnnulusSection();

ccGraphicEllipseAnnulusSection(
  const ccEllipseAnnulusSection& item,
  const ccColor& clr,
  bool arrow = false, bool forward = false);

ccGraphicEllipseAnnulusSection(
  const ccEllipseAnnulusSection& item,
  const ccGraphicProps& props);
```

- ```
  ccGraphicEllipseAnnulusSection();
  ```

  Creates an ellipse annulus section graphic.

- ```
  ccGraphicEllipseAnnulusSection(
    const ccEllipseAnnulusSection& item,
    const ccColor& clr,
    bool arrow = false, bool forward = false);
  ```

  Creates an ellipse annulus section graphic with the specified color, arrow heads, and arrow direction.

  Parameters

  item The ellipse annulus section.

clr	The color.
arrow	Flag to display arrows heads. True displays arrows heads. False hides arrow heads.
forward	Flag for arrow direction. True displays arrow forward. False displays arrow in reverse.

- ```
  ccGraphicEllipseAnnulusSection(
    const ccEllipseAnnulusSection& item,
    const ccGraphicProps& props);
  ```

  Creates an ellipse annulus section graphic using the specified drawing properties.

  Parameters

item	The ellipse annulus section.
props	The drawing properties.

Public Member Functions

item

```
const ccEllipseAnnulusSection& item() const;
ccEllipseAnnulusSection& item();
```

- ```
  const ccEllipseAnnulusSection& item() const;
  ```

  Returns this graphic item.

- ```
  ccEllipseAnnulusSection& item();
  ```

  Returns a non-**const** reference to this graphic item.

drawArrowHead

```
bool drawArrowHead() const;
void drawArrowHead(bool draw, bool forward);
```

- ```
  bool drawArrowHead() const;
  ```

  Gets the arrow head drawing status. If true, arrow heads are drawn. If false, arrow heads are not drawn.

- `void drawArrowHead(bool draw, bool forward);`

  Draws arrow heads in specified direction.

draw	Flag to draw arrows. True, draws arrow heads. False does not draw arrowheads.
forward	True draws arrows in forward direction. False draws arrows in reverse direction.

drawArrowHeadForward

`bool drawArrowHeadForward() const;`

Returns arrow direction. If true, arrows are drawn in forward direction. If false, arrows are drawn in reverse direction.

encloseRect `ccRect encloseRect() const;`

Returns the enclosing rectangle for underlying graphic item shape.

map `ccGraphicPtrh map(const cc2Xform& c) const;`

Returns a copy of this graphic item, mapped by the transformation object *c*.

Parameters

c	The transformation object.

clone `ccGraphicPtrh clone() const;`

Duplicates this object and returns a pointer to the duplicate.

distToPoint `double distToPoint(const cc2Vect& v) const;`

Retrieves the distance from the ellipse annulus section to the specified point.

Parameters

v	Two-dimensional vector specifying the coordinates of the point.

ccGraphicEllipseAnnulusSection

ccGraphicList

```
#include <ch_cvl/glist.h>

class ccGraphicList;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Simple

ccGraphicList is a container class for **ccGraphic** classes and provides an iterable list of graphic items.

Constructors/Destructors

ccGraphicList

```
ccGraphicList();

ccGraphicList(const ccGraphicList& gl);
```

- `ccGraphicList();`

  Creates a graphic list with no items.

- `ccGraphicList(const ccGraphicList& gl);`

  Creates a deep copy of a graphic list. Every item in the list is copied.

  Parameters

  gl The graphic list to copy.

Operators

operator=

```
ccGraphicList& operator=(const ccGraphicList& gl);
```

Parameters

gl The graphic list to assign.

Assigns a deep copy of the graphic list. Every item in the list is assigned.

Public Member Functions

items

```
const cmStd vector<ccGraphicPtrh>& items() const;
cmStd vector<ccGraphicPtrh>& items();
```

- `const cmStd vector<ccGraphicPtrh>& items() const;`

  Returns the items in this graphic list.

- `cmStd vector<ccGraphicPtrh>& items();`

  Returns a non-**const** reference to the items in this graphic list.

append

```
void append(ccGraphicPtrh item, bool deepCopy=true);
void append(const ccGraphicList& gl);
void append(ccGraphicList& gl, bool deepCopy=true);
```

- `void append(ccGraphicPtrh item, bool deepCopy=true);`

  Appends the graphic item to the end of this list.

  Parameters

item	The item to append.
deepCopy	If true appends a deep copy of the item. If false appends only a copy of the pointer handle to the item.

- `void append(const ccGraphicList& gl);`

  Appends a deep copy of all the items in the list to the end of this list.

  Parameters

gl	The graphic list to append.

- `void append(ccGraphicList& gl, bool deepCopy=true);`

  Appends a graphic list to the end of this list.

  Parameters

gl	The graphic list to append.

deepCopy If true appends a deep copy of all the items in the list. If false appends only the pointer handles to the items in the list.

Notes

If *gl* is appended with a *deepCopy* value of false, the list contains only the pointer handles to its items.

reset

```
void reset();
```

Remove and delete all items from this list.

draw

```
void draw(ccUITablet& tablet,
  ccUITablet::Layers layer = ccUITablet::eImageLayer)
  const;
```

Draw the items in this list into the given tablet. Items are added to the tablet in the same order as they exist in the **items()** vector.

Parameters

tablet The tablet to draw the items into.

layer The plane of the tablet to draw into.

sketch

```
ccUISketch sketch(
  ccUITablet::Layers layer = ccUITablet::eImageLayer)
  const;
```

Returns a sketch of the items in this list. Items are added to the sketch in the same order as they exist in the **items()** vector.

Parameters

layer The plane of the tablet to draw into.

ccGraphicPointIcon

```
#include <ch_cvl/glist.h>

class ccGraphicPointIcon : public ccGraphic;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This class provides the functionality of **ccUITablet::drawPointIcon()** for point icon graphic items.

Constructors/Destructors

ccGraphicPointIcon

```
ccGraphicPointIcon();

ccGraphicPointIcon(const ccPoint& pt, const ccColor& clr);

ccGraphicPointIcon(const ccPoint& pt,
  const ccGraphicProps& props);
```

- `ccGraphicPointIcon();`

  Creates a point icon graphic.

- `ccGraphicPointIcon(const ccPoint& pt, const ccColor& clr);`

  Creates a point icon graphic with specified location and color.

  Parameters

pt	The location of the point.
clr	The color.

- ```
  ccGraphicPointIcon(const ccPoint& pt,
    const ccGraphicProps& props);
  ```

  Creates a point icon graphic at the specified location using the specified drawing properties.
  ```

Parameters

pt	The location of the point.
props	The drawing properties.

Public Member Functions

item

```
const ccPoint& item() const;
ccPoint& item();
```

- `const ccPoint& item() const;`

  Returns the location of this point icon graphic item.

- `ccPoint& item();`

  Returns a non-**const** reference to the location of this point icon graphic item.

encloseRect

```
ccRect encloseRect() const;
```

Returns the enclosing rectangle for this point icon graphic item.

map

```
ccGraphicPtrh map(const cc2Xform& c) const;
```

Returns a copy of this point icon graphic item, mapped by the transformation object *c*.

Parameters

c	The transformation object.

clone

```
ccGraphicPtrh clone() const;
```

Duplicates this object and returns a pointer to the duplicate.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Retrieves the distance from the point icon to the specified point.

Parameters

v	Two-dimensional vector specifying the coordinates of the point.

ccGraphicProps

```
#include <dispprop.h>

class ccGraphicProps : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccGraphicProps** class provides an interface for specifying display properties (for example, rendering, line width, and pen attributes) for both static and manipulable shapes. All graphical shapes do not support all attributes and properties.

Constructors/Destructors

ccGraphicProps

```
ccGraphicProps();

ccGraphicProps(const ccColor &penColor,
  c_Int32 penWidth = 1,
  cePenStyle penStyle = ePenStyleSolid,
  bool penFill = false);

virtual ~ccGraphicProps();
```

- `ccGraphicProps();`

  Default constructor. Instantiates a **ccGraphicProps** object with data members initialized to the following values:

Attribute	Value
Pen color	ccColor::cyanColor()
Pen width	1
Pen style	ePenStyleSolid
Pen fill	false
Pen join	ePenJoinRound

Attribute	Value
Pen end cap	ePenEndCapRound
Arrowhead	true
Arrowhead forward	true
Show genPoly vertex	false

- `ccGraphicProps() ccGraphicProps(const ccColor &penColor, c_Int32 penWidth = 1, cePenStyle penStyle = ePenStyleSolid, bool penFill = false);`

  Convert constructor. Instantiates a **ccGraphicProps** object and initializes a minimum set of data members to the following values:

  Parameters

penColor	Color of the pen used for drawing graphics (default = cyan).
penWidth	Width of the pen used for drawing graphics (default = 1 pixel).
penStyle	Style of the pen used for drawing graphics (default = solid).
penFill	Fill property indicating whether to fill the graphic with color upon rendering (default = false).

- `virtual ~ccGraphicProps();`

  Destructor. Destroys a **ccGraphicProps** object.

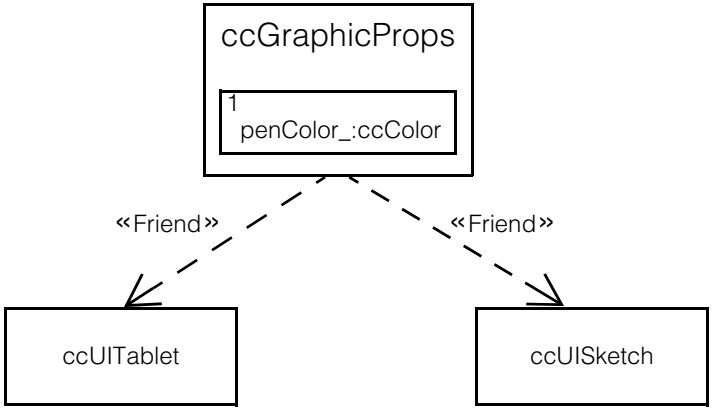

Figure 1. UML Class Diagram of Graphic Properties Class

Operators

operator==

```
bool operator==(const ccGraphicProps &p) const;
```

Returns true if the graphic properties object is equal to another one, false otherwise.

Parameters

p	The other graphics properties object.

operator!=

```
bool operator!=(const ccGraphicProps &p) const;
```

Returns true if the graphic properties object is not equal to another one, false otherwise.

Parameters

p	The other graphics properties object.

Enumerations

cePenStyle

```
enum cePenStyle
```

This enumeration specifies the predefined pen styles available for rendering graphics.

Value	Meaning	Example
ePenStyleSolid	Solid, unbroken pixels	
ePenStyleDash	Equally spaced large dashes	
ePenStyleDot	Equally spaced small dashes	
ePenStyleDashDot	Equally alternating large and small dashes	
ePenStyleDashDotDot	Equally alternating large dash and two small dashes	

cePenJoin

`enum cePenJoin`

This enumeration specifies the predefined pen join styles available for rendering graphics.

Value	Meaning	Example
ePenJoinRound	Rounded joins formed by centering circles with diameters equal to the pen width at each of the joins.	ePenJoinBeveled	Beveled joins formed by filling the corner gaps between each of the two flat-capped lines.	
cePenEndCap

`enum cePenEndCap`

This enumeration specifies the predefined pen end caps available for rendering graphics.

Value	Meaning	Example
ePenEndCapRound	Rounded end caps	
ePenEndCapFlat	Flat end caps abut the end of the line.	
ePenEndCapSquare	Square end caps extend beyond the end of the line.	

Public Member Functions

penColor

```
void penColor(const ccColor &penColor);
const ccColor &penColor() const;
```

- `void penColor(const ccColor &penColor);`

  Sets the pen color.

  Parameters

  penColor — Color used to draw graphics. Must be one of the colors defined by the **ccColor** class.

- `const ccColor &penColor() const;`

  Gets the current pen color.

penWidth

```
c_Int32 penWidth() const;
void penWidth(c_Int32 penWidth);
```

- `c_Int32 penWidth() const;`

  Gets the pen width in pixels.

- `void penWidth(c_Int32 penWidth);`

  Sets the pen width in pixels. The pen width applies to any pen style.

  Parameters

  penWidth — Width of the pen in pixels. Setting *penWidth* to 0 is equivalent to setting it to 1.

  Throws

  ccGraphicProps::BadParams
  If *penWidth* is less than 0

Notes

The default pen width is 1 pixel. The magnification factor of the display does not affect the pen width. A pen width of 0 maps to a 1 pixel wide pen and is used to take advantage of special hardware features when rendering of width 0 is available.

For pen widths greater than 8, the user will not be able to click on the displayed border to select the shape and the cursor will not change to a cross when positioned over the outer or inner perimeter of the fat border. To avoid this problem, call **ccUIManShape::touchDist(float)** to increase the distance at which selection can occur. For a larger pen with, adjust the argument value accordingly. The following is an example of code that increases the touch distance using this method:

```
ccGraphicProps props;
props.penWidth(30);
ccUICircle *uiC = new ccUICircle;
uiC->circle(ccCircle(cc2Vect(350, 350), 100));
uiC->condVisible(true);
uiC->pos(cc2Vect(200, 200));
uiC->condEnabled(true);
uiC->props(props);
uiC->touchDist(15.0);         // Call this to fix the problem
d.addShape(uiC, ccDisplay::eImageCoords);
```

penStyle

```
void penStyle(cePenStyle penStyle);

cePenStyle penStyle() const;
```

- `void penStyle(cePenStyle penStyle);`

Sets the pen rendering style.

Parameters

penStyle	Must be one of the pen styles enumerated by *ccGraphicProps::cePenStyle*.

- `cePenStyle penStyle() const;`

Gets the pen rendering style.

Notes

The default value for pen style is *ccGraphicProps::ePenStyleSolid*.

fill

```
void fill(bool fill);
bool fill() const;
```

- `void fill(bool fill);`

  Sets whether to fill the graphic with color upon rendering.

- `bool fill() const;`

  Gets whether the object is to be filled upon rendering.

  Notes

  The default behavior is to not fill when rendering. The **fill()** methods are implemented only for the graphic shapes **ccEllipse**, **ccRect**, **ccCircle**, and **ccGenRect**.

penJoin

```
void penJoin(cePenJoin penJoin);
cePenJoin penJoin() const;
```

- `void penJoin(cePenJoin penJoin);`

  Sets the pen rendering join shape. Must be one of the shapes enumerated by *ccGraphicProps::cePenJoin*.

- `cePenJoin penJoin() const;`

  Gets the pen rendering join shape.

  Notes

  The default value is *ccGraphicProps::ePenRound*. The pen join shape setting applies only if the pen width is greater than 1.

penEndCap

```
void penEndCap(cePenEndCap penCap);
cePenEndCap penEndCap() const;
```

- `void penEndCap(cePenEndCap penCap);`

  Sets the pen rendering end cap.

  Parameters

penCap	Pen rendering end cap style. Must be one of the end cap styles specified by **cePenEndCap**.

- `cePenEndCap penEndCap() const;`

  Gets the pen rendering end cap.

  Notes

  The default value for the pen rendering end cap is *ccGraphicProps::ePenEndCapRound*. The pen cap setting applies only if the pen width is greater than 1.

  The following is an example of code that sets the pen end cap to different styles:

```
ccDisplayConsole* console = new ccDisplayConsole(
  ccIPair(400,400));

ccPelBuffer<c_UInt8> pelbuf(256, 256);

for (c_Int32 y = 0; y < 256; y++)

    memset(pelbuf.pointToRow(y), y, 256);

console->image(pelbuf, true);

cc2Vect lineSeg_startPoint(0, 0);

cc2Vect lineSeg_endPoint(100, 200);

MessageBox(NULL, cmT("Click to draw lineSeg"),cmT("Example"),
  MB_OK);

ccColor c = ccColor::yellowColor();

ccLineSeg lineSeg(cc2Vect(50,50), cc2Vect(200,50));

ccLineSeg lineSeg1(cc2Vect(50,200),cc2Vect(200,200));

//  style=ePenStyleSolid

ccGraphicProps prop = ccGraphicProps(c, 100,
  ccGraphicProps::cePenStyle(0));

//endCap = ePenEndCapSquare

prop.penEndCap(ccGraphicProps::cePenEndCap(2));

ccGraphicLineSeg gLineSeg(lineSeg, prop);

prop.penEndCap(ccGraphicProps::cePenEndCap(1));

ccGraphicLineSeg gLineSeg1(lineSeg1, prop);

ccGraphicList glist;
```

```
glist.append(new ccGraphicLineSeg(gLineSeg));

glist.append(new ccGraphicLineSeg(gLineSeg1));

ccUITablet tablet;

glist.draw(tablet, ccUITablet::eImageLayer );

console->drawSketch(tablet.sketch(), ccDisplay::eImageCoords);

MessageBox(NULL, cmT("Pan the image or move the message box around
to update the endCapSquare"),cmT("Example"), MB_OK);

delete console;
```

arrowHead

```
void arrowHead(bool enable);

bool arrowHead() const;
```

- `void arrowHead(bool enable);`

  Sets whether arrowhead drawing is enabled for **ccEllipseAnnulusSection** and **cc2Wireframe** objects.

  Parameters

  enable True enables the drawing of arrowheads, false disables it.

  Notes

  The default behavior is for drawing of arrowheads to be enabled. This method applies only to **ccEllipseAnnulusSection** and **cc2Wireframe** objects.

- `bool arrowHead() const;`

  Gets whether arrowhead drawing is enabled for **ccEllipseAnnulusSection** and **cc2Wireframe** objects.

  Notes

  The default behavior is for drawing of arrowheads to be enabled. This method applies only to **ccEllipseAnnulusSection** and **cc2Wireframe** objects.

arrowHeadForward

```
void arrowHeadForward(bool dir);

bool arrowHeadForward() const;
```

- `void arrowHeadForward(bool dir);`

  Sets the direction of the arrow head for **ccEllipseAnnulusSection** objects.

  Parameters

  dir — Direction of the arrow head. True means the arrow faces forward, false means it faces backward.

  Notes

  The default behavior is for arrowheads to be drawn in a forward direction. This method applies only to **ccEllipseAnnulusSection** objects.

- `bool arrowHeadForward() const;`

  Gets the direction of the arrowhead for **ccEllipseAnnulusSection** objects.

  Notes

  The default behavior is for arrowheads to be drawn in a forward direction. This method applies only to **ccEllipseAnnulusSection** objects.

showVertex

```
void showVertex(bool showVertex);

bool showVertex() const;
```

- `void showVertex(bool showVertex);`

  Sets whether to show vertices for a **ccGenPoly** object.

  Parameters

  showVertex — Flag to show or hide the vertices. True means show the vertices, false means hide them.

  Each vertex of a **ccGenPoly** has a corner rounding value, interpreted as follows:

  - A corner rounding value of 0 (the default) causes the corner to be drawn as a sharp intersection of the two segments.
  - A positive corner rounding value causes the corner to be drawn as the radius of a circular arc, or *fillet*, which smoothly blends one segment into the other.
  - A negative corner rounding value tells the pattern matching tools to ignore what would be the circular arc, or *fillet*, if the value were positive.

The **ccGraphicProps::showVertex()** method controls only how vertices with negative corner rounding values are drawn. It is ignored when the rounding value is 0 or positive. Interactions between the corner rounding value of a **ccGenPoly** and **showVertex()** produce the following vertex renderings:

ccGenPoly Corner Rounding Radius	ccGraphicProps:: showVertex()	Rendering
0 (default)	N/A	
Positive	N/A	Negative	false (default)		true	
- `bool showVertex() const;`

  Gets whether to show vertices for a **ccGenPoly** object.

Notes

The default behavior is to hide vertices. The **showVertex** methods are implemented only for **ccGenPoly** objects.

ccGraphicSimple

```
#include <ch_cvl/glist.h>

template <class T>
class ccGraphicSimple : public ccGraphicBuiltin<T>;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

ccGraphicSimple is a template class for **ccGraphicBuiltin** items with no additional parameters. All **ccGraphicSimple** classes are wrapper classes for shapes defined in *shapes.h*. See *Typedefs* on page 1610 for the shapes that are supported by this class.

T Template parameter which specifies the shape of the graphic item. Use one of the **typedef** on page 1610 to specify the class instead of the actual template class name.

Constructors/Destructors

ccGraphicSimple

```
ccGraphicSimple();

ccGraphicSimple(const T& item, const ccColor& clr);

ccGraphicSimple(const T& item,
  const ccGraphicProps& props);
```

- `ccGraphicSimple();`

  Creates an empty simple graphic item.

- `ccGraphicSimple(const T& item, const ccColor& clr);`

  Creates a simple graphic item of specified type and color.

  Parameters

  item The graphic item.

  clr The color.

- ```
  ccGraphicSimple(const T& item,
    const ccGraphicProps& props);
  ```

  Creates a simple graphic of the specified type using the specified drawing properties.

  Parameters

item	The graphic item.
props	The drawing properties.

Public Member Functions

map

```
ccGraphicPtrh map(const cc2Xform& c) const;
```

Returns a copy of this graphic item, mapped by the transformation object *c*.

Parameters

c	The transformation object.

clone

```
ccGraphicPtrh clone() const;
```

Duplicates this object and returns a pointer to the duplicate.

Typedefs

Typedef aliases add Graphic to the class names they represent in *shapes.h*. For example, **ccGraphicPoint** is the synonym for class **ccPoint**.

ccGraphicPoint

```
typedef ccGraphicSimple<ccPoint> ccGraphicPoint;
```

ccGraphic2Point

```
typedef ccGraphicSimple<cc2Point> ccGraphic2Point;
```

ccGraphicLineSeg

```
typedef ccGraphicSimple<ccLineSeg> ccGraphicLineSeg;
```
```

ccGraphicLine
```
typedef ccGraphicSimple<ccLine> ccGraphicLine;
```

ccGraphicFLine
```
typedef ccGraphicSimple<ccFLine> ccGraphicFLine;
```

ccGraphicEllipseArc2
```
typedef ccGraphicSimple<ccEllipseArc2>
                                        ccGraphicEllipseArc2;
```

ccGraphicGenAnnulus
```
typedef ccGraphicSimple<ccGenAnnulus> ccGraphicGenAnnulus;
```

ccGraphicCoordAxes
```
typedef ccGraphicSimple<ccCoordAxes> ccGraphicCoordAxes;
```

ccGraphicPointSet
```
typedef ccGraphicSimple<ccPointSet> ccGraphicPointSet;
```

ccGraphicAffineRectangle
```
typedef ccGraphicSimple<ccAffineRectangle>
  ccGraphicAffineRectangle;
```

ccGraphicPolyline
```
typedef ccGraphicSimple<ccPolyline> ccGraphicPolyline;
```

ccGraphicGenPoly
```
typedef ccGraphicSimple<ccGenPoly> ccGraphicGenPoly;
```

ccGraphic2Wireframe
```
typedef ccGraphicSimple<cc2Wireframe> ccGraphic2Wireframe;
```

ccGraphicBezierCurve
```
typedef ccGraphicSimple<ccBezierCurve>
ccGraphicBezierCurve;
```

ccGraphicDeBoorSpline
```
typedef ccGraphicSimple<ccDeBoorSpline>
ccGraphicDeBoorSpline;
```

ccGraphicInterpSpline
```
typedef ccGraphicSimple<ccInterpSpline>
ccGraphicInterpSpline;
```

ccGraphicHermiteSpline

```
typedef ccGraphicSimple<ccHermiteSpline>
ccGraphicHermiteSpline;
```

Deprecated Members

ccGraphicEllipseArc

```
typedef ccGraphicSimple<ccEllipseArc> ccGraphicEllipseArc;
```

ccGraphicEllipseArc is deprecated. Use **ccGraphicEllipseArc2** above.

ccGraphicPolygon

```
typedef ccGraphicSimple<ccPolygon> ccGraphicPolygon;
```

ccGraphicText

```
#include <ch_cvl/glist.h>

class ccGraphicText : public ccGraphic;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This class provides text strings for graphic items.

Constructors/Destructors

ccGraphicText

```
ccGraphicText();

ccGraphicText(const ccCvlString& str,
  const ccPoint& location, const ccColor& ink,
  const ccColor& backgr, const ccUIFormat& fmt,
  const cc2Vect& oset = cc2Vect(0,0));
```

- `ccGraphicText();`

  Creates an empty graphic text item.

- ```
  ccGraphicText(const ccCvlString& str,
    const ccPoint& location, const ccColor& ink,
    const ccColor& backgr, const ccUIFormat& fmt,
    const cc2Vect& oset = cc2Vect(0,0));
  ```

  Creates a graphic text item with specified text string, location, color, background color, offset, and format.

  Parameters

str	The text string.
location	The text location.
ink	The text color.
backgr	The text background color.
  ```

fmt The text format.

oset The text offset.

Public Member Functions

item

```
const ccCvlString& item() const;
ccCvlString& item();
```

- `const ccCvlString& item() const;`

  Returns the text string and properties for the graphic item.

- `ccCvlString& item();`

  Returns a non-const reference to the text string and properties for the graphic item.

offset

```
cc2Vect offset() const;
void offset(const cc2Vect& oset);
```

- `cc2Vect offset() const;`

  Returns the new offset to original point to draw the label.

- `void offset(const cc2Vect& oset);`

  Sets the new offset to original point to draw the label.

  Parameters

  oset The size of the offset.

location

```
ccPoint location() const;
void location(const ccPoint& loc);
```

- `ccPoint location() const;`

  Gets the location specifying where the label is to be drawn.

- `void location(const ccPoint& loc);`

  Sets the location specifying where the label is to be drawn.

  Parameters

  loc The location.

backgroundColor

```
ccColor backgroundColor() const;
void backgroundColor(const ccColor& backgr);
```

- `ccColor backgroundColor() const;`

  Retrieves the color shown in the background of the label. The color is returned as an object of type **ccColor**.

- `void backgroundColor(const ccColor& backgr);`

  Sets the color displayed in the background of the label.

  Parameters

  backgr The background color.

  Notes

  Specify the background color using one of the static member functions defined in **ccColor**. For example, to specify a green background, use **ccColor::greenColor()**.

format

```
ccUIFormat format() const;
void format(const ccUIFormat& fmt);
```

- `ccUIFormat format() const;`

  Retrieves the format of the label.

  Notes

  The returned format object specifies the font and alignment of the text label. See **ccUIFormat** for more information.

- `void format(const ccUIFormat& fmt);`

  Sest the format of the text label.

Parameters

fmt The format. This object of type **ccUIFormat** specifies the font and alignment of the label. See **ccUIFormat** for more information.

map

```
ccGraphicPtrh map(const cc2Xform& c) const;
```

Returns a copy of this graphic item, mapped by the transformation object *c*.

Parameters

c The transformation object.

clone

```
ccGraphicPtrh clone() const;
```

Duplicates this graphic object and returns a pointer to the duplicate.

ccGraphicWithFill

```
#include <ch_cvl/glist.h>

template<class T, class RT>
class ccGraphicWithFill : public ccGraphicBuiltin<T>;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Yes

ccGraphicWithFill is a template wrapper class for the **ccGraphicBuiltin** graphic items with a fill parameter, **ccRect**, **ccCircle**, **ccEllipse2**, and **ccGenRect**.

T, *RT* — Template parameters which specify the shape of the graphic item. Use one of the **typedef**s on page 1619 to specify the class instead of the actual template class name.

Constructors/Destructors

ccGraphicWithFill

```
ccGraphicWithFill();

ccGraphicWithFill(const T& item, const ccColor& clr,
  bool fill = false);

ccGraphicWithFill(const T& item,
  const ccGraphicProps& props);
```

- `ccGraphicWithFill();`

  Creates an empty graphic with fill object.

- `ccGraphicWithFill(const T& item, const ccColor& clr, bool fill = false);`

  Creates a graphic with fill object of the specified type, color, and fill.

  Parameters

  item — The graphic item.

clr The color.

fill The fill property. True fills the graphic with the specified color. False does not fill the graphic (in other words, the shape is transparent).

- `ccGraphicWithFill(const T& item, const ccGraphicProps& props);`

Creates a graphic with fill object of the specified type using the specified drawing properties.

Parameters

item The graphic item.

props The drawing properties.

---

fill

```
bool fill() const;
void fill(bool f);
```

- `bool fill() const;`

Gets the fill property of this graphic item. If true, shape is filled. If false**,** shape is transparent.

- `void fill(bool f);`

Sets the fill property of this graphic item.

Parameters

f The fill property. True, fills shape with a color. False, does not fill shape. (The shape is transparent).

map

```
ccGraphicPtrh map(const cc2Xform& c) const;
```

Returns a copy of this graphic item, mapped by the transformation object *c*.

Parameters

c The transformation object *c*.

clone

```
ccGraphicPtrh clone() const;
```

Duplicates this graphic object and returns a pointer to the duplicate.

Typedefs

ccGraphicRect

```
typedef ccGraphicWithFill<ccRect,ccGenRect> ccGraphicRect;
```

ccGraphicCircle

```
typedef ccGraphicWithFill<ccCircle,ccEllipse2>
  ccGraphicCircle;
```

ccGraphicAnnulus

```
typedef ccGraphicWithFill<ccAnnulus,ccGenAnnulus>
  ccGraphicAnnulus;
```

ccGraphicEllipse2

```
typedef ccGraphicWithFill<ccEllipse2,ccEllipse2>
  ccGraphicEllipse2;
```

ccGraphicEllipseAnnulus

```
typedef
ccGraphicWithFill<ccEllipseAnnulus,ccEllipseAnnulus>
  ccGraphicEllipseAnnulus;
```

ccGraphicGenRect

```
typedef ccGraphicWithFill<ccGenRect,ccGenRect>
  ccGraphicGenRect;
```

ccGraphicGenAnnulusWithFill

```
typedef ccGraphicWithFill<ccGenAnnulus,ccGenAnnulus>
  ccGraphicGenAnnulusWithFill;
```

Deprecated Members

ccGraphicEllipse

```
typedef ccGraphicWithFill<ccEllipse,ccEllipse>
  ccGraphicEllipse;
```

ccGraphicEllipse is deprecated. Use **ccGraphicEllipse2** above.

ccGreyAcqFifo

```
#include <ch_cvl/acq.h>

class ccGreyAcqFifo : public ccAcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This class describes acquisition FIFO queues that return grey-scale images. There is no need for you to create objects of this type in your program.

Notes

It is recommended that you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()**. It returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccGreyAcqFifo

```
ccGreyAcqFifo(const ccVideoFormat& vf, ccFrameGrabber& fg);
```

Creates an idle acquisition FIFO suitable for capturing grey-scale images of the format *vf* from the frame grabber *fg*.

Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.

Public Member Functions

baseComplete

```
virtual PelBuffer* baseComplete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns a pointer to the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed or if the *maxWait* period elapsed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus — If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow

You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

complete

```
PelBuffer complete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus — If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow — You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

Typedefs

PelBuffer `typedef ccPelBuffer<c_UInt8> PelBuffer;`

ccGreyVideoFormat

```
#include <ch_cvl/vidfmt.h>

class ccGreyVideoFormat : public ccVideoFormat;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This is an abstract class that generates acquisition FIFOs of type **ccGreyAcqFifo**.

The acquisition software creates a single object of class **ccStdVideoFormat** (see page 3009) for each camera type and image size. You use these video format objects to create an acquisition FIFO that is appropriate for the camera and frame grabber that your application uses.

To get a video format, you use **ccStdVideoFormat::getFormat()** described on page 3012.

Notes

It is recommended that you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()**. It returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

There is no need for you to use this class directly in your code. Use the **ccStdVideoFormat** class for all of your format programming.

Constructors/Destructors

The acquisition software creates one object for each supported video format. You do not create video formats yourself.

Public Member Functions

newAcqFifo

```
ccGreyAcqFifo* newAcqFifo(ccFrameGrabber& fg);
```

Creates and returns a new acquisition FIFO suitable for acquiring images of this format from the frame grabber *fg*.

Parameters

fg	The frame grabber to use to acquire images

Throws

ccVideoFormat::NotSupported
The specified frame grabber does not support this video format.

ccGridCalibParams

```
#include <ch_cvl/calib.h>

class ccGridCalibParams: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the parameters you use to control the operation of the Calibration tool.

Constructors/Destructors

ccGridCalibParams

```
ccGridCalibParams(double gridPitchX, double gridPitchY,
  bool isLeftHanded = true,
  ccCalibDefs::CalibType calibType =
  ccCalibDefs::eGridLinear,
  ccCalibDefs::Polarity polarity =
  ccCalibDefs::eAutoDetect);
```

Constructs a **ccGridCalibParams** with the given parameters. The **ccGridCalibParams** will consider the grid angle of the input image.

Parameters

gridPitchX	The spacing between dots in the x-axis, in client units. *gridPitchX* must be greater than 0.
gridPitchY	The spacing between dots in the y-axis, in client units. *gridPitchY* must be greater than 0.
isLeftHanded	Specify true for this parameter to specify a left-handed client coordinate system.
calibType	The calibration type.
polarity	The polarity of the input image. *polarity* must be set to one of the following values:

ccCalibDefs::eDarkOnLight
ccCalibDefs::eLightOnDark
ccCalibDefs::eAutoDetect

Public Member Functions

gridPitchX

```
double gridPitchX() const;
void gridPitchX(double pitchX) const;
```

- `double gridPitchX() const;`

  Returns the grid pitch in the x-axis in client units.

- `void gridPitchX(double pitchX) const;`

  Sets the grid pitch in the x-axis to *pitchX* in client units.

  Parameters

pitchX	The value the grid pitch in the x-axis is set to

gridPitchY

```
double gridPitchY() const;
void gridPitchY(double pitchY) const;
```

- `double gridPitchY() const;`

  Returns the grid pitch in the y-axis in client units.

- `void gridPitchY(double pitchY) const;`

  Sets the grid pitch in the y-axis to *pitchY* in client units.

  Parameters

pitchY	The value the grid pitch in the y-axis is set to

isLeftHanded

```
bool isLeftHanded() const;
void isLeftHanded(bool hand) const;
```

- `bool isLeftHanded() const;`

  Returns the handedness of the client coordinate system.

- `void isLeftHanded(bool hand) const;`

  Select the handedness of the client coordinate system.

  Parameters

hand	Set to true to select a left handed client coordinate system. Set to false to select a right handed client coordinate system.

calibType

```
ccCalibDefs::CalibType calibType() const;
void calibType(ccCalibDefs::CalibType ctype) const;
```

- `ccCalibDefs::CalibType calibType() const;`

  Returns the calibration type.

- `void calibType(ccCalibDefs::CalibType ctype) const;`

  Sets the calibration type to *ctype*.

  Parameters

ctype	The calibration type this calibration is set to

polarity

```
ccCalibDefs::Polarity polarity() const;
void polarity(ccCalibDefs::Polarity pol) const;
```

- `ccCalibDefs::Polarity polarity() const;`

  Returns the polarity you specified for the input image.

- `void polarity(ccCalibDefs::Polarity pol) const;`

  Set the polarity of the input image to *pol*.

  Parameters

pol	The polarity the input image is set to.

ignoreGridAngle

```
bool ignoreGridAngle() const;
void ignoreGridAngle(bool flag);
```

- `bool ignoreGridAngle() const;`

  Returns true if this **ccGridCalibParams** is configured to ignore any angle between the image coordinate system and the calibration grid. Returns false if this **ccGridCalibParams** is configured to include any angle in the calibration transformation.

- `void ignoreGridAngle(bool flag);`

  Controls whether this **ccGridCalibParams** ignores any angle between the image coordinate system and the calibration grid.

  Parameters

flag	Set to *true* to ignore any angle between the image coordinate system and the calibration grid. Set to *false* to include any angle in the calibration transformation.

ccGridCalibResults

```
#include <ch_cvl/calib.h>

class ccGridCalibResults: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This class contains the results of applying the Calibration tool to an input image.

Constructors/Destructors

ccGridCalibResults

```
ccGridCalibResults();
```

Constructs a **ccGridCalibResults** with zero-length vector data members and identity transformations.

Public Member Functions

isMarkerFound

```
bool isMarkerFound() const;
```

Returns true if the most recent call to **cfCalibrationRun()** was able to locate the marker rectangles, false if it could not.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

markerPointInImage

```
cc2Vect markerPointInImage() const;
```

Returns the location of the anchor point (specified as the point where lines drawn through the centers of the marker rectangles intersect) in image coordinates.

Throws

ccCalibDefs::MarkerNotFound
One or both of the marker rectangles were not found.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

clientFromImageXformBase

```
cc2XformBasePtrh clientFromImageXformBase(
  cc2Vect pointInImageSpace = cc2Vect(0,0),
  cc2Vect pointInClientSpace = cc2Vect(0,0)) const;
```

Returns the pointer handle to the transformation that maps image coordinates to client coordinates. This function returns the full transformation, which will be either linear or polynomial depending on the requested calibration type. The optional arguments are used to correctly translate the client coordinate system with respect to the image coordinate system. The points *pointInImageSpace* and *pointInClientSpace* should correspond to the same real-world feature.

For example, to obtain the pointer handle to the transformation that places the intersection of marker rectangles to the client coordinate location 0.56, 0.87, you would make the following call

```
cc2XformBasePtrh myXform =
  myCalibResults.clientFromImageXformBase(
        myCalibResults.markerPointInImage(), // Image point
        cc2Vect(0.56, 0.87));               // Client point
```

Parameters

pointInImageSpace

A point in image coordinates

pointInClientSpace

A point in client coordinates that corresponds to *pointInImageSpace*

Notes

The previous call to **cfCalibrationRun()** must have been successful.

clientFromImageXform

```
cc2Xform clientFromImageXform(
  cc2Vect pointInImageSpace = cc2Vect(0,0),
  cc2Vect pointInClientSpace = cc2Vect(0,0)) const;
```

Returns the **cc2Xform** that maps image coordinates to client coordinates. This function returns the best linear fit, regardless of whether the requested calibration type is linear or polynomial. The optional arguments are used to correctly translate the client

coordinate system with respect to the image coordinate system. The points *pointInImageSpace* and *pointInClientSpace* should correspond to the same real-world feature.

For example, to obtain the **cc2Xform** to the transformation that places the intersection of marker rectangles to the client coordinate location 0.56, 0.87, you would make the following call:

```
cc2Xform myXform =
  myCalibResults.clientFromImageXform(
        myCalibResults.markerPointInImage(), // Image point
        cc2Vect(0.56, 0.87));                // Client point
```

Parameters

pointInImageSpace

A point in image coordinates

pointInClientSpace

A point in client coordinates that corresponds to *pointInImageSpace*

Notes

The previous call to **cfCalibrationRun()** must have been successful.

isLinear

```
bool isLinear() const;
```

Returns true if this object does not contain a polynomial calibration.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

maximumResidual

```
double maximumResidual() const;
```

Returns the maximum residual error in client coordinates.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

averageResidual

```
double averageResidual() const;
```

Returns the average residual error across all grid points in client coordinates.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

residuals

```
cmStd vector<cc2Vect> residuals(
  bool isClient = true) const;
```

Returns the residual error for each grid point in client coordinate system units (if *isClient* is true), or image coordinate units (if *isClient* is false). The ordering of these points in the returned vector is the same as that in the vector returned by **imagePoints()**.

Parameters

isClient — If true, return the residual error in client coordinate system units. If false, return the residual error in image coordinate system units.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

imagePoints

```
cmStd vector<cc2Vect> imagePoints() const;
```

Returns a vector containing the location of the center of each circle in the input image in image coordinates.

Notes

The previous call to **cfCalibrationRun()** must have been successful.

edgeImage

```
ccPelBuffer<c_UInt8> edgeImage() const;
```

Returns a binary edge image showing all the edges detected by the tool. The returned image will have non-edge pixels set to 0 and edge pixels set to 255.

Notes

This member function is provided only for debugging purposes and may not be available in future releases.

This is a diagnostic function; it can be called even if the previous call to **cfCalibrationRun()** was not successful.

segmentedImage

```
ccPelBuffer<c_UInt8> segmentedImage() const;
```

Returns the near-binary segmented image corresponding to the input image. Object pixels are set to 255, background pixels are set to 0 and the intermediate level pixels near the edge are set to a level between those values.

Notes

This member function is provided only for debugging purposes and may not be available in future releases.

This is a diagnostic function; it can be called even if the previous call to **cfCalibrationRun()** was not successful.

threshold

```
c_UInt8 threshold() const;
```

Returns the threshold value computed by **cfCalibrationRun()** to segment the image into grid dots and background.

Notes

This member function is provided only for debugging purposes and may not be available in future releases.

This is a diagnostic function; it can be called even if the previous call to **cfCalibrationRun()** was not successful.

polarity

```
ccCalibDefs::Polarity polarity() const;
```

Returns the actual polarity used by the most recent call to **cfCalibrationRun()**. This may not be the same value you specified. This function returns one of the following values:

ccCalibDefs::eDarkOnLight
ccCalibDefs::eLightOnDark

ccGUI

```
#include <ch_cvl/gui.h>

class ccGUI;
```

A name space that holds constants for console window styles.

Constants

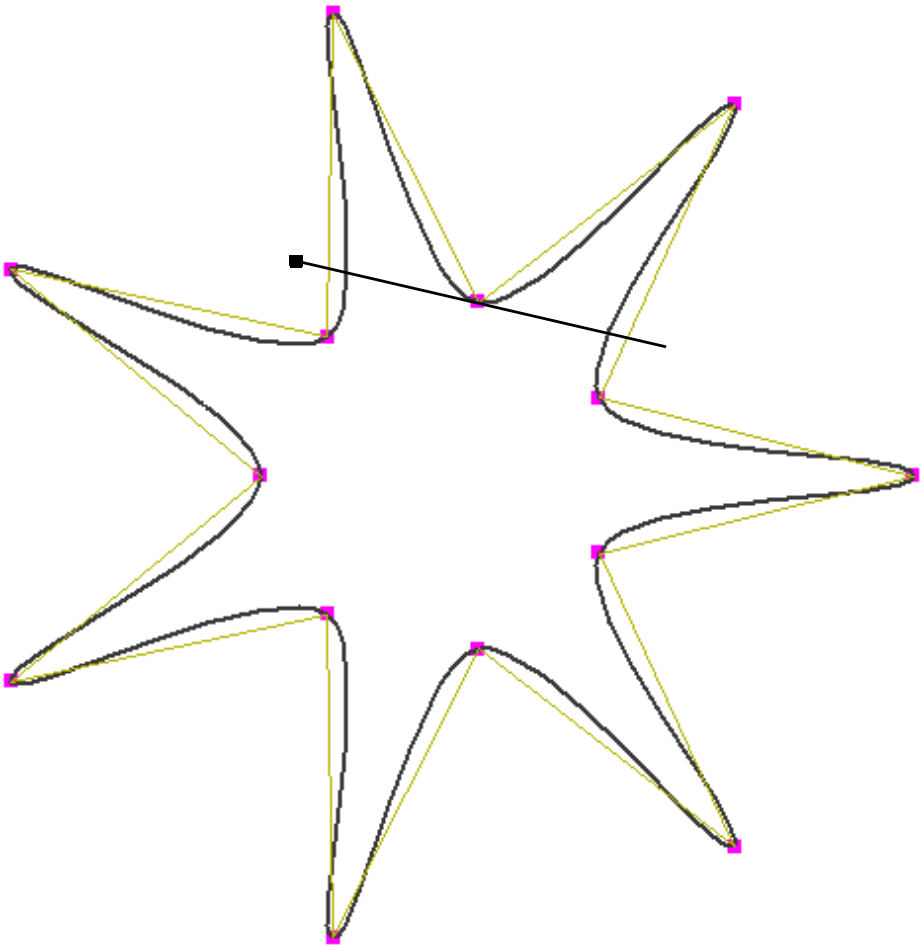
Value	Meaning
kStyleCreateNormal	Creates a visible window.
kStyleCreateMinimized	Creates a minimized window.
kStyleCreateMaximized	Creates a maximized window.
kStyleCreateGUI	Causes a GUI window to be created for the console. If this value is not specified, then output will be sent to **cout**, if it is available.
kStyleCreateNow	Creates and displays the window on construction.
kStyleCreateOnOutput	Creates the window but does not display it until output is sent to the window.
kStyleCloseIsHide	Hide (but do not close) the window when the user clicks the close box.
kStyleNoMessageLoop	Reserved for Cognex use only; do not use.

ccHermiteSpline

```
#include <ch_cvl/spline.h>

class ccHermiteSpline : public ccCubicSpline;
```

The **ccHermiteSpline** class is an implementation of 2D cubic C^1 Hermite interpolation splines. These are another type of cubic interpolation spline that offer additional control knobs. Besides specifying the 2D spline control points that the spline must interpolate, you can also specify the parametric tangent vector of the spline at each control point. Hermite interpolation refers to simultaneous interpolation of point and derivative data.



The above figure shows an example of a Hermite spline with a tangent vector shown at one of the control points.

Properties of Hermite Splines

Note that Hermite splines are not B-Splines, which do not offer control of tangent vectors at internal junction points. The price for the extra control is reduced differentiability at the junctions. In general, the curve is only C^1 at the spline control points; it is infinitely differentiable everywhere else.

The minimum number of spline control points needed to specify a non-empty **ccHermiteSpline** is two, regardless of whether the spline is open or closed. In other words, both open and closed **ccHermiteSpline**s are empty if they have fewer than two control points.

Default Tangent Vectors

When constructing a **ccHermiteSpline** from a list of control points, or when inserting or adding control points, you do not need to provide explicit tangent vectors. If not provided, reasonable tangent vectors are automatically computed using a simple heuristic. If there is only a single control point, its default tangent vector is the zero vector. Otherwise, for *n* control points the default tangent vector for control point *i* is defined in terms of the vector difference between a pair of control points. For open splines, the rules are shown in the following table.

Note In the table, cp[*i*] means controlPoint[*i*] and int[*i*] means interval[*i*].

Value of *i*	Rule
If *i* is equal to zero	(cp[1] - cp[0]) / int[0]
If *i* is greater than zero and less than *n* minus one:	(cp[*i*+1] - cp[*i*-1]) / (int[*i*-1] + int[*i*])
If *i* is equal to *n* minus one:	(cp[*n*-1] - cp[*n*-2]) / int[*n*-2]

Closed splines use the middle rule above in all cases, with modulo *n* indexing. If the denominators of any of the above expressions are zero, the default tangent is set to the zero vector.

Note For in-depth information on the theory and use of 2D cubic Bezier curves and splines, see any textbook on the subject, such as *Curves and Surfaces for Computer Aided Geometric Design* by Gerald Farin, Second Edition, Academic Press, 1990, ISBN 0-12-249051-7.

Note All methods defined for this class leave the **ccHermiteSpline** object unchanged when they throw an error.

Constructors/Destructors

ccHermiteSpline

```
explicit
ccHermiteSpline(bool isClosed = false,
  IntervaleMode intervalMode = eUniform);

explicit
ccHermiteSpline(const cmStd vector<cc2Vect> &ctrlPts,
  bool isClosed = false,
  IntervalMode intervalMode = eUniform);

ccHermiteSpline(const cmStd vector<cc2Vect> &ctrlPts,
  const cmStd vector<cc2Vect> &tangents,
  bool isClosed = false,
  IntervalMode intervalMode = eUniform);
```

- ```
  explicit
  ccHermiteSpline(bool isClosed = false,
    IntervalMode intervalMode = eUniform);
  ```

  Constructs an empty Hermite interpolation spline with no control points, with the given open/closed state, and the given interval mode. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

isClosed	The open/closed state (default = open).
intervalMode	The interval mode. Must be one of the following: *ccCubicSpline::eUniform (default)* *ccCubicSpline:eChordLength* *ccCubicSpline::eCentripetal* *ccCubicSpline::eFixed*

- ```
  explicit
  ccHermiteSpline(const cmStd vector<cc2Vect> &ctrlPts,
    bool isClosed = false,
    IntervalMode intervalMode = eUniform);
  ```

  Constructs a Hermite interpolation spline with the given control points, open/closed state, and interval mode. The tangents of all control points are initialized to default values. See *Default Tangent Vectors* on page 1640. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

ctrlPts	The vector of control points.
isClosed	The open/closed state (default = open).

intervalMode The interval mode. Must be one of the following:
ccCubicSpline::eUniform (default)
ccCubicSpline:eChordLength
ccCubicSpline::eCentripetal
ccCubicSpline::eFixed

- ```
  ccHermiteSpline(const cmStd vector<cc2Vect> &ctrlPts,
    const cmStd vector<cc2Vect> &tangents,
    bool isClosed = false,
    IntervalMode intervalMode = eUniform);
  ```

Constructs a Hermite interpolation spline with the given control points, tangents, open/closed state, and interval mode.

Parameters

ctrlPts The vector of control points.

tangents The vector of tangents.

isClosed The open/closed state (default = open).

intervalMode The interval mode. Must be one of the following:
ccCubicSpline::eUniform (default)
ccCubicSpline:eChordLength
ccCubicSpline::eCentripetal
ccCubicSpline::eFixed

Throws

ccShapesError::BadParams
The *ctrlPts* and *tangents* vectors have different sizes.

Operators

operator==

```
bool operator==(const ccHermiteSpline &rhs) const;
```

Returns true if and only if this **ccHermiteSpline** is equal to *rhs*. Two splines are equal if all of their defining parameters are identical (no tolerance is used).

Parameters

rhs The other **ccHermiteSpline**.

Notes

Splines that describe identical curves are not necessarily equal.
```

operator!=

```
bool operator!=(const ccHermiteSpline &rhs) const;
```

Returns the opposite truth value to **operator==()**.

Parameters

rhs The other **ccHermiteSpline**.

Notes

Splines that describe identical curves are not necessarily equal.

Public Member Functions

controlTangent

```
const cc2Vect &controlTangent(c_Int32 idx) const;

void controlTangent(c_Int32 idx, const cc2Vect &tangent);
```

- ```
  const cc2Vect &controlTangent(c_Int32 idx) const;
  ```

  Gets the tangent of the control point with the given index.

  Parameters

  idx The index.

- ```
  void controlTangent(c_Int32 idx, const cc2Vect &tangent);
  ```

  Sets the tangent of the control point with given index.

  Parameters

  idx The index.

  Throws

  ccShapesError::BadIndex
  idx is less than 0, or greater than or equal to **numControlPoints()**.

controlTangents

```
const cmStd vector<cc2Vect> &controlTangents() const;

void controlTangents(
  const cmStd vector<cc2Vect> &tangents);
```

- ```
  const cmStd vector<cc2Vect> &controlTangents() const;
  ```

  Gets the vector of all control point tangents.
  ```

- ```
  void controlTangents(
    const cmStd vector<cc2Vect> &tangents);
  ```

  Sets the vector of all control point tangents.

  Parameters

  tangents The vector of control point tangents.

  Throws

  ccShapesError::BadParams
  The size of *tangents* is not equal to **numControlPoints()**.

insertControlPoint

```
virtual void insertControlPoint(c_Int32 idx,
  const cc2Vect &point);

void insertControlPoint(c_Int32 idx,
  const cc2Vect &point, const cc2Vect &tangent);
```

- ```
  virtual void insertControlPoint(c_Int32 idx,
    const cc2Vect &point);
  ```

  Inserts a new control point before the point with the given index. The new control point is assigned the default tangent.

  Parameters

  idx The index.

  point The control point.

  Throws

  ccShapesError::BadIndex
  idx is less than 0, or greater than **numControlPoints()** before the insertion.

  Notes

  The new control point is assigned the default tangent. See *Default Tangent Vectors* on page 1640 for details.

- ```
  void insertControlPoint(c_Int32 idx,
    const cc2Vect &point, const cc2Vect &tangent);
  ```

  Inserts a new control point before the point with the given index. Identical to **ccCubicSpline::insertControlPoint()**, except that the new control point is assigned the given tangent rather than the default tangent.
  ```

Parameters

idx The index.

point The control point.

tangent The tangent vector.

Throws

ccShapesError::BadIndex
idx is less than 0, or greater than **numControlPoints()** before the insertion.

See **ccCubicSpline::insertControlPoint()** for details.

addControlPoint

```
void addControlPoint(const cc2Vect &point,
  const cc2Vect &tangent);
```

Convenience function. Appends a control point at the end of the sequence of control points and assigns it the given tangent vector. Equivalent to **insertControlPoint(numControlPoints(), point, tangent)**.

Parameters

point The control point.

tangent The tangent vector.

removeControlPoint

```
virtual void removeControlPoint(c_Int32 idx);
```

Removes the control point with the given index.

Parameters

idx The index.

Throws

ccShapesError::BadIndex
idx is less than 0, or greater than or equal to **numControlPoints()** before the removal.

See **ccCubicSpline::removeControlPoint()** for more information.

map

```
ccHermiteSpline map(const cc2Xform& X) const;
```

Returns this **ccHermiteSpline** mapped by *X*.

Parameters

X The transformation object.

Notes

This function maps the control point positions and tangents by X and leaves the intervals unchanged. It may be desirable to invoke **reparameterize()** on the returned spline. See *Mapping Splines* and *Reparameterizing Splines* on page 1112 for details.

Note Several of **ccCubicSpline**'s setter/getter pairs have a virtual setter and a non-virtual getter. The getters must be explicitly exposed in derived classes, or they will be hidden by the setter overrides.

---

isClosed

```
bool isClosed() const;

virtual void isClosed(bool);
```

- `bool isClosed() const;`

  Gets the open/closed state of this **ccHermiteSpline** (true = closed, false = open).

- `virtual void isClosed(bool);`

  Sets the open/closed state of this **ccHermiteSpline**.

  Parameters

  bool True sets this spline to closed, false sets it to open.

  See **ccCubicSpline::isClosed()** for more information.

---

controlPoint

```
cc2Vect controlPoint(c_Int32 idx) const;

virtual void controlPOint(c_Int32 idx,
  const cc2Vect &ctrlPt);
```

- `cc2Vect controlPoint(c_Int32 idx) const;`

  Gets the control point with the given index.

  Parameters

  idx The index.

- ```
  virtual void controlPoint(c_Int32 idx,
    const cc2Vect &ctrlPt);
  ```

  Sets the control point with the given index.
  ```

Parameters

idx The index.

ctrlPt The control point.

Notes

This function leaves the tangent of the control point unchanged.

See **ccCubicSpline::controlPoint()** for more information.

controlPoints

```
const cmStd vector<cc2Vect> &controlPoints() const;

virtual void controlPoints(
  const cmStd vector<cc2Vect> &ctrlPts);
```

- `const cmStd vector<cc2Vect> &controlPoints() const;`

  Gets the entire vector of control points.

- ```
  virtual void controlPoints(
    const cmStd vector<cc2Vect> &ctrlPts);
  ```

  Sets the entire vector of control points.

  Parameters

  ctrlPts The vector of control points.

  Notes

  This function leaves the tangents of existing control points unchanged. If *ctrlPts* has size *n*, the tangents of the first *n* existing control points will be used for the new points. If there are fewer than *n* existing control points, the surplus *ctrlPts* willreceive default tangents. See *Default Tangent Vectors* on page 1640 for details.

  See **ccCubicSpline::controlPoints()** for more information.

reparameterize

```
virtual void reparameterize();
```

Recomputes all intervals based on the current control points and interval mode. See **ccCubicSpline::reparameterize()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this Hermite spline.
```

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this **ccHermiteSpline**. See **ccShape::reverse()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this **ccHermiteSpline** mapped by *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

ccHistoStats

```
#include <ch_cvl/histstat.h>

class ccHistoStats;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is used to compute statistics for a histogram.

Constructors/Destructors

ccHistoStats

```
ccHistoStats();

ccHistoStats(cmStd vector<c_UInt32>& histogram,
  bool xown = false);
```

- `ccHistoStats();`

  Constructs a **ccHistoStats** with no histogram. No statistics can be computed by this **ccHistoStats** object.

- `ccHistoStats(cmStd vector<c_UInt32>& histogram, bool xown = false);`

  Constructs a **ccHistoStats** using the given histogram. All statistics will be computed for the supplied histogram.

  Parameters

  histogram — The histogram for which to compute statistics. *histogram* must have at least one element.

  xown — If *xown* is true, this **ccHistoStats** takes over ownership of *histogram*. The vector to which you supplied a reference is set to zero size following the execution of this constructor. If *xown* is false, this **ccHistoStats** makes a copy of *histogram* and the vector to which you supplied a reference is not changed.

Throws

ccHistoStats::Overflow
The sum of histogram bins exceeds *ckMaxUInt32*.

Public Member Functions

isValid

```
bool isValid() const;
```

Returns false if this **ccHistoStats** object was default constructed, otherwise returns true.

nSamp

```
c_UInt32 nSamp() const;
```

Returns the total number of samples in the histogram supplied at construction.

This **ccHistoStats** must not have been default constructed.

mean

```
double mean() const;
```

Returns the arithmetic mean of the values in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

mode

```
c_Int32 mode() const;
```

Returns the modal (most common) value in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

median

```
c_Int32 median() const;
```

Returns the median value in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

histMin

```
c_Int32 histMin() const;
```

Returns the minimum value in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

histMax

```
c_Int32 histMax() const;
```

Returns the maximum value in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

inverseCum

```
c_Int32 inverseCum(int percent) const;
```

Returns the value below which a specified percentage of values in the histogram fall. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

Parameters

percent The percentage below which to return the number of values.

Notes

This function clamps the input *percent* values to the range 0 through 100, inclusive.

sDev

```
double sDev() const;
```

Returns the standard deviation of the values in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

var

```
double var() const;
```

Returns the variance of the values in the histogram supplied at construction. Returns 0 if **nSamp()** returns 0.

This **ccHistoStats** must not have been default constructed.

histogram

```
const cmStd vector<c_UInt32> &histogram() const;
```

Returns the histogram given at construction

Deprecated Members

min

```
c_Int32 min() const;
```

This function is deprecated. Use **histMin()** instead for new development.

max `c_Int32 max() const;`

This function is deprecated. Use **histMax()** instead for new development.

Note The **min()** and **max()** functions can be used only when **min** and **max** are not defined in Windows. Prior to CVL 6.1, the only way you could include the *<histstat.h>* header file was to define **NOMINMAX** before including *<windows.h>* or *<afx.h>*. Therefore, all current CVL applications are not affected and can continue to use the **min()** and **max()** functions.

New applications created with CVL 6.1 and later can include *<histstat.h>* and use the **histMin()** and **histMax()** functions without first undefining the Windows **min** and **max** symbols.

ccIDDecodeParams

```
#include <ch_cvl/id.h>

class ccIDDecodeParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the decoding parameters for the ID tool. Individual members are provided for symbology-specific decoding parameters.

Constructors/Destructors

ccIDDecodeParams

```
ccIDDecodeParams();
```

Constructs a **ccIDDecodeParams**. The following symbologies are enabled in a default constructed object:

- Code39,
- Code93,
- Code128,
- Codabar,
- UPC/EAN

ccIDDecodeParams::qualityOption is set to *ccIDDefs::eQualityOptionNone* and the symbology-specific parameter members are set to default-constructed symbology-specific parameter objects.

Public Member Functions

isSymbologyEnabled

```
bool isSymbologyEnabled(ccIDDefs::Symbology symbology)
   const;
```

Returns true if the given symbology is enabled in this object, false otherwise.

Parameters

symbology The symbology.

Throws

ccIDDefs::BadParams

symbology is invalid.

enableSymbology

```
void enableSymbology(ccIDDefs::Symbology symbology,
   bool enable);
```

Enables or disables the specified symbology.

Parameters

symbology The symbology.

enable Specify true to enable the symbology, false to disable it.

Notes

In order to read EAN.UCC Composite code, both symbologies for the linear and Composite need to be enabled. For example, to read EAN.UCC RSS Composite code, both *ccIDDefs::eSymbologyRSS* and *ccIDDEfs::eSymbologyComposite* need to be enabled.

Throws

ccIDDefs::BadParams

symbology is invalid. *symbology* must be a member of **ccIDDefs::Symbology** and it must not be *ccIDDefs::eSymbologyUnknown*.

disableAllSymbologies

```
void disableAllSymbologies();
```

Disables all symbologies in this object.

resetEnabledSymbologies

```
void resetEnabledSymbologies();
```

Enables the symbologies that are enabled for a default-constructed **ccIDDecodeParams** object;

- Code39
- Code93
- Code128
- Codabar

- UPC/EAN

All other symbologies are disabled.

Notes

In order to read EAN.UCC Composite code, both symbologies for the linear and Composite need to be enabled. For example, to read EAN.UCC RSS Composite code, both *ccIDDefs::eSymbologyRSS* and *ccIDDEfs::eSymbologyComposite* need to be enabled.

Throws

ccIDDefs::BadParams

symbology is not a member of **ccIDDefs::Symbology**.

qualityOption

```
c_UInt32 qualityOption() const;

void qualityOption(c_UInt32 qualityOption);
```

- `c_UInt32 qualityOption() const;`

Returns the currently enabled quality options. The returned value is formed by ORing together 1 or more the following values:

ccIDQualityDefs::eQualityOptionNone
ccIDQualityDefs::eQualityOptionBasic

- `void qualityOption(c_UInt32 qualityOption);`

Sets the quality options. The quality options determine which quality measures are computed for a read symbol.

The available options are *ccIDQualityDefs::eQualityOptionNone* (no measures are computed) and *ccIDQualityDefs::eQualityOptionBasic* (the basic options including ANSI print quality are computed).

Parameters

qualityOption The options to compute. This value must be formed by ORing together one or more of the following values:

ccIDQualityDefs::eQualityOptionNone
ccIDQualityDefs::eQualityOptionBasic

Throws

ccIDDefs::BadParams

qualityOption is not a valid bitwise combination of the **ccIDQualityDefs::QualityOption** values.

paramsI2of5

```
const ccSymbologyParamsI2of5& paramsI2of5() const;

void paramsI2of5(
   const ccSymbologyParamsI2of5& paramsI2of5);
```

- `const ccSymbologyParamsI2of5& paramsI2of5() const;`

  Returns the currently specified 2 of 5 decoding parameters object.

- ```
  void paramsI2of5(
     const ccSymbologyParamsI2of5& paramsI2of5);
  ```

  Sets the 2 of 5 decoding parameters object.

  Parameters

  paramsI2of5 The parameter object to set.

paramsCode39

```
const ccSymbologyParamsCode39& paramsCode39() const;

void paramsCode39(
   const ccSymbologyParamsCode39& paramsCode39);
```

- `const ccSymbologyParamsCode39& paramsCode39() const;`

  Returns the currently specified Code 39 decoding parameters object.

- ```
  void paramsCode39(
     const ccSymbologyParamsCode39& paramsCode39);
  ```

  Sets the Code 39 decoding parameters object.

  Parameters

  paramsCode39 The parameter object to set.

paramsCode128

```
const ccSymbologyParamsCode128& paramsCode128() const;

void paramsCode128(
   const ccSymbologyParamsCode128& paramsCode128);
```

- `const ccSymbologyParamsCode128& paramsCode128() const;`

  Returns the currently specified Code 128 decoding parameters object.

- ```
  void paramsCode128(
     const ccSymbologyParamsCode128& paramsCode128);
  ```

  Sets the Code 128 decoding parameters object.

  Parameters
  paramsCode128 The parameter object to set.

paramsUPCEAN

```
const ccSymbologyParamsUPCEAN& paramsUPCEAN() const;

void paramsUPCEAN(
   const ccSymbologyParamsUPCEAN& paramsUPCEAN);
```

- `const ccSymbologyParamsUPCEAN& paramsUPCEAN() const;`

  Returns the currently specified UPC/EAN decoding parameters object.

- ```
  void paramsUPCEAN(
     const ccSymbologyParamsUPCEAN& paramsUPCEAN);
  ```

  Sets the UPC/EAN decoding parameters object.

  Parameters
  paramsUPCEAN The parameter object to set.

paramsCodabar

```
const ccSymbologyParamsCodabar& paramsCodabar() const;

void paramsCodabar(
   const ccSymbologyParamsCodabar& paramsCodabar);
```

- `const ccSymbologyParamsCodabar& paramsCodabar() const;`

  Returns the currently specified Codabar decoding parameters object.

- ```
  void paramsCodabar(
     const ccSymbologyParamsCodabar& paramsCodabar);
  ```

  Sets the Codabar decoding parameters object.

  Parameters
  paramsCodabar The parameter object to set.

paramsCode93

```
const ccSymbologyParamsCode93& paramsCode93() const;

void paramsCode93(
   const ccSymbologyParamsCode93& paramsCode93);
```

- `const ccSymbologyParamsCode93& paramsCode93() const;`

  Returns the currently specified Code 93 decoding parameters object.

- ```
  void paramsCode93(
     const ccSymbologyParamsCode93& paramsCode93);
  ```

  Sets the Code 93 decoding parameters object.

  Parameters
  paramsCode93 The parameter object to set.

paramsPDF417

```
const ccSymbologyParamsPDF417& paramsPDF417() const;

void paramsPDF417(const ccSymbologyParamsPDF417&
paramsPDF417);
```

- `const ccSymbologyParamsPDF417& paramsPDF417() const;`

  Returns the currently specified PDF417 decoding parameters object.

- `void paramsPDF417(const ccSymbologyParamsPDF417& paramsPDF417);`

  Sets the PDF417 decoding parameters object.

  Parameters
  paramsPDF417 The parameter object to set.

paramsRSS

```
const ccSymbologyParamsRSS& paramsRSS() const;

void paramsRSS(const ccSymbologyParamsRSS& paramsRSS);
```

- `const ccSymbologyParamsRSS& paramsRSS() const;`

  Returns the currently specified RSS decoding parameters object.

- `void paramsRSS(const ccSymbologyParamsRSS& paramsRSS);`

  Sets the RSS decoding parameters object.

  Parameters
  paramsRSS The parameter object to set.

paramsComposite

```
const ccSymbologyParamsComposite& paramsComposite() const;

void paramsComposite(
   const ccSymbologyParamsComposite& paramsComposite);
```

- `const ccSymbologyParamsComposite& paramsComposite() const;`

  Returns the currently specified Composite decoding parameters object.

- `void paramsComposite(`
  `const ccSymbologyParamsComposite& paramsComposite);`

  Sets the Composite decoding parameters object.

  Parameters
  paramsComposite
  The parameter object to set.

paramsPostal

```
const ccSymbologyParamsPostal& paramsPostal() const;

void paramsPostal(
   const ccSymbologyParamsPostal& paramsPostal);
```

- `const ccSymbologyParamsPostal& paramsPostal() const;`

  Returns the currently specified Postal decoding parameters object.

- ```
  void paramsPostal(
     const ccSymbologyParamsPostal& paramsPostal);
  ```

  Sets the Postal decoding parameters object.

  Parameters

  paramsPostal The parameter object to set.

Operators

operator==

```
bool operator== (const ccIDDecodeParams& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.
```

ccIDDecodeResult

```
#include <ch_cvl/id.h>

class ccIDDecodeResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the results from decoding a single symbol.

Constructors/Destructors

ccIDDecodeResult

```
ccIDDecodeResult();
```

Constructs a **ccIDDecodeResult** with the following values:

ccIDDecodeResult::symbology set to *ccIDDefs::eSymbologyUnknown*
ccIDDecodeResult::symbologySubtype set to 0
ccIDDecodeResult::symbolIdentifiers set to an empty string
ccIDDecodeResult::hasErrorInfo set to false

Public Member Functions

symbology

```
ccIDDefs::Symbology symbology() const;
```

Returns the type of this symbol. The returned value is a member of **ccIDDefs::Symbology**.

For composite symbologies, when **ccSymbologyParamsComposite::combineResults** is true, this function returns *ccIDDefs::eComposite*.

symbologySubtype

```
c_UInt32 symbologySubtype() const;
```

Returns the symbology subtype of this symbol, if applicable.

Valid for UPC/EAN, RSS and 4-State Postal Codes. Always use together with **symbology()** to determine the actual type of the decoded symbol. A Value 0 indicates that the symbology does not have subtypes.

Notes

The subtype values are defined in the symbology parameters classes (**ccSymbologyParamsRSS**, **ccSymbologyParamsPostal**, **ccSymbologyParamsComposite**, and **ccSymbologyParamsUPCEAN**).

symbolIdentifiers

```
const ccCvlString& symbolIdentifiers() const;
```

Returns a null-terminated string of three ASCII characters conforming to ***ISO/IEC 15424:2000*** *Information technology -- Automatic identification and data capture techniques - Data Carrier Identifiers (including Symbology Identifiers)*.

This string includes a flag character, a code character, and a modifier character. The structure of the symbology identifier is:

```
]cm
```

where

] (ASCII value 93 in accordance with ISO646) represents the symbology identifier flag character

c represents the code character which indicates to the host the bar code symbology of the symbol which has been read, where

A = Code 39,
C = Code 128,
E = UPC/EAN,
I = Interleaved 2 of 5,
G = Code 93,
L = PDF417,
e = RSS,
X = other bar codes.

m represents the modifier character as defined for the symbology in question. Specifically, the identifier character 'X' is used to specify symbologies that are not listed in ISO/IEC 15424:2000 and can have the following modifiers:

]X0 for POSTNET/CEPNet, reader has stripped the check character
]X1 for POSTNET/CEPNet, reader has transmitted the check character
]X2 for PLANET, reader has stripped the check character
]X3 for PLANET, reader has transmitted the check character
]X6 for Australia Post 4-state code
]X8 for UPU 4-State postal code
]X9 for Japan Post 4-State customer barcode
]XA for USPS 4-State postal code
]XB for Pharmacode one-track code

Throws

ccIDDefs::BadString
This is a default-constructed **ccIDDecodeResult**.

decodedMBCString

```
const cmStd vector<c_UInt8>& decodedMBCString() const;
```

Returns the decoded data as a double-null terminated multi-byte character string.

For symbologies that encode 8-bit characters, this function returns a string of single-byte characters. For symbologies that encode both single-byte and double-byte characters, it returns a stream of multibyte characters.

Throws

ccIDDefs::BadString
This is a default-constructed **ccIDDecodeResult**.

decodedString

```
ccCvlString decodedString() const;
```

Returns the decoded string.

This function should only be used for symbols which are known to not contain multibyte characters in the decoded data, and for which the interpretation of the characters in the decoded string is up to the application.

For symbols encoding non-alphanumeric data, use **decodedMBCString()** to obtain the decoded data.

Throws

ccIDDefs::BadString
This is a default-constructed **ccIDDecodeResult**.

decodedElementStream

```
const cmStd vector<c_Int32>& decodedElementStream() const;
```

Gets the uninterpreted stream. Interpretation is symbology-specific.

Throws

ccIDDefs::BadString
This is a default-constructed **ccIDDecodeResult**.

hasErrorInfo

```
bool hasErrorInfo() const;
```

Returns true if **numErrors()**, **numErrorBits()**, **numErrorWords()**, and u**nusedErrorCorrection()** will return meaningful information.

numErrors

```
c_Int32 numErrors() const;
```

Returns the number of erroneous data words encountered while decoding the symbol.

Throws

ccIDDefs::NotComputed
There is no error information for this result (**hasErrorInfo()** returns false).

numErrorBits

```
c_Int32 numErrorBits() const;
```

Returns the number of erroneous bits encountered while decoding the symbol.

Throws

ccIDDefs::NotComputed
There is no error information for this result (**hasErrorInfo()** returns false).

unusedErrorCorrection

```
c_Int32 unusedErrorCorrection() const;
```

Returns the amount of unused error correction in the decoded symbol.

The returned value is in the range of 0 through 100 inclusively to indicate the percentage unused error correction. This only applies to symbologies with strong error correction, such as PDF417.

For symbologies that have reserved codewords for error detection to prevent misreads, this value can be negative if the error detection codewords are used for error correction. A negative value indicates that the number of erasures and errors is beyond the specified limit for correction. The closer a negative value is to zero, the less the probability of getting a misread.

In applications where a high decode rate is desired at the risk of low probability misreads, **isDecoded()** can be used as the sole indication of a successful decode. When a slightly lower but more confident decode rate is preferred, you should check that the **unusedErrorCorrection()** is non-negative before considering the decoded result to be valid.

Throws

ccIDDefs::NotComputed
There is no error information for this result (**hasErrorInfo()** returns false).

Operators

operator==

```
bool operator== (const ccIDDecodeResult& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDDecodeResult

ccIDDefs

```
#include <ch_cvl/id.h>

class ccIDDefs;
```

A name space that holds enumerations, constants, and errors associated with the ID tool.

Enumerations

Symbology

```
enum Symbology;
```

This enumeration defines the symbology types supported by the ID tool. You use this enumeration to tell the tool what symbologies to attempt to decode, and the tool returns the actual symbology for a decoded symbol.

Value	Symbology
eSymbologyUnknown	Unknown.
eCodabar	Codabar
eCode128	Code 128
eCode39	Code 39
eCode93	Code 93
eI2of5	Interleaved 2 of 5
ePharmaCode	Pharmacode
eUPCEAN	UPC / EAN
ePostal	Postal codes (4-state Japan Post, Australia Post, UPU, and USPS; POSTNET, PLANET)
eRSS	RSS (DataBar)
ePDF417	PDF417 stacked code
eComposite	EAN.UCC Composite

Mirrored

```
enum Mirrored;
```

This enumeration defines whether or not the symbol is mirrored.

Value	meaning
eMirroredFalse	Symbol is not mirrored.
eMirroredTrue	Symbol is mirrored.
eMirroredUnknown	Mirroring is unknown.

Polarity

```
enum Polarity;
```

This enumeration defines whether the symbol consists of dark bars on a light background or light symbols on a dark background.

Value	meaning
eDarkOnLight	Dark bars on a light background.
eLightOnDark	Light bars on a dark background.
ePolarityUnknown	Unknown polarity
kDefaultPolarity	The default polarity for newly constructed objects.

OperatingMode

```
enum OperatingMode;
```

This enumeration defines the operating mode for the ID tool.

Value	meaning
eStandard = 1	Standard mode.
e1DMax = 2	1DMax mode.
kDefaultOperatingMode = *eStandard*	The default operating mode.

Notes

The e1DMax operating mode is recommended for dealing with hard-to-read codes. For more information on operating modes, see the ID Tool chapter in the CVL Vision Tools Guide.

FailureCode `enum FailureCode;`

This enumeration defines the failure codes that the ID tool can return. These codes provide specific information about decoding failures.

Value	Meaning
eFailureNotApplicable	No failure codes are available for this symbology.
eFailureFinderPatternNotFound	The finder pattern for this symbol was not found.
eFailureStartStopPatternNotComplete	The start/stop pattern for this symbol is not complete.
eFailureChecksumFailed	The checksum for this symbol is incorrect.
eFailureDegradedSymbol	This symbol contains unrecognized characters or characters recognized with low confidence.
eFailureUnexpectedStringLength	The decoded string length is outside the user specified range.
eFailureTooManyErrorBits	The number of error bits detected in the 2D symbol is beyond the capacity of error correction.
eFailureSymbolVersionNotFound	Version of the symbol could not be determined.
eFailureRowAddressPatternOutOfOrder	The detected Row Address patterns of a 2D result are out of sequence.
eFailureCodeLinesNotFound	The detected Row Address patterns of a 2D result cannot form data rows.
eFailureInternalError	The ID tool experienced an internal error.

DrawMode `enum DrawMode;`

This enumeration defines what type of result graphics to draw.

Value	meaning
eDrawCenter	Draw a cross at the center of the result location.
eDrawBoundary	Draw a boundary around the result location.
kDefaultDrawMode	The default graphics to draw.

ccIDQualityDefs

```
#include <ch_cvl/id.h>

class ccIDQualityDefs
```

Static Functions

numQualityMetrics

```
static c_Int32 numQualityMetrics();
```

Returns the number of quality metrics that are defined in the **QualityMetrics** enumeration.

Enumerations

QualityOption

```
enum QualityOption;
```

This enumeration defines which quality measures to compute.

Value	meaning
eQualityOptionNone	No measures.
eQualityOptionBasic	The basic measures: *eEdgeDetermination*, *eEdgeContrastMin*, *eModulation*, *eDefects*, *eReferenceDecode*, *eScanGrade*, and *eSymbolContrast*.
kDefaultQualityOption	The default quality option.

QualityMetrics

```
enum QualityMetrics;
```

This enumeration defines the quality measures. These measures are formally defined by *ANSI X3.182 - 1990 Bar Code Print Quality*.l

Value	meaning
eOverallGrade	The overall quality measure, from A to F.
eEdgeDetermination	Graded A if the count of global threshold based edges in the scan reflectance profile corresponds to a valid symbology, graded F otherwise.
eReflectMin	The lowest value in the reflectance profile.

Value	meaning
eEdgeContrastMin	Graded A if the minimum reflectance difference between symbol and adjacent background is >= 15% of greyscale range, graded F otherwise. See ANSI X3.182.
eModulation	Minimum edge contrast divided by overall symbol contrast. A: >= 0.7, B: >= 0.6, C: >= 0.5, D: >= 0.4, F: < 0.4. See ANSI X3.182.
eDefects	Maximum element reflectance non-uniformity divided by overall symbol contrast. A: <= 0.15, B: <= 0.20, C: <= 0.25, D: <= 0.30, F: > 0.30. See ANSI X3.182.
eReferenceDecode	Graded A if the ANSI Reference Decode algorithm can decode this symbol, graded F otherwise. See ANSI X3.182.
eDecodability	A measure of how close the symbol characteristics are to the nominal values defined for that symbology. See ANSI X3.182.
eScanGrade	The lowest grade received for any reflectance scan profile based quality measurement. See ANSI X3.182.
eSymbolContrast	Difference between highest and lowest reflectance values in the scan profile, as percentage of greyscale range. A: >= 70%, B: >= 55%, C: >= 40%, D: >= 20%, F: < 20%. See ANSI X3.182.

QualityGrade `enum QualityGrade;`

This enumeration defines the quality grades.

Value	meaning
eGradeNotComputed	The grade for this measure was not computed.
eGradeA	Grade A where A is Excellent and F is Fail.
eGradeB	Grade B where A is Excellent and F is Fail.
eGradeC	Grade C where A is Excellent and F is Fail.
eGradeD	Grade D where A is Excellent and F is Fail.
eGradeF	Grade F where A is Excellent and F is Fail.

ccIDQualityDefs

ccIDQualityResult

```
#include <ch_cvl/id.h>

class ccIDQualityResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the quality measures computed from a single decoded symbol.

Constructors/Destructors

ccIDQualityResult

```
ccIDQualityResult();
```

Constructs this object with all quality measures are set to *ccIDQualityDefs::eGradeNotComputed*.

Public Member Functions

qualityGrade

```
ccIDQualityDefs::QualityGrade qualityGrade(
   ccIDQualityDefs::QualityMetrics metric) const;
```

Returns the grading result for the supplied quality metric. The returned value is a member of the **ccIDQualityDefs::QualityGrade** enumeration.

Parameters

metric The metric to compute. The supplied value must be one of the following values:

ccIDQualityDefs::eOverallGrade
ccIDQualityDefs::eEdgeDetermination
ccIDQualityDefs::eReflectMin
ccIDQualityDefs::eEdgeContrastMin
ccIDQualityDefs::eModulation
ccIDQualityDefs::eDefects
ccIDQualityDefs::eReferenceDecode

ccIDQualityDefs::eDecodability
ccIDQualityDefs::eScanGrade
ccIDQualityDefs::eSymbolContrast

Notes

Returns *ccIDQualityDefs::eGradeNotComputed* if the requested metric was not computed.

Throws

ccIDDefs::BadParams

metric is not a member of **ccIDQualityDefs::QualityMetrics**.

operator==

```
bool operator== (const ccIDQualityResult& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that	The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDResult

```
#include <ch_cvl/id.h>

class ccIDResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing all of the result information from a symbol.

Constructors/Destructors

ccIDResult

```
ccIDResult();
```

Constructs this object with the **ccIDResult::subResults** set to a single default-constructed **ccIDSubResult** object.

Public Member Functions

numSubResults

```
c_Int32 numSubResults() const;
```

Returns the number of subresults in this result.

Notes

For composite symbologies this value can be greater than 1.

subResults

```
const cmStd vector<ccIDSubResult>& subResults() const;
```

Returns the vector of subresults contained in this result.

isFound

```
bool isFound() const;
```

Returns the value of **ccIDSubResult::isFound()** for the first subresult **(subResults(0)**).

isDecoded

```
bool isDecoded() const;
```

Returns the value of **ccIDSubResult::isDecoded()** for the first subresult **(subResults(0)**).

ccIDResult

failureCode

```
ccIDDefs::FailureCode failureCode() const;
```

Returns the value of **ccIDSubResult::failureCode()** for the first subresult **(subResults(0)**).

searchResult

```
const ccIDSearchResult& searchResult() const;
```

Returns the search result (**ccIDSubResult::searchResult())** from the first subresult **(subResults(0)**).

Throws

ccIDDefs::NotComputed
There are no results (**isFound()** is false).

decodeResult

```
const ccIDDecodeResult& decodeResult()const;
```

Returns the decode result (**ccIDSubResult::decodeResult())** from the first subresult **(subResults(0)**).

Throws

ccIDDefs::NotComputed
There is no decode result (**isDecoded()** is false).

qualityResult

```
const ccIDQualityResult& qualityResult() const;
```

Returns the quality result (**ccIDSubResult::qualityResult())** from the first subresult **(subResults(0)**).

Notes

When the symbol was decoded but **ccIDDecodeParams::qualityOption** was set to *ccIDQualityDefs::eQualityOptionNone*, a default constructed **ccIDQualityResult** is returned.

Throws

ccIDDefs::NotComputed
There is no decode result (**isDecoded()** is false).

draw

```
void draw(ccGraphicList& glist, c_UInt32 drawMode) const;
```

Appends graphics for this result to the supplied graphics list. *drawMode* is used to select which graphics are drawn and must be a bitwise combination of the following values:

ccIDDefs::eDrawCenter
ccIDDefs::eDrawBoundary

ccIDDefs::eDrawCenter draws a cross at this result's location; *ccIDDefs::eDrawBoundary* draws the boundary of this result, which is a polygon connecting the corners.

Graphics are drawn in *ccColor::green* if the result was successfully decoded, *ccColor::red* if the result was found but not decoded, and no graphics are drawn if no subresult has **isFound()** equal to true.

Parameters

glist	The graphics list to which to append the graphic.
drawMode	The drawing mode.

Notes

All graphics are drawn in client coordinates.

Operators

operator==

```
bool operator== (const ccIDResult& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that	The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDResult

ccIDResultSet

```
#include <ch_cvl/id.h>

class ccIDResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the results of a single invocation of the ID tool. One result is generated for each symbol found in the image, up to the requested number of symbols to find.

Constructors/Destructors

ccIDResultSet

```
ccIDResultSet();
```

Constructs this object with **time** set to 0.0 and **results** set to an empty vector.

Public Member Functions

numResults

```
c_Int32 numResults() const;
```

Returns the number of results in this result set.

time

```
double time() const;
```

Returns the time (in seconds) used to run the tool and create this result.

results

```
const cmStd vector<ccIDResult>& results() const;
```

Returns a vector containing the results of this result set.

draw `void draw(ccGraphicList& glist, c_UInt32 drawMode) const;`

Appends graphics for this result set to the supplied graphics list. *drawMode* is used to select which graphics are drawn and must be a bitwise combination of the following values:

ccIDDefs::eDrawCenter
ccIDDefs::eDrawBoundary

ccIDDefs::eDrawCenter draws a cross at this result's location; *ccIDDefs::eDrawBoundary* draws the boundary of this result, which is a polygon connecting the corners.

Graphics are drawn in *ccColor::green* if the result was successfully decoded, *ccColor::red* if the result was found but not decoded, and no graphics are drawn if no result in this set has **isFound()** equal to true.

Parameters

glist The graphics list to which to append the graphic.

drawMode The drawing mode.

Notes

All graphics are drawn in client coordinates.

Operators

operator== `bool operator== (const ccIDResultSet& that) const;`

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDSearchParams

```
#include <ch_cvl/id.h>

class ccIDSearchParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the search parameters for the ID tool.

Constructors/Destructors

ccIDSearchParams

```
ccIDSearchParams();
```

Constructs an object with the following default values:

numToFind: 1
isPostalOmniDirectional: false
mirror: *ccIDDefs::eMirroredFalse*
polarity: *ccIDDefs::kDefaultPolarity*
operatingMode: *ccIDDefs::kDefaultOperatingMode*

Public Member Functions

numToFind

```
c_Int32 numToFind() const;

void numToFind(c_Int32 numToFind);
```

- ```
  c_Int32 numToFind() const;
  ```

  Returns the number of symbols to find.

- ```
  void numToFind(c_Int32 numToFind);
  ```

  Sets the number of symbols to be found. The tool returns a result for each symbol that it finds up to the number that you specify.

Parameters
numToFind The number to find.

Throws
ccIDDefs::BadParams
numToFind is less than 1.

mirror

```
ccIDDefs::Mirrored mirror() const;
void mirror(ccIDDefs::Mirrored mirror);
```

- `ccIDDefs::Mirrored mirror() const;`

Returns whether the tool will search for mirrored images. The returned value is one of the following:

ccIDDefs::eMirroredFalse
ccIDDefs::eMirroredTrue
ccIDDefs::eMirroredUnknown

If **mirror()** is *ccIDDefs::eMirroredUnknown*, the tool will search for both mirrored and unmirrored symbols.

- `void mirror(ccIDDefs::Mirrored mirror);`

Determines whether the tool will search for mirrored images. Specifying *ccIDDefs::eMirroredUnknown* causes the tool to search for both mirrored and unmirrored symbols.

Parameters
mirror The mirroring flag. *mirror* must be one of the following values:

ccIDDefs::eMirroredFalse
ccIDDefs::eMirroredTrue
ccIDDefs::eMirroredUnknown

Throws
ccIDDefs::BadParams
mirror is invalid.

Notes

The mirror flag is ignored for linear symbologies.

For postal codes, when the mirror flag is set to *ccIDDefs::eMirroredUnknown*, the tool outputs the better decoded postal code result of either mirrored or non-mirrored. When the mirrored and non-mirrored results have the same evaluation, the tool outputs the non-mirrored result. Cognex recommends that you do not specify *ccIDDefs::eMirroredUnknown* for postal codes.

polarity

```
ccIDDefs::Polarity polarity() const;
void polarity(ccIDDefs::Polarity polarity);
```

- `ccIDDefs::Polarity polarity() const;`

Returns the polarity of symbols for which the tool will search. The returned value is one of the following:

ccIDDefs::eDarkOnLight
ccIDDefs::eLightOnDark
ccIDDefs::ePolarityUnknown

If **polarity()** is *ccIDDefs::ePolarityUnknown*, the tool will search for both dark-on-light and light-on-dark symbols.

- `void polarity(ccIDDefs::Polarity polarity);`

Sets the polarity of symbols for which the tool will search. A value of ccIDDefs::eDarkOnLight specifies dark code elements on a light background; ccIDDefs::eLightOnDark specifies light code elements on a dark background.

If you specify ccIDDefs::ePolarityUnknown, the tool will search for symbols of either polarity.

Parameters

polarity The polarity to set. *polarity* must be one of the following values:

ccIDDefs::eDarkOnLight
ccIDDefs::eLightOnDark
ccIDDefs::ePolarityUnknown

Throws

ccIDDefs::BadParams
polarity is invalid.

Notes

Symbol polarity only applies to postal and PDF417 codes; it is ignored for linear symbologies.

isPostalOmniDirectional

```
bool isPostalOmniDirectional() const;

void isPostalOmniDirectional(
   bool isPostalOmniDirectional);
```

- `bool isPostalOmniDirectional() const;`

  Returns whether or not the tool searches for postal codes at arbitrary orientations. If the value is false, the tool only finds codes that are approximately aligned to the X-axis of the image. If the value is true, the tool finds codes at any orientation.

- `void isPostalOmniDirectional(`
  `bool isPostalOmniDirectional);`

  Sets whether or not the tool searches for postal codes at arbitrary orientations. If the value is false, the tool only finds codes that are approximately aligned to the X-axis of the image. If the value is true, the tool finds codes at any orientation.

  Specifying omnidirectional search may cause the tool to run more slowly.

  Parameters

  isPostalOmniDirectional

  specify true to enable omnidirectional search, false to search only for horizontally aligned codes.

  Notes

  This parameter is ignored for non-postal symbologies.

operatingMode

```
ccIDDefs::OperatingMode operatingMode() const;

void operatingMode(ccIDDefs::OperatingMode operatingMode);
```

- `ccIDDefs::OperatingMode operatingMode() const;`

  Gets the tool's operating mode.

- `void operatingMode(ccIDDefs::OperatingMode operatingMode);`

Sets the tool's operating mode.

The default value is *ccIDDefs::kDefaultOperatingMode*

Notes

The operating mode applies to all bar code types.

The e1DMax mode is recommended for dealing with hard-to-read codes. You must use the setter to explicitly specify *e1DMax* in order to activate that mode because the default mode is *eStandard*.

Throws

ccIDDefs::BadParams
The *operatingMode* argument is invalid.

Operators

operator== `bool operator== (const ccIDSearchParams& that) const;`

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDSearchParams

ccIDSearchResult

```
#include <ch_cvl/id.h>

class ccIDSearchResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the search result for an individual symbol. A search result is generated for each symbol found during a run of the ID tool.

Constructors/Destructors

ccIDSearchResult

```
ccIDSearchResult();
```

Constructs an object with the following default values:

location: (0, 0)
angle: 0
moduleSize: -1.0
mirror: *ccIDDefs::eMirroredUnknown*
polarity: *ccIDDefs::ePolarityUnknown*
has2DInfo: false

Public Member Functions

location

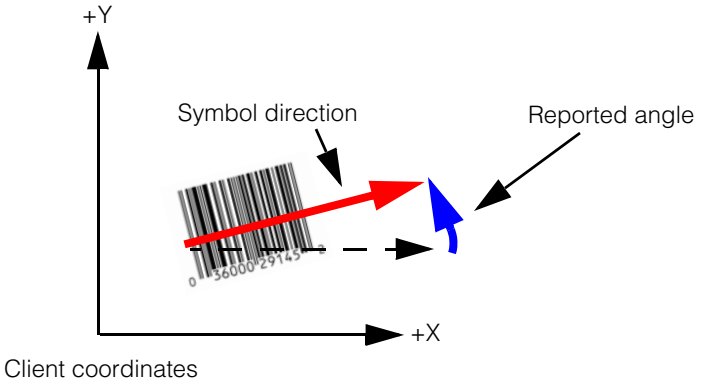
```
cc2Vect location() const;
```

Returns the center position of the found symbol in client coordinates.

angle

```
ccRadian angle() const;
```

Returns the found angle of the symbol, in radians. The returned value is the angle between the positive X-axis in client coordinate space and the symbol angle, which is the positive reading direction. The symbol direction is perpendicular to the code modules in the case of 1D codes.



The returned value is in the range of 0 through 2**TT.**

Notes

If the symbol is distorted, angle is the average value across the symbol.

moduleSize

```
double moduleSize() const;
```

Returns the size of a module of the symbology in client units. If the module size was not measured, this function returns -1.

mirror

```
ccIDDefs::Mirrored mirror() const;
```

Returns whether or not the found symbol was mirrored. This function returns one of the following values:

ccIDDefs::eMirroredFalse
ccIDDefs::eMirroredTrue
ccIDDefs::eMirroredUnknown

Notes

A value of *ccIDDefs::eMirroredUnknown* indicates the condition was not determined.

polarity

```
ccIDDefs::Polarity polarity() const;
```

Returns the polarity of the found symbol. This function returns one of the following values:

ccIDDefs::eDarkOnLight
ccIDDefs::eLightOnDark
ccIDDefs::ePolarityUnknown

Notes

A value of *ccIDDefs::ePolarityUnknown* indicates the polarity was not determined.

has2DInfo

```
bool has2DInfo() const;
```

Indicates whether 2D information is available for the found symbol. This function returns false for all linear, postal, and stacked codes.

numRows2D

```
c_Int32 numRows2D() const;
```

Returns the number of rows in the 2D symbol.

Throws

ccIDDefs::NotComputed
There is no 2D information (**has2DInfo()** returns false).

numCols2D

```
c_Int32 numCols2D() const;
```

Returns the number of columns in the 2D symbol.

Throws

ccIDDefs::NotComputed
There is no 2D information (**has2DInfo()** returns false).

symbolRegion `const ccPolyline& symbolRegion() const;`

Returns a polyline that describes the boundary of the symbol's found region.

The polyline traverses the four corners of the symbol, where the corners are defined by the ANSI or AIM specification for the symbol type:

Corner 0: upper left
Corner 1: upper right
Corner 2: lower right
Corner 3: lower left

For mirrored symbols, the corners are mirrored.

Throws

ccIDDefs::NotComputed
This **ccIDSearchResult** was default constructed.

Operators

operator== `bool operator== (const ccIDSearchResult& that) const;`

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDSubResult

```
#include <ch_cvl/id.h>

class ccIDSubResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing all of the result information for a subresult. For composite symbols, each **ccIDResult** contains multiple **ccIDSubResult**s. For non-composite symbols, only a single **ccIDSubResult** is present.

Constructors/Destructors

ccIDSubResult

```
ccIDSubResult();
```

Constructs this object with the following values:

isFound: false
isDecoded: false
failureCode: *ccIDDefs::eFailureNotApplicable*

Public Member Functions

isFound

```
bool isFound() const;
```

Returns true if a symbol was found, false otherwise.

In order for a symbol to be found, its symbology must be enabled in the **ccIDSearchParams** object supplied to the tool.

If the function returns false, additional information about the failure may be obtained by calling **failureCode()**.

isDecoded

```
bool isDecoded() const;
```

Returns true if the symbol was both found and decoded successfully, false otherwise.

ccIDSubResult

failureCode `ccIDDefs::FailureCode failureCode() const;`

If either **isFound()** or **isDecoded()** returns false, this function returns a failure code that describes the reason for the search or decode failure.

The returned value is a member of the **ccIDDefs::FailureCode** enumeration. If no failure code is available (either because this object is default-constructed or the search and decode succeeded), the function returns *ccIDDefs::eFailureNotApplicable*.

Notes

The codes returned by this function are for diagnostic and informational purposes only. The returned codes may change in future releases.

searchResult `const ccIDSearchResult& searchResult() const;`

Returns the search result from this subresult.

Throws

ccIDDefs::NotComputed
There are no results (**isFound()** is false).

decodeResult `const ccIDDecodeResult& decodeResult()const;`

Returns the decode result from this subresult.

Throws

ccIDDefs::NotComputed
There is no decode result(**isDecoded()** is false).

qualityResult

`const ccIDQualityResult& qualityResult() const;`

Returns the quality result from this subresult.

Notes

When the symbol was decoded but **ccIDDecodeParams::qualityOption** was set to *ccIDQualityDefs::eQualityOptionNone*, a default constructed **ccIDQualityResult** is returned.

Throws

ccIDDefs::NotComputed
There is no decode result(**isDecoded()** is false).

draw `void draw(ccGraphicList& glist, c_UInt32 drawMode) const;`

Appends graphics for this subresult to the supplied graphics list. *drawMode* is used to select which graphics are drawn and must be a bitwise combination of the following values:

ccIDDefs::eDrawCenter
ccIDDefs::eDrawBoundary

ccIDDefs::eDrawCenter draws a cross at this subresult's location; *ccIDDefs::eDrawBoundary* draws the boundary of this subresult, which is a polygon connecting the corners.

Graphics are drawn in *ccColor::green* if the subresult was successfully decoded, *ccColor::red* if the subresult was found but not decoded, and no graphics are drawn if **isFound()** is false.

Parameters

glist	The graphics list to which to append the graphic.
drawMode	The drawing mode.

Notes

All graphics are drawn in client coordinates.

Operators

operator== `bool operator== (const ccIDSubResult& that) const;`

Returns true if the supplied object is equal to this one.

Parameters

that	The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccIDSubResult

ccImageFont

```
#include <ch_cvl/synfont.h>

class ccImageFont;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccImageFont** class represents a set of characters that are each specified as bitmaps rather than as some synthetic specification.

Constructors/Destructors

The default constructor, copy constructor, assignment operator, and destructor are used.

Public Member Functions

name

```
const ccCvlString& name() const;

void name(const ccCvlString& n);
```

- `const ccCvlString& name() const;`

  Gets the name of this font.

- `void name(const ccCvlString& n);`

  Sets the name of this font.

  Parameters

n	The name of this font

characters

```
const cmStd vector<ccImageFontChar>& characters() const;

void characters(const cmStd vector<ccImageFontChar>& c,
  bool makeUniqueInstanceKeys = false);
```

- `const cmStd vector<ccImageFontChar>& characters() const;`

  Gets the characters in this font.

- `void characters(const cmStd vector<ccImageFontChar>& c, bool makeUniqueInstanceKeys = false);`

  Sets the characters in this font.

  Parameters

  c The characters in this font.

  makeUniqueInstanceKeys
  If true, then characters will all be assigned unique keys; specifically, later characters in the set will be reassigned unique instance values.

  Throws

  ccSynFontDefs::SameKey
  Two or more characters have the same key and *makeUniqueInstanceKeys* is false.

hasCharacter

```
bool hasCharacter(c_Int32 key) const;
```

Returns true if a character with the specified key exists in this font.

Parameters

key The specified key.

character

```
const ccImageFontChar& character(c_Int32 key) const;
```

Returns the character with the specified key.

Parameters

key The specified key.

Throws

ccSynFontDefs::BadParams
No character has the specified key.

add

```
void add(const ccImageFontChar& imageChar);
```

Adds the character to the font.

Parameters

imageChar The character to be added.

Throws

ccSynFontDefs::SameKey
Two or more characters have the same key.

---

remove

```
void remove(c_Int32 key);
void remove(const cmStd vector<c_Int32>& keys);
```

- `void remove(c_Int32 key);`

Removes the character with the specified key from the font.

Parameters

key The specified key.

Throws

ccSynFontDefs::BadParams
No character has the specified key.

- `void remove(const cmStd vector<c_Int32>& keys);`

Removes the characters with the specified keys from the font.

Parameters

keys The specified keys.

Throws

ccSynFontDefs::BadParams
No character has each specified key.

removeAll

```
void removeAll();
```

Removes all characters from the font.

leading

```
cc2Vect leading() const;
void leading(const cc2Vect&);
```

- `cc2Vect leading() const;`

  Gets the leading for this font.

- `void leading(const cc2Vect& leadingForFont);`

  Sets the leading for this font.

  Parameters

  leadingForFont The new leading for this font.

encloseCellRect

```
ccRect encloseCellRect() const;
```

Gets the enclosing cell rect for the font, which encloses all of the individual character cell rects.

encloseMarkRect

```
ccRect encloseMarkRect() const;
```

Gets the enclosing mark rect for the font, which encloses all of the individual character mark rects.

assignAlphabet

```
void assignAlphabet(const ccOCAlphabet& alphabet,
  bool makeDuplicateCharsWithUnicodeKeys = true);
```

Resets this font to be essentially identical to the OCV alphabet.

Parameters

alphabet The OCV alphabet.

makeDuplicateCharsWithUnicodeKeys
If true, duplicate characters are made with unicode keys.

Notes

Since an OCV alphabet does not specify all the information that needs to be specified for an image font, reasonable values will be chosen:

1) The advance for each character will be set equal to its width.

2) The mark rect for non-blank characters will be set equal to the cell rect.

3) The leading for the font will be set equal to the height of the tallest character.

If *makeDuplicateCharsWithUnicodeKeys* is true, then in addition to creating characters with the keys as they already are in the alphabet, copies of those characters will be made with key values that are typical ASCII values, on the assumption that the Unicode key value is in the upper 16 bits of the alphabet keys; such an encoding scheme is used by the VisionPro OCV font editor when it saves font files in CVL (".ocf") format.

makeAlphabet

```
ccOCAlphabetPtrh makeAlphabet() const;
```

Creates an OCV alphabet that is identical to this font.

moveCharOrigins

```
void moveCharOrigins( ccImageFontChar::Origin origin =
  ccImageFontChar::eDetectedMarkLowerLeft);
```

Move the origins of all characters as specified.

Parameters

origin The origin.

Notes

For blanks, *eDetectedMarkLowerLeft* and *eSpecifiedMarkLowerLeft* will compute a "reasonable" value based on the origin locations of other characters.

detectCharMarkRects

```
void detectCharMarkRects();
```

Detects the mark rects of all the characters.

detectCharPolarities

```
void detectCharPolarities(bool onlyIfUnknown = true,
  bool expectAllSamePolarity = true);
```

Detects the polarities of all the characters.

Parameters

onlyIfUnknown Only if the polarity is unknown.

expectAllSamePolarity
Expects that the polarity information is the same for all characters.

leftJustifyChars

```
void leftJustifyChars(double leftPadding = 2.);
```

Left-justifies all the characters.

Parameters

leftPadding The left padding value.

save

```
void save(const ccCvlString& filename,
  bool saveAsOcf = false) const;
```

Saves the font to a file with the given filename. If *saveAsOcf* is true, the file will be saved in the older ".ocf" file format, which loses some information in the metrics.

Parameters

filename The name of the file.

saveAsOcf If true, the file will be saved in the older ".ocf" file format.

load

```
void load(const ccCvlString& filename);
```

Loads the font from the file with the given filename; the file may be in either ".ocf" or ".ocm" format. The font will be unchanged if the load fails.

Parameters

filename The name of the file.

Throws

ccSynFontDefs::BadFileFormat if the file does not contain an image font; it can also throw other exceptions (for example, *ccArchive::Eof, ccArchive::UnknownVersion,* and so on).

tryLoad

```
bool tryLoad(const ccCvlString& filename);
```

Tries to load the font from the file with the given filename; the file may be in either ".ocf" or ".ocm" format. Returns true if successful or false if the file was in a bad format.

Caution *Does not throw* ccSynFontDefs::BadFileFormat *if the file is in a bad format.*

The font will be unchanged if the load fails.

Parameters

filename The name of the file.

makeUniqueInstanceKey

```
c_Int32 makeUniqueInstanceKey(c_Int32 key) const;
```

Returns a unique key to be used for a new instance of the given key, with the same Unicode character value.

Parameters

key The given key.

ccImageFont

ccImageFontChar

```
#include <ch_cvl/synfont.h>

class ccImageFontChar;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccImageFontChar** class represents a character from an image font, that is, a font that consists of character bitmaps rather than as some synthetic specification.

Constructors/Destructors

ccImageFontChar

```
ccImageFontChar();
```

Constructs a blank character with a key of -1 and polarity of *eUnknown*.

Notes

The default copy constructor, assign operator, and destructor are used.

Enumerations

Origin

```
enum Origin;
```

Type of origin for a character.

Value	Meaning
eImageCenter = 0	Center of character image
eImageLowerLeft	Lower left of character image
eSpecifiedMarkLowerLeft	Lower left of mark rect
eDetectedMarkLowerLeft	Lower left of detected mark rect

Public Member Functions

key

```
c_Int32 key() const;
void key(c_Int32 key);
```

- `c_Int32 key() const;`

  Gets character key.

- `void key(c_Int32 key);`

  Sets character key.

  Parameters

  key The new character key.

name

```
const ccCvlString& name() const;
void name(const ccCvlString& n);
```

- `const ccCvlString& name() const;`

  Gets the name for this character.

- `void name(const ccCvlString& n);`

  Sets the name for this character.

  Parameters

  n The name for this character.

description

```
const ccCvlString& description() const;
void description(const ccCvlString& n);
```

- `const ccCvlString& description() const;`

  Gets the description for this character.

- `void description(const ccCvlString& n);`

  Sets the description for this character.

Parameters

n The description.

polarity

```
ccSynFontDefs::Polarity polarity() const;

void polarity(ccSynFontDefs::Polarity p);
```

- `ccSynFontDefs::Polarity polarity() const;`

  Gets the polarity for this character.

- `void polarity(ccSynFontDefs::Polarity p);`

  Sets the polarity for this character.

  Parameters

  p The polarity for this character.

  Throws

  ccSynFontDefs::BadParams
  The polarity is not valid.

image

```
const ccPelBuffer_const<c_UInt8>& image() const;

void image(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelRect& maxRootCopyRect = ccPelRect());
```

- `const ccPelBuffer_const<c_UInt8>& image() const;`

  Gets the image for this character.

  Throws

  ccSynFontDefs::BadParams
  maxRootCopyRect is not a null rect and does not contain the image's window.

- `void image(const ccPelBuffer_const<c_UInt8>& image, const ccPelRect& maxRootCopyRect = ccPelRect());`

  Sets the image for this character.

  A deep copy of the image is made, including pixels from the root outside the image if specified.
  maxRootCopyRect may be a null rect to indicate that only the image's window should be copied; otherwise, it should enclose the image's window.

Parameters

image The image for this character.

Throws

ccSynFontDefs::BadParams

maxRootCopyRect is not a null rect and does not contain the image's window.

---

mask

```
const ccPelBuffer_const<c_UInt8>& mask() const;

void mask(const ccPelBuffer_const<c_UInt8>& mask,
  const ccPelRect& maxRootCopyRect = ccPelRect());
```

- `const ccPelBuffer_const<c_UInt8>& mask() const;`

Gets the mask for this character.

Notes

Getter returns an unbound image buffer if no mask has been specified for this character.

Throws

ccSynFontDefs::BadParams

maxRootCopyRect is not a null rect and does not contain the image's window.

- `void mask(const ccPelBuffer_const<c_UInt8>& mask, const ccPelRect& maxRootCopyRect = ccPelRect());`

Sets the mask for this character.

A deep copy of the image is made, including pixels from the root outside the image if specified.
maxRootCopyRect may be a null rect to indicate that only the image's window should be copied; otherwise, it should enclose the image's window.

Parameters

mask The mask for this character.

Throws

ccSynFontDefs::BadParams

maxRootCopyRect is not a null rect and does not contain the image's window.

imageArea

```
ccPelRect imageArea() const;
void imageArea(const ccPelRect& area);
```

- `ccPelRect imageArea() const;`

  Gets the character area for this character in image coordinates.

- `void imageArea(const ccPelRect& area);`

  Sets the character area for this character in image coordinates.

  Parameters

  area The character area for this character.

moveOrigin

```
bool moveOrigin(Origin origin = eDetectedMarkLowerLeft);
void moveOrigin(const cc2Vect& origin);
```

- `bool moveOrigin(Origin origin = eDetectedMarkLowerLeft);`

  Moves the origin to the specified location. Returns true if the origin could be moved as specified.

  Parameters

  origin The specified location to become the new origin.

  Notes

  For blanks, *eDetectedMarkLowerLeft* and *eSpecifiedMarkLowerLeft* are treated as *eImageLowerLeft*.

- `void moveOrigin(const cc2Vect& origin);`

  Moves the origin to the specified location, that is, makes the specified point become (0, 0) in client coordinates.

  Parameters

  origin The specified location to become the new origin.

metrics

```
const ccFontCharMetrics& metrics() const;
void metrics(const ccFontCharMetrics& m);
```

- `const ccFontCharMetrics& metrics() const;`

  Gets the metrics for this character.

- `void metrics(const ccFontCharMetrics& m);`

  Sets the metrics for this character.

  Parameters

  m The metrics for this character.

detectMarkRect

```
bool detectMarkRect();
```

Computes the detected mark rect and store it in the metrics.

Returns whether the mark rect detection was successful.

Notes

Detection will never be successful for a blank.

detectPolarity

```
bool detectPolarity(bool onlyIfPolarityUnknown = true);
```

Attempts to detect the polarity. Returns whether the polarity detection was successful.

Notes

The detection will not be successful for a blank whose polarity is currently unknown.

Parameters

onlyIfPolarityUnknown
Only if the polarity is unknown.

trim

```
void trim(const ccRect& rect, bool padIfLarger = true,
  bool resetAdvance = true,
  bool pelsOutsideImageAreaAreBackground = false);
```

Trims this character to be at most the greatest common rectangle of the character with the specified client rectangle. This may affect the cell rect, mark rect, *detectedMarkRect*, and *imageArea*.

Notes

The character will not be expanded if the specified rect lies partially outside the current character.

If *resetAdvance* is true, the advance will be set equal to the width of the new cell rect.

Parameters

rect The specified client rectangle.

Notes

This function may be useful when trying to get a set of characters to have a common size.

Throws

ccSynFontDefs::BadParams
The rect would cause the character to become empty.

trimRelative

```
void trimRelative(double left,
 double right,
 double top,
 double bottom,
 bool padIfLarger = true,
 bool resetAdvance = true,
 bool pelsOutsideImageAreaAreBackground = false);
```

Trims this character using its current *cellRect* modified by the specified amounts; negative values mean that the indicated border should be grown rather than shrunk. This may affect the cell rect, mark rect, *detectedMarkRect*, and *imageArea*.

Notes

The character will not be expanded if the specified rect lies partially outside the current character.

Parameters

left The amount by which to shrink (positive values) or grow (negative values) the left edge of the rectangle.

right The amount by which to shrink (positive values) or grow (negative values) the right edge of the rectangle.

top The amount by which to shrink (positive values) or grow (negative values) the top edge of the rectangle.

bottom The amount by which to shrink (positive values) or grow (negative values) the bottom edge of the rectangle.

Notes

This function may be useful when trying to get a set of characters to have a common size.

Throws

ccSynFontDefs::BadParams
The rect would cause the character to become empty.

trimY

```
void trimY(double minY,
  double maxY,
  bool padIfLarger = true,
  bool pelsOutsideImageAreaAreBackground = false);
```

Trims this character to be at most the greatest common rectangle of the character within the specified client lines. This may affect the cell rect, mark rect, *detectedMarkRect*, and *imageArea*.

Notes

The character will not be expanded if the specified rect lies partially outside the current character.

This function may be useful when trying to get a set of characters to have a common size.

Parameters

minY The y-position of the starting client line.

maxY The y-position of the ending client line.

Throws

ccSynFontDefs::BadParams
The rect would cause the character to become empty.

leftJustify

```
void leftJustify(double leftPadding = 2.);
```

Shifts this character so that the specified amount of background (in client units) exists to the left of the detected mark, without changing the character's width.

Parameters

leftPadding The left padding value.

ccImageFontChar

ccImageRegisterParams

```
#include <ch_cvl/imgreg.h>

class ccImageRegisterParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters for the Image Registration tool.

Constructors/Destructors

ccImageRegisterParams

```
ccImageRegisterParams();

ccImageRegisterParams(Method method, Algorithm algo);

ccImageRegisterParams(Method method, Algorithm algo,
  const ccIPair & start);
```

- `ccImageRegisterParams()`

  Constructs a **ccImageRegisterParams** with the default algorithm and scoring method and with no starting point.

- `ccImageRegisterParams(Method method, Algorithm algo);`

  Constructs a **ccImageRegisterParams** using the specified method and algorithm. No starting point is set.

  Parameters

  method — The scoring method to use. *method* must be one of the following values:

ccImageRegisterParams::eCorrelation
ccImageRegisterParams::eSumAbsDifferences
ccImageRegisterParams::kDefaultMethod

algo — The scoring algorithm to use. *algo* must be one of the following values:

ccImageRegisterParams::eLocalSearch
ccImageRegisterParams::eExhaustiveSearch
ccImageRegisterParams::kDefaultAlgorithm

- `ccImageRegisterParams(Method method, Algorithm algo, const ccIPair & start)`

  Constructs a **ccImageRegisterParams** using the specified method, algorithm, and starting point.

  Parameters

  method — The scoring method to use. *method* must be one of the following values:

  ccImageRegisterParams::eCorrelation
  ccImageRegisterParams::eSumAbsDifferences
  ccImageRegisterParams::kDefaultMethod

  algo — The scoring algorithm to use. *algo* must be one of the following values:

  ccImageRegisterParams::eLocalSearch
  ccImageRegisterParams::eExhaustiveSearch
  ccImageRegisterParams::kDefaultAlgorithm

  start — The whole-pixel starting point, specified in the source image's image coordinate system.

Enumerations

Algorithm

```
enum Algorithm;
```

This enumeration defines the Image Registration algorithms.

Value	Meaning
eLocalSearch	Search for the local minimum or maximum score.
eExhaustiveSearch	Exhaustively search the entire source image for the global minimum or maximum score.
kDefaultAlgorithm	The default algorithm defined in *imgreg.h*

Method

```
enum Method;
```

This enumeration defines the Image Registration tool scoring methods.

Value	Meaning
eCorrelation	Normalized correlation coefficient is computed between pixels in reference image and corresponding pixels in source image. Scores range from -1.0 (perfect mismatch) to +1.0 (perfect match).
eSumAbsDifferences	Sum of absolute differences between pixels in reference image and corresponding pixels in source image. Scores range from 0.0 (perfect match) to a value equal to 256 times the number of pixels in the reference image. Larger values indicate poorer matches.

Value	Meaning
eHighAccuracyCorrelation	The normalized correlation coefficient is computed, as described for *eCorrelation*, but an advanced technique is used to more accurately determine the sub-pixel location at which the score is the highest.
kDefaultMethod	The default scoring method defined in *imgreg.h*

Public Member Functions

algorithm

```
void algorithm(Algorithm algo);
Algorithm algorithm() const;
```

- `void algorithm(Algorithm algo);`

  Sets the algorithm used by this **ccImageRegisterParams**.

  Parameters

  algo — The scoring algorithm to use. *algo* must be one of the following values:

  ccImageRegisterParams::eLocalSearch
  ccImageRegisterParams::eExhaustiveSearch
  ccImageRegisterParams::kDefaultAlgorithm

- `Algorithm algorithm() const;`

  Returns the algorithm used by this **ccImageRegisterParams**. This function returns one of the following values:

  ccImageRegisterParams::eLocalSearch
  ccImageRegisterParams::eExhaustiveSearch

method

```
void method(Method method);
Method method() const;
```

- `void method(Method method);`

  Sets the scoring method used by this **ccImageRegisterParams**.

Parameters

method — The scoring method to use. *method* must be one of the following values:

ccImageRegisterParams::eCorrelation
ccImageRegisterParams::eSumAbsDifferences
ccImageRegisterParams::eHighAccuracyCorrelation
ccImageRegisterParams::kDefaultMethod

- `Method method() const;`

Returns the scoring method used by this **ccImageRegisterParams**. This function returns one of the following values:

ccImageRegisterParams::eCorrelation
ccImageRegisterParams::eSumAbsDifferences
ccImageRegisterParams::eHighAccuracyCorrelation

startPoint

```
void startPoint(const ccIPair &start);

ccIPair startPoint() const;
```

- `void startPoint(const ccIPair &start);`

Sets the starting point for the search. *start* is specified in the image coordinate system of the source image and should be within a few pixels of the upper-left corner of the part of the source image that corresponds to the reference image.

Parameters

start — The starting search point, in the source image's image coordinate system.

- `ccIPair startPoint() const;`

Returns the starting point for the search. The point is in the source image's image coordinate system.

isStartPointSet

```
bool isStartPointSet() const;
```

Returns true if this **ccImageRegisterParams**'s starting point has been set, either at construction or by calling **startPoint()**. Returns false if the starting point has not been set.

ccImageRegisterParams

ccImageRegisterResults

```
#include <ch_cvl/imgreg.h>

template <class P>class ccImageRegisterResults;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single result produced by the Image Registration tool.

Constructors/Destructors

ccImageRegisterResults

```
ccImageRegisterResults();
```

Constructs a **ccImageRegisterResults** which you can supply to **cfImageRegister()**.

Enumerations

EdgeHit

```
enum EdgeHit;
```

This enumeration defines the possible sides upon which the reference image might be clipped by the source image.

Value	Meaning
eLeftEdge	The left side of the reference image is clipped by the source image.
eTopEdge	The top of the reference image is clipped by the source image.
eRightEdge	The right side of the reference image is clipped by the source image.
eBottomEdge	The bottom of the reference image is clipped by the source image.

Public Member Functions

position

```
cc2Vect position() const;
```

Returns the location in the source image that corresponds to the upper-left corner of the reference image. The position is returned in the source image's image coordinate system.

score

```
double score() const;
```

Returns the score of this results.

If the sum of absolute differences scoring method is used, then scores range from 0 to 256 times the number of pixels in the reference image, with a score of 0.0 indicating a perfect match and larger scores indicating poorer matches.

If the normalized correlation scoring method is used, then scores range from -1.0, which indicates a perfect mismatch, to +1.0, which indicates a perfect match.

edgeHit

```
c_UInt32 edgeHit() const;
```

Returns which, if any, of the sides of the reference image were clipped by the source image. If the reference image was clipped then the accuracy of the result can be reduced.

This function returns 0 to indicate that no clipping occurred. If clipping occurred, then this function returns a value formed by ORing together 1 or more of the following values:

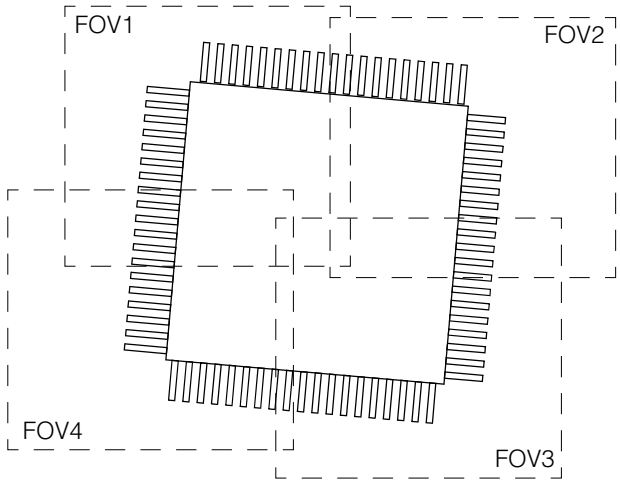
eLeftEdge
eTopEdge
eRightEdge
eBottomEdge

ccImageStitch

```
#include <stitch.h>

class ccImageStitch;
```

This class encapsulates the Image Stitching tool used to stitch multiple source images together into a single destination image. In applications where a single image field-of-view (FOV) cannot capture the entire scene, you can capture multiple FOVs and stitch them together to make a single result image that can then be processed by other vision tools. For example, the large leaded SMD device shown below is captured in four FOVs. Using the Image Stitching tool you can stitch these four images together to make a single result image of the entire device.



The FOV images can be provided by a single moving camera, or by multiple fixed cameras. Cameras need not be the same type or size but all FOVs must be calibrated so that the client coordinate transform associated with each image targets a common client coordinate space.

The following steps outline how you might typically use the Image Stitching tool in an application.

1. Construct a **ccImageStitch** object.
2. Call **init()** to initialize the tool and specify the source and destination images.
3. Call **clearImages()** to prepare the stitching tool.
4. Acquire an image to stitch.

5. Call **addImage()** to stitch the acquired image.

   Loop back to step 4 until all images are processed.

6. Call **stitchedImage()** to get the stitched result image, and **stitchedMaskImage()** to get the result image mask.

7. Run vision tools on the stitched image result or use the stitched image in some other way.

8. Return to Step 3 for the next stitching operation.

Constructors/Destructors

ccImageStitch

```
ccImageStitch();
```

Constructs an Image Stitch object with empty data buffers.

Notes

The default copy and assign operators make shallow copies.

Public Member Functions

reset

```
void reset();
```

Releases all resources and returns this object to the default constructed state.

computeEnclosingStitchedRect

```
ccPelRect computeEnclosingStitchedRect(
  const cmStd vector<ccPelRect>& srcImageWindows,
  const cmStd vector<cc2Xform>& srcImageFromClientXforms,
  const cc2Xform& dstImageFromClientXform) const;
```

Computes a destination image window that encloses all the specified source image windows after they are properly stitched together in the common client space. The returned destination image window maps to an affine rectangle region in the client space through the inverse of *dstImageFromClientXform*.

This is an optional utility function you can use to compute a bounding box result image window with an orientation you specify in *dstImageFromClientXform*. Use the **ccPelRect** returned by this function as *dstImageWindow* and the *dstImageFromClientXform* specified here when calling the second **init()** overload.

Parameters

srcImageWindows

A vector of source windows containing all of the images you wish to stitch together.

srcImageFromClientXforms
A vector of transforms corresponding to the windows in *srcImageWindows* above. These are the calibration transforms that map source image pixels into the common client space of the result.

dstImageFromClientXform
The transform that maps the result client space into the destination image.

Throws

ccImageStitchDefs::BadInput
if any one of the following is true:
- the sizes of the two input vectors differ,
- the two input vectors are empty,
- any element of *srcImageWindows* is null

ccImageStitchDefs::Singular
if any one of the following is true:
- any element of *srcImageFromClientXforms* is singular,
- *dstImageFromClientXform* is singular

Notes

This function can be called regardless of whether **isInitialized()** returns true or false.

This function does not alter the state of the object (const member function). In particular, it does not affect the value returned by **isInitialized()**.

The window of the image returned by **stitchedImage()** will be decided by **init()**, and is not affected by this function.

The elements in the *srcImageWindows* and *srcImageFromClientXforms* vectors must correspond to each other.

isInitialized

```
bool isInitialized() const;
```

Returns whether **init()** has been called successfully. The default is *false*

init

```
void init(
  const cmStd vector<ccPelRect>& srcImageWindows,
  const cmStd vector<cc2Xform>& srcImageFromClientXforms,
```

```
  ccImageStitchDefs::OutputMode
                        outputMode=ccImageStitchDefs::eBlend,
  c_Int32 valueForEmptyRegion = 0);

void init(
  const cmStd vector<ccPelRect>& srcImageWindows,
  const cmStd vector<cc2Xform>& srcImageFromClientXforms,
  const ccPelRect& dstImageWindow,
  const cc2Xform& dstImageFromClientXform,
  ccImageStitchDefs::OutputMode
                        outputMode=ccImageStitchDefs::eBlend,
  c_Int32 valueForEmptyRegion = 0);
```

Initializes internal data buffers and calls **clearImages()** to prepare the tool for image stitching.

-
```
void init(
  const cmStd vector<ccPelRect>& srcImageWindows,
  const cmStd vector<cc2Xform>& srcImageFromClientXforms,
  ccImageStitchDefs::OutputMode
                        outputMode=ccImageStitchDefs::eBlend,
  c_Int32 valueForEmptyRegion = 0);
```

Initializes the tool and sets the internal data buffers so that the result image window covers a region in client space that encloses all the specified source image windows. The tool is set to use the first element of *srcImageFromClientXforms* for *dstImageFromClientXform*.

Parameters

srcImageWindows

A vector of source windows containing the windows of all of the images you wish to stitch together.

srcImageFromClientXforms

A vector of transforms corresponding to the windows in *srcImageWindows* above. These are the calibration transforms that map source image pixels into the common client space of the result.

outputMode Specifies how pixel values from source images are combined to form a result pixel value in the destination image. Must be either *eBlend* or *eOverwrite*. In *eOverwrite* mode, each result pixel value is the value from the most recently stitched input image with a corresponding pixel. Earlier pixel values are overwritten. In *eBlend* mode each result pixel value is a blend of all of the corresponding pixel values in all the input images.

valueForEmptyRegion
Specifies the 8-bit pixel value assigned to destination image pixels that had no corresponding pixels in any input image.

Throws

ccImageStitchDefs::BadInput
if any one of the following is true:
- the sizes of the two input vectors differ,
- the two input vectors are empty,
- any element of *srcImageWindows* is null,
- *dstImageWindow* is null,
- *outputMode* is not a valid value for *ccImageStitchDefs::OutputMode*

ccImageStitchDefs::Singular
if *srcImageFromClientXforms* is singular

Notes

The elements in the two input vectors must correspond to each other.

Only the low-order 8 bits of *valueForEmptyRegion* are used.

- ```
  void init(
    const cmStd vector<ccPelRect>& srcImageWindows,
    const cmStd vector<cc2Xform>& srcImageFromClientXforms,
    const ccPelRect& dstImageWindow,
    const cc2Xform& dstImageFromClientXform,
    ccImageStitchDefs::OutputMode
                          outputMode=ccImageStitchDefs::eBlend,
    c_Int32 valueForEmptyRegion = 0);
  ```

Initializes the tool and sets the internal data buffers so that the result image window is *dstImageWindow*, using *dstImageFromClientXform* to map the result from client space.

Parameters

srcImageWindows
A vector of source windows containing the windows of all of the images you wish to stitch together.

srcImageFromClientXforms
A vector of transforms corresponding to the windows in *srcImageWindows* above. These are the calibration transforms that map source image pixels into the common client space of the result.

dstImageWindow
The destination image window.
  ```

dstImageFromClientXform
The transform that maps the result client space into the destination image.

outputMode Specifies how pixel values from source images are combined to form a result pixel value in the destination image. Must be either *eBlend* or *eOverwrite*. In *eOverwrite* mode, each result pixel value is the value from the most recently stitched input image with a corresponding pixel. Earlier pixel values are overwritten. In *eBlend* mode each result pixel value is a blend of all of the corresponding pixel values in all the input images.

valueForEmptyRegion
Specifies the 8-bit pixel value assigned to destination image pixels that had no corresponding pixels in any input image.

Throws

ccImageStitchDefs::BadInput
if any one of the following is true:
- the sizes of the two input vectors differ,
- the two input vectors are empty,
- any element of *srcImageWindows* is null,
- *dstImageWindow* is null,
- *outputMode* is not a valid value for *ccImageStitchDefs::OutputMode*

ccImageStitchDefs::Singular
if either of the following is true:
- any element of *srcImageFromClientXforms* is singular,
- *dstImageFromClientXform* is singular

Notes

The elements in the two vectors must correspond to each other.

Only the lowest 8 bits of *valueForEmptyRegion* are used.

outputMode `ccImageStitchDefs::OutputMode outputMode() const;`

Returns the output mode specified during initialization (see **init()**).

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

valueForEmptyRegion

```
c_Int32 valueForEmptyRegion() const;
```

Returns the pixel value specified during initialization for regions in the stitched image result not covered by any source image.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

Notes

Although only the low-order 8 bits are used by the tool, the full 32 bits you specify are returned.

clearImages

```
void clearImages();
```

Clears the content of internal data buffers in preparation for a new stitching operation.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

Notes

Sets **numImages()** to 0.

This function differs from **reset()** in that it just clears the contents of internal data buffers. It does not change image windows or client transforms and does not release any allocated resources.

addImage

```
void addImage(const ccPelBuffer_const<c_UInt8>& srcImage);

void addImage(const ccPelBuffer_const<c_UInt8>& srcImage,
              const ccPelBuffer_const<c_UInt8>& maskImage);
```

- ```
  void addImage(const ccPelBuffer_const<c_UInt8>& srcImage);
  ```

Adds an image for stitching.

Parameters

srcImage The image to add.
  ```

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

ccImageStitchDefs::BadImage
if *srcImage* is unbound or has a null window

ccImageStitchDefs::Singular
if any element of *srcImageFromClientXforms* is singular

ccImageStitchDefs::NotImplemented
if the *srcImage* client transform is non-linear,
or the output mode is *ccImageStitchDefs::eBlend* and the total number of images exceeds 255.

Notes

ccImageStitch does not support non-linear transforms. To stitch images with non-linear transforms such as the camera calibration transform, use the image warper (see **ccImageWarp**) to remove the non-linear distortion so that the images have linear client transforms.

If a time-out occurs (see **ccTimeout**) before this function completes, this function will automatically call **clearImages()** before throwing *ccTimeout::Expired*.

- ```
  void addImage(
    const ccPelBuffer_const<c_UInt8>& srcImage,
    const ccPelBuffer_const<c_UInt8>& maskImage);
  ```

Adds an image and an image mask for stitching. The *maskImage* window must be identical to that of *srcImage*. *maskImage* is aligned in image space to *srcImage*. The *maskImage* client transform is ignored.

maskImage is a binary mask image. Its pixel values must be either 0 or 255. A 0 specifies masked-out pixels (*srcImage* pixels to be ignored). A 255 identifies unmasked (effective) *srcImage* pixels.

Parameters

srcImage The image to add.

maskImage The *srcImage* mask.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

ccImageStitchDefs::BadImage
if any one of the following is true:
- *srcImage* is unbound or has a null window,
  ```

- *maskImage* is unbound or has a null window,
- *maskImage*'s window is different from *srcImage*'s window,
- *maskImage* has pixel values other than 0 or 255

ccImageStitchDefs::Singular
if either of the following is true:
- any element of *srcImageFromClientXforms* is singular,
- *dstImageFromClientXform* is singular

ccImageStitchDefs::NotImplemented
if the *srcImage* client transform is non-linear,
or the output mode is *ccImageStitchDefs::eBlend* and the total number of images exceeds 255.

Notes

ccImageStitch does not support non-linear transforms. To stitch images with non-linear transforms such as the camera calibration transform, use the image warper (see **ccImageWarp**) to remove the non-linear distortion so that the images have linear client transforms.

If a time-out occurs (see **ccTimeout**) before this function completes, this function will automatically call **clearImages()** before throwing *ccTimeout::Expired*.

addImageWithWeights

```
void addImageWithWeights(
  const ccPelBuffer_const<c_UInt8>& srcImage,
  const ccPelBuffer<c_UInt8>& weightsImage);

void addImageWithWeights(
  const ccPelBuffer_const<c_UInt8>& srcImage,
  const ccPelBuffer<c_UInt8>& weightsImage,
  const ccPelBuffer_const<c_UInt8>& maskImage);
```

- ```
  void addImageWithWeights(
    const ccPelBuffer_const<c_UInt8>& srcImage,
    const ccPelBuffer<c_UInt8>& weightsImage);
  ```

Adds one image to the internal blending buffer using custom weights. This function may only be called in blending mode.

Parameters

srcImage The image to add.

weightsImage The *srcImage* weighing.
  ```

Throws

ccImageStitchDefs::NotInitialized
isInitialized() returns false.

ccImageStitchDefs::NotSupported
If called while in Overwrite mode.

ccImageStitchDefs::BadImage
Any of the following is true:
- *srcImage* is unbound or has a null window;
- *weightsImage* is unbound or has a null window;
- *weightsImage*'s window is different from *srcImage*'s window;

ccImageStitchDefs::Singular
srcImage's client transform is singular.

ccImageStitchDefs::NotImplemented
srcImage has a non-linear transform,
or the output mode is *ccImageStitchDefs::eBlend* and the total number of images exceeds 255.

- ```
  void addImageWithWeights(
    const ccPelBuffer_const<c_UInt8>& srcImage,
    const ccPelBuffer<c_UInt8>& weightsImage,
    const ccPelBuffer_const<c_UInt8>& maskImage);
  ```

Adds one image to the internal blending buffer using custom weights. This function may only be called in blending mode. *maskImage* is a binary mask image. Its pixel values must be either 0 or 255:

- 0 identifies masked-out pixels (to be ignored);
- 255 identifies unmasked (effective) pixels.

Parameters

srcImage The image to add.

weightsImage The *srcImage* weighing.

maskImage The *srcImage* mask.

Throws

ccImageStitchDefs::NotInitialized
isInitialized() returns false.

ccImageStitchDefs::NotSupported
If called while in Overwrite mode.
  ```

ccImageStitchDefs::BadImage
Any of the following is true:
- *srcImage* is unbound or has a null window;
- *weightsImage* is unbound or has a null window;
- *weightsImage*'s window is different from *srcImage*'s window;
- *maskImage* is unbound or has a null window;
- *maskImage*'s window is different from *srcImage*'s window;
- *maskImage* has pixel values other than 0 or 255.

ccImageStitchDefs::Singular
srcImage's client transform is singular.

ccImageStitchDefs::NotImplemented
srcImage has a non-linear transform,
or the output mode is *ccImageStitchDefs::eBlend* and the total number of images exceeds 255.

Notes

If you added one image where all the pixel weights were set to 2, and then a second where all the pixel weights were set to 1, then in the blended image buffer, each pixel value would equal 2/3 times the corresponding pixel in the first image plus 1/3 times that in the second image. However, if the weights corresponding to a region of pixels in the second image were set to zero, then, in the blended image, the corresponding pixels would equal the values of those in the first image.

When copying data from *srcImage* to internal data buffers, the correspondence is in the client space. In other words, for any image pixel position in *dstImage* (call it D), its corresponding position in the client space position (call it C) is found via *dstImage*'s client transform; then the corresponding image pixel position in *srcImage* (call it S) is found via *srcImage*'s client transform. The pixel value is read from S in *srcImage* and used to update (by weighted sum) the pixel value at D in *dstImage*.

weightsImage's window must be identical to that of *srcImage*. *weightsImage* is aligned in image space to *srcImage*. Its client transform is ignored.

Setting a pixel in the weights image to zero is identical to masking out that pixel, that is, setting a mask value of zero at that location.

maskImage's window must be identical to that of *srcImage*. *maskImage* is aligned in image space to *srcImage*. Its client transform is ignored.

If a time-out occurs (see **ccTimeout** in <*ch_cvl/attent.h*>) before this function completes, this function will automatically call **clearImages()** before throwing *ccTimeout::Expired*.

numImages `c_Int32 numImages() const;`

Returns the number of images added in the current stitching.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

Notes

This is equal to the number of times **addImage()** has been called since the last call to **clearImages()**.

stitchedImage `const ccPelBuffer_const<c_UInt8>& stitchedImage() const;`

Returns the stitched result image.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

Notes

The stitched image and mask image are both bound with the same image window and client transform.

See **init()** for information on how the window and client transform are determined.

stitchedMaskImage

```
const ccPelBuffer_const<c_UInt8>& stitchedMaskImage()
                                                    const;
```

Returns the stitched result image mask with pixel values either 0 or 255. A 0 specifies masked-out pixels (the corresponding image result pixels should be ignored). A 255 identifies unmasked (effective) result pixels.

Throws

ccImageStitchDefs::NotInitialized
if **isInitialized()** returns *false*

Notes

The stitched image and mask image are both bound with the same image window and client transform.

See **init()** for information on how the window and client transform are determined.

ccImageStitchDefs

```
#include <stitch.h>

class ccImageStitchDefs;
```

A name space that holds enumerations and constants used with the Image Stitching tool. See **ccImageStitch.**

Enumerations

OutputMode

```
enum OutputMode
```

This enumeration defines constants that specify the mode for computing the pixel value in a stitched image result. The tool supports two modes: *Blend* mode and *Overwrite* mode.

Value	Meaning
eBlend = 0x1	Specifies *Blend* mode
eOverwrite = 0x2	Specifies *Overwrite* mode

ccImagingDevice

```
#include <ch_cvl/vpimgdev.h>

class ccImagingDevice : public ccUnknownFG,
   public ccUnknownFeatureAccess ;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes an Imaging Device (a software module provided by a third-party manufacturer that provides access to an imaging device such as a camera or frame grabber from that manufacturer). There is one instance of this class for each enabled Imaging Device. You use the static **get()** function to obtain a specific instance.

```
ccImagingDevice& myDevice = ccImagingDevice::get(0);
```

Calling the **name()** function (a member of **ccBoard**, from which this class is derived) returns the name of the Imaging Device,

Constructors/Destructors

A single instance of this class is created automatically for each Imaging Device connected to your system.

Public Member Functions

count

```
static c_Int32 count();
```

Returns the number of Imaging Device present in the system.

get

```
static ccImagingDevice& get(c_Int32 i = 0);
```

Returns a **ccImagingDevice** object that represents the specified device. If multiple Imaging Devices are enabled on your system, the index order of the devices is undefined. You can use the **name()** function to identify the device returned by this function.

Parameters

i The index of the device to get.

Throws

ccBoard::BadParams

i is less than zero or greater than or equal to **count()**.

Notes

For any given index value, the object returned by this function and the object returned by calling **ccBoard::get()** with the same index may not refer to the same device, since **ccBoard::get()** returns references to *all* devices, such as Cognex frame grabbers, not just Imaging Devices.

serialNumber

```
ccCvlString serialNumber() const;
```

Returns the serial number of the Imaging Device. The format of the returned string is specific to the Imaging Device type.

executeCommand

```
void executeCommand(ccCvlString featureName);
```

Executes the command as defined by the imaging device. Refer to the documentation supplied with your Imaging Device for information about supported commands.

Parameters

featureName The command to issue.

Throws

ccImagingDevice::FeatureError

nodeName was not a valid node name.

readValue

```
ccCvlString readValue(ccCvlString featureName);
```

Returns the value associated with the specified feature for this Imaging Device. For information about the supported features and values, refer to the documentation supplied with your imaging device.

Parameters

featureName The name of the feature.

Notes

Use this function to access features that are not implemented directly in CVL. Use the standard CVL acquisition fifo interface to view exposure, contrast, brightness, region of interest, and trigger mode..

Throws

ccImagingDevice::FeatureError

featureName was not a valid feature name.

writeValue

```
void writeValue (ccCvlString featureName,
     ccCvlString value);
```

Sets the value associated with the specified feature for this Imaging Device. For information about the supported features and values, refer to the documentation supplied with your imaging device.

Parameters

featureName The name of the feature to set.

value The value fo set for this feature.

Throws

ccImagingDevice::FeatureError
featureName was not a valid feature name.

Notes

Use this function to access features that are not implemented directly in CVL. Use the standard CVL acquisition fifo interface to set exposure, contrast, brightness, region of interest, and trigger mode..

ccImagingDevice

ccImageWarp

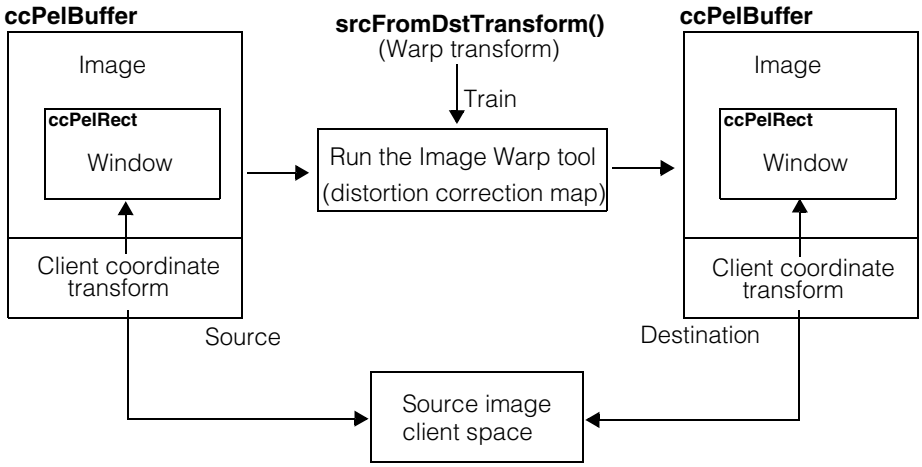
```
#include <ch_cvl/imgwarp.h>

class ccImageWarp;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class encapsulates a tool for warping images through 2-D transforms.



The tool can be used in one of following two modes:

General:

In this mode, you may specify any transform as the warp transform. This mode is selected when you call the function **srcFromDstTransform()** with a **cc2XformBase** object as its only argument.

Using calibration:

In this mode, a warp transform is set to a transform computed using the provided calibration transform plus additional information. This mode is selected when you call the function **srcFromDstTransform()** with a **cc2XformCalib2** object as one of its arguments. This mode is used to remove perspective and/or lens distortion from images.

These two modes differ only in following ways:

- How the warp transform is set.
- How the client transform of the warped image is set.

Constructors/Destructors

ccImageWarp

```
ccImageWarp();
ccImageWarp(const ccImageWarp &rhs);
~ccImageWarp();
```

- `ccImageWarp();`

  Default constructor.

- `ccImageWarp(const ccImageWarp &rhs);`

  Copy constructor.

- `~ccImageWarp();`

  Destructor.

Enumerations

Mode `enum Mode;`

Value	Meaning
eGeneral = *0x1*	You specify the warp transform.
eUsingCalibration = *0x2*	The warp transform is computed from a **cc2XformCalib2** transform and other parameters you provide.

UndistortMode `enum UndistortMode;`

Value	Meaning
eUndistortPerspective = 0x1	Correct perspective distortion. (Distortion that depends on the position and orientation of the object plane relative to the camera).
eUndistortRadial = 0x2	Correct radial distortion. (Barrel distortion or pincushion distortion).
eUndistortXYRotation = 0x4	Correct rotational distortion of the x-y axes in the image plane.
eUndistortDefault = *eUndistortPerspective* | *eUndistortRadial* | *eUndistortXYRotation*	

Operators

operator== `bool operator==(const ccImageWarp& other) const;`

Return true if this object is equal to *other*; return false otherwise.

Parameters

other Another **ccImageWarp** object to compare with this one.

operator= `ccImageWarp &operator=(const ccImageWarp &rhs);`

Assignment operator. Make this object a copy of *rhs*.

Parameters

rhs The object to copy.

Public Member Functions

srcRect

```
void srcRect(const ccPelRect& rect);

const ccPelRect& srcRect() const;
```

Defines a rectangular area (window) within the source image. See the **ccPelRect** reference page.

- `void srcRect(const ccPelRect& rect);`

  Sets the source image window. The object is set to the untrained state.

  Parameters

  rect The new source image window.

  Throws

  ccImageWarpDefs::BadWindow
  If *rect* is a null rectangle.

- `const ccPelRect& srcRect() const;`

  Returns the source image window.

srcFromDstTransform

```
cc2XformBasePtrh_const srcFromDstTransform() const;

void srcFromDstTransform(const cc2XformBase& xform);

void srcFromDstTransform (
  const cc2XformCalib2& fromPhysicalCalibrationXform,
  const cc2Vect& pt,
  c_UInt32 undistortMode = ccImageWarp::eUndistortDefault);
```

- `cc2XformBasePtrh_const srcFromDstTransform() const;`

  Returns the current warp transform. If the following setter was last used, the transform that was set is returned. If the second setter was last used, the warp transform computed from *fromPhysicalCalibrationXform*, *pt*, and *undistortMode* is returned.

- `void srcFromDstTransform(const cc2XformBase& xform);`

  Sets a new warp transform that maps destination image coordinates to source image coordinates. The object is set to untrained. Mode is set to *eGeneral*.

  This setter is provided as a way to use a **cc2XformLinear** or **cc2XformPoly** as the Warp transform.

  Parameters

  xform The new warp transform.

- ```
  void srcFromDstTransform (
    const cc2XformCalib2& fromPhysicalCalibrationXform,
    const cc2Vect& pt,
    c_UInt32 undistortMode);
  ```

  Compute and set the warp transform using the arguments provided. The object is set to untrained. Mode is set to *eUsingCalibration*.

  The warp transform that is computed can be retrieved using the **srcFromDstTransform()** getter above.

  Parameters

  fromPhysicalCalibrationXform
  A nonlinear calibration transform from physical space to image space. For information about this transform, see the **cc2XformCalib2** reference page.

  pt A 2-D point within the source window. The scale at this point in the source image is used as the scale for the entire destination image. This is done so that features in the undistorted image are approximately the same size as in the distorted image.

  undistortMode Specifies which distortions (perspective, lens, and so on) should be removed. *undistortMode* can be any combination of the modes defined in the **ccImageWarp::UndistortMode** enum.

  Note: If the calibration was done using a single image, only *eUndistortDefault* is allowed here.

  Throws

  cc2XformCalib2Defs::BadParams
  If *fromPhysicalCalibrationXform* has been initialized with a single correspondence and *undistortMode* != *eUndistortDefault*.
  ```

calibrationTransform

```
cc2XformCalib2Ptrh_const calibrationTransform() const;
```

In *eUsingCalibration* mode this function returns the **cc2XformCalib2** calibration transform. (See the *fromPhysicalCalibrationXform* parameter in **srcFromDstTransform()** above). In *eGeneral* mode it returns an identity transform.

pt

```
cc2Vect pt() const;
```

In *eUsingCalibration* mode this function returns the point used to create the warp transform. (See the *pt* parameter in **srcFromDstTransform()** above). In *eGeneral* mode it returns (0, 0).

undistortMode

```
c_UInt32 undistortMode() const;
```

In *eUsingCalibration* mode this function returns the undistort mode. (See the *undistortMode* parameter in **srcFromDstTransform()** above). In *eGeneral* mode it returns 0.

mode

```
ccImageWarp::Mode mode() const;
```

Returns the trained mode; *eUsingCalibration* or *eGeneral*.

accuracy

```
void accuracy(double threshold);

double accuracy() const;
```

Accuracy is the maximum allowed error, in source pixels, between a point's true position in the source image and its warped position in the destination image. Smaller accuracy values will typically make the transform more accurate, but will increase the time and memory space required for execution.

The training algorithm maps points from the source image to the destination image and builds a mapping table it uses when the tool is run. More granularity in this table creates better accuracy and uses more memory. To check accuracy during training, pixels are transposed to the destination and then back to the source. If pixels transposed back to the source have a location error greater than *accuracy* pixels, the table granularity is increased until the accuracy limit is reached.

The default is 0.001 pels.

- `void accuracy(double threshold);`

  Sets a new accuracy value and sets the object to the untrained state.

Parameters

threshold The new accuracy.

Throws

ccImageWarpDefs::BadParams
If *threshold* is negative.

- `double accuracy() const;`

  Returns the current accuracy value. The default is 0.001 pixels.

setDstClientFromImageXform

```
void setDstClientFromImageXform(
   bool setDstClientFromImageXform);

bool setDstClientFromImageXform() const;
```

- `void setDstClientFromImageXform(`
  `bool setDstClientFromImageXform);`

  Sets whether or not to compute and set the destination image's **clientFromImageXform()** as described in **warp** on page 1750.

  If your application acquires multiple images of the same scene using the same physical and optical configuration, you can optimize its speed by computing the **clientFromImageXform()** transform once, then applying that value to each warped image. Setting this member to *false* prevents the tool from recomputing the transform for each image, enabling the optimization.

  This member is set to *true* in a default-constructed **ccImageWarp** object.

  Parameters

  setDstClientFromImageXform
  If true, the transform will be computed.

- `bool setDstClientFromImageXform() const;`

  Returns whether or not the tool is computing the transform.

dstRect

```
void dstRect(const ccPelRect& rect);
const ccPelRect& dstRect() const;
```

- `void dstRect(const ccPelRect& rect);`

  Sets the destination window and sets the object to the untrained state.

  Parameters

  rect The new destination window.

  Throws

  ccImageWarpDefs::BadWindow
  If *rect* is a NULL rectangle.

- `const ccPelRect& dstRect() const;`

  Returns the current destination window.

trainedSrcRect

```
const ccPelRect& trainedSrcRect() const;
```

Returns the trained source window. If the object is not trained a null rectangle is returned. The size of the trained source window is the size of the overlap between the source window (**srcRect()**) and the destination window (**dstRect()**).

trainedDstRect

```
const ccPelRect& trainedDstRect() const;
```

Returns the trained destination window. If the object is not trained a null rectangle is returned. The size of the trained destination window is the size of the overlap between the source window (**srcRect()**) and the destination window (**dstRect()**).

dstMask

```
const ccPelBuffer<c_UInt8>& dstMask() const;
```

Returns the destination mask.

When you train the Image Warp tool it may not be possible for the tool to map every pixel from the source to the destination. To indicate which pixels are mapped and which are not, the tool creates a *destination mask*. Mask pixels set to (255) indicate pixels that are mapped. Mask pixels set to (0) indicate pixels that are not mapped.

The destination mask window is the same size and location as the trained destination window (**trainedDstRect()**).

train `void train();`

Trains this Image Warp tool. If the destination window is a null rectangle the entire source window is warped.

If source window is a null rectangle the source window is computed by mapping the destination window into source image.

If neither the source nor destination windows are null rectangles, source and destination windows are computed as the intersection of the two windows.

If the object is trained, it will be untrained first and then retrained.

Throws

ccImageWarpDefs::BadWindow

If the source and destination windows are null rectangles,
or if the destination window mapped to the source image coordinates does not overlap the source window,
or if the source window mapped to the destination image coordinates does not overlap the destination window,
or if any of the (x,y) coordinates in the computed source or the destination is greater than or equal to 2^{31} or less than -2^{31}

Notes

The trained source and destination windows can be accessed by calling **trainedSrcRect()** and **trainedDstRect()**. Trained source and destination windows are computed using all boundary points of mapped source and destination.

untrain `void untrain();`

Untrains this object and releases memory.

isTrained `bool isTrained() const;`

Returns true if this object is currently trained, and returns false otherwise.

warp

```
void warp(
  const ccPelBuffer_const<c_UInt8>& src,
  ccPelBuffer<c_UInt8>& dst);
```

Calling this function runs the tool which transforms the source into the destination using the warp transform. The destination client from image transform maps destination pels to the source client space.

This object must be trained before calling **warp()**.

The window of the supplied destination image must contain the trained destination window. If the destination is unbound it will be created using the trained destination window.

Parameters

src The source image.

dst The destination image.

Throws

ccImageWarp::BadImage
If the source image is not bound.

ccImageWarp::NotTrained
If this object is not trained.

ccImageWarp::BadWindow
If the window of the supplied source image does not contain the trained source window,

or if the window of the supplied destination image is not contained in the trained destination window.

Notes

If **setDstClientFromImageXform()** is *true*, **clientFromImageXform()** of the destination pel buffer is set according to following rules:

eGeneral mode;

destination **clientFromImageXform()** =
(source **clientFromImageXform()**) * (**srcFromDstTransform()** provided).

eUsingCalibration mode;

(A) destination **clientFromImageXform()** =
(B) inverse of **fromPhysicalCalibrationXform()** provided
(C) * (**clientFromImageXform()** of source image)
(D) * (**srcFromDstXform()** computed internally)

For example, using the names A, B, C, D as shown above, for any point p in the destination, the following holds true:

A*p = B*C*D*p

ccImageWarp1D

```
#include <ch_cvl/imgwrp1d.h>

class ccImageWarp1D;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class encapsulates a specialized image warper intended for rectifying images acquired from a line scan camera. The functionality of this warper is equivalent to the functionality of the 2D image warper (encapsulated in the class **ccImageWarp** on page 1741) were that warper to be trained using a transformation that was linear in the y-direction.

The 1D warper can warp images of any height and any y-offset, as long as the width is the same as that used for training.

For additional information on this class, thee the file *ch_cvl/imgwrp1d.h*.

Constructors/Destructors

ccImageWarp1D

```
ccImageWarp1D();

ccImageWarp1D(const ccImageWarp1D &rhs);
```

- `ccImageWarp1D();`

  Default-constructs a **ccImageWarp1D** with the following values:

  - **srcFromDstTransform**: default-constructed **cc2XformLinear**.
  - **srcRect**: default-constructed **ccPelRect**.
  - **dstSpan**: default-constructed **ccPelSpan**.

- `ccImageWarp1D(const ccImageWarp1D &rhs);`

  Copy constructor.

- `~ccImageWarp1D();`

  Destructor.

Public Member Functions

srcRect

```
void srcRect(const ccPelRect& rect);
const ccPelRect &srcRect() const;
```

Defines a rectangular area (window) within the source image.

- `void srcRect(const ccPelRect& rect);`

  Sets the source image window. The object is set to the untrained state.

  Parameters

  rect The new source image window.

  Throws

  ccImageWarpDefs::BadWindow
  If *rect* is a null rectangle.

- `const ccPelRect& srcRect() const;`

  Returns the source image window.

dstSpan

```
void dstSpan(const ccPelSpan& span);
const ccPelSpan &dstSpan() const;
```

- `void dstSpan(const ccPelSpan& span);`

  Sets the destination span for the unwarp. Calling this overload untrains the warper.

  Since the 1D warper may be used to unwarp images of any height, the output region is specified as a span rather than a rectangle.

  Parameters

  span The span.

  Throws

  ccImageWarp1DDefs::BadWindow
  span is a null span.

- `const ccPelSpan &dstSpan() const;`

  Returns the current destination span for the unwarp.

srcFromDstTransform

```
void srcFromDstTransform(const cc2XformBase& xform);

cc2XformBasePtrh_const srcFromDstTransform() const;
```

- `void srcFromDstTransform(const cc2XformBase& xform);`

  Sets the transformation used for the warping. In most cases, this is the transform produced by calling **cfCalibrateLineScanCamera()**.

  Calling this overload untrains the warper.

  Parameters

  xform The transform.

- `cc2XformBasePtrh_const srcFromDstTransform() const;`

  Returns the current warping transform.

setDstClientFromImageXform

```
void setDstClientFromImageXform(
   bool setDstClientFromImageXform);

bool setDstClientFromImageXform() const;
```

- ```
  void setDstClientFromImageXform(
     bool setDstClientFromImageXform);
  ```

  Sets whether or not to compute and set the destination image's **clientFromImageXform()**.

  If your application acquires multiple images of the same scene using the same physical and optical configuration, you can optimize its speed by computing the **clientFromImageXform()** transform once, then applying that value to each warped image. Setting this member to *false* prevents the tool from recomputing the transform for each image, enabling the optimization.

  Parameters

  setDstClientFromImageXform

  If true, the transform will be computed.
  ```

- `bool setDstClientFromImageXform() const;`

  Returns whether or not the tool is computing the transform.

accuracy

```
void accuracy(double threshold);
double accuracy() const;
```

- `void accuracy(double threshold);`

  Accuracy is the maximum allowed error, in source pixels, between a point's true position in the source image and its warped position in the destination image. Smaller accuracy values will typically make the transform more accurate, but will increase the time and memory space required for execution.

  The training algorithm maps points from the source image to the destination image and builds a mapping table it uses when the tool is run. More granularity in this table creates better accuracy and uses more memory. To check accuracy during training, pixels are transposed to the destination and then back to the source. If pixels transposed back to the source have a location error greater than *accuracy* pixels, the table granularity is increased until the accuracy limit is reached.

  The default is 0.001 pels.

  Parameters

  threshold The threshold in pixels.

  Throws

  ccImageWarp1DDefs::BadParams
  threshold is negative.

- `double accuracy() const;`

  Returns the current accuracy threshold.

trainedSrcRect

`const ccPelRect &trainedSrcRect() const;`

Returns the trained source window. If the object is not trained a null rectangle is returned.

trainedDstSpan

`const ccPelSpan &trainedDstSpan() const;`

Returns the trained destination window. If the object is not trained a null rectangle is returned.

Notes

train `void train();`

Train the warper. If **dstSpan** is a null span, the whole source window is warped. If **srcRect** is a null rectangle, the source rect is computed by mapping **dstSpan** into source image coordinates. If both **srcRect** and **dstSpan** are not null, then **trainedSrcRect** and **trainedDstSpan** are computed as an intersection of **srcRect** and **dstSpan** (the source rect is computed in source image coordinates and the destination span is computed in destination image coordinates).

Notes

If the object is already trained, then it is first untrained and then retrained

The trained windows for src and dst can be accessed using **trainedSrcRect** and **trainedDstSpan**. **trainedSrcRect** and **trainedDstSpan** are computed using all boundary points of mapped source and destination.

Throws

ccImageWarp1DDefs::BadWindow

The source window and destination span are null, or the destination span when mapped into source image coordinates does not overlap the source window, or any of the (x,y) coordinates in the computed source or the destination is greater than or equal to 2^{31} or less than -2^{31}

untrain `void untrain();`

This function untrains the warper and releases memory.

isTrained `bool isTrained() const;`

Returns true if this is currently trained, false otherwise.

warp

```
void warp(const ccPelBuffer_const<c_UInt8>& src,
   ccPelBuffer<c_UInt8>& dst) const;

void warp(const ccPelBuffer_const<c_UInt8>& src,
   ccPelBuffer<c_UInt8>& dst,
   ccPelBuffer<c_UInt8>& dstMask) const;
```

- ```
  void warp(const ccPelBuffer_const<c_UInt8>& src,
     ccPelBuffer<c_UInt8>& dst) const;
  ```

  Calling this function runs the tool which transforms the source into the destination using the warp transform. The destination client from image transform maps destination pels to the source client space.

  This object must be trained before calling **warp()**.

  The window of the supplied destination image must contain the trained destination span. If the destination is unbound it will be created using the trained destination window.

  Parameters

  src The source image. *src* may be of an arbitrary height and y-offset.

  dst The destination image.

  Notes

  The x extents of the supplied dst image must contain the trained dst span. If dst is unbound it will be created using trained dst span.

  If setDstClientFromImageXform() is *true*, clientFromImageXform() of the destination pel buffer is set according to following rule:

  destination **clientFromImageXform()** =
  (source **clientFromImageXform()**) * (**srcFromDstTransform()** provided).

  Throws

  ccImageWarp1DDefs::BadImage
  If the source image is not bound.

  ccImageWarp1DDefs::NotTrained
  If this object is not trained.

  ccImageWarp1DDefs::BadWindow
  If the window of the supplied source image does not contain the trained source window,

  or if the x-span of the supplied destination span is not contained in the trained destination span.
  ```

- ```
  void warp(const ccPelBuffer_const<c_UInt8>& src,
     ccPelBuffer<c_UInt8>& dst,
     ccPelBuffer<c_UInt8>& dstMask) const;
  ```

  Calling this function runs the tool which transforms the source into the destination using the warp transform. The destination client from image transform maps destination pels to the source client space.

  Compute and store the destination mask where care pixels (255) in *dstMask* correspond to the dst coordinates that are mapped to the valid src pixels and don't care pixels (0) correspond to the coordinates in the dst image that do not have valid mapping to the src image.

  This object must be trained before calling **warp()**.

  The window of the supplied destination image must contain the trained destination span. If the destination is unbound it will be created using the trained destination window.

  Parameters

  src The source image. *src* may be of an arbitrary height and y-offset.

  dst The destination image.

  dstMask The mask image.

  Notes

  The x extents of the supplied dst image must contain the trained dst span. If dst is unbound it will be created using trained dst span.

  If setDstClientFromImageXform() is *true*, clientFromImageXform() of the destination pel buffer is set according to following rule:

  destination **clientFromImageXform()** =
  (source **clientFromImageXform()**) * (**srcFromDstTransform()** provided).

  Throws

  ccImageWarp1DDefs::BadImage
  If the source image is not bound.

  ccImageWarp1DDefs::NotTrained
  If this object is not trained.

  ccImageWarp1DDefs::BadWindow
  If the window of the supplied source image does not contain the trained source window, if the x-span of the supplied destination span is not contained in the trained destination span, or if the x-span of the supplied destination mask image is not contained in the trained destination span.
  ```

Static Functions

computeSrcFromDstTransform

```
static cc2XformBasePtrh_const computeSrcFromDstTransform (
   const cc2XformBase& fromPhysicalCalibrationXform,
   const cc2Vect& pt);
```

Compute warping transform using the arguments provided: that

- *fromPhysicalCalibrationXform* is a calibration transform from physical space.
- *pt* is a 2d point. It is used to set the scale so that in the features in undistorted image are approximately of same size as in the distorted image.

Parameters

fromPhysicalCalibrationXform
The calibration transform.

pt A point that defines the x- and y-scale.

Operators

operator=

```
ccImageWarp1D &operator=(const ccImageWarp1D &rhs);
```

Assignment operator.

operator==

```
bool operator==(const ccImageWarp1D& other) const;
```

Return true if this object is equal to the supplied object, false otherwise.

Parameters

other The object to compare to this one.

ccIndexChain

```
#include <ch_cvl/chain.h>

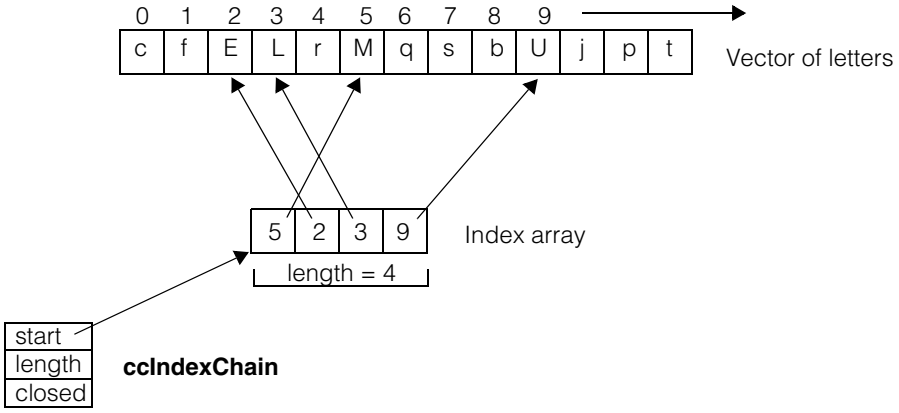
class ccIndexChain;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class encapsulates the parameters necessary to identify a chain of related items in an array, without altering the array. It includes a pointer to an index array that you create independently, the length of the index array, and a boolean that indicates if the chain is closed. In a closed chain, the first and last items are adjacent.

The following is an example of using a **ccIndexChain** to identify the uppercase characters in an array of characters. The uppercase characters form a chain. *start* points to an array that holds indices into the character array above where the uppercase letters are stored. *length* specifies that there are four characters in the chain, and *closed* will be false in this example.



ccIndexChain objects are used by the Edge tool to identify found edgelets that are related. See the **cfEdgeDetect()** reference page and also the **cfFilterEdgeletChains()** reference page other examples.

Constructors/Destructors

ccIndexChain

```
ccIndexChain();

ccIndexChain(
  c_Int32 *start,
  c_Int32 len,
  bool closed);
```

- `ccIndexChain();`

  Default constructor. Sets the following default values:

Parameter	Default Value
start	0
len	0
closed	false

- ```
  ccIndexChain(
    c_Int32 *start,
    c_Int32 len,
    bool closed);
  ```

  Constructor.

  Parameters

  start — A pointer to the beginning of an index array that holds indices into another array. The index array specifies the chain.

  len — The chain length.

  closed — True is the chain is closed, false otherwise.

Public Member Functions

start

```
const c_Int32 *start () const;
```

Returns a pointer to the start of an index array.

length

```
c_Int32 length () const;
```

Returns the number of indices in the chain. This is also the size of the index array.
```

closed

```
bool closed () const;
```

Returns true if a closed chain is specified, and false otherwise.

ccIndexChain

ccIndexChainList

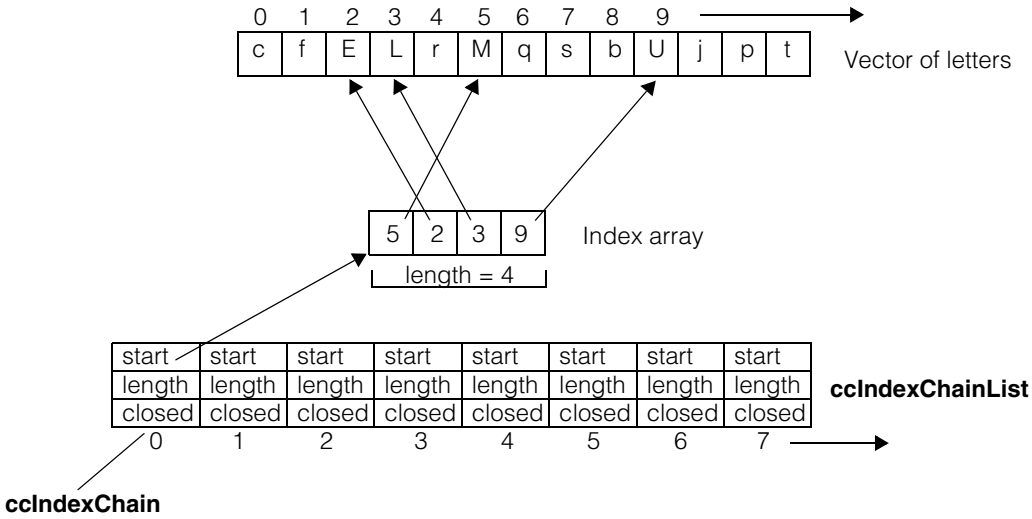
```
#include <ch_cvl/chain.h>

class ccIndexChainList
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class holds an array of **ccIndexChain** objects, a chain list. See the following diagram.



See the **ccIndexChain** reference page for information about this class.

Constructors/Destructors

ccIndexChainList

```
ccIndexChainList ();
~ccIndexChainList ();
ccIndexChainList (const ccIndexChainList&);
```

- `ccIndexChainList ();`

  Default constructor.

- `~ccIndexChainList ();`

  Destructor.

- `ccIndexChainList (const ccIndexChainList&);`

  Copy constructor.

Operators

operator= `ccIndexChainList& operator= (const ccIndexChainList&);`

Efficient deep copy.

operator[] `const ccIndexChain& operator[] (int i) const;`

Returns chain *i*.

Parameters

i The chain index.

Throws

ccIndexChainList::OutOfBounds
If *i* is not a valid chain index.

Public Member Functions

size `int size () const;`

Returns the number of chains on the list.

ccInputLine

```
#include <ch_cvl/pio.h>

class ccInputLine;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class describes a single input line. You obtain a **ccInputLine** by calling the **inputLine()** member of the class that describes your hardware platform. A value of true for an input line generally designates a high state (+5V); a value of false generally designates a low state (0V).

Notes

Do not attempt to construct a **ccInputLine** directly.

Enumerations

ceTrigCondition This enumeration specifies the transitions of an input line that cause a trigger.

Value	Meaning
ceHighToLow	Transition from 1 to 0 causes a trigger.
ceLowToHigh	Transition from 0 to 1causes a trigger.
ceBoth	Any transition causes a trigger.
ceNone	No transition causes a trigger.

Public Member Functions

get

```
bool get() const;
```

Returns the current state of the line represented by this **ccInputLine**. True designates a high state. False designates a low state.

Throws

ccParallelIO::NotEnabled

The input line object was not constructed correctly.

lineNumber `c_Int32 lineNumber() const;`

Returns the logical line number associated with this **ccInputLine**. The value returned is determined by the configuration set by **ccParallelIO::setIOConfig()**.

Throws

ccParallelIO::NotEnabled
The input line object was not constructed correctly.

Notes

See the documentation for the class that describes your specific hardware platform for the equivalence between logical line numbers and physical lines.

enable `void enable(bool value);`

Enables the input line associated with this **ccInputLine**.

Parameters

value True enables the line. False disables the line.

Throws

ccParallelIO::CannotEnable
This **ccInputLine** cannot be enabled. If you are using a hardware platform that supports bidirectional lines, then it may not be possible to enable an input line if other lines in the same group have been configured as output lines.

Notes

If this input line was set up as a trigger, and *value* is false, any callback function associated with this line is uninstalled.

enabled `bool enabled() const;`

Returns true if this line is enabled. Returns false if this line not enabled.

canEnable `bool canEnable() const;`

Returns true if the input line associated with this **ccInputLine** can be enabled. Returns false if **enable(true)** would throw an error.

Throws

ccParallelIO::NotEnabled
The input line object was not constructed correctly.

enableCallback

```
ccInputLine::Token enableCallback(
  const ccCallback1Ptrh& action,
  void* arg,
  cePriority priority,
  ceTrigCondition polarity);
```

Returns a **ccInputLine::Token** object that represents a callback function. When the token is destroyed, either by deletion, by going out of scope, or by assignment to another token, the callback is disabled. The callback remains enabled for the lifetime of the token.

To verify that **enableCallback()** completed successfully, cast the token to a boolean. True indicates successful completion. False indicates a failure. Multiple callbacks on the same physical input line may have requirements such as using a common polarity.

Parameters

action — A pointer to the action routine to be executed when a transition is detected on the line.

If you want to remove a callback function but leave the input line enabled, assign the callback token to a default-constructed token, for example using:

```
myToken = ccInputLine::Token();
```

This call will unregister the callback associated with *myToken*.

Assigning NULL to this parameter does not disable the callback.

Disabling the input line does not unregister callbacks, it will only temporarily deactivate them. The callbacks will become active again when the line is enabled. Callbacks remain registered throughout the life of their associated token. To unregister a callback, use the above method.

See **ccCallback** and **ccCallback1** for further information on the use of callbacks.

arg — This argument is passed to the callback function when it is invoked.

priority — The thread priority of the callback function. See **cfCreateThread()**

polarity — The condition on which this input line should trigger. Must be one of the following:

ceInputLine::ceHighToLow
ceInputLine::ceLowToHigh
ceInputLine::ceBoth

Throws

ccParallelIO::BadParams
One of the parameters was not valid.

ccParallelIO::CannotEnable
This **ccInputLine** cannot be enabled or may be in use.

Notes

Callbacks are supported on Cognex frame grabbers as follows:

- On the MVS-8500 series, callbacks are supported on any bidirectional line that has been configured as an input line.

See the sample *pio.cpp*, provided in the *%VISION_ROOT%\sample\cvl* directory, for code demonstrating how to create and use input callbacks.

ccInterpSpline

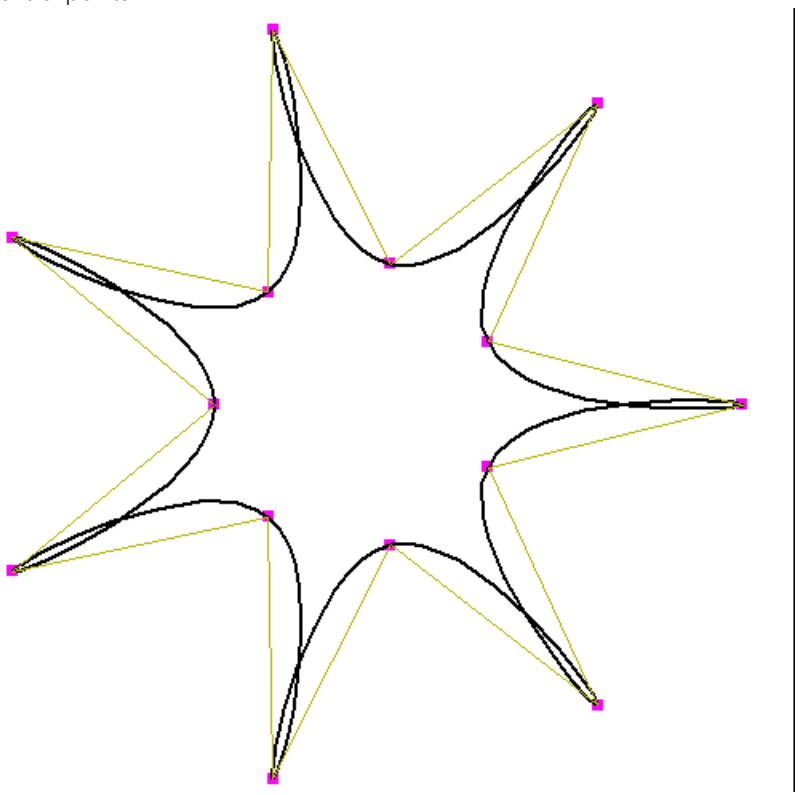
```
#include <ch_cvl/spline.h>

class ccInterpSpline : public ccCubicSpline;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccInterpSpline** class is an implementation of a 2D cubic C^2 interpolation spline, a type of cubic B-Spline in which the spline curve interpolates (passes through) all of the spline control points.



The above figure shows an example of a cubic C^2 interpolation spline.

Properties of Interpolation Splines

Interpolation of all of the control points is often a desirable property when using splines for modeling or design. Each component Bezier curve lies between two successive control points, and the spline is twice differentiable at the junction points (unless there are duplicated knots), and infinitely differentiable everywhere else.

The minimum number of spline control points needed to specify a non-empty **ccInterpSpline** is two for an open spline, and three for a closed spline. In other words, a **ccInterpSpline** is empty if it has fewer than two control points; a closed **ccInterpSpline** is empty if is has fewer than three control points.

End Conditions

Tangent vectors at the junction points of a cubic C^2 interpolation spline are determined by the B-spline differentiability constraints. Open cubic C^2 interpolation splines require the specification of end conditions, which determine the tangent vectors at the endpoints of the spline. There are several options:

Condition	Endpoint Tangents
Bessel	Chosen as tangent vectors to the interpolating parabolas through the first three and last three control points.
Quadratic	Chosen so the first and last cubic Bezier curves are quadratic (cubic coefficients are zero).
Natural	Chosen so second derivatives of x(*t*) and y(*t*) vanish at the endpoints; the spline exhibits low curvature near the ends.
Clamped	Explicitly specified.

Bessel end conditions are a good default choice.

Comparison of de Boor Splines and C^2 Interpolation Splines

The three properties described for cubic de Boor splines do not hold for cubic C^2 interpolation splines.

Cubic Spline Property	de Boor Splines	C^2 Interpolation Splines
Curve must lie within the convex hull of the spline control points	Yes	No
Number of component Bezier curves affected by moving a spline control point	Limited number	All are affected, however those farther away from the moved control point are affected less.
Assigning any non-negative weight to control points produces a valid spline	Yes	N/A

Interpolating splines with one or more zero intervals are not well defined. As a fallback, the cubic Bezier curve representation computed for such an interpolating spline is the control polygon itself, whether it be open or closed. It is generally advisable to avoid zero intervals with interpolating splines.

Note Avoiding zero-length intervals also means that successive interpolation points should not be coincident when parameterizations based on distance between interpolation points are in effect.

Computing Bezier control points from the spline control points is a more expensive operation for cubic C^2 interpolation splines than for cubic de Boor splines. However, once the Bezier curves are computed (and cached), you can query or render a cubic C^2 interpolation spline as quickly as a cubic de Boor spline of similar size.

Note For in-depth information on the theory and use of 2D cubic Bezier curves and splines, see any textbook on the subject, such as *Curves and Surfaces for Computer Aided Geometric Design* by Gerald Farin, Second Edition, Academic Press, 1990, ISBN 0-12-249051-7.

Note All methods defined for this class leave the **ccInterpSpline** object unchanged when they throw an error.

Enumerations

EndConditions `enum EndConditions;`

See *End Conditions* on page 1772 for details.

Value	Meaning
eBessel	Endpoint tangents are chosen as tangent vectors to the interpolating parabolas through the first three and last three control points.
eQuadratic	Endpoint tangents are chosen so the first and last cubic Bezier curves are quadratic (cubic coefficients are zero).
eNatural	Endpoint tangents are chosen so the second derivatives of x(*t*) and y(*t*) vanish at the endpoints; the spline exhibits low curvature near the ends.
eClamped	Endpoint tangents are explicitly specified.

Operators

operator== `bool operator==(const ccInterpSpline &rhs) const;`

Returns true if and only if this **ccInterpSpline** is equal to *rhs*. Two splines are equal if all of their defining parameters are identical (no tolerance is used).

Parameters

rhs — The other **ccInterpspline**.

Notes

Splines that describe identical curves are not necessarily equal.

operator!= `bool operator!=(const ccInterpSpline &rhs) const;`

Returns the opposite truth value to **operator==()**.

Parameters

rhs — The other **ccInterpspline**.

Constructors/Destructors

```
explicit
ccInterpSpline(bool isClosed = false,
  IntervalMode intervalMode = eUniform,
  EndConditions endConditions = eBessel);

explicit ccInterpSpline(
  const cmStd vector<cc2Vect> &ctrlPts,
  bool isClosed = false,
  IntervalMode intervalMode = eUniform,
  EndConditions endConditions = eBessel);
```

- ```
  explicit
  ccInterpSpline(bool isClosed = false,
    IntervalMode intervalMode = eUniform,
    EndConditions endConditions = eBessel);
  ```

  Constructs an empty interpolating B-spline with no control points, with the given open/closed state, interval mode, and end conditions. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

isClosed	The open/closed state of this **ccInterpSpline** (default = open).
intervalMode	The interval mode. Must be one of the following: *ccCubicSpline::eUniform (default)* *ccCubicSpline:eChordLength* *ccCubicSpline::eCentripetal* *ccCubicSpline::eFixed*
endConditions	Conditions that determine the tangent vectors at the endpoints of the spline. Must be one of the following: *ccInterpSpline::eBessel* (default) *ccInterpSpline::eQuadratic* *ccInterpSpline::eNatural* *ccInterpSpline::eClamped*

- ```
  explicit ccInterpSpline(
    const cmStd vector<cc2Vect> &ctrlPts,
    bool isClosed = false,
    IntervalMode intervalMode = eUniform,
    EndConditions endConditions = eBessel);
  ```

  Constructs an interpolating B-spline with the given control points, open/closed state, interval mode, and end conditions. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

ctrlPts	The vector of control points.
isClosed	The open/closed state of this **ccInterpSpline** (default = open).
intervalMode	The interval mode. Must be one of the following: *ccCubicSpline::eUniform (default)* *ccCubicSpline:eChordLength* *ccCubicSpline::eCentripetal* *ccCubicSpline::eFixed*
endConditions	Conditions that determine the tangent vectors at the endpoints of the spline. Must be one of the following: *ccInterpSpline::eBessel* (default) *ccInterpSpline::eQuadratic* *ccInterpSpline::eNatural* *ccInterpSpline::eClamped*

endConditions

```
EndConditions endConditions() const;

void endConditions(EndConditions endConditions);
```

- `EndConditions endConditions() const;`

  Returns the end conditions of this spline, which determine the tangent vectors at the endpoints of the spline. See **EndConditions** on page 1774.

- `void endConditions(EndConditions endConditions);`

  Sets the end conditions of this spline.

  Parameters

endConditions	Conditions that determine the tangent vectors at the endpoints of the spline. Must be one of the following: *ccInterpSpline::eBessel* (default) *ccInterpSpline::eQuadratic* *ccInterpSpline::eNatural* *ccInterpSpline::eClamped*

  Notes

  This value is only significant if this spline is open and has clamped end conditions. Otherwise the value is ignored.

startDeriv

```
cc2Vect startDeriv() const;
void startDeriv(const cc2Vect &v);
```

- `cc2Vect startDeriv() const;`

  Gets the derivative vector at the start point of this spline.

- `void startDeriv(const cc2Vect &v);`

  Sets the derivative vector at the start point of this spline.

  Parameters

  v The derivative vector.

  Notes

  This value is significant only if this spline is open and has clamped end conditions, otherwise the value is ignored.

endDeriv

```
cc2Vect endDeriv() const;
void endDeriv(const cc2Vect &v);
```

- `cc2Vect endDeriv() const;`

  Gets the derivative vector at the end point of this spline.

- `void endDeriv(const cc2Vect &v);`

  Get/set the derivative vector at the end point of this spline.

  Parameters

  v The derivative vector.

  Notes

  This value is only significant if this spline is open and has clamped end conditions, otherwise the value is ignored.

map

```
ccInterpSpline map(const cc2Xform& X) const;
```

Returns this ccInterpSpline mapped by *X*.

Parameters

X The transformation object.

Notes

This function maps the control point positions by *X* and leaves the weights and intervals unchanged. It may be desirable to invoke reparameterize() on the returned spline. See *Mapping Splines* and *Reparameterizing Splines* on page 1112 for details.

Note Several of **ccCubicSpline**'s setter/getter pairs have a virtual setter and a non-virtual getter. The getters must be explicitly exposed in derived classes, or they will be hidden by the setter overrides.

---

isClosed

```
bool isClosed() const;

virtual void isClosed(bool);
```

- `bool isClosed() const;`

  Returns true if this **ccInterpSpline** is closed, false if it is open.

- `virtual void isClosed(bool);`

  Sets the open/closed state of this **ccInterpSpline**.

  Parameters

  bool True sets this spline to closed, false sets it to open.

  See **ccCubicSpline::isClosed()** for more information.

---

controlPoint

```
cc2Vect controlPoint(c_Int32 idx) const;

virtual void controlPoint(c_Int32 idx,
  const cc2Vect &ctrlPt);
```

- `cc2Vect controlPoint(c_Int32 idx) const;`

  Gets the control point with the given index.

  Parameters

  idx The index.

- ```
  virtual void controlPoint(c_Int32 idx,
    const cc2Vect &ctrlPt);
  ```

  Sets the control point with the given index.
  ```

Parameters

idx The index.

ctrlPt The control point.

See **ccCubicSpline::controlPoint()** for more information.

controlPoints

```
const cmStd vector<cc2Vect> &controlPoints() const;

virtual void controlPoints(
  const cmStd vector<cc2Vect> &ctrlPts);
```

- `const cmStd vector<cc2Vect> &controlPoints() const;`

  Gets the entire vector of control points.

- ```
  virtual void controlPoints(
    const cmStd vector<cc2Vect> &ctrlPts);
  ```

  Sets the entire vector of control points.

  Parameters

  ctrlPts The vector of control points.

  See **ccCubicSpline::controlPoints()** for more information.

insertControlPoint

```
virtual void insertControlPoint(c_Int32 idx,
  const cc2Vect &point);
```

Inserts a new control point before the point with the given index.

Parameters

idx The index.

point The control point.

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than **numControlPoints()** before the insertion.

See **ccCubicSpline::insertControlPoint()** for more information.
```

removeControlPoint

```
virtual void removeControlPoint(c_Int32 idx);
```

Remvoes the control point with the given index.

Parameters

idx The index.

Throws

ccShapesError::BadIndex

idx is less than 0, or greater than **numControlPoints()** before the removal.

See **ccCubicSpline::removeControlPoint()** for more information.

reparameterize

```
virtual void reparameterize();
```

Recomputes all intervals based on the current control points and interval mode.

See **ccCubicSpline::reparameterize()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this interpolation spline.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this **ccInterpSpline**. See **ccShape::reverse()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this **ccInterpSpline** mapped by *X*.

Parameters

X The transformation object.

See **ccShape::mapShape()** for more information.

ccIO8500l

```
#include <ch_cvl/pioconfg.h>

class ccIO8500l : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8500L frame grabber when used with cable 300-0390 and the pass-through TTL connection module, P/N 800-5818-1.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines();
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines();
```

Returns the number of output lines for this hardware configuration.

ccIO8501

```
#include <ch_cvl/pioconfg.h>

class ccIO8501 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8501 frame grabber or a Cognex MVS-8511 (and MVS-8511e) frame grabber when used with cable 300-0390 and the pass-through TTL connection module, P/N 800-5818-1.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines();
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines();
```

Returns the number of output lines for this hardware configuration.

ccIO8504

```
#include <ch_cvl/pioconfg.h>

class ccIO8504 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8504 (and MVS-8504e) frame grabber or a Cognex MVS-8514 (and MVS-8514e) frame grabber when used with cable 300-0390 and the pass-through TTL connection module.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber) const;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines();
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

ccIO8600DualLVDS

```
#include <ch_cvl/pioconfg.h>

class ccIO8600DualLVDS : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on Cognex MVS-8600 and MVS-8600e frame grabbers when used with cable 300-0538 and the 800-5885-1 I/O connection module. The MVS-8600 and MVS-8600e series support cameras that use the Camera Link LVDS protocol.

Use this class to support I/O in the case shown in Table 1.

Model	Camera connection type	Code
MVS-8601 and MVS-8601e	Not used	
MVS-8602 and MVS-8602e	Two line scan cameras, both using LVDS encoders	2LL

Table 1. Supported I/O cases for ccIO8600DualLVDS

Wires are connected from strobe, trigger, and encoder devices according to the pinout information in Table 2. Codes in Table 2 have the following meanings:

- S*n* = Strobe for camera port *n*
- T*n* = Trigger for camera port *n*
- A*n*, B*n* = A and B channel connections from LVDS encoder for camera port *n*
- The camera connection type code is from Table 1

MVS-8602 and MVS-8602e only	Connector pins		
2LL	**Hirose (P3)**	**P4**	**P6**
A0	3	11	
B0	5	22	
A1	12		11
B1	8		22
A0’	4	13	
B0’	6	24	
A1’	7		13
B1’	9		24
T0+, T1+		5	
T0–		7	
T1–		9	
S1+		1	
S1–		3	
S0+		4	
S0–		6	

Table 2. Wire connection cases for ccIO8600DualLVDS

For this I/O configuration, trigger and strobe connections are opto-isolated.

Some pin connections are duplicated between the Hirose connector on the back faceplate of the MVS-8600 and MVS-8600e, and the onboard 26-pin headers labeled P4 and P6.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines() const;`

Returns the number of output lines for this hardware configuration.

NOTES

ccIO8600LVDS

```
#include <ch_cvl/pioconfg.h>

class ccIO8600LVDS : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on Cognex MVS-8600 and MVS-8600e frame grabbers when used with cable 300-0539 and the 800-5885-1 I/O connection module. The MVS-8600 and MVS-8600e series support cameras that use the Camera Link LVDS protocol. This class is the default I/O class for an instance of **cc8600**.

Use this class to support I/O in the cases shown in Table 1.

Model	Camera connection type	Code
MVS-8601, MVS-8601e, MVS-8602, MVS-8602e	One area scan camera	1A
	One line scan camera using an LVDS encoder	1LL
MVS-8602 and MVS-8602e only	Two area scan cameras	2A
	One line scan camera using an LVDS encoder, plus one area scan camera	1LL+1A

Table 1.Supported I/O cases for ccIO8600LVDS

When connecting only one line scan camera to the MVS-8602 or MVS-8602e, it must be connected to camera port 0. When connecting one line scan and one area scan camera, the line scan camera must be connected to camera port 0.

Wires are connected from strobe, trigger, and encoder devices according to the pinout information in Table 2. Codes in Table 2 have the following meanings:

- S*n* = Strobe for camera port *n*
- T*n* = Trigger for camera port *n*
- A0, B0 = A and B channel connections from LVDS encoder for camera port 0
- The camera connection type codes are from Table 1

All Models		MVS-8602 and MVS-8602e only		Connector pins		
1A	**1LL**	**2A**	**1LL+1A**	**Hirose (P3)**	**P4**	**P6**
	A0		A0	3	11	
	B0		B0	5	22	
S0	S0	S0	S0	12		11
T0	T0	T0	T0	8		22
	A0’		A0’	4	13	
	B0’		B0’	6	24	
		S1	S1	7		13
		T1	T1	9		24

Table 2. Wire connection cases for ccIO8600LVDS

Some pin connections are duplicated between the Hirose connector on the back faceplate of the MVS-8600 and MVS-8600e, and the onboard 26-pin headers labeled P4 and P6.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

ccParallelIO::BadParams

The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines();
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

NOTES

ccIO8600TTL

```
#include <ch_cvl/pioconfg.h>

class ccIO8600TTL : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on Cognex MVS-8600 MVS-8600e frame grabbers when used with cable 300-0540 and the 800-5885-1 I/O connection module. The MVS-8600 and MVS-8600e series support cameras that use the Camera Link LVDS protocol.

Use this class to support I/O in the cases shown in Table 1.

Model	Camera connection type	Code
MVS-8601, MVS-8601e MVS-8602, MVS-8602e	One area scan camera	1A
	One line scan camera using a TTL encoder	1LT
MVS-8602 and MVS-8602e only	Two area scan cameras	2A
	Two line scan cameras, both using TTL encoders	2LT
	One line scan camera using a TTL encoder, plus one area scan camera	1LT+1A

Table 1.Supported I/O cases for ccIO8600TTL

When connecting only one line scan camera to the MVS-8602 or MVS-8602e, it must be connected to camera port 0. When connecting one line scan and one area scan camera, the line scan camera must be connected to camera port 0.

Wires are connected from strobe, trigger, and encoder devices according to the pinout information in Table 2. Codes in Table 2 have the following meanings:

- S*n* = Strobe for camera port *n*
- T*n* = Trigger for camera port *n*
- A*n,* B*n* = A and B channel connections from TTL encoder for camera port *n*
- The camera connection type codes are from Table 1

All Models		MVS-8602 and MVS-8602e only			Connector pins		
1LT	**1A**	**2A**	**2LT**	**1LT+1A**	**Hirose (P3)**	**P4**	**P6**
A0			A0	A0	3	11	
B0			B0	B0	5	22	
S0	S0	S0	S0	S0	12		11
T0	T0	T0	T0	T0	8		22
			A1		4	13	
			B1		6	24	
		S1	S1	S1	7		13
		T1	T1	T1	9		24

Table 2. Wire connection cases for ccIO8600TTL

Some pin connections are duplicated between the Hirose connector on the back faceplate of the MVS-8600 and MVS-8600e, and the onboard 26-pin headers labeled P4 and P6.

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s

The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines();
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

NOTES

ccIOConfig

```
#include <ch_cvl/pioconfg.h>

class ccIOConfig;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	No

ccIOConfig is an abstract base used to check the validity of logical line numbers for an installed hardware I/O configuration. The derived classes are used to specify the I/O configuration of your frame grabber.

Derived class	Description
ccIOStandardOption	Specifies: • Universal parallel I/O board in standard configuration, P/N 800-5726-1 • One or both of the ISA-based parallel I/O boards, the TTL and OPTO/TTL boards.
ccIOLightControlOption	Specifies the universal parallel I/O board in light control configuration, P/N 800-5726-2
ccIOExternalOption	Specifies the universal parallel I/O board in external configuration, P/N 800-5726-3, used with the Cognex external I/O module, P/N 800-5712-2
ccIO8501 **ccIO8504**	Specifies the sixteen bidirectional TTL lines on an MVS-8500 series frame grabber, when connected to the pass-through TTL connection module (P/N 800-5818-1 with cable 300-0390.
ccIOExternal8501 **ccIOExternal8504**	Specifies the sixteen bidirectional TTL lines on an MVS-8500 series frame grabber, when connected to the external opto-isolated I/O module (P/N 800-5712-2) with cable 300-0389.

Derived class	Description
ccIOSplit8501 **ccIOSplit8504**	Specifies the sixteen bidirectional TTL lines on an MVS-8500 series frame grabber, when connected to the half TTL, half opto cable 300-0399. One branch of this cable terminates in a 10-pin screw terminal block for TTL lines. The other branch connects to the external opto-isolated I/O module, (P/N 800-5712-2).
ccIO8600LVDS	Specifies the I/O configuration appropriate when connecting one or two area scan cameras, or one line scan camera on camera port 0 using an LVDS encoder, with or without one area scan camera. This is the default I/O configuration for the MVS-8600. Use this configuration with cable 300-0539 and the 800-5885-1 I/O connection module.
ccIO8600TTL	Specifies the I/O configuration appropriate when connecting one or two line scan cameras using TTL encoders, one or two area scan cameras, or one line scan camera with TTL encoder plus one area scan camera. Use this configuration with cable 300-0540 and the 800-5885-1 I/O connection module.
ccIO8600DualLVDS	Specifies the I/O configuration appropriate when connecting two line scan cameras both using LVDS encoders. Use this configuration with cable 300-0538 and the 800-5885-1 I/O connection module.

To specify one of these I/O configurations, use the **setIOConfig()** member function of the class that represents your frame grabber. For example, **cc8501::setIOConfig()**.

Constructors/Destructors

This is an abstract base class.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber)
  const = 0;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

ccParallelIO::BadParams
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber)
  const = 0;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines() const = 0;
```

Returns the total number of usable input lines for this I/O configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const = 0;
```

Returns the total number of usable output lines for this I/O configuration.

ccIOConfig

ccIOExternal8500l

```
#include <ch_cvl/pioconfg.h>

class ccIOExternal8500l : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8500L frame grabber when used with cable 300-0389 and the external opto-isolated I/O module, P/N 800-5712-2.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

ccIOExternal8500I

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOExternal8501

```
#include <ch_cvl/pioconfg.h>

class ccIOExternal8501 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8501 frame grabber or a Cognex MVS-8511 (and MVS-8511e) frame grabber when used with cable 300-0389 and the external opto-isolated I/O module, P/N 800-5712-2.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

ccIOExternal8501

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOExternal8504

```
#include <ch_cvl/pioconfg.h>

class ccIOExternal8504 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8504 (and MVS-8504e) frame grabber or a Cognex MVS-8514 (and MVS-8514e) frame grabber when used with cable 300-0389 and the external opto-isolated I/O module, P/N 800-5712-2.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

ccIOExternal8504

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOExternalOption

```
#include <ch_cvl/pioconfg.h>

class ccIOExternalOption : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers for a parallel I/O board in external configuration (Cognex P/N 800-5726-3), which is used with the Cognex external I/O module (P/N 800-5712-2).

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber) const;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines() const;
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

ccIOLightControlOption

```
#include <ch_cvl/pioconfg.h>

class ccIOLightControlOption : public ccIOLightControl8100;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers for a parallel I/O board in light control configuration (Cognex P/N 800-5726-2).

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber) const;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines() const;
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

ccIOSplit8500l

```
#include <ch_cvl/pioconfg.h>

class ccIOSplit8500l : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8500L frame grabber when used with cable 300-0399. One branch of this cable connects to the external opto-isolated I/O module, P/N 800-5712-2; the other branch terminates in a Phoenix screw terminal strip.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

ccIOSplit8500I

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOSplit8501

```
#include <ch_cvl/pioconfg.h>

class ccIOSplit8501 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8501 frame grabber or a Cognex MVS-8511 (and MVS-8511e) frame grabber when used with cable 300-0399. One branch of this cable connects to the external opto-isolated I/O module, P/N 800-5712-2; the other branch terminates in a Phoenix screw terminal strip.

Public Member Functions

isValidInputLine `virtual void isValidInputLine(c_UInt8 linenumber) const;`

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

`virtual void isValidOutputLine(c_UInt8 linenumber) const;`

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOSplit8504

```
#include <ch_cvl/pioconfg.h>

class ccIOSplit8504 : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers available on a Cognex MVS-8504 (and MVS-8504e) frame grabber or a Cognex MVS-8514 (and MVS-8514e) frame grabber when used with cable 300-0399. One branch of this cable connects to the external opto-isolated I/O module, P/N 800-5712-2; the other branch terminates in a Phoenix screw terminal strip.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber) const;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams
The specified output line number is not valid for this I/O configuration.

numInputLines `virtual c_UInt32 numInputLines();`

Returns the number of input lines for this hardware configuration.

numOutputLines `virtual c_UInt32 numOutputLines();`

Returns the number of output lines for this hardware configuration.

ccIOStandardOption

```
#include <ch_cvl/pioconfg.h>

class ccIOStandardOption : public ccIOConfig;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class is used to check the validity of I/O logical line numbers for a parallel I/O board in standard configuration (Cognex P/N 800-5726-1).

Constructors/Destructors

A default-constructed instance of this class is intended to be used only as an argument to **setIOConfig()**.

Public Member Functions

isValidInputLine

```
virtual void isValidInputLine(c_UInt8 linenumber) const;
```

No effect if specified input line number is valid.

Parameters

linenumber The input line number.

Throws

*ccParallelIO::BadParam*s
The specified input line number is not valid for this I/O configuration.

isValidOutputLine

```
virtual void isValidOutputLine(c_UInt8 linenumber) const;
```

No effect if specified output line number is valid.

Parameters

linenumber The output line number.

Throws

ccParallelIO::BadParams

The specified output line number is not valid for this I/O configuration.

numInputLines

```
virtual c_UInt32 numInputLines() const;
```

Returns the number of input lines for this hardware configuration.

numOutputLines

```
virtual c_UInt32 numOutputLines() const;
```

Returns the number of output lines for this hardware configuration.

ccKeyboardEvent

```
#include <ch_cvl/uievent.h>

class ccKeyboardEvent;
```

Class Properties

Copyable	No
Derivable	Not intended
Archiveable	Complex

This class encapsulates information associated with a keyboard event. For example, when a keyboard key is pressed down.

Constructors/Destructors

ccKeyboardEvent

```
ccKeyboardEvent ();
```

Enumerations

Event

This enumeration specifies types of keyboard events.

Value	Meaning
eNone	There is no key associated with this mouse event.
eKeyDown	A keyboard key was depressed. (Also, see **repeatKey()**).
eKeyUp	A keyboard key was released.
eKeyPress	An ASCII or Unicode key was pressed down.

eKeyDown and *eKeyUp* events are only generated for virtual keys.

ccKeyboardEvent

KeyType This enumeration specifies key types for keyboard events.

Value	Meaning
eAscii	An ASCII key.
eUnicode	A Unicode key.
eVirtual	A virtual key

VirtualKey This enumeration specifies virtual key types associated with keyboard events.

Value	Meaning
eNoVKey = 0	The keyboard event was not caused by a virtual key.
eBackspace = 0x08	**Backspace** key.
eTab	**Tab** key.
eReturn = 0xD0	**Enter** key.
eShift = 0x10	**Shift** key.
eControl	**Ctrl** key.
eMenu	Menu key.
ePause	**Pause** key.
eCapLock	**Caps Lock** key.
eEscape = 0x1B	**Esc** key.
eSpace = 0x20	Space bar.
ePrior	**Page Up** key.
eNext	**Page Down** key.
eEnd	**End** key.
eHome	**Home** key.
eLeft	Left Arrow key.
eUp	Up Arrow key.
eRight	Right Arrow key.
eDown	Down Arrow key.

Value	Meaning
eInsert = 0x2D	**Insert** Key
eDelete	**Delete** key.
eHelp	**F1** function key.
eF1 = 0x70	**F1** function key.
eF2	**F2** function key.
eF3	**F3** function key.
eF4	**F4** function key.
eF5	**F5** function key.
eF6	**F6** function key.
eF7	**F7** function key.
eF8	**F8** function key.
eF9	**F9** function key.
eF10	**F10** function key.
eF11	**F11** function key.
eF12	**F12** function key.
eF13	**F13** function key.
eF14	**F14** function key.
eF15	**F15** function key.
eF16	**F16** function key.
eF17	**F17** function key.
eF18	**F18** function key.
eF19	**F19** function key.
eF20	**F20** function key.
eF21	**F21** function key.
eF22	**F22** function key.

Value	Meaning
eF23	**F23** function key.
eF24	**F24** function key.

Public Member Functions

event

```
void event(Event e);
Event event() const;
```

- `void event(Event e);`

  Sets the keyboard event type. Must be one of the **Event** enums.

  Parameters

  e The event type.

- `Event event() const;`

  Returns the keyboard event type.

key

```
void key(char ch);
void key(wchar_t uc);
void key(VirtualKey vk);
```

- `void key(char ch);`

  Sets the key for this event (an ASCII character).

  Parameters

  ch The ASCII character.

- `void key(wchar_t uc);`

  Sets the key for this event (a Unicode character).

  Parameters

  uc The Unicode character.

- `void key(VirtualKey vk);`

  Sets the key for this event (a virtual key). Must be one of the **VirtualKey** enums.

  Parameters

  vk The virtual key character.

keyType `KeyType keyType() const;`

Returns the key type; ASCII, Unicode, or virtual.

Use this method to determine which of the following three methods to call to get the key code.

asciiKey `TCHAR asciiKey() const;`

Returns an ASCII key character.

unicodeKey `c_Int16 unicodeKey() const;`

Returns a Unicode key character.

virtualKey `VirtualKey virtualKey() const;`

Returns a virtual key.

repeatKey

```
void repeatKey(bool b);
bool repeatKey() const;
```

Specifies whether an **Event::eKeyDown** event is due to a key press or a key repeat. If set true, its due to the repeat key. If set false, its due to a key press.

- `void repeatKey(bool b);`

  Set the repeatKey flag, true or false.

  Parameters

  b The new flag value.

- `bool repeatKey() const;`

  Return the repeatKey flag.

Static Functions

toVirtualKey

```
static VirtualKey toVirtualKey(c_Int32 key);
```

Returns the virtual key corresponding to the specified value. Returns *eNoKey* if the value is not valid.

Parameters

key	The value to convert to a virtual key.

ccLabeledProjection

```
#include <ch_cvl/lablproj.h>

class ccLabeledProjection;
```

A name space class that holds enumerations and constants used with labeled projection.

Enumerations

BinOrder

```
enum BinOrder
```

This enumeration defines the bin ordering methods used to construct circular and radial projection models.

Value	Meaning
eRadial	Bins are numbered from innermost to outermost annulus within each sector.
eAngular	Bins are numbered from first to last sector within each annulus.
kDefaultBinOrder	The default bin order, as defined in *lablproj.h*

Orientation

```
enum Orientation
```

This enumeration defines the direction in which angles are measured and the order in which sectors are numbered.

Value	Meaning
eClockwise	Clockwise
eCounterClockwise	Counter-clockwise
kDefaultOrientation	The default orientation, as defined in *lablproj.h*

ccLabeledProjection

ccLabeledProjectionModel

```
#include <ch_cvl/lablproj.h>

template <class M>
class ccLabeledProjectionModel;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class represents a projection model used by the Labeled Projection tool. A projection model consists of an image where the value of each pixel in the image determines the bin into which the value of the corresponding pixel in an input image is added.

This class is a templated class, where

M — Template parameter specifying the value associated with each pixel in the model. CVL provides instantiations of **ccLabeledProjectionModel** for the types **c_UInt8**, **c_UInt16**, and **c_UInt32**

Constructors/Destructors

ccLabeledProjectionModel

```
ccLabeledProjectionModel();
```

A **ccLabeledProjectionModel** created by the default constructor cannot be used to project an image.

Public Member Functions

train

```
void train(const ccPelBuffer_const<M> &model);
```

Trains this **ccLabeledProjectionModel** using the supplied image as the projection model.

Parameters

model — The image to use as the projection model. The template type for *model* must be an integer.

Throws

ccLabeledProjection::UnboundImage
model is unbound.

ccLabeledProjection::BadImage
Every pixel in *model* has a value of 0.

Notes

Any previous training information is discarded.

hist

```
const cmStd vector<c_UInt32>& hist() const;
```

Returns a histogram of the distribution of pixel values in this **ccLabeledProjectionModel**. This histogram tells you how many pixels in the model are associated with each bin in the projection image produced using the model.

histInv

```
const cmStd vector<float>& histInv() const;
```

Returns the inverse of the histogram of the distribution of pixel values in this **ccLabeledProjectionModel**. Each element of the returned vector of **float**s is equal to the inverse of the corresponding element of the vector of **c_UInt32**s returned by **hist()**.

model

```
const ccPelBuffer_const<M>& model() const;
```

Returns a **ccPelBuffer_const<M>** containing the projection model.

offset

```
ccIPair offset() const;
void offset(ccIPair offset);
```

- `ccIPair offset() const;`

  Returns the image offset of this **ccLabeledProjectionModel**'s projection model.

- `void offset(ccIPair offset);`

  Sets the image offset of this **ccLabeledProjectionModel**'s projection model.

  Parameters

  offset The image offset to set.

projectionLength

```
c_Int32 projectionLength() const;
```

Returns the projection length of this **ccLabeledProjectionModel**. The projection length is equal to the largest value found in this **ccLabeledProjectionModel**'s projection model. The projection length is the minimum size that must be allocated for a projection image created using this **ccLabeledProjectionModel**.

maxPel

```
c_Int32 maxPel() const;
```

Returns the same value as **projectionLength()**.

isTrained

```
bool isTrained() const;
```

Returns false if this **ccLabeledProjectionModel** is default-constructed, true otherwise.

ccLabeledProjectionModel

ccLine

```
#include <ch_cvl/shapes.h>

class ccLine : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a line passing through a point in a given direction. The direction can be specified as a vector or as an angle. Lines have infinite length. To specify line segments of finite length, see **ccLineSeg**.

Constructors/Destructors

ccLine

```
ccLine();

ccLine(const cc2Vect& dir, const cc2Vect& pos);

ccLine(const ccRadian& t, const cc2Vect& pos);

ccLine(const cc2Vect& v);
```

- `ccLine();`

  Default constructor. Constructs a line with direction (1,0), that is horizontal, passing through the point (0,0).

- `ccLine(const cc2Vect& dir, const cc2Vect& pos);`

  Constructs a line in the direction *dir* passing through the point *pos*.

  Parameters

dir	The direction of the line. Must be a unit vector.
pos	The point through which the line passes.

  Notes

  If *dir* is not a unit (normalized) vector, then projections, distances, and other mathematical line operations may be calculated incorrectly.

Throws

ccShapesError::DegenerateShape
dir is (0,0).

- `ccLine(const ccRadian& t, const cc2Vect& pos);`

Constructs a line with direction *t* passing through the point *pos*.

Parameters

t	The direction of the line in radians.
pos	The point through which the line passes.

- `ccLine(const cc2Vect& v);`

Conversion constructor. Constructs a line in the direction **v.angle()** passing through the point (**v.x()**, **v.y()**). Essentially, this is a line passing through the points (0,0) and *v*.

Parameters

v	The vector the specifies the angle and the point through which the line passes.

Throws

ccMathError::NullVector
v is (0,0).

Operators

operator== `bool operator==(const ccLine& line) const;`

Returns true if this line has the same direction and position as another line.

Parameters

line	The other line.

operator!= `bool operator!=(const ccLine& line) const;`

Returns true if this line is not equal to another line.

Parameters

line	The other line.

Public Member Functions

dir

```
const cc2Vect& dir() const;
cc2Vect& dir();
```

- `const cc2Vect& dir() const;`

  Gets the direction vector for this line.

- `cc2Vect& dir();`

  This overload is deprecated. Use the previous overload, which returns a **const** vector, instead.

pos

```
const cc2Vect& pos() const;
cc2Vect& pos();
void pos(const cc2Vect& p);
```

- `const cc2Vect& pos() const;`

  Gets the point through which this line is constrained to pass.

  Notes

  For a line created with the conversion constructor **ccLine(const cc2Vect& v)**, this function returns the point (**v.x()**, **v.y()**) and not (0,0).

- `cc2Vect& pos();`

  This overload is deprecated. Use the previous overload, which returns a **const** vector, instead.

- `void pos(const cc2Vect& p);`

  Sets the point through which this line is constrained to pass.

  Parameters

p	The point.

map

```
ccLine map(const cc2Xform& c) const;
void map(const cc2Xform& c, ccLine& result) const;
```

- `ccLine map(const cc2Xform& c) const;`

  Returns a line that is the result of mapping this line with the transformation object *c*.

  Parameters

c	The transformation object.

- `void map(const cc2Xform& c, ccLine& result) const;`

  Sets *result* to be a line that is the result of mapping this line with the transformation object *c*.

  Parameters

c	The transformation object.
result	The mapped line.

angle

```
ccRadian angle() const;
void angle(ccRadian a);
ccRadian angle (const ccLine& l) const;
```

- `ccRadian angle() const;`

  Returns the line angle. The returned angle is greater than $-\pi$ and less than or equal to $+\pi$.

- `void angle(ccRadian a);`

  Sets the line angle.

  Parameters

a	The angle in radians.

- `ccRadian angle (const ccLine& l) const;`

  Returns the angle from this line to the given *line*. The returned angle is greater than $-\pi$ and less than or equal to $+\pi$.

  Parameters

l	The other line.

intersect

```
ccPoint intersect(const ccLine& line) const;
```

Returns the point at which this line intersects with the given *line*.

Parameters

line The other line.

Throws

ccShapesError::LinesParallel
The two lines are parallel.

parallel

```
ccLine parallel(const cc2Vect& point) const;
```

Returns a line parallel to this one that passes through the given *point*.

Parameters

point The point through which the parallel line passes.

isParallel

```
bool isParallel(const ccLine& line) const;
```

Returns true if this line is parallel to the given *line*.

Parameters

line The other line.

normal

```
ccLine normal(const cc2Vect& point) const;
```

Returns the line rotated 90 degrees through the given *point*.

Parameters

point The point through which the rotated line passes.

proj

```
ccPoint proj(const cc2Vect& point) const;
```

Returns the projection of the given *point* onto this line. In other words, returns the point *p* such that the line **normal(p)** passes through the given *point*.

Parameters

point The point to project.

offset

```
double offset(const cc2Vect& point) const;
```

Returns the signed distance from **pos()** to the projection of the point on this line.

Parameters

point The point to project.

clone `virtual ccShapePtrh clone() const;`

Returns a pointer to a copy of this directional line.

isOpenContour `virtual bool isOpenContour() const;`

Returns true if this shape is an open contour. For directional lines, this function always returns false.

See **ccShape::isOpenContour()** for more information.

isRegion `virtual bool isRegion() const;`

Returns true if this shape is a region. For directional lines, this function always returns false.

See **ccShape::isRegion()** for more information.

isFinite `virtual bool isFinite() const;`

Returns true if this shape is finite. For directional lines, this function always returns false.

See **ccShape::isFinite()** for more information.

isEmpty `virtual bool isEmpty() const;`

Returns true if the set of points that lie on the boundary of this shape is empty. For directional lines, this function always returns false.

See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

Returns true if the set of points on the boundary of this shape is infinite, and there is a well-defined tangent at all but a finite number of these points. For directional lines, this function always returns true.

See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

Returns true if this shape is already decomposed. For directional lines, this function always returns false.

See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

Returns true if this shape can be reversed. For directional lines, this function always returns true.

Notes

ccLines are reversible, but **ccFLine**s are not.

See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccLine**s.

See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on this directional line to the given point.

Parameters

p The point.

See **ccShape::nearestPoint()** for more information.

perimeter

```
virtual double perimeter() const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccLine**s.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this line to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this line.

point The point.

See **ccShape::nearestPerimPos()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this directional line.

See **ccShape::reverse()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Throws

ccShapesError::InfiniteExtent
For all **ccLine**s.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this directional line mapped by *X*.

Parameters

X	The transformation object.

Notes

If *X* is singular, the mapping may collapse this line to a single point.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccGeneralShapeTree** without any children.

See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the line segment describing the portion of this line over the given range. The length of the final returned line segment is equal to the absolute value of the distance component of *range*.

Parameters

info	Shape information for this line.
range	The perimeter range.

See **ccShape::subShape()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

ccLineFitDefs

```
#include <ch_cvl/fit.h>

class ccLineFitDefs;
```

A name space that holds enumerations and constants used with the Line Fitting tool (**cfLineFit()**).

Enumerations

fit_mode

```
enum fit_mode
```

This enumeration defines types of fitting supported by the Line Fitting tool.

Value	Meaning
eLeastSquares	Fits a line by minimizing the sum of the squares of the distances between the points and the fit line.
eMinMaxDistance	Fits a line by minimizing the maximum distance between any one point and the fit line.
kDefaultFitMode = eLeastSquares	

ccLineFitDefs

ccLineFitParams

```
#include <ch_cvl/fit.h>

class ccLineFitParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the parameters for the Line Fitting tool. See **cfLineFit()**.

Constructors/Destructors

ccLineFitParams

```
ccLineFitParams(
  enum ccLineFitParams::fit_mode fitMode =
                          ccLineFitParams::kDefaultFitMode,
  c_UInt32 numIgnore=0,
  double threshold=HUGE_VAL);
```

Constructs a **ccLineFitParams** params object

Parameters

fitMode — The type of fitting to perform. *fitMode* must be one of the following values:

ccLineFitParams::eLeastSquares
ccLineFitParams::eMinMaxDistance

numIgnore — The number of outlying points to ignore.

threshold — The maximum error for a valid fit. If the fitted line has an error equal to or greater than *threshold*, it is not considered a valid fit.

Throws

ccLineFitParams::BadParams
threshold is less than 0.

Operators

operator==

```
bool operator== (const ccLineFitParams& that) const;
```

Two **ccLineFitParams** objects are considered equal if and only if the values returned by **fitMode()**, **numIgnore()**, and **threshold()** are equal.

Public Member Functions

fitMode

```
enum ccLineFitParams::fit_mode fitMode() const;
```

```
void fitMode(enum ccLineFitParams::fit_mode fitMode);
```

- ```
  enum ccLineFitParams::fit_mode fitMode() const;
  ```

  Returns the type of fitting this **ccLineFitParams** is configured to perform. The function returns one of the following values:

  ccLineFitParams::eLeastSquares
  ccLineFitParams::eMinMaxDistance

- ```
  void fitMode(enum ccLineFitParams::fit_mode fitMode);
  ```

  Sets the type of fitting this **ccLineFitParams** is configured to perform.

  Parameters

  fitMode — The type of fitting to perform. *fitMode* must be one of the following values:

  ccLineFitParams::eLeastSquares
  ccLineFitParams::eMinMaxDistance

numIgnore

```
c_UInt32 numIgnore() const;
```

```
void numIgnore(c_UInt32 numIgnore);
```

- ```
  c_UInt32 numIgnore() const;
  ```

  Returns the number of outlying points ignored by this **ccLineFitParams**.

- ```
  void numIgnore(c_UInt32 numIgnore);
  ```

  Sets the number of outlying points ignored by this **ccLineFitParams**.

Parameters

numIgnore The number of points to ignore.

---

threshold

```
double threshold() const;
void threshold(double threshold);
```

- `double threshold() const;`

  Returns the current threshold, which is checked by the Line Fitting tool as it evaluates potential fit lines. If the error value calculated by the Line Fitting tool equals or exceed this value, the potential fit line is not valid.

- `void threshold(double threshold);`

  Sets the threshold. If the error value calculated by the Line Fitting tool for a potential fit line is greater than or equal to this value, the line is invalid.

  Parameters

  threshold The error threshold. *threshold* can have any positive value.

  If the fit mode is *ccLineFitParams::eLeastSquares*, the threshold is compared to the computed least squares value. If the fit mode is *ccLineFitParams::eMinMaxDistance*, the threshold is compared to the maximum distance between a point and the line.

  Throws

  ccLineFitParams::BadParams
  threshold is less than 0.

ccLineFitParams

ccLineFitResults

```
#include <ch_cvl/fit.h>

class ccLineFitResults;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that holds the results from the Line Fitting tool. See **cfLineFit()**.

Constructors/Destructors

ccLineFitResults

```
ccLineFitResults();
```

Constructs a **ccLineFitResults** with no result.
found() = false, **error()** = 0, **time()** = 0.

Operators

operator==

```
bool operator== (const ccLineFitResults& that) const;
```

Two **ccLineFitResults** objects are considered equal if and only if the values returned by **found**, **line**, and **error** are equal.

Public Member Functions

found

```
bool found() const;
```

Returns true if the RMS error of this line is less than the threshold you supplied. Returns false otherwise.

reset

```
void reset();
```

Reset this **ccLineFitResults**. Calling **found** returns false after calling this function.

ccLineFitResults

line

```
const ccFLine &line() const;
```

Returns the fitted line.

error

```
double error() const;
```

The measured error between the data and the estimated line. The default value is 0.

Notes

The way the error is computed is specified by the fit mode. For *ccLineFitDefs::eLeastSquares*, the error is the root mean squared error between the selected subset of points and the fitted line. For *ccLineFitDefs::eMinMaxDistance*, the error is the maximum distance between the selected subset of points and the fitted line.

runParams

```
const ccLineFitParams &runParams() const;
```

Returns the **ccLineFitParams** used to fit this line. If **found** returns false, then this function's return value is undefined.

outliers

```
const cmStd vector<c_UInt32> &outliers() const;
```

Returns the indices of the points that were ignored. If **found** returns false, then this function's return value is undefined.

time

```
double time() const;
```

Returns the time in milliseconds required to compute this result. If **found** returns false, then this function's return value is undefined.

ccLineScanDistortionCorrection

```
#include <ch_cvl/lnscdist.h>

class ccLineScanDistortionCorrection;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccLineScanDistortionCorrection** class contains all the methods necessary to train and run the Line Scan Distortion Correction tool.

Constructors/Destructors

ccLineScanDistortionCorrection

```
ccLineScanDistortionCorrection();

~ccLineScanDistortionCorrection();

ccLineScanDistortionCorrection(const
  ccLineScanDistortionCorrection&);
```

- `ccLineScanDistortionCorrection();`

  Constructs a default-constructed line scan distortion object.

- `~ccLineScanDistortionCorrection();`

  Destructor.

- `ccLineScanDistortionCorrection(const ccLineScanDistortionCorrection&);`

  Copy constructor.

  Parameters

  ccLineScanDistortionCorrection
  The source of the copy.

Operators

```
ccLineScanDistortionCorrection& operator= (const
 ccLineScanDistortionCorrection&);
```

Assignment operator.

Parameters

ccLineScanDistortionCorrection
The assignment source.

operator==

```
bool operator==(const ccLineScanDistortionCorrection
 &that) const;
```

Returns true if *this* object equals to *that* object. Returns false otherwise.

Parameters

that The line scan distortion object to compare with this line scan distortion object.

Notes

All members must be equal to double precision in order to be considered equal.

Public Member Functions

isTrained

```
bool isTrained() const;
```

Returns whether or not this distortion tool has been trained.

train

```
void train(const cmStd vector<double>
 &positionsOfRegularPeriodicPattern,
 const ccPelSpan &xExtents);

void train(const ccPelBuffer_const<c_UInt8> &trainImage);
```

- ```
  void train(const cmStd vector<double>
   &positionsOfRegularPeriodicPattern,
   const ccPelSpan &xExtents);
  ```

  Manually trains the Line Scan Distortion Correction tool from positions of the regular period pattern.

  Parameters

  positionsOfRegularPeriodicPattern
  The positions of the regular period pattern.
  ```

xExtents The x extents for the tool.

Notes

Retrains the tool even if it was already trained

Throws

ccLineScanDistortionCorrectionDefs::BadParams
The positions are not monotonically increasing.

ccLineScanDistortionCorrectionDefs::BadParams
Any of the positions fall outside the specified range.

- `void train(const ccPelBuffer_const<c_UInt8> &trainImage);`

Manually trains the Line Scan Distortion Correction tool from positions of the regular period pattern.

Parameters

trainImage The supplied training image.

Notes

Retrains the tool even if it was already trained.

Throws

ccPel::UnboundWindow
The image is unbound.

ccLineScanDistortionCorrectionDefs::BadImage
The tool cannot find at least four instances of the repeating pattern in the training image.

positionsOfRegularPeriodicPattern

```
cmStd vector<double> positionsOfRegularPeriodicPattern()
 const;
```

Returns the positions used to train the tool.

Throws

ccLineScanDistortionCorrectionDefs::NotTrained
This tool was not trained from a set of *positionsOfRegularPeriodicPattern*

trainImage `const ccPelBuffer_const<c_UInt8> &trainImage() const;`

Returns the positions used to train the tool.

Throws

ccLineScanDistortionCorrectionDefs::NotTrained
This tool was not trained from a set of *positionsOfRegularPeriodicPattern*

xExtents

```
const ccPelSpan &xExtents() const;
```

Returns the x extents of the trained tool.

Throws

ccLineScanDistortionCorrectionDefs::NotTrained
This tool was not trained (neither manually trained nor image-based trained).

---

run

```
void run(const ccPelBuffer_const<c_UInt8> &srcImage,
 ccPelBuffer<c_UInt8> &dstImage) const;

ccPelBuffer<c_UInt8> run(const ccPelBuffer_const<c_UInt8>
 &src) const;
```

-
```
void run(const ccPelBuffer_const<c_UInt8> &srcImage,
 ccPelBuffer<c_UInt8> &dstImage) const;
```

Undistorts the source image and stores the results in the destination image.

Parameters

srcImage The source image.

dstImage The destination image.

Notes

This function follows the same behavior patterns as CVL pelfuncs. See *EFFECTS COMMON TO ALL MULTIPLE WINDOWS FUNCTIONS* in *<ch_cvl/pelfunc.h>*

The input image's client coordinates will be copied to the output image's client coordinates.

Throws

ccLineScanDistortionCorrectionDefs::NotTrained
This tool is untrained.

ccLineScanDistortionCorrectionDefs::MismatchedRanges
The x extents of the source image do not exactly match the trained x extents.

- `ccPelBuffer<c_UInt8> run(const ccPelBuffer_const<c_UInt8> &src) const;`

  Undistorts the source image and returns the result.

  Parameters

  src The source image.

  Notes

  The output image will have the same size as the source image.

  The input image's client coordinates will be copied to the output image's client coordinates.

  Throws

  ccLineScanDistortionCorrectionDefs::NotTrained
  This tool is untrained.

  ccLineScanDistortionCorrectionDefs::MismatchedRanges
  The x extents of the source image do not exactly match the trained x extents.

ccLineScanDistortionCorrection

ccLineSeg

```
#include <ch_cvl/shapes.h>

class ccLineSeg : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a line segment of finite length passing through two points. To specify lines, see **ccLine**.

Constructors/Destructors

ccLineSeg

```
ccLineSeg();

ccLineSeg(const cc2Vect& p1, const cc2Vect& p2);
```

- `ccLineSeg();`

  Default constructor. Creates a line segment with start and end points both equal to (0,0).

- `ccLineSeg(const cc2Vect& p1, const cc2Vect& p2);`

  Creates a line segment with the specified start and end points.

  Parameters

p1	The start point of the line segment.
p2	The end point of the line segment.

Operators

operator==

```
bool operator==(const ccLineSeg& other) const;
```

Returns true if this line segment has the same start and end points as another line segment.

Parameters

other	The other line segment.

operator!=

```
bool operator!=(const ccLineSeg& other) const;
```

Returns true if this line segment is not equal to another line segment.

Parameters

other The other line segment.

Public Member Functions

p1

```
const ccPoint& p1() const;
```

```
void p1(const cc2Vect& p);
```

- ```
  const ccPoint& p1() const;
  ```

  Gets the start point of the line segment.

- ```
  void p1(const cc2Vect& p);
  ```

  Sets the start point of the line segment.

  Parameters

  p The start point.

p2

```
const ccPoint& p2() const;
```

```
void p2(const cc2Vect& p);
```

- ```
  const ccPoint& p2() const;
  ```

  Gets the end point of the line segment.

- ```
  void p2(const cc2Vect& p);
  ```

  Sets the end point of the line segment.

  Parameters

  p The end point.

map

```
ccLineSeg map(const cc2Xform& c) const;
```

Returns a line segment that is the result of mapping this line segment with the transformation object *c*.

Parameters

c The transformation object.

line

```
ccLine line() const;
```

Converts the line segment into a line.

Throws

ccShapesError::DegenerateShape
The line segment is degenerate.

degen

```
bool degen() const;
```

Returns true if this line segment is degenerate (start point and end point are equal).

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this line segment.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For line segments, this function always returns true. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For line segments, this function always returns false. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For line segments, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For line segments, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

Thus function returns true for most line segments. It returns false for line segments of zero length. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For line segments, this function always returns true. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For line segments, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this line segment. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on this line segment to the given point.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

perimeter

```
virtual double perimeter() const;
```

Returns the length of this line segment.

See **ccShape::perimeter()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this line segment to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this line segment.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

startPoint

```
virtual cc2Vect startPoint() const;
```

Returns the starting point of this line segment. See **ccShape::startPoint()** for more information.

endPoint

```
virtual cc2Vect endPoint() const;
```

Returns the ending point of this line segment. See **ccShape::endPoint()** for more information.

startAngle

```
virtual ccRadian startAngle() const;
```

Returns the starting tangent direction of this line segment.

Throws

ccShapesError::NoTangent
hasTangent() is false for this line segment.

See **ccShape::startAngle()** for more information.

endAngle

```
virtual ccRadian endAngle() const;
```

Returns the ending tangent direction of this line segment.

Throws

ccShapesError::NoTangent
hasTangent() is false for this line segment.

See **ccShape::endAngle()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns 0.0 for a line segment.

Throws

ccShapesError::NoTangent
hasTangent() is false for this line segment.

See **ccShape::tangentRotation()** for more information.

windingAngle `virtual ccRadian windingAngle(const cc2Vect &p) const;`

Returns the signed angle determined by the rays from the given point through the start and end points of this line segment. This is sometimes called a subtended angle. The result always has a magnitude less than or equal to π radians.

Parameters

p	The point.

See **ccShape::windingAngle()** for more information.

reverse `virtual ccShapePtrh reverse() const;`

Returns the reversed version of this line segment. See **ccShape::reverse()** for more information.

sample
```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly the tangent, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores line segments for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape `virtual ccShapePtrh mapShape(const cc2Xform& X) const;`

Returns this line segment mapped by *X*.

Parameters

X	The transformation object.

See **ccShape::mapShape()** for more information.

decompose `virtual ccShapePtrh decompose() const;`

Returns a clone of this line segment. As a line segment is already a decomposed shape, this method is equivalent to **clone()** for line segments. See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the line segment describing the portion of this line segment over the given perimeter range. The length of the final returned line segment is equal to the absolute value of the distance component of *range*.

Parameters

info	Shape information for this line segment.
range	The perimeter range.

See **ccShape::subShape()** for more information.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

ccLiveDisplayProps

```
#include <ch_cvl/liveprop.h>

class ccLiveDisplayProps;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class allows you to control various apects of the display of live images. To influence live display, you pass a pointer to an instance of the **ccLiveDisplayProps** class as an argument to **ccDisplay::startLiveDisplay()**.

Once live display has started, you must stop it by calling **ccDisplay::stopLiveDisplay()** before you can change live display properties. You change live display properties using setters of **ccLiveDisplayProps**. The new properties take effect the next time you call **ccDisplay::startLiveDisplay()**.

Note Some member functions of the **ccLiveDisplayProps** class have no effect on certain frame grabbers or platforms. Such cases are noted where applicable.

Constructors/Destructors

ccLiveDisplayProps

```
ccLiveDisplayProps ();
```

Default constructor. Constructs a **ccLiveDisplayProps** object with the following default values:

Property	Description	Default Value
frameRateInterval	The sampling time interval (in seconds) used to compute the live display frame rate.	0
displayOutput	True causes all acquired images to be displayed. False causes all acquired images to be discarded and not displayed.	True

Property	Description	Default Value
restartDelay	The amount of delay (in seconds) inserted between the start of an acquisition and the call to complete the acquisition.	0.0 (no delay)
makeLocal	Make the pel buffer returned from a completed acquisition local as opposed to remote. This property is currently supported only on the MVS-8120 frame grabber. Using remote pel buffers can dramatically improve the performance of live display on the MVS-8120 (see also the **makeLocal()** method). This property is supported only when the magnification of the display is set to 1.0.	False
threadPriority	The priority of the live display thread. Takes effect on the first call to **startLiveDisplay()**. Subsequent calls have no effect until live display is stopped.	

Operators

operator==()

```
bool operator==(const ccLiveDisplayProps& p) const;
```

Returns true if this **ccLiveDisplayProps** object is equal to the supplied one, otherwise false.

Parameters

p The other **ccLiveDisplayProps** object.

operator!=

```
bool operator!=(const ccLiveDisplayProps& p) const;
```

Returns true if this **ccLiveDisplayProps** object is not equal to the supplied one, otherwise false.

Parameters

p The other **ccLiveDisplayProps** object.

Public Member Functions

clientTransform

```
const cc2Xform& clientTransform () const;
```

```
void clientTransform (const cc2Xform& xform);
```

- ```
  const cc2Xform& clientTransform () const;
  ```

  Returns the transform used to convert image coordinates to client coordinates.

- ```
  void clientTransform (const cc2Xform& xform);
  ```

  Sets the transform applied to each pel buffer acquired for live display. Internally calls the pel buffer's **clientFromImageXformBase()** method to set the transform.

  Parameters

  xform The transform used to convert image coordinates to client coordinates. Must not be singular.

  Notes

  Once this method has been called, the specified transform is applied to each acquired pel buffer while live display is running, overriding the pel buffer's own transform.

  Throws

  ccMathError::Singular

  xform is singular.

frameRateInterval

```
double frameRateInterval () const ;
```

```
void frameRateInterval (double time) ;
```

- ```
  double frameRateInterval () const ;
  ```

  Returns the frame rate interval.
  ```

- `void frameRateInterval (double time) ;`

  Sets the sampling time interval used to compute the live display frame rate. The default is zero. To retrieve the live display frame rate, use **ccDisplay::liveFrameRate()**.

  Parameters

  time The time in seconds. Must be greater than or equal to zero.

  Notes

  By default, **ccDisplay::liveFrameRate()** is calculated by dividing the number of frames that have been displayed by the time elapsed since **ccDisplay::startLiveDisplay()** was called. This is achieved by setting the frame rate sampling interval to zero (this is also the default).

  The live display frame rate calculation can be improved by setting the frame rate sampling interval higher than zero. This causes the calculation to be based on the most recent images within that sampling interval. The reference time of the sample is reset each time **ccDisplay::liveFrameRate()** is called.

  The live frame rate calculation is based on an exponential moving average over the sampling interval. The benefit of setting a sampling interval is that this allows the frame rate calculation to recover more quickly and to be more accurate when other external applications, or a screen saver, negatively affects the display update rate of the hardware.

  For example, if you set **frameRateInterval()** to 1.0, then the live display frame rate is based on the number of frames acquired and displayed over the last second.

useSoftwareLiveDisplay

```
bool useSoftwareLiveDisplay () const ;

void useSoftwareLiveDisplay (bool on) ;
```

- `bool useSoftwareLiveDisplay () const ;`

  Returns the state of the *useSoftwareLiveDisplay* flag. This flag is false for all frame grabbers.

- `void useSoftwareLiveDisplay (bool on) ;`

  If true, disables the hardware implementation of live display.

  Parameters

  on True enables software live display and disables hardware live display.

Notes

This method is supported only on the MVS-8200 with CVM3, the only platform to support hardware live display.

displayOutput

```
bool displayOutput() const;
void displayOutput(bool on);
```

- `bool displayOutput() const;`

  Gets the *displayOutput* flag. This flag controls whether all acquired images are displayed or not displayed during live display.

- `void displayOutput(bool on);`

  Sets the *displayOutput* flag.

  Parameters

on	If true, all acquired images are displayed. If false, none of the acquired images are displayed. However, acquisition still occurs.

restartDelay

```
double restartDelay() const ;
void restartDelay(double seconds) ;
```

- `double restartDelay() const ;`

  Returns the amount of delay that is inserted between the end of one acquisition and the start of the next.

  Notes

  The default value of 0.0 means that no delay is inserted, allowing live display to run at the maximum frame rate possible.

- `void restartDelay(double seconds) ;`

  Sets the amount of delay that is inserted between the end of one acquisition and the start of the next.

  Parameters

seconds	The delay in seconds. Must be greater than or equal to 0.0.

Notes

You can use the restart delay to control the acquisition/display frame rate of the internal live display thread. The delay is implemented as a non-blocking sleep function call that does not block other threads in the system.

Use caution when using this function, as increasing the delay also reduces the frame rate.

---

makeLocal

```
bool makeLocal() const ;

void makeLocal(bool on) ;
```

- `bool makeLocal() const ;`

Returns the *makeLocal* flag. True means that the image is stored locally. False (the default) means that the image is stored remotely. *Local storage* refers to the memory space of the processor. On a frame grabber, memory is local in the host system and remote on the frame grabber.

In the case of an MVS-8120, it is generally desirable to use local images (in PC memory) for processing and remote images (on the frame grabber) for live display. Live images can be displayed at a higher rate if they are DMAed, or sent directly from the frame grabber to the video card without having to go through PC host memory.

Notes

The *makeLocal* property is currently supported only on the MVS-8120 frame grabber.

If **makeLocal()** returns false, then any user-supplied color map is not used when displaying images.

- `void makeLocal(bool on) ;`

Sets the *makeLocal* flag.

Parameters

on	If true, the pel buffer is stored locally (in PC memory). If false, the pel buffer is stored remotely (on the frame grabber).

Notes

Internally, this method sets the *makeLocal* parameter to **fifo->complete()**. This parameter controls whether the pel buffer returned by this method is local or remote.

The *makeLocal* property is currently supported only on the MVS-8120 frame grabber. Setting this property to false greatly improves live display performance on the MVS-8120.

The *makeLocal* property is supported only when the magnification (zoom) of the display is set to 1.0. This is true when **ccDisplay::mag()** and **ccDisplay::magExact()** both return 1.0. When the magnification is other than 1.0, this parameter is ignored and the internal display system determines the best type of pel buffer, local or remote, for the application.

See the reference page for the **ccPelBuffer** class for more information on the proper use of remote or local pel buffers.

See *When Do Color Maps Apply* and *Live Display Using One FIFO on an MVS-8120* in the *Displaying Images* chapter of the *CVL User's Guide* for more information on the *makeLocal* property.

threadPriority

```
cePriority threadPriority() const;

void threadPriority(cePriority priority);
```

Note These methods are not supported on any MVS-8200 platform.

- `cePriority threadPriority() const;`

  Retrieves the priority of the live display thread.

- `void threadPriority(cePriority priority);`

  Sets the priority of the live display thread.

  Parameters

  priority The thread priority.

  Notes

  The priority of the live display thread is set on the first call to **ccDisplay::startLiveDisplay()**. Subsequent calls to this method do not change the thread priority, unless all live displays on all display objects are stopped.

  If **ccDisplay::stopLiveDisplay()** is called on all display objects, then the next call to **ccDisplay::startLiveDisplay()** sets the new thread priority.

pelbufferCallback

```
const ccCallback1Ptrh& pelbufferCallback() const;

void pelbufferCallback(const ccCallback1Ptrh& callback);
```

- `const ccCallback1Ptrh& pelbufferCallback() const;`

  Retrieves the pel buffer callback. If set, this pel buffer callback is called every time a pel buffer is acquired during live display.

  Notes

  The callback is passed a void pointer that points to the acquired pel buffer.

  See *Using a Live Display Callback* in the Displaying Images chapter of the *CVL User's Guide* for sample code demonstrating how to use a pel buffer callback with live display.

- `void pelbufferCallback(const ccCallback1Ptrh& callback);`

  Sets the pel buffer callback to be called each time an image is acquired during live display.

  Parameters

  callback The callback object.

  Notes

  The supplied callback must take a void pointer that points to the acquired pel buffer.

  The callback, consisting of an overridden **operator()**, should be as fast as possible to avoid adversely affecting the live display frame rate. Cognex does not recommend placing image processing tasks that take a significant amount of time to run inside the callback, as this processing would occur at the same priority as the live display thread.

ccLock

```
#include <ch_cvl/threads.h>

class ccLock;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A class sets a lock on a mutex, semaphore, or event. You set a lock by constructing a **ccLock** and supplying the resource to lock.

In most cases, you should declare your **ccLock** objects as automatic local variables; there is generally no reason to instantiate global or static **ccLock** objects.

Because the **ccLock** destructor is guaranteed to unlock the resource, this class is useful for ensuring that resources are unlocked even if an exception is thrown.

Constructors/Destructors

ccLock

```
ccLock(cc_Resource& m, bool locked=true);

~ccLock();
```

- `ccLock(cc_Resource& m, bool locked=true);`

Construct a **ccLock** object to access the given mutex, semaphore, or event. You can construct a lock without locking the resource by specifying false for the *locked* argument to the constructor.

Parameters

m	The resource. *m* must be derived from **cc_Resource**.
locked	If true, *m* is locked immediately. If false, *m* is not locked. If *locked* is true (the default), the current thread will block until the specified resource is available.

- `~ccLock();`

  Unlocks the resource supplied at construction. If this **ccLock** has been locked more times than it has been unlocked, the missing unlock operations are performed and the resource is unlocked.

Public Member Functions

lock `bool lock(double timeout=HUGE_VAL);`

Locks the resource supplied to this **ccLock** at construction. This function returns true if the resource becomes available, false if the timeout expires.

Parameters

timeout The number of seconds to block. If you specify *HUGE_VAL* for *timeout*, the thread will wait forever.

Throws

cc_Resource::BrokenLock
The **cc_Resource::breakLocks()** static function was invoked on this thread.

lockOrElse `void lockOrElse(double timeout);`

This function is identical to **lock()** except that it throws *cc_Resource::Timeout* if the timeout is exceeded.

Parameters

timeout The number of seconds to wait for the lock. If *timeout* is HUGE_VAL, then the lock waits forever. *timeout* must be greater than or equal to 0.

Throws

cc_Resource::BrokenLock
The **cc_Resource::breakLocks()** static function was invoked on this thread.

cc_Resource::Timeout
The timeout was exceeded.

unlock `void unlock();`

Unlocks the resource supplied to this **ccLock** at construction.

ccLSLineFitter

```
#include <ch_cvl/cfit.h>

class ccLSLineFitter;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class computes the line that produces the best least-squares fit for a set of points.

Notes

This class is deprecated and is maintained for backward compatibility only. It is replaced by the new global function **cfLineFit()**.

Constructors/Destructors

ccLSLineFitter

```
ccLSLineFitter ();

ccLSLineFitter (const cmStd vector<cc2Vect> & points);
```

- `ccLSLineFitter ();`

  Constructs a **ccLSLineFitter** that does not contain any points.

- `ccLSLineFitter (const cmStd vector<cc2Vect> & points);`

  Constructs a **ccLSLineFitter** and initializes it with the supplied points.

  Parameters

  points The points to which to fit a line.

Operators

operator*

```
friend ccLSLineFitter operator* (
  const cc2Xform & pointsXform, const ccLSLineFitter & S);
```

If you multiply a **ccLSLineFitter** by a **cc2Xform**, all of the points in the resulting **ccLSLineFitter** will have been transformed by the supplied **cc2Xform**, and the line produced by this **ccLSLineFitter** is similarly updated.

Parameters

pointsXform The **cc2Xform** by which to multiply this **ccLSLineFitter**

S The **ccLSLineFitter**.

operator+=

```
ccLSLineFitter& operator+=(const ccLSLineFitter& rhs);
```

Adds the points in *rhs* to the current object. This operation is equivalent to, but much more efficient than, calling **update()** repeatedly for each added point.

Parameters

rhs A **ccLSLineFitter** object containing the point set you wish to add to this object.

operator+

```
ccLSLineFitter operator+(const ccLSLineFitter& rhs) const;
```

Returns a **ccLSLineFitter** whose point set includes the *rhs* point set and the point set in this object.

Parameters

rhs The **ccLSLineFitter** object containing the point set you wish to add.

Public Member Functions

reset

```
void reset ();
```

Removes all the points from this **ccLSLineFitter**.

update

```
void update (const cc2Vect & point);
```

Updates this **ccLSLineFitter** to account for a new point. The next call to **fit()** returns a line that reflects the added point.

Parameters

point The point to add.

numPoints

```
int numPoints () const;
```

Returns the number of points accounted for by this **ccLSLineFitter**.

fit

```
ccFLine fit () const;
bool fit(ccFLine& line) const;
```

- `ccFLine fit () const;`

  Returns the computed line that is the best least squares fit of the point set contained in this object.

  The fitter requires at least 2 distinct points

  Throws

  ccLSLineFitter::UnstableErr
  There are fewer than 2 points in this **ccLSLineFitter** or the solution is singular.

- `bool fit(ccFLine& line) const;`

  This is equivalent to the function above except it returns the computed line in *line*, and never throws.

  The function returns false if the point set count is < 2, or if the fit is singular. Otherwise, returns true.

  Parameters

  line The object where the computed line is placed.

error

```
double error (const ccFLine & line) const;
```

Returns the summed absolute error between the points in this **ccLSLineFitter** and the supplied line.

Parameters

line The line to use for computing the error.

fitAndError

```
bool fitAndError(ccFLine* pLine, double* pError) const;
```

Computes the best fit line and the associated error. The computed line is placed in *pLine*, and the computed error is placed in *pError*.

Returns false if the stored point set count is < 2, or if the fit is singular. Otherwise, returns true.

pLine and/or *pError* may be 0 if not needed. (**Note**: with *pLine* = 0, this function provides a faster way to compute the error).

Parameters

pLine	Where the tool places the computed line.
pError	Where the tool places the error. (see **error()**).

ccLSPointToLineFitter

```
#include <ch_cvl/cfit.h>

class ccLSPointToLineFitter;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class computes the transformation that provides the best fit between one or more points and one or more corresponding lines, as determined by the least-squares error.

Constructors/Destructors

ccLSPointToLineFitter

```
ccLSPointToLineFitter ();

ccLSPointToLineFitter (
  const cmStd vector<cc2Vect> & points,
  const cmStd vector<ccFLine> & lines);

ccLSPointToLineFitter (const ccRect & rect,
  const cmStd vector<cc2Vect> &topPoints,
  const cmStd vector<cc2Vect> &bottomPoints,
  const cmStd vector<cc2Vect> &leftPoints,
  const cmStd vector<cc2Vect> &rightPoints,
  bool isLeftHanded = false);
```

- `ccLSPointToLineFitter ();`

  Constructs a **ccLSPointToLineFitter** which contains no points.

- ```
  ccLSPointToLineFitter (
    const cmStd vector<cc2Vect> & points,
    const cmStd vector<ccFLine> & lines);
  ```

  Constructs a **ccLSPointToLineFitter** with the supplied sets of points and lines. Each point in *points* is assumed to correspond to the corresponding line in *lines*.

  Each of the lines in *lines* must be parallel to the x-axis or the y-axis.
  ```

Parameters

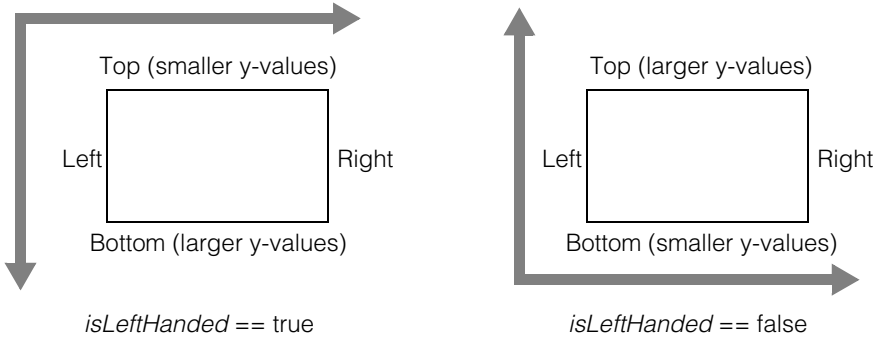
points	The points.
lines	The lines

Throws

ccLSPointToLineFitter::BadArgErr
The size of *lines* does not equal the size of *points,* or one or more of the lines in *lines* is parallel to neither the x-axis nor the y-axis.

-
```
ccLSPointToLineFitter (const ccRect & rect,
  const cmStd vector<cc2Vect> &topPoints,
  const cmStd vector<cc2Vect> &bottomPoints,
  const cmStd vector<cc2Vect> &leftPoints,
  const cmStd vector<cc2Vect> &rightPoints,
  bool isLeftHanded = false);
```

Constructs a **ccLSPointToLineFitter** with the supplied sets of points and lines. Each of the four sets of points is assumed to correspond to a line coincident with one of the sides of the supplied rectangle. The handedness of the points' coordinate system is determined by the *isLeftHanded* argument, as shown below:



Parameters

rect	The rectangle to fit to the supplied points.
topPoints	The points to fit to the top of *rect*.
bottomPoints	The points to fit to the bottom of *rect*.
leftPoints	The points to fit to the left side of *rect*.
rightPoints	The points to fit to the right side of *rect*.

isLeftHanded If true, the top of *rect* is in the negative y-direction from the center and the bottom of *rect* is in the positive y-direction. If false, the top of *rect* is in the positive y-direction from the center and the bottom of *rect* is in the negative y-direction.

Operators

operator*

```
friend ccLSPointToLineFitter operator* (
  const cc2Xform & pointsXform,
  const ccLSPointToLineFitter & S);
```

If you multiply a **ccLSPointToLineFitter** by a **cc2Xform**, all of the points in the resulting **ccLSPointToLineFitter** will have been transformed by the supplied **cc2Xform**. Using this operator is much faster than transforming the points individually.

Parameters

pointsXform The **cc2Xform** by which to multiply this **ccLSPointToLineFitter**

S The **ccLSPointToLineFitter**.

Public Member Functions

reset

```
void reset ();
```

Removes all of the points and lines from this **ccLSPointToLineFitter**.

---

update

```
void update (const cmStd vector<cc2Vect> & points,
  const ccFLine & line);

void update (const cc2Vect & point, ccFLine & line);

void update (const ccRect & rect,
  const cmStd vector<cc2Vect> & topPoints,
  const cmStd vector<cc2Vect> & bottomPoints,
  const cmStd vector<cc2Vect> & leftPoints,
  const cmStd vector<cc2Vect> & rightPoints,
  bool isLeftHanded = false);
```

-

```
void update (const cmStd vector<cc2Vect> & points,
  const ccFLine & line);
```

Updates this **ccLSPointToLineFitter** to include an additional line and corresponding set of points. The next call to **fit()** returns a transformation that reflects the added points and line.

Parameters

points	The points to add.
line	The line to add.

- `void update (const cc2Vect & point, ccFLine & line);`

  Updates this **ccLSPointToLineFitter** to include an additional point-line pair. The next call to **fit()** returns a transformation that reflects the added point and line.

  Parameters

point	The point to add.
line	The line to add.

- ```
  void update (const ccRect & rect,
    const cmStd vector<cc2Vect> & topPoints,
    const cmStd vector<cc2Vect> & bottomPoints,
    const cmStd vector<cc2Vect> & leftPoints,
    const cmStd vector<cc2Vect> & rightPoints,
    bool isLeftHanded = false);
  ```

  Updates this **ccLSPointToLineFitter** to include an additional four lines (specified as being coincident with the sides of a **ccRect**) and four additional sets of points. The next call to **fit()** returns a transformation that reflects the added lines and points.
