  Each of the four sets of points is assumed to correspond to a line coincident with one of the sides of the supplied rectangle. The handedness of the points' coordinate system is determined by the *isLeftHanded* argument, as shown below:

  Parameters

rect	The rectangle to fit to the supplied points.
  ```

topPoints	The points to fit to the top of *rect*.
bottomPoints	The points to fit to the bottom of *rect*.
leftPoints	The points to fit to the left side of *rect*.
rightPoints	The points to fit to the right side of *rect*.
isLeftHanded	If true, the top of *rect* is in the negative y-direction from the center and the bottom of *rect* is in the positive y-direction. If false, the top of *rect* is in the positive y-direction from the center and the bottom of *rect* is in the negative y-direction.

numPoints `int numPoints () const;`

Returns the number of point-line correspondences in this **ccLSPointToLineFitter**.

numXPoints `int numXPoints () const;`

Returns the number of point-line correspondences in this **ccLSPointToLineFitter** where the line is parallel to the x-axis.

numYPoints `int numYPoints () const;`

Returns the number of point-line correspondences in this **ccLSPointToLineFitter** where the line is parallel to the y-axis.

fit `cc2Xform fit (int dof);`

Returns the linear transformation that best fits the points to the corresponding lines, given the specified degrees of freedom.

Parameters

dof	The degrees of freedom to enable. The value of *dof* determines which degrees of freedom are enabled as follows: if *dof* is 3, x- and y-translation and rotation are enabled; if *dof* is 4, x- and y-translation, rotation, and uniform scale are enabled; if *dof* is 6, x- and y-translation, rotation, uniform scale, aspect ratio, and skew are enabled.

Notes

The transformation is computed taking into account all point-to-line correspondences that have been added to this **ccLSPointToLineFitter**.

You must have specified a minimum number of point-line correspondences for this **ccLSPointToLineFitter** before calling **fit()**. The minimum number of points depends on the value you specify for *dof*.

- If you specify 3 for *dof*, you must supply at least three point-line correspondences, at least one of them must have a line parallel to the x-axis, and at least one of them must have a line parallel to the y-axis.
- If you specify 4 for *dof*, you must supply at least two point-line correspondences that have a line parallel to the x-axis and at least two point-line correspondences that have a line parallel to the y-axis.
- If you specify 6 for *dof*, you must supply at least three point-line correspondences that have a line parallel to the x-axis and at least three point-line correspondences that have a line parallel to the y-axis.

Throws

ccLSPointToLineFitter::UnstableErr
The solution is either unstable or singular, or an insufficient number of point-line correspondences were supplied.

ccLSPointToLineFitter::BadArgErr
dof is not 3, 4, or 6.

error

```
double error (const cc2Xform & linesTpoints) const;
```

Returns the summed squared error of all the point-line correspondences defined for this **ccLSPointToLineFitter** after applying the supplied transformation to the first set of points.

Parameters

linesTpoints The transformation for which to compute the error.

errorX

```
double errorX (const cc2Xform & linesTpoints) const;
```

Returns the summed squared error of all the point-line correspondences with a line parallel to the x-axis defined for this **ccLSPointToLineFitter** after applying the supplied transformation to the first set of points.

Parameters

linesTpoints The transformation for which to compute the error.

errorY

```
double errorY (const cc2Xform & linesTpoints) const;
```

Returns the summed squared error of all the point-line correspondences with a line parallel to the y-axis defined for this **ccLSPointToLineFitter** after applying the supplied transformation to the first set of points.

Parameters

linesTpoints The transformation for which to compute the error.

fitRect

```
static double fitRect (int dof, const ccRect & rect,
  const cmStd vector<cc2Vect> & topPoints,
  const cmStd vector<cc2Vect> & bottomPoints,
  const cmStd vector<cc2Vect> & leftPoints,
  const cmStd vector<cc2Vect> & rightPoints,
  cc2Xform & pointsTrect, bool isLeftHanded = false);
```

Computes the transformation that best fits the supplied rectangle to the four supplied sets of points, given the supplied degrees of freedom.

Parameters

dof The degrees of freedom to enable. The value of *dof* determines which degrees of freedom are enabled as follows:

If *dof* is 3, x- and y-translation and rotation are enabled.

If *dof* is 4, x- and y-translation, rotation, and uniform scale are enabled.

If *dof* is 6, x- and y-translation, rotation, uniform scale, aspect ratio, and skew are enabled.

rect The rectangle to fit to the supplied points.

topPoints The points to fit to the top of *rect*.

bottomPoints The points to fit to the bottom of *rect*.

leftPoints The points to fit to the left side of *rect*.

rightPoints The points to fit to the right side of *rect*.

pointsTrect A reference to a **cc2Xform** in which the computed transformation is placed.

isLeftHanded If true, the top of *rect* is in the negative y-direction from the center and the bottom of *rect* is in the positive y-direction. If false, the top of *rect* is in the positive y-direction from the center and the bottom of *rect* is in the negative y-direction.

Notes

This is a static member function. Calling it on an instantiated **ccLSPointToLineFitter** has no effect on that **ccLSPointToLineFitter**.

ccLSPointToPointFitter

```
#include <ch_cvl/cfit.h>

class ccLSPointToPointFitter;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class computes the transformation that provides the best fit between two sets of points, as determined by the least-squares error.

Constructors/Destructors

ccLSPointToPointFitter

```
ccLSPointToPointFitter ();

ccLSPointToPointFitter (
  const cmStd vector<cc2Vect> & set1Points,
  const cmStd vector<cc2Vect> & set2Points);
```

- ```
  ccLSPointToPointFitter ();
  ```

  Constructs a **ccLSPointToPointFitter** which contains no points.

- ```
  ccLSPointToPointFitter (
    const cmStd vector<cc2Vect> & set1Points,
    const cmStd vector<cc2Vect> & set2Points);
  ```

  Constructs a **ccLSPointToPointFitter** with the supplied sets of points. Each point in *set1Points* is assumed to correspond to the corresponding point in *set2points*.

  Parameters

  set1Points The first set of points.

  set2Points The second set of points.

  Throws

  ccLSPointToPointFitter::BadArgErr
  The size of *set1Points* is not the same as the size of *set2Points*.

Operators

operator*

```
friend ccLSPointToPointFitter operator* (
  const cc2Xform & set1Xform,
  const ccLSPointToPointFitter & S);
```

If you multiply a **ccLSPointToPointFitter** by a **cc2Xform**, all of the points in the first set of points in the resulting **ccLSPointToPointFitter** will have been transformed by the supplied **cc2Xform**. Using this operator is much faster than transforming the points individually.

Parameters

set1Xform	The **cc2Xform** by which to multiply this **ccLSPointToPointFitter**
S	The **ccLSPointToPointFitter**.

Public Member Functions

reset

```
void reset ();
```

Removes all of the points from this **ccLSPointToPointFitter**.

update

```
void update (const cc2Vect & set1Point,
  const cc2Vect & set2Point);
```

Updates this **ccLSPointToPointFitter** to include an additional pair of points. The next call to **fit()** returns a transformation that reflects the added points.

Parameters

set1Point	The point to add to the first set of points.
set2Point	The point to add to the second set of points.

numPoints

```
int numPoints () const;
```

Returns the number of pairs of points in this **ccLSPointToPointFitter**.

fit

```
cc2Xform fit (int dof);
```

Returns the linear transformation that best fits the points in the second set of points to the points in the first set of points, given the specified degrees of freedom.

Parameters

dof	The degrees of freedom to enable. The value of *dof* determines which degrees of freedom are enabled as follows:

If *dof* is 3, x- and y-translation and rotation are enabled.

If *dof* is 4, x- and y-translation, rotation, and uniform scale are enabled.

If *dof* is 5, x- and y-translation, rotation, uniform scale, and aspect ratio are enabled.

If *dof* is 6, x- and y-translation, rotation, uniform scale, aspect ratio, and skew are enabled.

Notes

The transformation is computed taking into account all point-to-point correspondences that have been added to this **ccLSPointToPointFitter**.

You must have specified a minimum number of points for this **ccLSPointToPointFitter** before calling **fit()**. The minimum number of points depends on the value you specify for *dof*.

- If you specify 3 or 4 for *dof*, you must supply at least 2 points.
- If you specify 5 or 6 for *dof*, you must supply at least 3 points.

Throws

ccLSPointToPointFitter::UnstableErr
The solution is either unstable or singular.

ccLSPointToPointFitter::BadArgErr
dof is not 3, 4, 5, or 6.

error

```
double error (const cc2Xform & set1Tset2) const;
```

Returns the summed squared error between all the point-point correspondences defined for this **ccLSPointToPointFitter** after applying the supplied transformation to the first set of points. Using this function is much faster than applying the transformation to each point in the set, then computing the error.

Parameters

set1Tset2 The transformation for which to compute the error.

ccLSPointToPointFitter

ccMemoryArchive

```
#include <ch_cvl/archive.h>

class ccMemoryArchive : public ccArchive;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	Not applicable

The **ccMemoryArchive** class is a concrete class derived from **ccArchive** that implements a memory archive.

Constructors/Destructors

ccMemoryArchive

```
ccMemoryArchive(
  ccArchive::Ordering ord = ccArchive::eLittleEndian,
  bool seekable=true);

ccMemoryArchive(const char* buf, long length,
  bool seekable=true, bool own=false);

~ccMemoryArchive();
```

- ```
  ccMemoryArchive(
    ccArchive::Ordering ord =ccArchive::eLittleEndian,
    bool seekable=true);
  ```

  Constructs a **ccMemoryArchive** in storing mode. The archive will allocate memory as objects are stored to it.

  Parameters

ord	The endianness of this archive. *ord* must be one of the following values: *ccArchive::eBigEndian* *ccArchive::eLittleEndian*
seekable	If true, the seek position within this archive can be specified.
  ```

- `ccMemoryArchive(const char* buf, c_Int32 length, bool seekable=true, bool own=false);`

Constructs a **ccMemoryArchive** in loading mode using the storage that you supply. If *own* is nonzero the storage buffer will be deleted by this **ccMemoryArchive** when the **ccMemoryArchive** is destroyed.

Parameters

buf	The memory which contains the archive. *buf* must not be null.
length	The number of bytes in the archive. *length* must be greater than or equal to 0.
seekable	If true, the seek position within this archive can be specified.
own	Specifies whether the **ccMemoryArchive** owns the storage pointed to by *buf*. If *own* is nonzero, the storage buffer will be deleted by this **ccMemoryArchive** when the **ccMemoryArchive** is destroyed.

Throws

ccArchive::UnknownArchiveVersion
The loading archive was stored with a later version.

Notes

You must not modify the memory pointed to by *buf* nor delete *buf* while this archive exists.

Public Member Functions

storage

```
const char* storage() const;
```

Returns a pointer to this **ccMemoryArchive**'s current storage. You can call the **ccArchive::tell()** function to find out this **ccMemoryArchive**'s current position; for a storing archive, this is the number of bytes that have been stored into the archive.

Notes

The pointer returned by this function is only valid until the next storing operation on this **ccMemoryArchive**.

You should not delete the storage pointed to by the pointer returned by this function.

ccMouseBite

```
#include <ch_cvl/pmifproc.h>

class ccMouseBite : public cc_FeatureRange;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that describes a single mousebite. A mousebite is a set of boundary points within a matched feature that have the following attributes: the boundary points are contiguous within the feature, and the distance between the boundary points in the run-time image and the corresponding points in the trained image exceeds the standard deviation of all boundary points from their ideal locations in the feature by a specified factor.

You do not instantiate **ccMouseBite**s yourself. You can obtain a vector of **ccMouseBite**s by calling **cfDetectMouseBites()**.

To obtain information about the location of a mousebite, use the functions in the **cc_FeatureRange** class, from which **ccMouseBite** is derived.

Constructors/Destructors

ccMouseBite

```
ccMouseBite();
```

Constructs a **ccMouseBite**.

ccMouseBite

ccMouseEvent

```
#include <ch_cvl/uievent.h>

class ccMouseEvent;
```

Class Properties

Copyable	No
Derivable	Not intended
Archiveable	Complex

This class encapsulates information associated with a mouse event. Mouse events include mouse button clicking and mouse movement.

See the *Displaying Graphics* chapter of the *CVL User's Guide* for a discussion of mouse events associated with using **ccDisplayConsole** windows.

Constructors/Destructors

ccMouseEvent

```
ccMouseEvent();
```

Enumerations

Event

This enumeration specifies the possible reasons for a mouse event.

Value	Meaning
eNone	No key.
eMovement	The mouse moved.
eDownClick	The left mouse button was pressed down.
eDoubleClick	The left mouse button was double clicked.
eUpClick	The left mouse button was released.
eDwell	Currently dwelling.

Button This enumeration specifies the mouse button associated with this mouse event.

Value	Meaning
eNoButton = 0	There is no button associated with this event.
eLeft = 1	The left mouse button.
eMid = 2	The middle mouse button.
eRight = 4	The right mouse button.

Key This enumeration specifies a keyboard key associated with this mouse event.

Value	Meaning
eNoKey = 0	There is no key associated with this mouse event.
eAlt = 1	The **Alt** key.
eControl = 2	The **Ctrl** key.
eShift = 4	The **Shift** key.

Public Member Functions

event

```
void event(Event e);
Event event() const;
```

Mouse events must be one of the **Event** enums.

- `void event(Event e);`

  Sets a new mouse event type.

  Parameters

  e The new mouse event.

- `Event event() const;`

  Returns the mouse event.

whichButton

```
void whichButton(Button b);
Button whichButton() const;
```

Specifies a mouse button associated with this mouse event. Must be one of the **Button** enums.

- `void whichButton(Button b);`

  Sets a button type.

  Parameters

  b The new button type.

- `Button whichButton() const;`

  Returns the button type.

buttons

```
void buttons(c_UInt32 b);
c_UInt32 buttons() const;
```

Specifies the button(s) associated with this mouse event. The mouse buttons are represented by individual bits so that more than one button can be specified in the same event.

Left mouse button = 1
Middle mouse button = 2
Right mouse button = 4

- `void buttons(c_UInt32 b)`

  Sets a new buttons specifier.

  Parameters

  b The new buttons specifier.

- `c_UInt32 buttons() const;`

  Returns the button specifier.

keys

```
void keys(c_UInt32 k);
c_UInt32 keys() const;
```

Specifies the keyboard key(s) associated with this mouse event. The keyboard keys are represented by individual bits so that more than one key can be specified in the same event.

Alt key = 1
Ctrl key = 2
Shift key = 4

- `void keys(c_UInt32 k);`

  Sets a new key word.

  Parameters

k	The new key word.

- `c_UInt32 keys() const;`

  Returns the key word.

position

```
void position(const ccIPair& p);
const ccIPair& position() const;
```

Specifies the mouse position at the time of the event.

- `void position(const ccIPair& p);`

  Sets a new mouse position.

  Parameters

p	The new mouse position.

- `const ccIPair& position() const;`

  Returns the current mouse position setting.

ccMovePartCallbackProp

```
#include <ch_cvl/prop.h>

class ccMovePartCallbackProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

As of CVL 6.1, this class is one of two ways to register a callback class for the move-part state:

Method	Features	See
ccAcqFifo:: movePartInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	*movePartInfoCallback* on page 230
ccMovePartCallbackProp	Calls your callback function.	this section

If you are writing a new CVL application, consider using **ccAcqFifo::movePartInfoCallback()** to register your move-part callback function.

This class describes the move-part callback property of an acquisition FIFO queue. An acquisition enters the movable state (**ccAcqFifo::isMovable()** returns true) when the camera's field of view can be changed without affecting the acquired image. At this point, the acquisition software invokes the move-part callback function that you register with this property.

The callback function you write should set flags or semaphores in your application that allow your program to proceed to another state the next time it executes. Your callback function is executed internally by the acquisition software, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

In general, an acquisition enters the movable state during the acquisition's next-to-last vertical blank interval. With an RS-170 camera, for example, an acquisition would enter the movable state 17 ms (one field time) before it enters the complete state.

Not all frame grabbers can detect the next-to-last vertical blank interval. When using one of these frame grabbers, the acquisition enters the movable and complete states at the same time. In such cases, the move-part callback is always invoked first, followed immediately by the completion callback.

On the MVS-8100M, MVS-8100C, and MVS-8100C/CPCI (but not the MVS-8100M+ when using CCF-based video formats), you can select between default and optimum timing of the move-part callback function's execution. See **movePartTimingChoice** on page 210.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

Constructors/Destructors

ccMovePartCallbackProp

```
ccMovePartCallbackProp();

explicit ccMovePartCallbackProp(ccCallbackPtrh& callback);
```

- `ccMovePartCallbackProp();`

  Creates a new move-part callback property not associated with any FIFO. The default callback function is an unbound handle, meaning no callback function is invoked.

- `explicit ccMovePartCallbackProp(ccCallbackPtrh& callback);`

  Creates a new move-part callback property not associated with any FIFO, registering the function pointed to by *callback* as the move-part callback function.

  Parameters

  callback — Effectively, the callback function to be invoked when the acquisition process enters the move-part state. This is generally when the image has been captured by the camera, but before the image has finished being transferred into local memory. An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

Public Member Functions

movePartCallback

```
void movePartCallback(const ccCallbackPtrh& callback);
const ccCallbackPtrh& movePartCallback() const;
```

- `void movePartCallback(ccCallbackPtrh& callback);`

  callback points to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

  Parameters

callback	Effectively, the callback function to be invoked when the acquisition process enters the move-part state. This is generally when the image has been captured by the camera, but before the image has finished being transferred into local memory. An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

- `const ccCallbackPtrh& movePartCallback() const;`

  Returns the callback function to be invoked when the acquisition enters the move-part state.

ccMovePartCallbackProp

ccMutex

```
#include <ch_cvl/threads.h>

class ccMutex: public cc_Resource;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A resource that can only be locked by a single thread at a time. Any number of other threads can attempt to lock a mutex, but only one thread can have it locked at a time. A single thread can lock a mutex more than once.

Constructors/Destructors

ccMutex

```
ccMutex(bool locked = false);
```

Construct a new **ccMutex**. You can specify whether this **ccMutex** is locked or unlocked at construction.

Parameters

locked — If true, this **ccMutex** is locked. If false, it is unlocked.

Public Member Functions

lock

```
bool lock(double timeout=HUGE_VAL);
```

Locks this **ccMutex**. Any other thread that attempts to lock this **ccMutex** will block until this **ccMutex** is released. This function returns true if it was able to lock this **ccMutex**. If this **ccMutex** is already locked and remains so for the duration of the specified timeout, this function returns false.

Parameters

timeout — The number of seconds to block. If you specify *HUGE_VAL* for *timeout*, the thread will wait forever or until the **ccMutex** becomes available.

Throws

cc_Resource::BrokenLock — The **cc_Resource::breakLocks()** static function was invoked on this thread.

unlock `void unlock();`

Unlocks this **ccMutex**.

ccOCAlphabet

```
#include <ch_cvl/oc.h>

class ccOCAlphabet : public ccPersistent, public ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class contains the set of character models from which you can construct a line of characters. It also incorporates a confusion score table, which indicates the probability that character pairs may be confused with each other during verification. An optical verification tool uses the information provided by this class to perform optical verification of the characters.

Constructors/Destructors

ccOCAlphabet

```
ccOCAlphabet();

ccOCAlphabet(
  const cmStd vector<ccOCModelPtrh_const>& characters,
  double confusionThreshold = 0.5,
  bool compile = true,
  const ccCvlString& name = cmT(""));

ccOCAlphabet(
  const cmStd vector<ccOCModelPtrh>& characters,
  double confusionThreshold = 0.5,
  bool compile = true,
  const ccCvlString& name = cmT(""));

~ccOCAlphabet();

ccOCAlphabet(const ccOCAlphabet& a);
```

- `ccOCAlphabet();`

  Constructs a nameless, compiled alphabet with no characters. The confusion threshold defaults to 0.5.

- ```
  ccOCAlphabet(
    const cmStd vector<ccOCModelPtrh_const>& characters,
    double confusionThreshold = 0.5,
    bool compile = true,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a named alphabet from the supplied character models.

  Parameters

  characters The character models from which to create the alphabet.

  confusionThreshold
  The confusion threshold for the characters in the alphabet. The confusion threshold determines whether characters are easily confused with each other during optical verification. If the confusion score for a character pairing is greater than the confusion threshold, the two characters are easily confused. The confusion threshold has a range of 0 to 1.

  compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

  name The name of the alphabet.

  Throws

  ccOCDefs::BadParams
  confusionThreshold is less than 0 or greater than 1.

  ccOCDefs::SameKey
  Two or more characters have the same key. Each key in the alphabet must be unique.

- ```
  ccOCAlphabet(
    const cmStd vector<ccOCModelPtrh>& characters,
    double confusionThreshold = 0.5,
    bool compile = true,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a named alphabet from the supplied character models.

  Parameters

  characters The character models from which to create the alphabet.

confusionThreshold
The confusion threshold for the characters in the alphabet. The confusion threshold determines whether characters are easily confused with each other during optical verification. If the confusion score for a character pairing is greater than the confusion threshold, the two characters are easily confused. The confusion threshold has a range of 0 to 1.

compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

name The name of the alphabet.

Throws

ccOCDefs::BadParams
confusionThreshold is less than 0 or greater than 1.

ccOCDefs::SameKey
Two or more characters have the same key. Each key in the alphabet must be unique.

- `~ccOCAlphabet();`

  Destroys this alphabet.

- `ccOCAlphabet(const ccOCAlphabet& a);`

  Creates a new alphabet by copying the specified alphabet.

  Parameters
  a The alphabet to copy.

Operators

operator= `ccOCAlphabet& operator=(const ccOCAlphabet& a);`

Assignment operator.

Parameters
a The source alphabet for the assignment.

operator==

```
bool operator==(const ccOCAlphabet& other) const;
```

Returns true if this alphabet is equal to the specified alphabet.

Parameters

other The alphabet with which to compare for equality.

operator!=

```
bool operator!=(const ccOCAlphabet& other) const;
```

Returns true if this alphabet is not equal to the specified alphabet.

Parameters

other The alphabet with which to compare for inequality.

Public Member Functions

name

```
const ccCvlString& name() const;

void name(const ccCvlString& n);
```

- ```
  const ccCvlString& name() const;
  ```

  Returns the name of this alphabet.

- ```
  void name(const ccCvlString& n);
  ```

  Sets the name of this alphabet.

  Parameters

  n A name string.

characters

```
const cmStd vector<ccOCModelPtrh_const>&
  characters() const;

void characters(
  const cmStd vector<ccOCModelPtrh_const>& chars,
  bool compile = true);

void characters(const cmStd vector<ccOCModelPtrh>& chars,
  bool compile = true);
```

- ```
  const cmStd vector<ccOCModelPtrh_const>&
    characters() const;
  ```

  Returns the characters in this alphabet.
  ```

- ```
  void characters(
    const cmStd vector<ccOCModelPtrh_const>& chars,
    bool compile = true);
  ```

  Sets the characters in this alphabet.

  Parameters

  chars The characters that the alphabet comprises.

  compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

  Throws

  ccOCDefs::SameKey
  Two or more characters have the same key. Each key in the alphabet must be unique.

- ```
  void characters(const cmStd vector<ccOCModelPtrh>& chars,
    bool compile = true);
  ```

  Sets the characters in this alphabet.

  Parameters

  chars The characters that the alphabet comprises.

  compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

  Throws

  ccOCDefs::SameKey
  Two or more characters have the same key. Each key in the alphabet must be unique.

confusionThreshold

```
double confusionThreshold() const;
void confusionThreshold(double t);
```

- `double confusionThreshold() const;`

  Returns the confusion threshold.

- `void confusionThreshold(double t);`

  Sets the confusion threshold for the characters in the alphabet. If the computed confusion score for a character pairing is greater than the confusion threshold, the characters are easily confused with each other during optical verification.

  Parameters

  t The confusion threshold. The valid range is between 0 and 1.

  Notes

  Changing the confusion threshold does not necessitate recompiling the confusion scores for pairings of characters in the alphabet.

  Throws

  ccOCDefs::BadParams

  confusionThreshold is less than 0 or greater than 1.

numChars

```
c_Int32 numChars() const;
```

Returns the number of character models in this alphabet.

hasCharacter

```
bool hasCharacter(c_Int32 key) const;
```

Returns true if a character with the specified key exists in this alphabet.

Parameters

key The key of the character to find.

character

```
const ccOCModelPtrh_const& character(c_Int32 key) const;
```

Returns the character with the specified key.

Parameters

key The key of the character to find.

Throws

ccOCDefs::BadKey
There is no character with the supplied key.

add

```
void add(const ccOCModelPtrh_const& c,
 bool compile = true);

void add(const cmStd vector<ccOCModelPtrh_const>& chars,
 bool compile = true);

void add(const cmStd vector<ccOCModelPtrh>& chars,
 bool compile = true);
```

- ```
  void add(const ccOCModelPtrh_const& c,
   bool compile = true);
  ```

Adds the specified character to the alphabet.

Parameters

c The character to add to the alphabet.

compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

Throws

ccOCDefs::SameKey
The supplied character has the same key as a character that already exists in the alphabet. Each key in the alphabet must be unique. If the function throws an error, the alphabet remains unchanged.

- ```
  void add(const cmStd vector<ccOCModelPtrh_const>& chars,
   bool compile = true);
  ```

Adds the specified characters to the alphabet.

Parameters

chars The characters to add to the alphabet.

compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

Throws

ccOCDefs::SameKey

Two or more of the supplied characters have the same key or the key already exists in the alphabet. Each key in the alphabet must be unique. If the function throws an error, the alphabet remains unchanged.

- ```
  void add(const cmStd vector<ccOCModelPtrh>& chars,
    bool compile = true);
  ```

Adds the specified characters to the alphabet.

Parameters

chars The characters to add to the alphabet.

compile Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

Throws

ccOCDefs::SameKey

Two or more of the supplied characters have the same key or the key already exists in the alphabet. Each key in the alphabet must be unique. If the function throws an error, the alphabet remains unchanged.

remove

```
void remove(c_Int32 key);

void remove(const cmStd vector<c_Int32>& keys);
```

- ```
  void remove(c_Int32 key);
  ```

Removes the character with the specified key from the alphabet. If the alphabet was previously compiled, it remains compiled.

Parameters

key The key of the character to remove.

Throws

ccOCDefs::BadKey

The character specified by the key does not exist in this alphabet.

- `void remove(const cmStd vector<c_Int32>& keys);`

  Removes the characters with the specified keys from the alphabet. If the alphabet was previously compiled, it remains compiled.

  Parameters

  keys The keys of characters to remove.

  Throws

  ccOCDefs::BadKey
  The characters with the specified keys do not exist in this alphabet.

  ccOCDefs::SameKey
  Two or more supplied keys are the same.

confusion `double confusion(c_Int32 key1, c_Int32 key2) const;`

Returns the confusion score for the pairing of characters given by the keys. The confusion score, a number between 0 and 1, indicates the probability that the characters can be confused with one another during optical verification. A returned value of 0 means that the characters will never be confused with each other; a value of 1 means that they will always be confused.

Parameters

key1 The first key, which selects a character from a row of the confusion table.

key2 The second key, which selects a character from a column of the confusion table.

Notes

Confusion scores are based on comparing the characters at the same position, angle, and scale.

Throws

ccOCDefs::BadKey
The specified character keys do not exist in this alphabet.

ccOCDefs::NotCompiled
Confusion scores have not been compiled for characters.

areConfusable

```
bool areConfusable(c_Int32 key1, c_Int32 key2) const;
```

Returns true if the two characters referred to by *key1* and *key2* are easily confused. Two characters are easily confused if their confusion score is greater than the confusion threshold.

Parameters

key1 The first key, which selects a character from a row of the confusion table.

key2 The second key, which selects a character from a column of the confusion table.

Throws

ccOCDefs::BadKey
The specified character keys do not exist in this alphabet.

ccOCDefs::NotCompiled
Confusion scores have not been compiled for characters.

compile

```
void compile(ccDiagObject* diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Computes the confusion score for all possible pairings of characters in the alphabet.

Parameters

diagObject A valid diagnostic object or null.

diagFlags Any diagnostic flags.

Notes

Calling **compile()** has no effect (other than re-generating diagnostic information if you have supplied a value for *diagObject*) if confusion scores are already compiled.

isCompiled

```
bool isCompiled() const;
```

Returns true if the alphabet has compiled confusion scores for all character pairs.

Typedefs

ccOCAlphabetPtrh

```
typedef ccPtrHandle<ccOCAlphabet> ccOCAlphabetPtrh;
```

ccOCAlphabetPtrh_const

```
typedef ccPtrHandle_const<ccOCAlphabet>
  ccOCAlphabetPtrh_const;
```

Deprecated Members

confusionThreshold

```
void confusionThreshold(double t, bool compile);
```

This function is deprecated. You should not use it in new applications.

Sets the confusion threshold for the characters in the alphabet. If the computed confusion score for a character pairing is greater than the confusion threshold, the characters are easily confused with each other during optical verification.

Parameters

t — The confusion threshold. The valid range is between 0 and 1.

compile — Determines whether the alphabet should compile confusion scores for each pairing of characters. Each confusion score indicates the probability that one character can be confused with another. If true, the alphabet compiles the confusion scores for all character pairings at construction-time.

Notes

Changing the confusion threshold does not necessitate recompiling the confusion scores for pairings of characters in the alphabet.

Throws

ccOCDefs::BadParams

confusionThreshold is less than 0 or greater than 1.

ccOCAlphabet

ccOCChar

```
#include <ch_cvl/occhar.h>

class ccOCChar;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCChar** class contains data associated with characters in OCR/OCV. This includes the character codes, images, and other metadata.

Constructors/Destructors

ccOCChar

```
ccOCChar();

ccOCChar(const ccOCChar& rhs);
```

- `ccOCChar();`

  Constructs a character with a default constructed key, a polarity of *eUnknown*, and metrics equal to **ccCharMetrics::blankMetrics()**.

- `ccOCChar(const ccOCChar& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

  Notes

  Compiler-generated destructor is used.

  Copy operator performs deep copy (for example, deep copy of the contained images).

Public Member Functions

reset

```
void reset();
```

Resets the character to a default state.

key

```
const ccOCCharKey& key() const;
void key(const ccOCCharKey& k);
```

- `const ccOCCharKey& key() const;`

  Gets a character key.

- `void key(const ccOCCharKey& k);`

  Sets a character key.

  Parameters

k	The character key.

characterCode

```
c_Char32 characterCode() const;
void characterCode(c_Char32 c);
```

- `c_Char32 characterCode() const;`

  Gets the character code of the character's key.

- `void characterCode(c_Char32 c);`

  Sets the character code of the character's key.

  Parameters

c	The character code.

  Notes

  The setter sets the value within the key.

name32

```
void name32(const ccCvlString32& n);
const ccCvlString32& name32() const;
```

- `void name32(const ccCvlString32& n);`

  Sets the name for this character in Unicode UTF-32.

  Parameters

  n The name to be set.

- `const ccCvlString32& name32() const;`

  Gets the name for this character in Unicode UTF-32.

  Notes

  name32() and **name()** are always kept in sync; therefore, setting one also changes the other one appropriately.

name

```
void name(const ccCvlString& n);
const ccCvlString& name() const;
```

- `void name(const ccCvlString& n);`

  Sets the name for this character.

  Parameters

  n The name to be set.

- `const ccCvlString& name() const;`

  Gets the name for this character.

  Throws

  ccCharCodeDefs::NotRepresentable
  Any character in the underlying UTF-32 representation of the name cannot be represented as a TCHAR.

  Notes

  name32() and **name()** are always kept in sync; therefore, setting one also changes the other one appropriately.

description32

```
void description32(const ccCvlString32& n);
const ccCvlString32& description32() const;
```

- `void description32(const ccCvlString32& n);`

  Sets the description for this character in Unicode UTF-32.

  Parameters

  n The description to be set.

- `const ccCvlString32& description32() const;`

  Gets the description for this character in Unicode UTF-32.

  Notes

  description32() and **description()** are always kept in sync; therefore, setting one also changes the other one appropriately.

description

```
void description(const ccCvlString& n);
const ccCvlString& description() const;
```

- `void description(const ccCvlString& n);`

  Sets the description for this character.

  Parameters

  n The description to be set.

- `const ccCvlString& description() const;`

  Gets the description for this character.

  Throws

  ccCharCodeDefs::NotRepresentable
  Any character in the underlying UTF-32 representation of the description cannot be represented as a TCHAR.

  Notes

  description32() and **description()** are always kept in sync; therefore, setting one also changes the other one appropriately.

polarity

```
ccOCDefs::Polarity polarity() const;

void polarity(ccOCDefs::Polarity p);
```

- `ccOCDefs::Polarity polarity() const;`

  Gets the polarity for this character.

- `void polarity(ccOCDefs::Polarity p);`

  Sets the polarity for this character.

  Parameters

  p The polarity to be set.

  Throws

  ccOCDefs::BadParams
  The polarity is not valid.

image

```
void image(const ccPelBuffer_const<c_UInt8>& image,
 const ccPelRect& maxRootCopyRect = ccPelRect());

ccPelBuffer_const<c_UInt8> image(
 bool rewindowToImageArea = false) const;
```

imageMarkRect

```
ccPelBuffer_const<c_UInt8> imageMarkRect() const;
```

- `void image(const ccPelBuffer_const<c_UInt8>& image, const ccPelRect& maxRootCopyRect = ccPelRect());`

  Sets the image for this character.

  Parameters

  image The image.

  Throws

  ccOCDefs::BadParams
  maxRootCopyRect is not a null rectangle and does not contain the image's window.

Notes

It makes a deep copy of the image, including pixels from the root image outside the image window, if so specified.

maxRootCopyRect may be a null rectangle to indicate that only the image's window should be copied; otherwise, it should enclose the image's window. To copy the entire root, use **image.windowEntire()** for *maxRootCopyRect*.

- ```
  ccPelBuffer_const<c_UInt8> image(
    bool rewindowToImageArea = false) const;
  ```

Gets the image for this character.

Throws

ccOCDefs::BadParams

rewindowToImageArea is true and
a) the image is bound and
b1) the image's window does not contain **imageArea()**, or
b2) **imageArea()** is null.

Notes

Returns a shallow copy of the image.

Returns an unbound image buffer if no image has been specified for this character.

If *rewindowToImageArea* is true, the returned image's window will be set to that returned by **imageArea()**.

- ```
  ccPelBuffer_const<c_UInt8> imageMarkRect() const;
  ```

Gets the image for this character.

Throws

ccOCDefs::RectNotSpecified

The mark rectangle is unspecified in the metrics.

Notes

Returns a shallow copy of the image.

Returns an unbound image buffer if no image has been specified for this character.

mask

```
void mask(const ccPelBuffer_const<c_UInt8>& mask,
 const ccPelRect& maxRootCopyRect = ccPelRect());

ccPelBuffer_const<c_UInt8> mask(
 bool rewindowToImageArea = false) const;
```

maskMarkRect

```
ccPelBuffer_const<c_UInt8> maskMarkRect() const;
```

- ```
  void mask(const ccPelBuffer_const<c_UInt8>& mask,
   const ccPelRect& maxRootCopyRect = ccPelRect());
  ```

  Sets the mask for this character.

  Parameters

  mask The mask.

  Throws

  ccOCDefs::BadParams

  maxRootCopyRect is not a null rectangle and does not contain the image's window.

  Notes

  It makes a deep copy of the image, including pixels from the root image outside the image window, if so specified.

  maxRootCopyRect may be a null rectangle to indicate that only the image's window should be copied; otherwise, it should enclose the image's window. To copy the entire root, use **mask.windowEntire()** for *maxRootCopyRect*.

- ```
  ccPelBuffer_const<c_UInt8> mask(
   bool rewindowToImageArea = false) const;
  ```

  Gets the mask for this character.

  Throws

  ccOCDefs::BadParams

  rewindowToImageArea is true and
  a) the mask is bound and
  b1) the mask's window does not contain imageArea(), or
  b2) imageArea() is null.

Notes

It returns a shallow copy of the mask image.

It returns an unbound image buffer if no mask has been specified for this character.

If *rewindowToImageArea* is true and the mask image is bound, the returned image's window will be set to that returned by **imageArea()**.

- `ccPelBuffer_const<c_UInt8> maskMarkRect() const;`

Gets the mask for this character.

Throws

ccOCDefs::RectNotSpecified
The mark rectangle is unspecified in the metrics.

Notes

It returns a shallow copy of the mask image.

It returns an unbound image buffer if no mask has been specified for this character.

normalizedImage

```
void normalizedImage(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPelRect& maxRootCopyRect = ccPelRect());

ccPelBuffer_const<c_UInt8> normalizedImage(
  bool rewindowToImageArea = false) const;
```

normalizedImageMarkRect

```
ccPelBuffer_const<c_UInt8> normalizedImageMarkRect()
  const;
```

- `void normalizedImage(`
  `const ccPelBuffer_const<c_UInt8>& image,`
  `const ccPelRect& maxRootCopyRect = ccPelRect());`

Sets the normalized image for this character.

Parameters

image The normalized image.

Throws

ccOCDefs::BadParams

maxRootCopyRect is not a null rectangle and does not contain the image's window.

Notes

It makes a deep copy of the image, including pixels from the root image outside the image window, if so specified.

maxRootCopyRect may be a null rectangle to indicate that only the image's window should be copied; otherwise, it should enclose the image's window. To copy the entire root, use **image.windowEntire()** for *maxRootCopyRect*.

- ```
  ccPelBuffer_const<c_UInt8> normalizedImage(
    bool rewindowToImageArea = false) const;
  ```

Gets the normalized image for this character.

Throws

ccOCDefs::BadParams

rewindowToImageArea is true and
a) the normalized image is bound and
b1) the normalized image's window does not contain **imageArea()**, or
b2) **imageArea()** is null.

Notes

It returns a shallow copy of the image.

It returns an unbound image buffer if no normalized image has been specified for this character.

If *rewindowToImageArea* is true and the normalized image is bound, the returned image's window will be set to that returned by **imageArea()**.

- ```
  ccPelBuffer_const<c_UInt8> normalizedImageMarkRect()
    const;
  ```

Gets the normalized image for this character.

Throws

ccOCDefs::RectNotSpecified

The mark rectangle is unspecified in the metrics.

Notes

It returns a shallow copy of the image.

It returns an unbound image buffer if no normalized image has been specified for this character.

normalizedImage

```
void normalizedImage(
  const ccPelBuffer_const<c_UInt8>& image,
  bool hasThresholdAndInvert,
  c_Int32 threshold,
  bool invert,
  const ccPelRect& maxRootCopyRect = ccPelRect());
```

Sets the normalized image for this character and also sets the *threshold* and *invert* values to allow producing a binarized image. A deep copy of the image is made, including pixels from the root image outside the image window, if so specified.

Parameters

image The normalize image to be set.

hasThresholdAndInvert
Whether it has threshold and invert values.

threshold The threshold value.

invert The invert value.

Notes

maxRootCopyRect may be a null rectangle to indicate that only the image's window should be copied; otherwise, it should enclose the image's window. To copy the entire root, use **image.windowEntire()** for *maxRootCopyRect*.

Throws

ccOCDefs::BadParams
maxRootCopyRect is not a null rectangle and does not contain the image's window; or
threshold < 0 or *threshold* > 256

hasThresholdAndInvert

```
bool hasThresholdAndInvert() const;
void hasThresholdAndInvert(bool h);
```

- `bool hasThresholdAndInvert() const;`

  Gets whether the character has threshold and invert values specified to allow binarizing the normalized image.

- `void hasThresholdAndInvert(bool h);`

  Sets whether the character has threshold and invert values specified to allow binarizing the normalized image.

  Parameters

  h Whether the character has threshold and invert values.

  Notes

  See documentation for **ccBlobParams::setSegmentationHardThresh()** in <*ch_cvl/blobtool.h*> for the description of *threshold* and *invert*.

threshold

```
c_Int32 threshold() const;
void threshold(c_Int32 t);
```

- `c_Int32 threshold() const;`

  Gets the threshold value to allow binarizing the normalized image.

  Throws

  ccOCDefs::ThresholdAndInvertNotSpecified
  hasThresholdAndInvert() is false.

- `void threshold(c_Int32 t);`

  Sets the threshold value to allow binarizing the normalized image.

  Parameters

  t The threshold value.

Notes

Setting *threshold* and *invert* values does not also set whether or not the *threshold* and *invert* values are considered specified. You must also explicitly call **hasThresholdAndInvert(***true***)** for these values to be considered specified and thus to allow binarization of the normalized image.

Throws

ccOCDefs::BadParams
t < 0

---

invert

```
bool invert() const;

void invert(bool i);
```

- `bool invert() const;`

Gets the invert value to allow binarizing the normalized image.

Throws

ccOCDefs::ThresholdAndInvertNotSpecified
hasThresholdAndInvert() is false.

- `void invert(bool i);`

Sets the invert value to allow binarizing the normalized image.

Parameters

i The invert value.

Notes

Setting *threshold* and *invert* values does not also set whether or not the *threshold* and *invert* values are considered specified. You must also explicitly call **hasThresholdAndInvert(***true***)** for these values to be considered specified and thus to allow binarization of the normalized image.

---

binarizedImage

```
ccPelBuffer_const<c_UInt8> binarizedImage(
  bool rewindowToImageArea = false) const;
```

binarizedImageMarkRect

```
ccPelBuffer_const<c_UInt8> binarizedImageMarkRect() const;
```

- `ccPelBuffer_const<c_UInt8> binarizedImage(`
  `bool rewindowToImageArea = false) const;`

Gets the binarized image for this character.

Throws

ccOCDefs::ThresholdAndInvertNotSpecified
hasThresholdAndInvert() is false.

ccOCDefs::BadParams
threshold() > 256.

ccOCDefs::BadParams
normalizedImage() returns a bound image, and
hasThresholdAndInvert() is true, and
rewindowToImageArea is true, and
a) The binarized image's window does not contain **imageArea()**
or
b) **imageArea()** is null.

- `ccPelBuffer_const<c_UInt8> binarizedImageMarkRect() const;`

Gets the binarized image for this character.

Notes

The binarized image is always a hard-thresholded version of the normalized image, produced using the current **threshold()** and **invert()** values. If the *threshold* and *invert* values were not specified, it is an error to try to get the binarized image.

Requires that **hasThresholdAndInvert()** is true.

Returns a shallow copy of the binarized image if **normalizedImage()** returns a bound image; otherwise returns an unbound image.

When returning a bound image, if *rewindowToImageArea* is true, the returned image's window will be set to that returned by **imageArea()**.

Throws

ccOCDefs::ThresholdAndInvertNotSpecified
hasThresholdAndInvert() is false.

ccOCDefs::BadParams
threshold() > 256.

ccOCDefs::BadParams
normalizedImage() returns a bound image, and
hasThresholdAndInvert() is true, and
rewindowToImageArea is true, and
a) The binarized image's window does not contain **imageArea()**
or
b) **imageArea()** is null.

ccOCDefs::RectNotSpecified
The mark rectangle is unspecified in the metrics.

imageArea

```
ccPelRect imageArea() const;
void imageArea(const ccPelRect& area);
```

- `ccPelRect imageArea() const;`

  Gets the character area for this character in image coordinates.

- `void imageArea(const ccPelRect& area);`

  Sets the character area for this character in image coordinates.

  The default is **ccPelRect()**

  Parameters
  area The character area.

markOrImageArea

```
ccPelRect markOrImageArea() const;
```

Returns the image-coordinate mark rectangle if it is specified and non-null, or else returns **imageArea()**.

moveOrigin

```
void moveOrigin(const cc2Vect& origin);
```

Moves the origin to the specified location; that is, makes the specified point become (0, 0) in client coordinates.

Parameters
origin The origin.

metrics

```
const ccOCCharMetrics& metrics() const;
void metrics(const ccOCCharMetrics& m);
```

- `const ccOCCharMetrics& metrics() const;`

  Gets the metrics for this character.

- `void metrics(const ccOCCharMetrics& m);`

  Sets the metrics for this character.

  Parameters

m	The metrics to be set.

makeUniqueInstanceKey

```
static ccOCCharKey makeUniqueInstanceKey(
  const ccOCCharKey& key,
  const cmStd vector<ccOCChar>& characters);

static ccOCCharKey makeUniqueInstanceKey(
  const ccOCCharKey& key,
  const cmStd vector<ccOCCharKey>& keys);
```

- ```
  static ccOCCharKey makeUniqueInstanceKey(
    const ccOCCharKey& key,
    const cmStd vector<ccOCChar>& characters);
  ```

  Returns a unique key to be used for a new instance of the given key that does not match any of the other characters provided, with the same character code, variant, and font ID.

  Parameters

key	The given key.
characters	The provided characters.

- ```
  static ccOCCharKey makeUniqueInstanceKey(
    const ccOCCharKey& key,
    const cmStd vector<ccOCCharKey>& keys);
  ```

  Returns a unique key to be used for a new instance of the given key that does not match any of the other keys provided, with the same character code, variant, and font ID.

  Parameters

key	The given key.
keys	The provided keys.

makeUniqueInstanceKeys

```
static bool makeUniqueInstanceKeys(
  cmStd vector<ccOCCharKey>& keys);
```

Makes all keys unique by assigning new instance values if necessary, with the same character code, variant, and font ID.

Parameters

keys The keys.

Returns true if any keys had their instance values changed or false otherwise.

Operators

operator=

```
ccOCChar& operator=(const ccOCChar& rhs);
```

Assignment operator.

Parameters

rhs The object to assign to this one.

Notes

Assignment operator performs deep copy.

operator==

```
bool operator==(const ccOCChar& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCChar& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharKey

```
#include <ch_cvl/occhar.h>

class ccOCCharKey;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a character key, specifying the full identity of a character. The key consists of a Unicode UTF-32 code point as well as an instance number, a variant number, and a font ID.

Constructors/Destructors

ccOCCharKey

```
explicit ccOCCharKey(
  c_Char32 characterCode = ccCharCode::eUnknown,
  c_Int32 instance = eUnspecified,
  c_Int32 variant = eUnspecified,
  c_Int32 fontID = eUnspecified);
```

Constructor.

Parameters

characterCode	The character code.
instance	The instance.
variant	The variant.
fontID	The font ID.

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Enumerations

enum

```
enum { eUnspecified = -1 };
```

Special value for a key to indicate that a field is unspecified. This value may be used for the instance, variant, and/or font ID of a key. Note that this is NOT the same value as *ccCharCode::eUnknown*, which is the corresponding value for a character code.

Public Member Functions

reset

```
void reset();
```

Resets the key to a default state.

See the default constructor for default values.

isCharacterCodeKnown

```
bool isCharacterCodeKnown() const;
```

Returns whether the character code is not *ccCharCode::eUnknown*.

characterCode

```
c_Char32 characterCode() const;

void characterCode(c_Char32 c);
```

- `c_Char32 characterCode() const;`

  Gets the character code, which is a Unicode UTF-32 code point.

- `void characterCode(c_Char32 c);`

  Sets the character code, which is a Unicode UTF-32 code point.

  Parameters

c	The character code.

  Notes

  The value can be *ccCharCode::eUnknown* to indicate that the character code is not known.

  It is not recommended to set a character code outside the UTF-32 code range. See <*ch_cvl/charcode.h*>.

isInstanceSpecified

```
bool isInstanceSpecified() const;
```

Returns whether instance is not equal to *eUnspecified*.

instance

```
c_Int32 instance() const;
```

```
void instance(c_Int32 i);
```

- `c_Int32 instance() const;`

  Gets the instance number, which can be used to uniquely identify a particular instance of a character with a given character code within a particular font.

- `void instance(c_Int32 i);`

  Sets the instance number, which can be used to uniquely identify a particular instance of a character with a given character code within a particular font.

  Parameters

  i The instance number.

  For example, a set of characters (including an image for each character) might have two different instances of a character code (for example, the letter “A”) to represent two different appearances that both corresponded to that character code. If that font also had a single instance of the letter “B”, then the character codes and instances might reasonably be the following:

  (characterCode=”A”, instance=0)

  (characterCode=”A”, instance=1)

  (characterCode=”B”, instance=0)

  Notes

  The value can be *eUnspecified* to indicate that the instance is not specified.

isVariantSpecified

```
bool isVariantSpecified() const;
```

Returns whether variant is not equal to *eUnspecified*.

variant

```
c_Int32 variant() const;
void variant(c_Int32 v);
```

- `c_Int32 variant() const;`

  Gets the variant number, which can be used to indicate a distinct appearance of a character code.

- `void variant(c_Int32 v);`

  Sets the variant number, which can be used to indicate a distinct appearance of a character code.

  Parameters

  v The variant number.

  For example, a particular font might contain two visually distinct appearances for the digit zero “0”, one of which might simply be an ellipse and another that is an ellipse with a diagonal stroke through it.

Notes

instance is independent of *variant*; for example, in a given set of characters one would typically have no duplicate *instance* values regardless of whether the characters had different *variant* values.

variant is provided for your convenience, and its interpretation is application-specific. OCR and OCV functions preserve this value but otherwise make no use of it.

The concept of variant is related to the concept of *variant selectors* in the Unicode Standard, but the value of the *variant* does not need to be a Unicode variant selector value.

The value can be *eUnspecified* to indicate that the variant is not specified.

isFontIDSpecified

```
bool isFontIDSpecified() const;
```

Returns whether the font ID is not equal to *eUnspecified*.

fontID

```
c_Int32 fontID() const;
void fontID(c_Int32 id);
```

- `c_Int32 fontID() const;`

  Gets the font ID.

- `void fontID(c_Int32 id);`

  Sets the font ID.

  Parameters

  id The font ID.

Notes

This is the ID of the font (that is, set of characters) of which this character is a member. One potential use for this value would be to have each font use a distinct value for the characters in that font, so that an application could refer to a set of character keys from all the fonts and still be able to distinguish which character came from which font.

fontID is provided for your convenience, and its interpretation is application-specific. OCR and OCV functions preserve this value but otherwise make no use of it.

For applications that choose to use font IDs to keep track of different fonts, the *instance* values should typically be required to be distinct only within a single font and not across all fonts.

The value can be *eUnspecified* to indicate that the font ID is not specified.

isRepresentableAsChar

```
bool isRepresentableAsChar() const ;
```

Returns whether the character code is representable as type char. See <*ch_cvl/charcode.h*>.

isRepresentableAsWChar

```
bool isRepresentableAsWChar() const;
```

Returns whether the character code is representable as type wchar_t. See <*ch_cvl/charcode.h*>.

isRepresentableAsTChar

```
bool isRepresentableAsTChar() const;
```

Returns whether the character code is representable as type TCHAR. See <*ch_cvl/charcode.h*>.

isSpace

```
bool isSpace() const;
```

Returns whether the character code is a space character.

Notes

This test is performed by **ccCharCode::isSpace()**.

This is entirely different and separate from blank metrics (**ccOCCharMetrics::isBlank()**).

equalCharacterCode

```
bool equalCharacterCode(const ccOCCharKey& rhs) const;
bool equalCharacterCode(c_Char32 characterCode) const;
```

- `bool equalCharacterCode(const ccOCCharKey& rhs) const;`

  Returns whether the two keys have the same character code.

  Parameters

  rhs The character key to compare to this one.

- `bool equalCharacterCode(c_Char32 characterCode) const;`

  Returns whether this key has the given character code.

  Parameters

  characterCode The character code.

isMatch

```
bool isMatch(const ccOCCharKey& otherKey) const;
```

Returns whether this key matches the other key.

Parameters

otherKey The other key.

Notes

Two keys match each other if all their corresponding data members match. A match is determined as follows:

For character code:

- The value *ccCharCode::eUnknown* never matches anything, including itself. In other words, two keys do not match if they both have the character code *ccCharCode::eUnknown*.
- Otherwise, two character codes match each other only if they are equal.

For fontID, instance, and variant:

- The value *eUnspecified* matches everything, including itself. For example, an unspecified instance number matches another unspecified instance number; it also matches any other specified instance number.
- Otherwise, two numbers match each other only if they are equal.

Operators

operator char()

```
operator char() const;
```

Convert **characterCode()** to a character.

Throws

ccCharCodeDefs::NotRepresentable
characterCode is not representable as the given type.

operator wchar_t()

```
operator wchar_t() const;
```

Convert **characterCode()** to a wide character.

Throws

ccCharCodeDefs::NotRepresentable
characterCode is not representable as the given type.

operator<

```
bool operator<(const ccOCCharKey& rhs) const;
```

Compares this key to *rhs*. Keys are ordered first by *characterCode*, then by *fontID*, then by instance, then by variant.

Parameters

rhs The base of comparison.

Notes

Character codes that are unknown and other values that are unspecified are considered greater than known/specified values.

operator==

```
bool operator==(const ccOCCharKey& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharKey& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharKey

ccOCCharMetrics

```
#include <ch_cvl/occhar.h>

class ccOCCharMetrics;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCCharMetrics contains metadata associated with characters for OCR/OCV.

Constructors/Destructors

ccOCCharMetrics

```
ccOCCharMetrics();
```

Constructor.

As default, all metrics are unspecified. All metrics values are default constructed or zero.

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Enumerations

RectType

```
enum RectType;
```

This enumeration specifies the particular rectangle of interest; that is, cell, mark, and detected mark rectangles, and whether in client or image coordinates.

Value	Meaning
eCellRectClient = 0x01	Cell rectangle in client coordinates. Note: The internal representation is a floating-point rectangle.
eCellRectImage = 0x02	Cell rectangle in image coordinates. Note: The internal representation is a fixed-point rectangle.
eMarkRectClient = 0x04	Mark rectangle in client coordinates. Note: The internal representation is a floating-point rectangle.
eMarkRectImage = 0x08	Mark rectangle in image coordinates. Note: The internal representation is a fixed-point rectangle.
eDetectedMarkRectClient = 0x10	Detected mark rectangle in client coordinates. Note: The internal representation is a floating-point rectangle.
eDetectedMarkRectImage = 0x20	Detected mark rectangle in image coordinates. Note: The internal representation is a fixed-point rectangle.

Public Member Functions

reset

```
void reset();
```

Resets the metrics to a default state.

isRectSpecified

```
bool isRectSpecified(RectType rectType) const;
void isRectSpecified(RectType rectType, bool isSpecified);
```

- `bool isRectSpecified(RectType rectType) const;`

  Gets whether the given type of rectangle is specified.

  Parameters

  rectType The rectangle type.

- `void isRectSpecified(RectType rectType, bool isSpecified);`

  Sets whether the given type of rectangle is specified.

  Parameters

  rectType The rectangle type.

  isSpecified Whether the given type of rectangle is specified.

  Notes

  It is legal for the image-coordinate version of a rectangle (for example, *eCellRectImage*) to be specified but the client-coordinate version of that same rectangle (for example, *eCellRectClient*) not to be specified, or vice versa.

  Throws

  ccOCDefs::BadParams

  rectType is not a valid enum value

rect

```
ccRect rect(RectType rectType) const;
void rect(RectType rectType, const ccRect& r);
void rect(RectType rectType, const ccPelRect& r);
```

- `ccRect rect(RectType rectType) const;`

  Gets the specified type of rectangle as a floating-point rectangle.

  It is legal to get any of the rectangle types using this function, even the image-coordinate rectangles that are stored internally as fixed-point integers.

  Parameters

  rectType The rectangle type.

Throws

ccOCDefs::BadParams
rectType is not a valid enum value.

ccOCDefs::RectNotSpecified
The rectangle of the given type is not specified.

- `void rect(RectType rectType, const ccRect& r);`

Sets the specified type of rectangle as a floating-point rectangle.

Parameters

rectType The rectangle type.

r The rectangle to set.

- `void rect(RectType rectType, const ccPelRect& r);`

Sets the specified type of rectangle as a floating-point rectangle.

Parameters

rectType The rectangle type.

r The rectangle to set.

Notes

It is legal to set any of the rectangle types using this function, even the image-coordinate rectangles that are stored internally as fixed-point integers, as long as the values can be represented without overflow. Note that underflow will not be reported as an error.

Setting a rectangle does not also set whether or not the rectangle is considered specified. The user must also explicitly call **isRectSpecified(***rectType, true***)** for the given rectangle type to be considered specified.

Throws

ccOCDefs::BadParams
rectType is not a valid enum value.

ccOCDefs::IntegerOverflow
Integer overflow occurs.

encloseRect

```
ccPelRect encloseRect(RectType rectType) const;
```

Gets the enclosing rectangle of the specified type of rectangle.

It is legal to get any of the rectangle types using this function, even the client-coordinate rectangles that are stored internally as floating-point numbers.

Parameters

rectType The rectangle type.

Throws

ccOCDefs::BadParams
rectType is not a valid enum value.

ccOCDefs::RectNotSpecified
The rectangle of the given type is not specified.

ccOCDefs::IntegerOverflow
Integer overflow occurs.

encloseRectImage

```
ccPelRect encloseRectImage(RectType rectType,
  const cc2Xform& imageFromClientXform) const;

ccPelRect encloseRectImage(RectType rectType,
  const cc_PelBuffer& image) const;
```

- ```
  ccPelRect encloseRectImage(RectType rectType,
    const cc2Xform& imageFromClientXform) const;
  ```

  Gets the enclosing rectangle of the specified type of rectangle in image coordinates.

  Parameters

  rectType The rectangle type.

  imageFromClientXform
  A **cc2Xform** that specifies the transformation from the image coordinate system.

  Throws

  ccOCDefs::BadParams
  rectType is not a valid enum value.

  ccOCDefs::RectNotSpecified
  The rectangle of the given type is not specified.

  ccOCDefs::IntegerOverflow
  Integer overflow occurs.
  ```

- ```
  ccPelRect encloseRectImage(RectType rectType,
    const cc_PelBuffer& image) const;
  ```

  Gets the enclosing rectangle of the specified type of rectangle in image coordinates.

  For *eCellRectImage*, *eMarkRectImage*, and *eDetectedMarkRectImage*, this function is the same as **encloseRect()**. For *eCellRectClient*, *eMarkRectClient*, and *eDetectedMarkRectClient*, the specified client-coordinate rectangle is first converted to image coordinates using the image's *imageFromClient* xform, and the enclosing rectangle of that rectangle is returned.

  Parameters

  rectType The rectangle type.

  image The image whose *imageFromClient* xform is used for conversion.

  Notes

  It is legal to get any of the rectangle types using this function, even the client-coordinate rectangles that are stored internally as floating-point numbers.

  It is legal for image to be unbound.

  Throws

  ccOCDefs::BadParams
  rectType is not a valid enum value.

  ccOCDefs::RectNotSpecified
  The rectangle of the given type is not specified.

  ccOCDefs::BadParams
  image.imageFromClientXformBase()->**isLinear()** returns false.

  ccOCDefs::IntegerOverflow
  Integer overflow occurs.

setImageRectsFromClientRects

```
void setImageRectsFromClientRects(
  const cc2Xform& imageFromClientXform);

void setImageRectsFromClientRects(
  const cc_PelBuffer& image);
```

- ```
  void setImageRectsFromClientRects(
    const cc2Xform& imageFromClientXform);
  ```

  For each of the client-coordinate rectangle types, set the corresponding image-coordinate rectangle type.

Parameters

imageFromClientXform
A **cc2Xform** that specifies the transformation from the image coordinate system.

Throws

ccOCDefs::BadParams
image.imageFromClientXformBase()->**isLinear()** returns false.

ccOCDefs::IntegerOverflow
Integer overflow occurs.

- ```
  void setImageRectsFromClientRects(
    const cc_PelBuffer& image);
  ```

For each of the client-coordinate rectangle types, set the corresponding image-coordinate rectangle type.

Parameters

image Image that defines the client-coordinates for this rectangle.

Notes

In addition to setting the rectangle data, this also updates the image-coordinate rectangle's **isRectSpecified()** status to be the same as the corresponding client-coordinate rectangle.

It is legal for image to be unbound.

Throws

ccOCDefs::IntegerOverflow
Integer overflow occurs.

---

cellRect

```
ccRect cellRect() const;

void cellRect(const ccRect& r);
```

- ```
  ccRect cellRect() const;
  ```

Gets the client-coordinate cell rectangle.

Throws

ccOCDefs::RectNotSpecified
The rectangle of the given type is not specified.

- `void cellRect(const ccRect& r);`

  Sets the client-coordinate cell rectangle.

  Parameters
  r The client-coordinate cell rectangle.

  See **rect()**.

markRect

```
ccRect markRect() const;
void markRect(const ccRect& r);
```

- `ccRect markRect() const;`

  Gets the client-coordinate mark rectangle.

  Throws
  ccOCDefs::RectNotSpecified
  The rectangle of the given type is not specified.

- `void markRect(const ccRect& r);`

  Sets the client-coordinate mark rectangle.

  Parameters
  r The client-coordinate mark rectangle.

  See **rect()**.

isMarkRectSpecified

```
bool isMarkRectSpecified() const;
void isMarkRectSpecified(bool isSpecified);
```

- `bool isMarkRectSpecified() const;`

  Gets whether the mark rectangle is specified.

- `void isMarkRectSpecified(bool isSpecified);`

  Sets whether the mark rectangle is specified.

  Parameters
  isSpecified Whether the mark rectangle is specified.

Notes

A blank character has a mark rectangle that is specified but degenerate.

hasDetectedMarkRect

```
bool hasDetectedMarkRect() const;
void hasDetectedMarkRect(bool isSpecified);
```

- `bool hasDetectedMarkRect() const;`

  Gets whether there is a detected mark rectangle.

- `void hasDetectedMarkRect(bool isSpecified);`

  Sets whether there is a detected mark rectangle.

  Parameters

  isSpecified Whether there is a detected mark rectangle.

  Notes

  A blank character does not have a detected mark rectangle.

detectedMarkRect

```
ccRect detectedMarkRect() const;
void detectedMarkRect(const ccRect& r);
```

- `ccRect detectedMarkRect() const;`

  Gets the client-coordinate detected mark rectangle.

  Throws

  ccOCDefs::RectNotSpecified
  The rectangle of the given type is not specified.

- `void detectedMarkRect(const ccRect& r);`

  Sets the client-coordinate detected mark rectangle.

  Parameters

  r The client-coordinate detected mark rectangle.

  See **rect()**.

isBlank `bool isBlank() const;`

Gets whether or not the character is a blank.

This is the same as testing for a mark rectangle that is specified and degenerate.

Notes

This is entirely different and separate from the character code being a space character (**ccOCCharKey::isSpace()**).

makeBlank `void makeBlank();`

Sets the character blank.

Making the character blank is the same as specifying a degenerate mark rectangle.

Notes

This is entirely different and separate from the character code being a space character (**ccOCCharKey::isSpace()**).

blankMetrics `static ccOCCharMetrics blankMetrics();`

Returns an object with a specified and degenerate mark rectangle, with all other values default constructed.

isAdvanceSpecified

```
bool isAdvanceSpecified() const;
void isAdvanceSpecified(bool isSpecified);
```

- `bool isAdvanceSpecified() const;`

  Gets whether the advance is specified.

- `void isAdvanceSpecified(bool isSpecified);`

  Sets whether the advance is specified.

  Parameters

  isSpecified Whether the advance is specified.

advance

```
cc2Vect advance() const;
void advance(const cc2Vect& a);
```

- `cc2Vect advance() const;`

  Gets the advance for the character in client coordinates.

  Throws

  ccOCDefs::MetricNotSpecified
  isAdvanceSpecified() returned false.

- `void advance(const cc2Vect& a);`

  Sets the advance for the character in client coordinates.

  Parameters

  a The advance value.

  Notes

  Setting the advance does not also set whether or not the advance is considered specified. You must also explicitly call **isAdvanceSpecified(***true***)** for the advance to be considered specified.

Operators

operator==

```
bool operator==(const ccOCCharMetrics& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

ccOCCharMetrics

ccOCCharSegmentLineResult

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentLineResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the segmentation line result, representing an entire line of segmented characters.

Constructors/Destructors

ccOCCharSegmentLineResult

```
ccOCCharSegmentLineResult();

ccOCCharSegmentLineResult(
  const ccOCCharSegmentLineResult& rhs);
```

- `ccOCCharSegmentLineResult();`

  Constructor.

  isFound = false

- `ccOCCharSegmentLineResult(`
  `  const ccOCCharSegmentLineResult& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

  Notes

  Copy performs deep copies of images.

  Compiler-generated destructor is used.

Public Member Functions

reset

```
void reset();
```

Resets this result to a default state.

Notes

This sets *isFound* to false.

isFound

```
bool isFound() const;
```

Returns whether the segmenter found a line of characters.

Notes

All other getters throw *ccOCRDefs::NotComputed* if **isFound()** returns false.

positionResults

```
const cmStd vector<ccOCCharSegmentPositionResult>&
 positionResults() const;
```

Returns results for all segmented characters in this line.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

rectifiedLineImage

```
ccPelBuffer_const<c_UInt8> rectifiedLineImage() const;
```

Returns an image of the line of the segmented characters after rectification.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

Notes

The client coordinates of the *rectifiedLineImage* have uniform scale in x and y. That uniform scale is based on the scale of the original input image. That uniform scale is computed as the square root of the *mapArea* of the original input image.

The client coordinate axes of the *rectifiedLineImage* are approximately parallel to the coordinate axes specified by the search region affine rectangle.

hasNormalizedRectifiedLineImage

```
bool hasNormalizedRectifiedLineImage() const;
```

Returns whether this object contains an image of the line of the segmented characters after rectification and normalization.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

normalizedRectifiedLineImage

```
ccPelBuffer_const<c_UInt8> normalizedRectifiedLineImage()
  const;
```

Returns an image of the line of the segmented characters after rectification and normalization.

Throws

ccOCRDefs::NotComputed
isFound() returns false.

ccOCRDefs::NotComputed
hasNormalizedRectifiedLineImage() returned false.

Notes

The client coordinates of the *normlizedRectifiedLineImage* have uniform scale in x and y. That uniform scale is based on the scale of the original input image. That uniform scale is computed as the square root of the *mapArea* of the original input image.

The client coordinate axes of the *normalizedRectifiedLineImage* are approximately parallel to the coordinate axes specified by the search region affine rectangle.

hasThresholdAndInvert

```
bool hasThresholdAndInvert() const;
```

Gets whether this object has threshold and invert values specified to allow binarizing the normalized image.

Notes

See the documentation for **ccBlobParams::setSegmentationHardThresh()** and the <*ch_cvl/blobtool.h*> header file for the description of *threshold* and *invert*.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

threshold `c_Int32 threshold() const;`

Gets the threshold value used to binarize the normalized image.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

ccOCRDefs::NotComputed
hasThresholdAndInvert() returned false.

invert `bool invert() const;`

Gets the invert value used to binarize the normalized image.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

ccOCRDefs::NotComputed
hasThresholdAndInvert() returned false.

binarizedRectifiedLineImage

```
ccPelBuffer_const<c_UInt8> binarizedRectifiedLineImage()
const;
```

Returns an image of the line of the segmented characters after rectification, normalization, and binzarization.

Throws

ccOCRDefs::NotComputed
isFound() returned false.

ccOCRDefs::NotComputed
hasNormalizedRectifiedLineImage() returned false.

ccOCRDefs::NotComputed
hasThresholdAndInvert() returned false.

Notes

The binarized image is always a hard-thresholded version of the normalized image, produced using the **threshold()** and **invert()** values. If the *threshold* and *invert* values were not specified, it is an error to try to get the binarized image.

The client coordinates of the *binarizedRectifiedLineImage* have uniform scale in x and y. That uniform scale is based on the scale of the original input image. That uniform scale is computed as the square root of the *mapArea* of the original input image.

The client coordinate axes of the *binarizedRectifiedLineImage* are approximately parallel to the coordinate axes specified by the search region affine rectangle.

Operators

operator=

```
ccOCCharSegmentLineResult& operator=(
  const ccOCCharSegmentLineResult& rhs);
```

Assignment operator.

Parameters

rhs The object to assign to this one.

Notes

Assignment performs deep copies of images.

operator==

```
bool operator==(const ccOCCharSegmentLineResult& rhs)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentLineResult& rhs)
  const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharSegmentLineResult

ccOCCharSegmentParagraphResult

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentParagraphResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the segmentation paragraph result, representing one or more lines of segmented characters.

Constructors/Destructors

ccOCCharSegmentParagraphResult

```
ccOCCharSegmentParagraphResult();
```

Constructor.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Resets this result to a default state.

Notes

This sets *isComputed* to false.

isComputed

```
bool isComputed() const;
```

Gets whether the result contains computed information.

Notes

All other getters will throw *ccOCRDefs::NotComputed* if **isComputed()** returns false.

lineResults

```
const cmStd vector<ccOCCharSegmentLineResult>&
  lineResults() const;
```

Returns results for all segmented lines in this paragraph.

Throws

ccOCRDefs::NotComputed
isComputed() returned false.

Operators

operator==

```
bool operator==(const ccOCCharSegmentParagraphResult& rhs)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentParagraphResult& rhs)
  const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharSegmentPositionResult

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentPositionResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the segmentation position result, representing a single segmented character.

Constructors/Destructors

ccOCCharSegmentPositionResult

```
ccOCCharSegmentPositionResult();
```

Constructor.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Reset this result to a default state.

Notes

This sets *isComputed* to false.

isComputed

```
bool isComputed() const;
```

Gets whether the result contains computed information.

Notes

All other getters throw *ccOCRDefs::NotComputed* if **isComputed()** returns false.

character `const ccOCChar& character() const;`

Gets the segmented character from the result.

Throws

ccOCRDefs::NotComputed
isComputed() returned false.

Notes

The client coordinates of the character have uniform scale in x and y, the same scale as the *rectifiedLineImage*. That uniform scale is based on the scale of the original input image. That uniform scale is computed as the square root of the *mapArea* of the original input image.

isSpace `bool isSpace() const;`

Gets whether the segmented character is a space.

Throws

ccOCRDefs::NotComputed
isComputed() returned false.

spaceScore `double spaceScore() const;`

Gets the score of the segmented character, if the segmented character is a space. The score is in the range [0, 1]. See the documentation for **ccOCCharSegmentSpaceParams::SpaceScoreMode**.

Throws

ccOCRDefs::NotComputed
isComputed() returned false.

ccOCRDefs::NotComputed
isSpace() returned false.

markRect `const ccAffineRectangle& markRect() const;`

Gets the mark rectangle of the segmented character.

The mark rectangle is specified in the client coordinates of the input image used for segmentation. The mark rectangle of a character is a tight bounding box enclosing all of the foreground (for example, ink) pixels in the character image.

Notes

If **isSpace()** is true, the returned affine rectangle is degenerate.

Throws

ccOCRDefs::NotComputed
isComputed() returned false.

cellRect

```
const ccAffineRectangle& cellRect() const;
```

Gets the cell rectangle of the segmented character.

The cell rectangle is specified in the client coordinates of the input image used for segmentation. The cell rectangle is a bounding box that encloses not only all of the foreground (for example, ink) pixels of a character image, but also typically some additional padding region. Cell rectangles are typically the height of the full line of text containing the character. Ideally, all of the cell rectangles in a line of text horizontally touch their adjacent neighbors.

Throws
ccOCRDefs::NotComputed
isComputed() returned false.

Operators

operator==

```
bool operator==(const ccOCCharSegmentPositionResult& rhs)
 const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters
rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentPositionResult& rhs)
 const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters
rhs The object with which to compare for inequality.

ccOCCharSegmentPositionResult

ccOCCharSegmentResult

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the segmentation result, representing one or more paragraphs of segmented characters.

Constructors/Destructors

ccOCCharSegmentResult

```
ccOCCharSegmentResult();
```

Constructor.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Resets this result to a default state.

Notes

This sets *isComputed* to false.

isComputed

```
bool isComputed() const;
```

Gets whether the result contains computed information.

Notes

All other getters throw *ccOCRDefs::NotComputed* if **isComputed()** returns false.

paragraphResults

```
const cmStd vector<ccOCCharSegmentParagraphResult>&
paragraphResults() const;
```

Returns results for all segmented paragraphs.

Throws

ccOCRDefs::NotComputed
isComputed() returns false.

Operators

operator==

```
bool operator==(const ccOCCharSegmentResult& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentResult& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharSegmentRunParams

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains runtime parameters for character segmentation.

Character segmentation consists of the following named stages, performed in sequence:

1. Refine line:
   Determine line location, angle, skew, and/or polarity.
2. Normalize:
   Normalize the input image to produce a normalized image. The normalized image should be binarizable using a single global threshold.
3. Binarize:
   Determine a threshold and use it to binarize the normalized image to produce a binarized image.
4. Fragment:
   Perform blob analysis to produce character fragments, where each character fragment is a single blob. See <ch_cvl/blob.h>.
5. Group:
   Group character fragments together to form characters. Grouping may include merging and/or splitting fragments. Small characters may be discarded.
6. Analyze:
   Optionally perform additional analysis to determine a more optimal grouping.

Each runtime parameter is used in one or more stages of segmentation; each parameter notes which stage(s) it is used in with a comment of the form “Stage: Name”, where “Name” is one of the names listed above.

Constructors/Destructors

ccOCCharSegmentRunParams

```
ccOCCharSegmentRunParams();
```

Constructor.

Notes

See individual getters for default values.

Compiler-generated copy constructor, assignment operator, and destructor are used.

Enumerations

NormalizationMode

```
enum NormalizationMode;
```

This enumeration defines how to normalize the image so that the normalized image can be binarized well using only a global threshold.

Value	Meaning
eNormalizationModeNone = 0x1	No normalization is performed; the input image is used as the normalized image.
eNormalizationModeGlobal = 0x2	A global normalization is performed, using only information about the image as a whole, not local variations.
eNormalizationModeLocal = 0x4	A local normalization is performed, using information about each local region of the image to normalize that region.
eNormalizationModeLocalAdvanced = 0x8	A local normalization is performed, using information about each local region of the image to normalize that region, including adjusting not only for the background but also for the contrast of the foreground.
kDefaultNormalizationMode = *eNormalizationModeLocalAdvanced*	The default mode for image normalization.

CharacterFragmentMergeMode

```
enum CharacterFragmentMergeMode;
```

This enumeration defines how to merge character fragments to form characters during the Group stage. Note that the Analyze stage may perform additional merges.

Value	Meaning
eMergeModeRequireOverlap = 0x1	Character fragments must overlap horizontally by at least one pixel to be merged.
eMergeModeSpecifyMinIntercharacterGap = 0x2	Character fragments with a horizontal gap between them may be merged to form characters, where any two fragments with a gap less than the specified minimum intercharacter gap will be merged.
eMergeModeSpecifyGaps = 0x4	Character fragments with a horizontal gap between them may be merged to form characters, with the decision to merge two fragments based on both the specified minimum intercharacter gap and the specified maximum intracharacter gap.
kDefaultMergeMode = *eMergeModeRequireOverlap*	The default is *eMergeModeRequireOverlap*.

AnalysisMode `enum AnalysisMode;`

This enumeration defines the type of analysis to perform to determine the optimal character segmentation.

Value	Meaning
eAnalysisModeMinimal = 0x1	Perform minimal segmentation. This mode performs only straightforward segmentation.
eAnalysisModeStandard = 0x2	Perform standard segmentation, which consists of straightforward segmentation followed by additional analysis to determine the optimal segmentation using the entire line of characters rather than just treating each character individually.
kDefaultAnalysisMode = *eAnalysisModeStandard*	The default mode for character segmentation analysis.

Public Member Functions

reset `void reset();`

Resets all parameters to default values.

Notes

See individual getters for default values.

polarity

```
ccOCDefs::Polarity polarity() const;
void polarity(ccOCDefs::Polarity p);
```

- `ccOCDefs::Polarity polarity() const;`

  Gets the polarity of the characters in the input image.

- `void polarity(ccOCDefs::Polarity p);`

  Sets the polarity of the characters in the input image.

  If the value is *ccOCDefs::eUnknown*, the polarity is automatically determined.

  The default value is *ccOCDefs::eUnknown*.

Parameters

p The polarity.

Throws

ccOCRDefs::BadParams

p is not a valid enum value.

Notes

Stage: Refine line, Normalize

angleHalfRange

```
ccDegree angleHalfRange() const;

void angleHalfRange(const ccDegree& a);
```

- `ccDegree angleHalfRange() const;`

Gets half of the angle search range.

Throws

ccOCRDefs::BadParams

a < 0 degrees or *a* > 180 degrees.

- `void angleHalfRange(const ccDegree& a);`

Sets half of the angle search range.

Parameters

a Half of the angle search range.

Throws

ccOCRDefs::BadParams

a < 0 degrees or *a* > 180 degrees.

Notes

The line angle search range is centered on the *xRotation* of the affine rectangle used as the ROI for the OCR Segmenter tool. In other words, the full search range is [*xRotation* - *angleHalfRange*, *xRotation* + *angleHalfRange*].

Increasing *angleHalfRange* increases the OCR Segmenter tool's run time.

Setting *angleHalfRange* to 0 effectively disables angle search.

Stage: Refine line

The default value is 0 degrees.

skewHalfRange

```
ccDegree skewHalfRange() const;

void skewHalfRange(const ccDegree& s);
```

- `ccDegree skewHalfRange() const;`

  Gets half of the skew search range.

  Throws

  ccOCRDefs::BadParams
  s < 0 degrees or *s* >= 90 degrees.

- `void skewHalfRange(const ccDegree& s);`

  Sets half of the skew search range.

  Parameters

  s Half of the skew range.

  Throws

  ccOCRDefs::BadParams
  s < 0 degrees or *s* >= 90 degrees.

  Notes

  The line skew search range is centered on the skew of the affine rectangle used as the ROI for the OCR Segmenter tool. In other words, the full search range is [*skew* - *skewHalfRange*, *skew* + *skewHalfRange*].

  Increasing *skewHalfRange* increases the OCR Segmenter tool's run time.

  Setting *skewHalfRange* to 0 effectively disables skew search.

  Stage: Refine line

  The default value is 0 degrees.

normalizationMode

```
NormalizationMode normalizationMode() const;

void normalizationMode(NormalizationMode m);
```

- `NormalizationMode normalizationMode() const;`

  Gets the method used to normalize the input image.

- `void normalizationMode(NormalizationMode m);`

  Sets the method used to normalize the input image.

  Parameters

  m The method.

  Throws

  ccOCRDefs::BadParams

  m is not a valid enum value.

  The default value is *ccOCCharSegmentRunParams::kDefaultNormalizationMode*.

  Notes

  Stage: Normalize

useStrokeWidthFilter

```
bool useStrokeWidthFilter() const;

void useStrokeWidthFilter(bool u);
```

- `bool useStrokeWidthFilter() const;`

  Gets whether to remove from the normalized image everything that does not appear to have the same stroke width as the rest of the image.

- `void useStrokeWidthFilter(bool u);`

  Sets whether to remove from the normalized image everything that does not appear to have the same stroke width as the rest of the image.

  This can be useful if, for example, characters appear to be connected to each other by thin noise streaks. However, using the stroke width filter might incorrectly remove real characters if the stroke widths are inconsistent.

  The default value is true.

  Parameters

  u Whether to use stroke width filter.

  Notes

  Stage: Normalize

foregroundThresholdFrac

```
double foregroundThresholdFrac() const;
void foregroundThresholdFrac(double t);
```

- `double foregroundThresholdFrac() const;`

  Gets a modifier in the range [0, 1] that is used to compute the binarization threshold, in the normalized image, that binarizes between foreground and background.

  Throws

  ccOCRDefs::BadParams
  t < 0 or *t* > 1.

- `void foregroundThresholdFrac(double t);`

  Sets a modifier in the range [0, 1] that is used to compute the binarization threshold, in the normalized image, that binarizes between foreground and background.

  Parameters

  t The modifier used to compute the threshold.

  Throws

  ccOCRDefs::BadParams
  t < 0 or *t* > 1.

  - When the input character polarity is *ccOCDefs::eLightOnDark*:

    threshold = round(max((1 - *foregroundThresholdFrac*) * 255, 1))

    invert = false

    where *threshold* and *invert* are used in the same sense as in the Blob tool. (See the documentation for the Blob tool and <*ch_cvl/blobtool.h*>)

    A value of zero results in a binarization threshold value of 255, indicating that only the pixels with the value of 255 (considered most certain to be foreground) should be treated as foreground. A value of one gives a binarization threshold value of 1, indicating that all pixels should be treated as foreground except that those with the value of 0 (considered most certain to be background) should be treated as background.

  - When the input character polarity is *ccOCDefs::eDarkOnLight*:

    threshold = round(max(*foregroundThresholdFrac* * 255, 1))

    invert = true

where *threshold* and *invert* are used in the same sense as in the Blob tool. (See the documentation for the Blob tool and <*ch_cvl/blobtool.h*>)

A value of zero results in a binarization threshold value of 1, indicating that only the pixels with the value of 0 (considered most certain to be foreground) should be treated as foreground. A value of one gives a binarization threshold value of 255, indicating that all pixels should be treated as foreground except that those with the value of 255 (considered most certain to be background) should be treated as background.

In summary, a value of zero indicates that only the pixels considered most certain to be foreground should be treated as foreground, and a value of one indicates that all pixels should be treated as foreground except for those considered most certain to be background.

Notes

As shown by the formulas above, the fraction refers to the greylevel range of the input image type (for example, [0, 255] for an 8-bit greyscale image), and does not refer to an area fraction of the image. In particular, the fraction does not correspond to *threshPercent* in **ccBlobRunParams::setSegmentationHardThresh()** [percent overload]; see *ch_cvl/blobtool.h*.

Stage: Binarize

The default value is 0.5.

characterFragmentMaxDistanceToMainLine

```
double characterFragmentMaxDistanceToMainLine() const;
void characterFragmentMaxDistanceToMainLine(double t);
```

- `double characterFragmentMaxDistanceToMainLine() const;`

  Gets a modifier that is the maximum distance a fragment can have outside the main line of characters as percentage of estimated line height.

- `void characterFragmentMaxDistanceToMainLine(double t);`

  Sets a modifier that is the maximum distance a fragment can have outside the main line of characters as percentage of estimated line height.

  The default value is 0.

  Parameters

t	The modifier to be set.

Notes
Stage: Fragment

ignoreBorderFragments

```
bool ignoreBorderFragments() const;
void ignoreBorderFragments(bool ignore);
```

- `bool ignoreBorderFragments() const;`

  Gets whether to completely ignore any fragments that touch any border of the ROI.

- `void ignoreBorderFragments(bool ignore);`

  Sets whether to completely ignore any fragments that touch any border of the ROI.

  Ignoring such fragments can be useful for excluding non-text features such as the edges of labels that might be included within the ROI.

  The default value is false.

  Parameters

  ignore — Whether to completely ignore any fragments that touch any border of the ROI.

  Notes

  Stage: Fragment

characterFragmentMinNumPels

```
c_Int32 characterFragmentMinNumPels() const;
void characterFragmentMinNumPels(c_Int32 n);
```

- `c_Int32 characterFragmentMinNumPels() const;`

  Gets the minimum number of foreground (that is, text) pixels that a character fragment must have in order to be considered for possible inclusion in a character.

  Throws

  ccOCRDefs::BadParams
  $n < 1$.

- `void characterFragmentMinNumPels(c_Int32 n);`

  Sets the minimum number of foreground (that is, text) pixels that a character fragment must have in order to be considered for possible inclusion in a character.

  A character fragment is a blob in the binarized image. Character fragments that contain fewer foreground pixels than this value are completely ignored for all further processing, as though that fragment had never been detected.

  The default value is 15.

  Parameters

  n The minimum number of foreground.

  Throws

  ccOCRDefs::BadParams
  n < 1.

  Notes

  Stage: Fragment

characterFragmentContrastThreshold

```
double characterFragmentContrastThreshold() const;

void characterFragmentContrastThreshold(double c);
```

- `double characterFragmentContrastThreshold() const;`

  Gets the minimum amount of contrast (in normalized image greylevels) that a fragment must have, relative to the binarization threshold, in order to be considered for possible inclusion in a character.

- `void characterFragmentContrastThreshold(double c);`

  Sets the minimum amount of contrast (in normalized image greylevels) that a fragment must have, relative to the binarization threshold, in order to be considered for possible inclusion in a character.

  Parameters

  c The minimum amount of contrast to be set.

  See the comments for **foregroundThresholdFrac()** for the value of the binarization threshold.

  Any character fragment with a contrast lower than this value is completely ignored for all further processing, as though that fragment had never been detected.

The default value is 30.

Throws

ccOCRDefs::BadParams
c is less than 0.

Notes

Stage: Fragment

characterFragmentMergeMode

```
CharacterFragmentMergeMode characterFragmentMergeMode()
 const;

void characterFragmentMergeMode(
 CharacterFragmentMergeMode m);
```

- `CharacterFragmentMergeMode characterFragmentMergeMode()
 const;`

  Gets the mode used to determine whether to merge two fragments into one character during the Group stage.

- `void characterFragmentMergeMode(
 CharacterFragmentMergeMode m);`

  Sets the mode used to determine whether to merge two fragments into one character during the Group stage.

  Parameters

  m The mode to be set.

Mode values are summarized in the following table.

Value	Meaning
eMergeModeRequireOverlap	Character fragments must overlap horizontally by at least one pixel to be merged. The amount of overlap required is specified by *characterFragmentMinXOverlap*.
eMergeModeSpecifyMinIntercharacterGap	Character fragments with a horizontal gap between them may be merged to form characters, where any two fragments with a gap less than **minIntercharacterGap()** will be merged.
eMergeModeSpecifyGaps	Character fragments with a horizontal gap between them may be merged to form characters, with the decision to merge two fragments based on both **minIntercharacterGap()** and **maxIntracharacterGap()**.

Notes

Using *eMergeModeSpecifyMinIntercharacterGap* is equivalent to using *eMergeModeSpecifyGaps* with *maxIntracharacterGap* = *minIntercharacterGap* - 1.

Stage: Group, Analyze.

The default value is *kDefaultMergeMode.*

characterFragmentMinXOverlap

```
double characterFragmentMinXOverlap() const;

void characterFragmentMinXOverlap(double x);
```

- `double characterFragmentMinXOverlap() const;`

Gets the minimum fraction by which two character fragments must overlap each other in the x-direction for the two fragments to be considered part of the same character.

Throws

ccOCRDefs::BadParams

$x < 0$ or $x > 1$.

- `void characterFragmentMinXOverlap(double x);`

  Sets the minimum fraction by which two character fragments must overlap each other in the x-direction for the two fragments to be considered part of the same character.

  The default value is 0.0.

  Parameters

  x The minimum fraction.

  Throws

  ccOCRDefs::BadParams
  x < 0 or *x* > 1.

  Notes

  This value is used only if *characterFragmentMergeMode* is *eMergeModeRequireOverlap*.

  Stage: Group

characterMinNumPels

```
c_Int32 characterMinNumPels() const;

void characterMinNumPels(c_Int32 n);
```

- `c_Int32 characterMinNumPels() const;`

  Gets the minimum number of foreground (that is, text) pixels that a character must have in order to be reported.

  Throws

  ccOCRDefs::BadParams
  n < 1.

- `void characterMinNumPels(c_Int32 n);`

  Sets the minimum number of foreground (that is, text) pixels that a character must have in order to be reported.

  The default value is 30.

  Parameters

  n The minimum number of foreground pixels.

  Throws

  ccOCRDefs::BadParams
  n < 1.

Notes
Stage: Group, Analyze

characterMinWidth

```
c_Int32 characterMinWidth() const;

void characterMinWidth(c_Int32 w);
```

- `c_Int32 characterMinWidth() const;`

  Gets the minimum width of a character's mark rectangle, in pixels, that a character must have to be reported.

  Throws
  ccOCRDefs::BadParams
  w < 1.

- `void characterMinWidth(c_Int32 w);`

  Sets the minimum width of a character's mark rectangle, in pixels, that a character must have to be reported.

  The default value is 3.

  Parameters
  w The minimum width of a character's mark rectangle.

  Throws
  ccOCRDefs::BadParams
  w < 1.

  Notes
  Stage: Group, Analyze

useCharacterMaxWidth

```
bool useCharacterMaxWidth() const;

void useCharacterMaxWidth(bool u);
```

- `bool useCharacterMaxWidth() const;`

  Gets whether to use *characterMaxWidth* to split wide characters.

- `void useCharacterMaxWidth(bool u);`

  Get/set whether to use *characterMaxWidth* to split wide characters.

  The default value is false.

  Parameters

  u Whether to use *characterMaxWidth*.

  Notes

  Stage: Group, Analyze

characterMaxWidth

```
c_Int32 characterMaxWidth() const;
void characterMaxWidth(c_Int32 m);
```

- `c_Int32 characterMaxWidth() const;`

  Gets the maximum allowable width of a character's mark rectangle in pixels.

  Throws

  ccOCRDefs::BadParams
  m < 1.

- `void characterMaxWidth(c_Int32 m);`

  Sets the maximum allowable width of a character's mark rectangle in pixels.

  A character wider than this value is split into pieces that are not too wide. This value is used only if *useCharacterMaxWidth* is true. The technique used to split the character into pieces depends on the value of *widthType*. If *widthType* is *eFontCharWidthTypeFixed*, the OCR Segmenter tool tries to break the character into pieces of approximately equal width. If *widthType* is *eFontCharWidthTypeVariable* or *eFontCharWidthTypeUnknown*, the OCR Segmenter tool tries to break the character into pieces that are not required to be approximately the same width.

  Parameters

  m The maximum allowable width of a character's mark rectangle.

Notes

The OCR Segmenter tool may sometimes choose to return characters slightly wider than this value if it cannot find a reasonable split.

characterMinAspect is another way of specifying a maximum character width.

Stage: Group, Analyze

The default value is 100.

Throws

ccOCRDefs::BadParams
m < 1.

characterMinHeight

```
c_Int32 characterMinHeight() const;

void characterMinHeight(c_Int32 h);
```

- `c_Int32 characterMinHeight() const;`

  Gets the minimum height of a character's mark rectangle, in pixels, that a character must have to be reported.

  Throws

  ccOCRDefs::BadParams
  h < 1.

- `void characterMinHeight(c_Int32 h);`

  Sets the minimum height of a character's mark rectangle, in pixels, that a character must have to be reported.

  The default value is 3.

  Parameters

  h The minimum height of a character's mark rectangle.

  Throws

  ccOCRDefs::BadParams
  h < 1.

  Notes

  Stage: Group, Analyze

useCharacterMaxHeight

```
bool useCharacterMaxHeight() const;

void useCharacterMaxHeight(bool u);
```

- `bool useCharacterMaxHeight() const;`

  Gets whether to use *characterMaxHeight* to limit the maximum height of a character and/or the line of characters.

- `void useCharacterMaxHeight(bool u);`

  Sets whether to use *characterMaxHeight* to limit the maximum height of a character and/or the line of characters.

  The default value is false.

  Parameters

  u Whether to use *characterMaxHeight*.

  Notes

  Stage: Refine line, Group, Analyze

characterMaxHeight

```
c_Int32 characterMaxHeight() const;

void characterMaxHeight(c_Int32 m);
```

- `c_Int32 characterMaxHeight() const;`

  Gets the maximum allowable height of a character's mark rectangle, in pixels.

  Throws

  ccOCRDefs::BadParams
  g < 1.

- `void characterMaxHeight(c_Int32 m);`

  Sets the maximum allowable height of a character's mark rectangle, in pixels.

  This value is used in two ways. First, this value is used when finding the line as a whole; for example, to reject vertically adjacent noise and/or other lines of vertically adjacent characters. Second, an individual character whose height exceeds this value will be trimmed to meet this height. This value is used only if *useCharacterMaxHeight* is true.

Parameters

m The maximum allowable height of a character's mark rectangle.

Notes

A tall character may be trimmed to a height below *characterMaxHeight* if the OCR Segmenter tool chooses so.

The default value is 100.

Throws

ccOCRDefs::BadParams

g < 1.

Notes

Stage: Refine line, Group, Analyze

minIntercharacterGap

```
c_Int32 minIntercharacterGap() const;

void minIntercharacterGap(c_Int32 g);
```

- `c_Int32 minIntercharacterGap() const;`

  Gets the minimum gap size, in pixels, that can occur between two characters.

  Throws

  ccOCRDefs::BadParams

  g < 0.

- `void minIntercharacterGap(c_Int32 g);`

  Sets the minimum gap size, in pixels, that can occur between two characters.

  If the gap between two fragments is smaller than this, then they must be considered to be part of the same character, unless the combined character would be too wide (as specified by *characterMaxWidth* and/or *characterMinAspect*). The gap is measured from the right edge of the mark rectangle of one character to the left edge of the mark rectangle of the next character.

  This value is used only if *characterFragmentMergeMode* is *eMergeModeSpecifyMinIntercharacterGap* or *eMergeModeSpecifyGaps*.

  The default value is 1.

  Parameters

  g The minimum gap size.

Throws

ccOCRDefs::BadParams
g < 0.

Notes

Stage: Group, Analyze

maxIntracharacterGap

```
c_Int32 maxIntracharacterGap() const;

void maxIntracharacterGap(c_Int32 g);
```

- `c_Int32 maxIntracharacterGap() const;`

  Gets the maximum gap size, in pixels, that can occur within a single character, even for damaged characters.

- `void maxIntracharacterGap(c_Int32 g);`

  Sets the maximum gap size, in pixels, that can occur within a single character, even for damaged characters.

  An intracharacter gap might occur, for example, between successive columns of dots in dot matrix print, or between two pieces of a solid character that was damaged by a scratch. Any gap larger than this value is always interpreted as a break between two separate characters, whereas gaps less than or equal to this value may be interpreted either as a break between two separate characters or as a gap within a single character.

  This value is used only if *characterFragmentMergeMode* is *eMergeModeSpecifyGaps*.

  The default value is 0.

  Parameters

  g Maximum gap size.

  Throws

  ccOCRDefs::BadParams
  g < 0.

  Notes

  Stage: Group, Analyze

useCharacterMinAspect

```
bool useCharacterMinAspect() const;
void useCharacterMinAspect(bool u);
```

- `bool useCharacterMinAspect() const;`

  Gets whether to use *characterMinAspect* to split wide characters.

- `void useCharacterMinAspect(bool u);`

  Sets whether to use *characterMinAspect* to split wide characters.

  The default value is true.

  Parameters

  u Whether to use *characterMinAspect*.

  Notes

  Stage: Group, Analyze

characterMinAspect

```
double characterMinAspect() const;
void characterMinAspect(double m);
```

- `double characterMinAspect() const;`

  Gets the minimum allowable aspect of a character, where the aspect is defined as the height of the entire line of characters divided by the width of the character's mark rectangle.

  Throws

  ccOCRDefs::BadParams
  m < 0.

- `void characterMinAspect(double m);`

  Sets the minimum allowable aspect of a character, where the aspect is defined as the height of the entire line of characters divided by the width of the character's mark rectangle.

  A character whose aspect is smaller than this value (that is, whose width is too large) is split into pieces that are not too wide. This value is used only if *useCharacterMinAspect* is true. The technique used to split the character into pieces depends on the value of *widthType*. If *widthType* is *eFontCharWidthTypeFixed*, the OCR Segmenter tool tries to break the character into pieces of approximately equal width. If *widthType* is *eFontCharWidthTypeVariable* or *eFontCharWidthTypeUnknown*, the OCR Segmenter tool tries to break the character into pieces that are not required to be approximately the same width.

  Parameters

  m The minimum allowable aspect of a character.

  Notes

  The segmenter may sometimes choose to return characters slightly wider than the width indicated by this value if it cannot find a reasonable split.

  characterMaxWidth is another way of specifying a maximum character width.

  This definition of aspect is more convenient than simply using the height of the character's mark rectangle divided by the width of the character's mark rectangle; for example, so that allowing a dash "–" does not require using a tiny *characterMinAspect* value.

  The default value is 0.8.

  Throws

  ccOCRDefs::BadParams
  m < 0.

  Notes

  Stage: Group, Analyze

widthType

```
ccOCRDefs::FontCharWidthType widthType() const;
void widthType(ccOCRDefs::FontCharWidthType w);
```

- `ccOCRDefs::FontCharWidthType widthType() const;`

  Gets how the widths of characters in the font are expected to vary.

  Throws

ccOCRDefs::BadParams
w is not a valid enum value.

- `void widthType(ccOCRDefs::FontCharWidthType w);`

Sets how the widths of characters in the font are expected to vary.

Notes

The character width is the width of the mark rectangle (for example, the bounding box of the ink), not the cell rectangle (which would typically include padding around the mark rectangle).

Stage: Group, Analyze

The default value is *ccOCRDefs::kDefaultFontCharWidthType*.

Parameters

w How the widths of characters in the font are expected to vary.

Throws

ccOCRDefs::BadParams
w is not a valid enum value.

analysisMode

```
AnalysisMode analysisMode() const;
void analysisMode(AnalysisMode a);
```

- `AnalysisMode analysisMode() const;`

Gets whether to perform *minimal analysis* or *standard analysis*.

Throws

ccOCRDefs::BadParams
a is not a valid enum value.

- `void analysisMode(AnalysisMode a);`

Sets whether to perform *minimal analysis* or *standard analysis*.

Minimal analysis performs straightforward segmentation according to the previous parameters. Standard analysis performs an analysis of the line as a whole (including, for example, character spacing) to determine the optimal segmentation.

The default value is *ccOCRDefs::kDefaultAnalysisMode*.

Parameters

a Whether to perform *minimal analysis* or *standard analysis*.

Throws
ccOCRDefs::BadParams
a is not a valid enum value.

Notes
Stage: Analyze

pitchMetric

```
ccOCRDefs::FontPitchMetric pitchMetric() const;
void pitchMetric(ccOCRDefs::FontPitchMetric m);
```

- `ccOCRDefs::FontPitchMetric pitchMetric() const;`

Gets the metric used to specify the spacing of characters.

Throws
ccOCRDefs::BadParams
m is not a valid enum value.

- `void pitchMetric(ccOCRDefs::FontPitchMetric m);`

Sets the metric used to specify the spacing of characters.

Notes
Pitch is the distance between (approximately) corresponding points on adjacent characters and not the distance from the end of one character to the beginning of the next character (which is called the “intercharacter gap”).

Also note that specifying the pitch metric does not necessarily imply that the measured pitch values are expected to be constant.

Stage: Analyze

Parameters
m The metric to specify the spacing of characters.

Notes
This parameter is not used if *analysisMode* is *eAnalysisModeMinimal*.

The default value is *ccOCRDefs::kDefaultFontPitchMetric*.

Throws
ccOCRDefs::BadParams
m is not a valid enum value.

pitchType

```
ccOCRDefs::FontPitchType pitchType() const;
void pitchType(ccOCRDefs::FontPitchType t);
```

- `ccOCRDefs::FontPitchType pitchType() const;`

  Gets how individual pitch values are expected to vary; the pitch values are measured as specified by the pitch metric.

  Throws

  ccOCRDefs::BadParams
  t is not a valid enum value.

- `void pitchType(ccOCRDefs::FontPitchType t);`

  Sets how individual pitch values are expected to vary; the pitch values are measured as specified by the pitch metric.

  Parameters

  t How individual pitch values are expected to vary.

  Notes

  This parameter is not used if *analysisMode* is *eAnalysisModeMinimal*.

  Stage: Analyze

  The default value is *ccOCRDefs::kDefaultFontPitchType*.

  Throws

  ccOCRDefs::BadParams
  t is not a valid enum value.

minPitch

```
c_Int32 minPitch() const;
void minPitch(c_Int32 m);
```

- `c_Int32 minPitch() const;`

  Gets the minimum pitch, in pixels, that can occur between two characters, where the pitch is computed as specified by the pitch metric.

  Throws

  ccOCRDefs::BadParams
  $m < 0$.

- `void minPitch(c_Int32 m);`

  Sets the minimum pitch, in pixels, that can occur between two characters, where the pitch is computed as specified by the pitch metric.

  If the pitch between two fragments is smaller than this, then they must be considered to be part of the same character, unless the combined character would be too wide (as specified by *characterMaxWidth* and/or *characterMinAspect*).

  Parameters

  m The minimum pitch.

  Notes

  This parameter is not used if *analysisMode* is *eAnalysisModeMinimal*.

  Stage: Analyze

  The default value is 0.

  Throws

  ccOCRDefs::BadParams
  m < 0.

spaceParams

```
const ccOCCharSegmentSpaceParams& spaceParams() const;

void spaceParams(
  const ccOCCharSegmentSpaceParams& params);
```

- `const ccOCCharSegmentSpaceParams& spaceParams() const;`

  Gets parameters to control whether and how to insert space characters.

- `void spaceParams(`
  `const ccOCCharSegmentSpaceParams& params);`

  Sets parameters to control whether and how to insert space characters.

  Parameters

  params Parameters to control whether and how to insert space characters.

  Notes

  Stage: Analyze

Operators

operator==

```
bool operator==(const ccOCCharSegmentRunParams& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentRunParams& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCCharSegmentRunParams

ccOCCharSegmentSpaceParams

```
#include <ch_cvl/ocsegmnt.h>

class ccOCCharSegmentSpaceParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains parameters to control how space characters are handled by the OCR Segmenter tool.

Constructors/Destructors

ccOCCharSegmentSpaceParams

```
ccOCCharSegmentSpaceParams();
```

Constructor.

Notes

See individual getters for default values.

Compiler-generated copy constructor, assignment operator, and destructor are used.

Enumerations

SpaceInsertMode

```
enum SpaceInsertMode;
```

This enumeration defines how to handle insertion of space characters into gaps between other characters.

Value	Meaning
eSpaceInsertModeNone = 0	Never insert a space character, no matter how large an intercharacter gap is.
eSpaceInsertModeSingle = 1	Insert at most one space character per intercharacter gap, no matter how large the gap is.

Value	Meaning
eSpaceInsertModeMultiple = 2	Insert a number of space characters (zero or more) per intercharacter gap based on how large the gap is.
kDefaultSpaceInsertMode = *eSpaceInsertModeNone*	The default mode for inserting space characters.

SpaceScoreMode

```
enum SpaceScoreMode;
```

This enumeration defines how to compute the score of a space character.

Value	Meaning
eSpaceScoreModeOne = 0	Space characters always get a score of 1.0.
eSpaceScoreModeClutter = 1	The score of a space character is based on the fraction of pixels that are background. A space character that consists entirely of background receives a score of 1.0.
kDefaultSpaceScoreMode = *eSpaceScoreModeClutter*	The default mode for scoring a space character.

Public Member Functions

reset

```
void reset();
```

Resets all parameters to default values.

Notes

See individual getters for default values.

spaceInsertMode

```
SpaceInsertMode spaceInsertMode() const;

void spaceInsertMode(SpaceInsertMode mode);
```

- `SpaceInsertMode spaceInsertMode() const;`

  Gets the insert mode, which specifies how to handle insertion of space characters into gaps between other characters.

- `void spaceInsertMode(SpaceInsertMode mode);`

  Sets the insert mode, which specifies how to handle insertion of space characters into gaps between other characters.

  Parameters
  mode The insert mode.

  Throws
  ccOCRDefs::BadParams
  mode is not a valid enum value.

  The default value is *kDefaultSpaceInsertMode*.

spaceScoreMode

```
SpaceScoreMode spaceScoreMode() const;
void spaceScoreMode(SpaceScoreMode mode);
```

- `SpaceScoreMode spaceScoreMode() const;`

  Gets the score mode, which specifies how to handle scoring of space characters.

- `void spaceScoreMode(SpaceScoreMode mode);`

  Sets the score mode, which specifies how to handle scoring of space characters.

  Parameters
  mode The score mode.

  Throws
  ccOCRDefs::BadParams
  mode is not a valid enum value.

  The default value is *kDefaultSpaceScoreMode*.

spaceMinWidth

```
c_Int32 spaceMinWidth() const;
void spaceMinWidth(c_Int32 w);
```

- `c_Int32 spaceMinWidth() const;`

  Gets the minimum width of a space character, in pixels.

- `void spaceMinWidth(c_Int32 w);`

  Sets the minimum width of a space character, in pixels.

  Parameters

  w The minimum width of a space character.

  Throws

  ccOCRDefs::BadParams
  The width is < 1

  The default value is 10.

spaceMaxWidth

```
c_Int32 spaceMaxWidth() const;
void spaceMaxWidth(c_Int32 w);
```

- `c_Int32 spaceMaxWidth() const;`

  Gets the maximum width of a space character, in pixels.

- `void spaceMaxWidth(c_Int32 w);`

  Sets the maximum width of a space character, in pixels.

  Parameters

  w The maximum width of a space character.

  Throws

  ccOCRDefs::BadParams
  The width is < 1

  The default value is 100.

Operators

operator==

```
bool operator==(const ccOCCharSegmentSpaceParams& rhs)
const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCCharSegmentSpaceParams& rhs)
  const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for inequality.

ccOCCharSegmentSpaceParams

ccOCFont

```
#include <ch_cvl/ocfont.h>

class ccOCFont;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCFont** class represents a set of characters, including their character codes, images, and other metadata, primarily for use with OCR and OCV and also more generally to represent a font.

Constructors/Destructors

The default constructor, copy constructor, assignment operator, and destructor are used.

Public Member Functions

name32

```
const ccCvlString32& name32() const;

void name32(const ccCvlString32& n,
  TCHAR replacementIfUnrepresentableCharacterCode =
  _T('#'));
```

- ```
  const ccCvlString32& name32() const;
  ```

  Gets the name of this font, in Unicode UTF-32.

- ```
  void name32(const ccCvlString32& n,
    TCHAR replacementIfUnrepresentableCharacterCode =
    _T('#'));
  ```

  Sets the name of this font, in Unicode UTF-32.

  For the setter, if the name contains any 32-bit character codes that are not representable as TCHAR, those character codes are replaced by the specified replacement value in **name()**, but is kept in **name32()**.

Parameters

n The name of this font.

replacementIfUnrepresentableCharacterCode
Replacement value.

Notes

name32() and **name()** are always kept in sync, so that setting one also changes the other one appropriately.

The default value is an empty string.

name

```
const ccCvlString& name() const;

void name(const ccCvlString& n);
```

- `const ccCvlString& name() const;`

Gets the name of this font.

Throws

If any character in the underlying UTF-32 representation of the name cannot be represented as a TCHAR, it is replaced by a different value that was specified when the **name32()** setter was called.

- `void name(const ccCvlString& n);`

Sets the name of this font.

Parameters

n The name of this font.

Notes

name32() and **name()** are always kept in sync, so that setting one also changes the other one appropriately.

The default value is an empty string.

characters

```
const cmStd vector<ccOCChar>& characters() const;

void characters(
  const cmStd vector<ccOCChar>& c,
  bool makeUniqueInstanceKeys = false);
```

- `const cmStd vector<ccOCChar>& characters() const;`

  Gets the characters in this font.

- ```
  void characters(
    const cmStd vector<ccOCChar>& c,
    bool makeUniqueInstanceKeys = false);
  ```

  Sets the characters in this font.

  If *makeUniqueInstanceKeys* is true, then characters are all assigned unique keys; specifically, later characters in the set are reassigned unique instance values.

  Parameters

  c The characters in this font.

  makeUniqueInstanceKeys
  Whether characters are all assigned unique keys.

  Throws

  ccOCDefs::SameKey
  Two or more characters have the same key and *makeUniqueInstanceKeys* is false.

  ccOCDefs::SameKey
  Any of the characters' keys' instances are *ccOCCharKey::eUnspecified* and *makeUniqueInstanceKeys* is false.

  The default value is an empty vector.

hasCharacter

```
bool hasCharacter(const ccOCCharKey& key) const;
```

Returns true if a character with the specified key exists in this font.

Parameters

key The specified character key.

character

```
const ccOCChar& character(const ccOCCharKey& key) const;
```

Returns the character with the specified key.
```

Parameters
key The specified character key.

Throws
ccOCDefs::BadKey
No character has the specified character key.

add

```
void add(const ccOCChar& character);
```

Adds the character to the font.

Parameters
character The character to be added.

Throws
ccOCDefs::SameKey
Two or more characters have the same key, or
the character's key's instance is *ccOCCharKey::eUnspecified*.

remove

```
void remove(const ccOCCharKey& key);
void remove(const cmStd vector<ccOCCharKey>& keys);
```

- `void remove(const ccOCCharKey& key);`

Removes the character with the specified key from the font.

Parameters
key The specified character key.

Throws
ccOCDefs::BadKey
No character has the specified key.

- `void remove(const cmStd vector<ccOCCharKey>& keys);`

Removes the characters with the specified keys from the font.

Parameters
keys The specified character keys.

Throws
ccOCDefs::BadKey
No character has each specified key.

Notes

This function has no effect if **keys.size()** == 0.

removeAll

```
void removeAll();
```

Removes all characters from the font.

leading

```
cc2Vect leading() const;
void leading(const cc2Vect&);
```

- `cc2Vect leading() const;`

  Gets the leading for this font.

- `void leading(const cc2Vect&);`

  Sets the leading for this font.

  The default value is **cc2Vect(***0., 0.***)**

  Parameters

  cc2Vect The leading for this font.

encloseCellRect

```
ccRect encloseCellRect() const;
```

Gets the enclosing cell rectangle for the font, which encloses all of the individual character cell rectangles.

Notes

This function only considers the *eCellRectClient rectangles* for which *isRectSpecified* is true.

If no characters specify the *eCellRectClient* rectangles, this function returns a default constructed **ccRect**.

encloseMarkRect

```
ccRect encloseMarkRect() const;
```

Gets the enclosing mark rectangle for the font, which encloses all of the individual character mark rectangles.

Notes

This function only considers the *eMarkRectClient* rectangles for which *isRectSpecified* is true.

If no characters specify the *eMarkRectClient* rectangles, this function returns a default constructed **ccRect**.

assignImageFont

```
void assignImageFont(const ccImageFont& imageFont);
```

Resets this font to be essentially identical to the image font.

Parameters

imageFont The image font.

save

```
void save(const ccCvlString& filename) const;
```

Saves the font to a file with the given filename.

Parameters

filename The filename.

Notes

The standard file extension for use with **ccOCFont** font files is ".ocr".

load

```
void load(const ccCvlString& filename);
```

Loads the font from the file with the given filename; the file may be in ".ocr" format or in the older ".ocf" or ".ocm" formats.

The font is unchanged if the load fails.

Parameters

filename The filename.

Throws

ccOCDefs::BadFileFormat
The file does not contain a font in a supported format.

Notes

It can also throw other exceptions (for example, *ccArchive::Eof*, *ccArchive::UnknownVersion*, and so on). See file *ch_cvl/archive.h*.

tryLoad

```
bool tryLoad(const ccCvlString& filename);
```

Tries to load the font from the file with the given filename; the file may be in ".ocr" format or in the older ".ocf" or ".ocm" formats.

It returns true if successful or false if the file was in a bad format. Does not throw *ccOCDefs::BadFileFormat* if the file is in a bad format.

The font is unchanged if the load fails.

Parameters

filename The filename.

makeUniqueInstanceKey

```
ccOCCharKey makeUniqueInstanceKey(const ccOCCharKey& key)
const;
```

Returns a unique key to be used for a new instance of the given key, with the same Unicode character value.

Parameters

key The given key.

Operators

operator==

```
bool operator==(const ccOCFont& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCFont& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

ccOCFont

ccOCKeySet

```
#include <ch_cvl/oc.h>

class ccOCKeySet;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class comprises the set of keys for characters from one alphabet that may be used at a particular position within a **ccOCLine** object. It also maintains a set of indices for multiple characters that are allowed to appear at a line position. The OCV tool uses these indices to determine the characters to compare with the run-time character image found at a line position.

The OC Key Set class contains information about the keys of character models that is relevant to a particular position within a **ccOCLine** object. It contains the following information:

Keys

The set of unique keys for characters that may be used at a position. For example, if only numbers are possible for a position, this set would contain all of the number keys and none no letter keys.

Current keys

A subset of keys (represented as indices into keys) for the characters of which exactly one is currently expected at the position. That is, any one of the characters represented by the current keys is allowed at the position. Typically, the current keys simply represent character models for multiple versions (appearances) of the same character. In the case that one or more of the current character indices is -1, the current key is by definition unknown. That is, it could be a key for any character in any alphabet, not just the ones listed in the set (in the case of OCV, this would correspond to a wild card character).

Confusion keys overrides

Specified for any subset of keys in the key set. An override for a particular key specifies the set of keys for the characters that are *confusable* with the character for that particular key. If no override is specified for a particular key in the key set, the confusable keys for that key are simply the subset of keys in the alphabet (associated with the OC Line within which the position resides) for which **areConfusable()** is true and that are not part of the current key set.

Constructors/Destructors

ccOCKeySet

```
ccOCKeySet();

ccOCKeySet(const cmStd vector<c_Int32>& theKeys,
  c_Int32 currentKeyIndex = -1);

ccOCKeySet(const cmStd vector<c_Int32>& theKeys,
  const cmStd vector<c_Int32> curKeyIndices);

ccOCKeySet(const ccOCAlphabetPtrh_const& alphabet,
  const cmStd vector<ccCvlString> &charNames,
  const ccCvlString &currentCharName);
```

- `ccOCKeySet();`

  Constructs an empty set of keys and sets the current key index to -1. A current key index of -1 indicates a wildcard for the position. Anything found at the position will pass verification.

- `ccOCKeySet(const cmStd vector<c_Int32>& theKeys, c_Int32 currentKeyIndex = -1);`

  Constructs a key set using the supplied keys and current key index.

  Parameters

  theKeys The keys of character models from one alphabet from which to create this key set.

  currentKeyIndex The index of the key to set as the current key or -1 to specify that the current key corresponds to a wildcard character. Setting *currentKeyIndex* to -1 means that anything found at the position will pass verification.

  Throws

  ccOCDefs::SameKey
  Two or more keys are the same. Keys must be unique.

  ccOCDefs::BadIndex
  The current key index does not exist in the key set and is not -1.

- ```
  ccOCKeySet(const cmStd vector<c_Int32>& theKeys,
    const cmStd vector<c_Int32> curKeyIndices);
  ```

  Constructs a key set using the given keys and a set of current key indices. You can supply multiple versions of a character to be verified at a line position by selecting these from the key set. At run-time, the OCV tool determines which of the current characters is the best match for the found character.

  Parameters

  theKeys The keys of character models from one alphabet from which to create this key set.

  curKeyIndices A set of indices from the *theKeys* for characters that may appear at a line position and for which you want to perform verification.

  If you set an index value to -1, the OCV tool treats the set as a single wildcard character, and therefore any character found at the line position passes verification.

  Throws

  ccOCDefs::SameKey
  Two or more keys are the same. Keys must be unique.

  ccOCDefs::BadIndex
  At least one of the current key indices is not valid or unique, and is not -1.

- ```
  ccOCKeySet(const ccOCAlphabetPtrh_const& alphabet,
    const cmStd vector<ccCvlString> &charNames,
    const ccCvlString &currentCharName);
  ```

  Constructs a key set using the given alphabet, character names, and current character name. All characters from the alphabet with the same name as *currentCharName* are marked as current keys: these may, for example, include multiple versions of a character. At run-time, the OCV tool determines which of the current characters is the best match for the character found at a line position.

  Parameters

  alphabet The alphabet that contains characters from which to create the key set.

  charNames The names of characters in the alphabet to include in the key set.

  currentCharName
  The character name used to determine which members of the key set are selected as current character keys.

Throws

ccOCDefs::SameKey
Two or more character names are the same.

ccOCDefs::BadKey
A character in *charNames* cannot be found in the specified alphabet.

ccOCDefs::BadIndex
The current character is not valid for the specified set of possible character names.

Operators

operator==

```
bool operator==(const ccOCKeySet& other) const;
```

Returns true if this key set is equal to the specified key set.

Parameters

other The key set with which to compare for equality.

operator!=

```
bool operator!=(const ccOCKeySet& other) const;
```

Returns true if this key set is not equal to the specified key set.

Parameters

other The key set with which to compare for inequality.

Public Member Functions

keys

```
void keys(const cmStd vector<c_Int32>& ks);
const cmStd vector<c_Int32>& keys() const;
```

- ```
  void keys(const cmStd vector<c_Int32>& ks);
  ```

Sets the keys for this key set. Any existing confusion override keys are discarded when this function is called.

Parameters

ks The keys of character models from one alphabet.

Throws

ccOCDefs::SameKey
Two or more keys are the same. Keys must be unique.
  ```

ccOCDefs::BadIndex
The current key index does not exist in the key set and is not -1.

- `const cmStd vector<c_Int32>& keys() const;`

  Returns the keys for this key set.

currentKeyIndex

```
void currentKeyIndex(c_Int32 index);

c_Int32 currentKeyIndex() const;
```

- `void currentKeyIndex(c_Int32 index);`

  Sets the index of the current key for the key set (if the set of current key indices has only one element). For more flexibility in setting current keys, use **currentKeyIndices()**.

  The OCV tool uses the current key index to determine the character to compare with the run-time character image found at a line position. A current key index of -1 indicates a wildcard, and anything found at the position will pass verification.

  Parameters

  index The index of the key to set as the current key or -1 to specify that the current key corresponds to a wildcard character.

  Throws

  ccOCDefs::BadIndex
  The supplied key index does not exist in the key set and is not -1.

  ccOCDefs::BadParam
  The set of current key indices has more than one element.

- `c_Int32 currentKeyIndex() const;`

  Returns the index of the current key for the key set (if the set of current key indices has only one element).

  Throws

  ccOCDefs::BadParam
  The set of current key indices has more than one element.

currentKeyIndices

```
void currentKeyIndices(
  const cmStd vector<c_Int32> &indices);

const cmStd vector<c_Int32> &currentKeyIndices() const;
```

- ```
  void currentKeyIndices(
    const cmStd vector<c_Int32> &indices);
  ```

  Sets the indices of the current keys for the key set.

  The OCV tool uses the current key indices to determine the character to compare with the run-time character image found at a line position. To specify a wildcard character for a line position, set one or more of the current key indices to -1. Any character found at the position will pass verification.

  Parameters

  indices The set of character key indices to use as the current keys. If any any index value is -1, the set is treated as a single wildcard character.

  Throws

  ccOCDefs::BadIndex
  A supplied key index is not unique or valid, and it is not -1.

- ```
  const cmStd vector<c_Int32> &currentKeyIndices() const;
  ```

  Returns the indices of the current keys for the key set.

isCurrentWildcard

```
bool isCurrentWildcard() const;
```

Returns true if any of the current key indices is set to -1.

currentKey

```
c_Int32 currentKey() const;
```

Returns the current key if the set of current key indices has only one element.

Throws

ccOCDefs::BadKey
The current key index is set to -1, the wildcard character.

ccOCDefs::BadParams
The set of current key indices has more than one element.

currentKeys

```
cmStd vector<c_Int32> currentKeys() const;
```

Returns the current keys.

Throws

ccOCDefs::BadKey
isCurrentWildcard() returns true.

confusionOverrides

```
void confusionOverrides(c_Int32 key,
 const cmStd vector<c_Int32>& confusionKeys);

const cmStd vector<c_Int32>& confusionOverrides(
 c_Int32 key) const;
```

- ```
  void confusionOverrides(c_Int32 key,
   const cmStd vector<c_Int32>& confusionKeys);
  ```

  Sets the confusion override keys for the specified key.

  If confusion override keys are defined for a particular key, then the OCV tool will use the override keys as the confusable keys for the particular key. If no override keys are defined, then all characters in the current alphabet that have confusion scores above the confusion threshold (and which are not members of the current key set for the character position) are treated as confusable.

  Specifying override keys lets you perform OCR (Optical Character Recognition) using the OCV tool. By specifying which characters are confusable, you can force the tool to check for confusion among the characters defined as part of the current key set. This lets you determine not only that one of the valid characters is present, but which one is present.

  Notes

  Any confusion keys that are not valid in the alphabet associated with the line in which this key is used are ignored. Duplicate confusion keys are counted only once.

  Parameters

  key The key for which the overrides are defined.

  confusionKeys The override keys.

  Throws

  ccOCDefs::BadKey
  key is not a member of this **ccOCKeySet**.
  ```

- `const cmStd vector<c_Int32>& confusionOverrides( c_Int32 key) const;`

  Returns the confusion override keys for the specified key.

  Parameters

  key The key for which to return the override keys.

  Throws

  ccOCDefs::BadKey

  key is not a member of this **ccOCKeySet** or there are no confusion overrides defined for *key*.

removeConfusionOverrides

```
void removeConfusionOverrides(c_Int32 key);
```

Removes all the confusion overrides for the specified key.

Throws

ccOCDefs::BadKey

key is not a member of this **ccOCKeySet** or there are no confusion overrides defined for *key*.

hasConfusionOverrides

```
bool hasConfusionOverrides(c_Int32 key);
```

Returns true if this key has confusion overrides defined for it, false otherwise.

Throws

ccOCDefs::BadKey

key is not a member of this **ccOCKeySet**.

ccOCLine

```
#include <ch_cvl/oc.h>

class ccOCLine : public ccPersistent, public ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class represents a spatial arrangement of characters from one alphabet. A typical line consists of evenly spaced, upright characters as found on a product label, however you can configure arbitrary arrangements of characters by supplying information about the uncertainty in position, angle, and scale of each character. For each line position, this class maintains a set of keys for characters that can appear at the position. An optical verification tool uses the information provided by the **ccOCLine** class to verify characters in a line of text.

Constructors/Destructors

ccOCLine

```
ccOCLine();

ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
  const ccOCAlphabetPtrh_const& alphabet,
  const cc2Rigid& spacing, double charScale = 1.0,
  double transUnc = 0.0,
  const ccRadian& rotUnc = ccRadian(0),
  double scaleUnc = 0.0,
  const ccCvlString& name = cmT(""));

ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
  const ccOCAlphabetPtrh_const& alphabet,
  const cmStd vector<cc2Rigid>& charPoses,
  double charScale = 1.0,
  double transUnc = 0.0,
  const ccRadian & rotUnc = ccRadian(0),
  double scaleUnc = 0.0,
  const ccCvlString& name = cmT(""));

ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
  const ccOCAlphabetPtrh_const& alphabet,
  const cmStd vector<cc2Rigid>& charPoses,
  const cmStd vector<double>& charScales,
```

```
  const cmStd vector<double>& transUncs,
  const cmStd vector<ccRadian>& rotUncs,
  const cmStd vector<double>& scaleUncs,
  const ccCvlString& name = cmT(""));
```

- `ccOCLine();`

  Constructs an empty line with an empty alphabet.

- ```
  ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
    const ccOCAlphabetPtrh_const& alphabet,
    const cc2Rigid& spacing,
    double charScale = 1.0,
    double transUnc = 0.0,
    const ccRadian& rotUnc = ccRadian(0),
    double scaleUnc = 0.0,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line using the specified alphabet and sequence of character key sets. Characters are uniformly spaced with respect to their origins, and the scaling and uncertainty factors apply to all characters in the line.

  Parameters

  keySetSequence A sequence of key sets that indicates which characters can appear at each position in the line. Specify the key sets in line position order.

  alphabet The alphabet to associate with this line. The alphabet must already be compiled.

  spacing The spacing between the origin of each character. This factor is applied to all characters in the line.

  charScale The scaling for all characters. This must be greater than 0.

  transUnc The translation uncertainty for all characters. This must be greater than or equal to 0.

  rotUnc The rotation uncertainty for all characters. This must be greater than or equal to 0.

  scaleUnc The scaling uncertainty for all characters. This must be greater than or equal to 0.

  name The name of this line.
  ```

Notes

For the typical case of a horizontal line of upright characters (x- and y-axes of all characters parallel with the x- and y-axes of the first character in the line), specify a *spacing* value that has only an x-axis translation component.

Throws

ccOCDefs::BadParams

If *charScale* is less than or equal to 0,
or if a value for *transUncs*, *rotUncs*, or *scaleUncs* is less than 0,
or if *alphabet* is NULL.

ccOCDefs::BadKey

A character model associated with a key does not exist in the specified alphabet.

- ```
  ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
    const ccOCAlphabetPtrh_const& alphabet,
    const cmStd vector<cc2Rigid>& charPoses,
    double charScale = 1.0,
    double transUnc = 0.0,
    const ccRadian & rotUnc = ccRadian(0),
    double scaleUnc = 0.0,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line using the specified alphabet and sequence of character key sets. Each character has a rigid pose with respect to an implicit character line coordinate system. Scaling and uncertainty factors apply to all characters.

  Parameters

  keySetSequence A sequence of key sets that indicates which characters can appear at each position in the line. Specify the key sets in line position order.

  alphabet The alphabet to associate with this line. The alphabet must already be compiled.

  charPoses The rigid pose of each character, specified in line position order.

  charScale The scaling for all characters. This must be greater than 0.

  transUnc The translation uncertainty for all characters. This must be greater than or equal to 0.

  rotUnc The rotation uncertainty for all characters. This must be greater than or equal to 0.

  scaleUnc The scaling uncertainty for all characters. This must be greater than or equal to 0.
  ```

name The name of this line.

Throws

ccOCDefs::BadParams
If the number of elements in *keySetSequence* does not equal the number of character poses,
or if *charScale* is less than or equal to 0,
or if a value for *transUncs*, *rotUncs*, or *scaleUncs* is less than 0,
or if *alphabet* is NULL.

ccOCDefs::BadKey
A character model associated with a key does not exist in the specified alphabet.

- ```
  ccOCLine(const cmStd vector<ccOCKeySet>& keySetSequence,
    const ccOCAlphabetPtrh_const& alphabet,
    const cmStd vector<cc2Rigid>& charPoses,
    const cmStd vector<double>& charScales,
    const cmStd vector<double>& transUncs,
    const cmStd vector<ccRadian>& rotUncs,
    const cmStd vector<double>& scaleUncs,
    const ccCvlString& name = cmT(""));
  ```

Constructs a line using the specified sequence of character key sets and an alphabet. Each character has a rigid pose with respect to an implicit line coordinate system. You supply scaling and uncertainty factors for each character in the line.

Parameters

keySetSequence A sequence of key sets that indicates which characters can appear at each position in the line. Specify the key sets in line position order.

alphabet The alphabet to associate with this line. The alphabet must already be compiled.

charPoses The pose for each character, specified in line position order.

charScales The scale for each character, specified in line position order. Each of these values must be greater than 0.

transUncs The translation uncertainty for each character, specified in line position order. These values must be greater than or equal to 0.

rotUncs The rotation uncertainty for each character, specified in line position order. These values must be greater than or equal to 0.

scaleUncs The scaling uncertainty for each character, specified in line position order. These values must be greater than or equal to 0.
  ```

name The name of the line.

Throws

ccOCDefs::BadParams
If the number of elements in each of the supplied vectors are unequal,
or if *charScale is less than or equal to 0,*
or if a value for *transUncs*, *rotUncs*, or *scaleUncs* is less than 0,
or if alphabet is NULL.

ccOCDefs::BadKey
A character model associated with a key does not exist in the specified alphabet.

Notes

This constructor allows you to specify different scales for each character in a line. However, varying character scales decreases the ability of an optical tool to perform effective character recognition and verification. This is because confusion scores are based on comparing characters at similar positions angles, and scales. You should try to use separate lines to describe characters at different scales.

Operators

operator==

```
bool operator==(const ccOCLine& other) const;
```

Return true if this line is equal to the specified line.

Parameters

other The line with which to compare for equality.

Notes

The equality operator considers the alphabets associated with two lines equivalent if their names are the same. The equality operator does not compare the models within the alphabets for equality.

operator!=

```
bool operator!=(const ccOCLine& other) const;
```

Returns true if this line is not equal to the specified line.

Parameters

other The line with which to compare for inequality.

Public Member Functions

numPositions

```
c_Int32 numPositions() const;
```

Returns the number of character positions in this line.

numNormalChars

```
c_Int32 numNormalChars() const;
```

Returns the number of normal characters in this line.

isWildcard

```
bool isWildcard(c_Int32 posIndex) const;
```

Returns true if the current character at the supplied index is a wildcard character.

Parameters

posIndex The index of the character position to test.

Throws

ccOCDefs::BadIndex
posIndex value is not a valid position index.

character

```
const ccOCModelPtrh_const & character(
  c_Int32 posIndex) const;
```

Returns the first character model for the current characters at the specified position.

Parameters

posIndex The character position index.

Throws

ccOCDefs::BadIndex
The position index is invalid or one of the current characters at this position is a wildcard character.

characters

```
cmStd vector<ccOCModelPtrh_const> characters(
  c_Int32 posIndex) const;
```

Returns the character models for the current characters at the specified position.

Parameters

posIndex The character position index.

Throws

ccOCDefs::BadIndex

The position index is invalid or one of the current characters at this position is a wildcard character.

alphabet

```
const ccOCAlphabetPtrh_const& alphabet() const;
```

Returns the alphabet for this line.

keySetSequence

```
const cmStd vector<ccOCKeySet>& keySetSequence() const;
```

Returns the character key set sequence for this line.

charPoses

```
const cmStd vector<cc2Rigid>& charPoses() const;
```

Returns the character poses for this line with respect to the line coordinate system.

charScales

```
const cmStd vector<double>& charScales() const;
```

Returns the character scales for this line with respect to the line coordinate system.

translationUncertainties

```
const cmStd vector<double>&
  translationUncertainties() const;
```

Returns the character translation uncertainties.

rotationUncertainties

```
const cmStd vector<ccRadian>&
  rotationUncertainties() const;
```

Returns the character rotation uncertainties.

scaleUncertainties

```
const cmStd vector<double>& scaleUncertainties() const;
```

Returns the character scale uncertainties.

name

```
const ccCvlString& name() const;
```

Returns the name of this line.

encloseRect

```
ccRect encloseRect(
  const cc2Xform& clientFromLine = cc2Xform(),
  const cc2Xform& lineOffset = cc2Xform(),
  const cc2Xform& clientFromImage = cc2Xform(),
  double translationUncertainty = 0,
  const ccRadian& rotationUncertainty = ccRadian(0),
  double scaleUncertainty = 0,
  bool includeConfusion = false) const;
```

Returns the smallest rectangle that contains this line. The enclosing rectangle is aligned with respect to the specified image coordinate system.

Parameters

clientFromLine

A transformation that maps the line's coordinate system to the client coordinate system.

lineOffset

A transformation that maps the origin of the line to the origin of the client coordinate system.

clientFromImage

A transformation that maps the image coordinate system to the client coordinate system.

translationUncertainty

The translation uncertainty for the line. This value must be greater than or equal to 0.

rotationUncertainty

The rotation uncertainty for the line. This value must be greater than or equal to 0.

scaleUncertainty

The scale uncertainty for the line. This value must be greater than or equal to 0. You should not specify a value greater than 0.10 for the scale uncertainty.

includeConfusion

If true, the returned enclosing rectangle contains any confusing characters in place of those nominally present.

Throws

ccOCDefs::BadParams

translationUncertainty, *rotationUncertainty*, or *scaleUncertainty* is less than 0.

Typedefs

ccOCLinePtrh

```
typedef ccPtrHandle<ccOCLine> ccOCLinePtrh;
```

ccOCLinePtrh_const

```
typedef ccPtrHandle_const<ccOCLine> ccOCLinePtrh_const;
```

ccOCLine

ccOCLineArrangement

```
#include <ch_cvl/oc.h>

class ccOCLineArrangement : public ccPersistent, public ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class represents a spatial arrangement of lines. A typical line arrangement consists of horizontal, parallel lines as found on a product label, however you can configure arbitrary arrangements of lines by supplying information about the uncertainty in position, angle, and scale for each line. An optical verification tool uses the information provided by this class to verify the lines in an area of text.

Constructors/Destructors

ccOCLineArrangement

```
ccOCLineArrangement();

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh_const>& lines,
  const cc2Rigid& spacing,
  double transUnc = 0.0,
  const ccRadian& rotUnc = ccRadian(0),
  const ccCvlString& name = cmT(""));

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh>& lines,
  const cc2Rigid& spacing,
  double transUnc = 0.0,
  const ccRadian& rotUnc = ccRadian(0),
  const ccCvlString& name = cmT(""));

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh_const>& lines,
  const cmStd vector<cc2Rigid>& linePoses,
```

```
  double transUnc = 0.0,
  const ccRadian & rotUnc = ccRadian(0),
  const ccCvlString& name = cmT(""));

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh>& lines,
  const cmStd vector<cc2Rigid>& linePoses,
  double transUnc = 0.0,
  const ccRadian & rotUnc = ccRadian(0),
  const ccCvlString& name = cmT(""));

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh_const>& lines,
  const cmStd vector<cc2Rigid>& linePoses,
  const cmStd vector<double>& transUncs,
  const cmStd vector<ccRadian>& rotUncs,
  const ccCvlString& name = cmT(""));

ccOCLineArrangement(
  const cmStd vector<ccOCLinePtrh>& lines,
  const cmStd vector<cc2Rigid>& linePoses,
  const cmStd vector<double>& transUncs,
  const cmStd vector<ccRadian>& rotUncs,
  const ccCvlString& name = cmT(""));
```

- `ccOCLineArrangement();`

  Constructs a line arrangement with no lines.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh_const>& lines,
    const cc2Rigid& spacing,
    double transUnc = 0.0,
    const ccRadian& rotUnc = ccRadian(0),
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line arrangement from the specified set of lines. Lines are uniformly spaced with respect their origins, and the scaling and uncertainty factors apply to all characters in the line.

  Parameters

lines	The set of lines that this arrangement comprises. If any line contains space characters in all positions, the line arrangement is invalid.
spacing	The spacing between the origin of each line. This factor is applied to all lines in the arrangement.
  ```

transUnc The translation uncertainty for all lines. This must be greater than or equal to 0.

rotUnc The rotation uncertainty for all lines. This must be greater than or equal to 0.

name The name of this line arrangement

Notes

For the typical case of parallel, horizontal lines of text, specify a *spacing* value that has only a y-axis translation component.

Throws

ccOCDefs::BadParams

transUnc or *rotUnc* is less than 0.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh>& lines,
    const cc2Rigid& spacing,
    double transUnc = 0.0,
    const ccRadian& rotUnc = ccRadian(0),
    const ccCvlString& name = cmT(""));
  ```

Constructs a line arrangement from the specified set of lines. Lines are uniformly spaced with respect their origins, and the scaling and uncertainty factors apply to all characters in the line.

Parameters

lines The set of lines that this arrangement comprises. If any line contains space characters in all positions, the line arrangement is invalid.

spacing The spacing between the origin of each line. This factor is applied to all lines in the arrangement.

transUnc The translation uncertainty for all lines. This must be greater than or equal to 0.

rotUnc The rotation uncertainty for all lines. This must be greater than or equal to 0.

name The name of this line arrangement.

Notes

For the typical case of parallel, horizontal lines of text, specify a *spacing* value that has only a y-axis translation component.
  ```

Throws

ccOCDefs::BadParams

transUnc or *rotUnc* is less than 0.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh_const>& lines,
    const cmStd vector<cc2Rigid>& linePoses,
    double transUnc = 0.0,
    const ccRadian & rotUnc = ccRadian(0),
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line arrangement from the specified set of lines. For each line, you can supply an arbitrary pose with respect to the implicit line arrangement coordinate system. You can also supply translation and rotation uncertainty factors that apply to all lines in the arrangement.

  Parameters

  lines — The set of lines which this arrangement comprises. If any line contains space characters in all positions, the line arrangement is invalid.

  linePoses — The set of poses for the lines in the arrangement, specified in line order and with respect to the implicit line arrangement coordinate system.

  transUnc — The translation uncertainty for all lines. This must be greater than or equal to 0.

  rotUnc — The rotation uncertainty for all lines. This must be greater than or equal to 0.

  name — The name of this line arrangement.

  Throws

  ccOCDefs::BadParams

  The number of line poses does not equal the number of lines; or *transUnc* or *rotUnc* is less than 0.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh>& lines,
    const cmStd vector<cc2Rigid>& linePoses,
  ```

```
double transUnc = 0.0,
const ccRadian & rotUnc = ccRadian(0),
const ccCvlString& name = cmT(""));
```

Constructs a line arrangement from the specified set of lines. For each line, you can supply an arbitrary pose with respect to the implicit line arrangement coordinate system. You can also supply translation and rotation uncertainty factors that apply to all lines in the arrangement.

Parameters

lines The set of lines that this arrangement comprises. If any line contains space characters in all positions, the line arrangement is invalid.

linePoses The set of poses for the lines in the arrangement, specified in line order and with respect to the implicit line arrangement coordinate system.

transUnc The translation uncertainty for all lines. This must be greater than or equal to 0.

rotUnc The rotation uncertainty for all lines. This must be greater than or equal to 0.

name The name of this line arrangement.

Throws

ccOCDefs::BadParams
The number of line poses does not equal the number of lines; or *transUnc* or *rotUnc* is less than 0.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh_const>& lines,
    const cmStd vector<cc2Rigid>& linePoses,
    const cmStd vector<double>& transUncs,
    const cmStd vector<ccRadian>& rotUncs,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line arrangement from the specified set of lines. For each line, you can supply an arbitrary pose with respect to the implicit line arrangement coordinate system. You also supply the uncertainty in translation and rotation for each line.

  Parameters

  lines The set of lines that this arrangement comprises.

  linePoses The set of poses for the lines in the arrangement, specified in line order and with respect to the implicit line arrangement coordinate system.
  ```

transUncs The set of translation uncertainty factors for the lines, specified in line order. These values must be greater than or equal to 0.

rotUncs The set of rotation uncertainty factors for the lines, specified in line order. These values must be greater than or equal to 0.

name The name of this line arrangement.

Throws

ccOCDefs::BadParams
transUnc or *rotUnc* is less than 0.

- ```
  ccOCLineArrangement(
    const cmStd vector<ccOCLinePtrh>& lines,
    const cmStd vector<cc2Rigid>& linePoses,
    const cmStd vector<double>& transUncs,
    const cmStd vector<ccRadian>& rotUncs,
    const ccCvlString& name = cmT(""));
  ```

  Constructs a line arrangement from the specified set of lines. For each line, you can supply an arbitrary pose with respect to the implicit line arrangement coordinate system. You also supply the uncertainty in translation and rotation for each line.

  Parameters

  lines The set of lines that this arrangement comprises. If any line contains space characters in all positions, the line arrangement is invalid.

  linePoses The set of poses for the lines in the arrangement, specified in line order and with respect to the implicit line arrangement coordinate system.

  transUncs The set of translation uncertainty factors for the lines, specified in line order. These values must be greater than or equal to 0.

  rotUncs The set of rotation uncertainty factors for the lines, specified in line order. These values must be greater than or equal to 0.

  name The name of this line arrangement.

  Throws

  ccOCDefs::BadParams
  The number of line poses or uncertainties does not equal the number of lines; or *transUnc* or *rotUnc* is less than 0.
  ```

Operators

operator==

```
bool operator==(const ccOCLineArrangement& other) const;
```

Return true if this line arrangement is equal to the specified line arrangement.

Parameters

other The line arrangement with which to compare for equality.

operator!=

```
bool operator!=(const ccOCLineArrangement& other) const;
```

Return true if this line arrangement is not equal to the specified line arrangement.

Parameters

other The line arrangement with which to compare for inequality.

Public Member Functions

numLines

```
const c_Int32 numLines() const;
```

Returns the number of lines in this arrangement.

lines

```
const cmStd vector<ccOCLinePtrh_const>& lines() const;
```

Returns the set of lines for this arrangement.

linePoses

```
const cmStd vector<cc2Rigid>& linePoses() const;
```

Returns the set of line poses for this arrangement. Line poses are aligned with respect to the line arrangement coordinate system.

translationUncertainties

```
const cmStd vector<double>&
  translationUncertainties() const;
```

Returns the set of translation uncertainties for the lines in this arrangement.

rotationUncertainties

```
const cmStd vector<ccRadian>&
  rotationUncertainties() const;
```

Returns the set of rotation uncertainties for the lines in this arrangement.

name

```
const ccCvlString& name() const;
```

Returns the name of this line arrangement.

encloseRect

```
ccRect encloseRect(
  const cc2Xform& clientFromArr = cc2Xform(),
  const cc2Xform& arrOffset = cc2Xform(),
  const cc2Xform& clientFromImage = cc2Xform(),
  double translationUncertainty = 0,
  const ccRadian& rotationUncertainty = ccRadian(0),
  double scaleUncertainty = 0,
  bool includeConfusion = false) const;
```

Returns the smallest rectangle that contains this line arrangement. The enclosing rectangle is aligned with respect to the specified image coordinate system. If *includeConfusion* is true, the enclosing rectangle also contains any confusing characters in place of those nominally present.

Parameters

clientFromArr A transformation that maps the line arrangement's coordinate system to the client coordinate system.

arrOffset A transformation that maps the origin of the line arrangement to the origin of the client coordinate system.

clientFromImage A transformation that maps the image coordinate system to the client coordinate system.

translationUncertainty
The translation uncertainty for the line arrangement. This value must be greater than or equal to 0.

rotationUncertainty
The rotation uncertainty for the line arrangement. This value must be greater than or equal to 0.

scaleUncertainty
The scale uncertainty for the line arrangement. This value must be greater than or equal to 0. You should not specify a value greater than 0.10 for the scale uncertainty.

includeConfusion
If true, the returned enclosing rectangle contains any confusing characters in place of those nominally present.

Throws

ccOCDefs::BadParams

translationUncertainty, *rotationUncertainty*, or *scaleUncertainty* is less than 0.

Typedefs

ccOCLineArrangementPtrh

```
typedef ccPtrHandle<ccOCLineArrangement>
  ccOCLineArrangementPtrh;
```

ccOCLineArrangementPtrh_const

```
typedef ccPtrHandle_const<ccOCLineArrangement>
  ccOCLineArrangementPtrh_const;
```

ccOCLineArrangement

ccOCModel

```
#include <ch_cvl/oc.h>

class ccOCModel : public ccPersistent, public ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class represents a single character for optical character verification by the OCV tool.

Constructors/Destructors

ccOCModel

```
ccOCModel();

ccOCModel(c_Int32 key,
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPelRect& imageArea,
  CharType ctype,
  const ccCvlString& name = cmT(""),
  const ccCvlString& description = cmT(""));

ccOCModel(c_Int32 key,
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPelRect& imageArea, CharType ctype,
  const ccCvlString& name = cmT(""),
  const ccCvlString& description = cmT(""));
```

- ```
  ccOCModel();
  ```

  The default constructor creates a model for a blank character with no area.

- ```
  ccOCModel(c_Int32 key,
    const ccPelBuffer_const<c_UInt8>& image,
    const ccPelRect& imageArea,
  ```

```
  CharType ctype,
  const ccCvlString& name = cmT(""),
  const ccCvlString& description = cmT(""));
```

Creates a character model from the specified parameters.

Parameters

key A unique key used to refer to the character model.

image The image for the character model.

imageArea The rectangle defining the area of the character in image coordinates.

ctype The character type, which can be either *eNormal*, a normal character, or *eBlank*, a blank character.

name A string used to name the character model

description A string used to describe the character model.

Throws

ccOCDefs::BadImage
The *image* is unbound but *ctype* is *eNormal*.

ccOCDefs::NotImplemented
The *image* is bound but *ctype* is *eBlank*.

ccOCDefs::BadParams
The *image* is bound and the *imageArea* does not fit within the window region.

-
```
ccOCModel(c_Int32 key,
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPelRect& imageArea, CharType ctype,
  const ccCvlString& name = cmT(""),
  const ccCvlString& description = cmT(""));
```

Creates a character model that includes an image mask. If the mask is unbound, this constructor behaves the same as the previous overloaded constructor.

Parameters

key A unique key used to refer to the character model.

image The image for the character model.

mask An image that denotes certain areas of the character image that the OCV tool should ignore when training.

imageArea The rectangle defining the area of the character in image coordinates.

ctype The character type, which can be either *eNormal*, a normal character, or *eBlank*, a blank character.

name A string used to name the character model.

description A string used to describe the character model.

Throws

ccOCDefs::BadImage
The *image* is unbound but *ctype* is *eNormal*.

ccOCDefs::NotImplemented
The *image* is bound but *ctype* is *eBlank*.

ccOCDefs::BadParams
image and *mask* are both bound but their window regions are unequal; or the *image* or *mask* is bound but the specified image area does not fit within the window region.

Operators

operator==

```
bool operator==(const ccOCModel& other) const;
```

Returns true if this character model is equal to the specified character model.

Parameters

other A character model to compare with this one.

operator!=

```
bool operator!=(const ccOCModel& other) const;
```

Returns true if this object is not equal to the specified character model.

Parameters

other A character model to compare with this one.

Enumerations

CharType `enum CharType`

This enumeration defines the types of character models.

Value	Meaning
eNormal	Specifies a model for a normal character. A normal character can be verified by matching its shape. For example, any alphanumeric character or distinctive shape, such as a logo or graphic, is a normal character.
eBlank	Specifies a model for a blank character. A blank character represents “white space,” and can be verified by the absence of shape.

Public Member Functions

key

```
void key(c_Int32 key);
c_Int32 key() const;
```

- `void key(c_Int32 key);`

  Sets the key with which you refer to this character. Typically, you supply the ASCII code for the character as its key.

  Parameters

  key The character key.

- `c_Int32 key() const;`

  Returns the key for this character.

charType `CharType charType() const;`

Returns the character type for this model.

name

```
void name(const ccCvlString& n);
const ccCvlString& name() const;
```

- `void name(const ccCvlString& n);`

  Sets the name of this character model.

  Parameters

  n The name string.

- `const ccCvlString& name() const;`

  Returns the name for this character model.

description

```
void description(const ccCvlString& n);
const ccCvlString& description() const;
```

- `void description(const ccCvlString& n);`

  Sets the description string for this character model.

  Parameters

  n A string that describes the character model.

- `const ccCvlString& description() const;`

  Returns the description string for this character model.

image

```
void image(const ccPelBuffer_const<c_UInt8>& image);
const ccPelBuffer_const<c_UInt8>& image() const;
```

- `void image(const ccPelBuffer_const<c_UInt8>& image);`

  Sets the image for this character model. If the image is bound, it represents the prototype for a normal character. If unbound, the image represents a blank character. The image client coordinate system determines the origin, orientation, and scale of the character.

  Parameters

  image A pel buffer that contains either a bound or unbound image for the character.

Throws

ccOCDefs::BadImage
image is unbound but the character type for this model is *eNormal*.

ccOCDefs::NotImplemented
image is bound but the character type for this model is *eBlank*.

ccOCDefs::BadParams
image and the character's mask are both bound but their window regions are unequal; or the *image* is bound but its area does not fit within the window region.

- `const ccPelBuffer_const<c_UInt8>& image() const;`

Returns the image for this character model.

mask

```
void mask(const ccPelBuffer_const<c_UInt8>& mask);
const ccPelBuffer_const<c_UInt8>& mask() const;
```

- `void mask(const ccPelBuffer_const<c_UInt8>& mask);`

Sets the mask for this character model. A mask specifies certain areas of the character image that the OCV tool should ignore when training. Pixels with a value less than 128 denote Don't Care pixels. Those with a value equal to or greater than 128 denote Care pixels. An unbound mask is equivalent to a mask of all Care pixels (the same as specifying no mask).

Parameters

mask A pel buffer that contains the character mask.

Throws

ccOCDefs::BadParams
The *mask* and the character image are both bound but their window regions are unequal; or the *mask* is bound but its area does not fit within the window region.

- `const ccPelBuffer_const<c_UInt8>& mask() const;`

Returns the mask for this character model or, if you have not specified a mask, an unbound image buffer.

model

```
void model(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask);
```

Sets both the image and mask for this character model. If the mask is unbound, this function has the same effect as the **image()** function.

Parameters

image A pel buffer that contains either a bound or unbound image for the character.

mask A pel buffer that contains the character mask.

Throws

ccOCDefs::BadImage
image is unbound but the character type for this model is *eNormal*.

ccOCDefs::NotImplemented
image is bound but the character type for this model is *eBlank*.

ccOCDefs::BadParams
image and *mask* are both bound but their window regions are unequal; or the *image* or *mask* is bound but the specified image area does not fit within the window region.

---

imageArea

```
void imageArea(const ccPelRect& area);

const ccPelRect& imageArea() const;
```

- `void imageArea(const ccPelRect& area);`

Sets the area for this character.

Parameters

area The area for the character in image coordinates.

- `const ccPelRect& imageArea() const;`

Returns the area for this character in image coordinates.

encloseRect

```
ccRect encloseRect(
  const cc2Xform& clientFromModel = cc2Xform(),
  const cc2Xform& modelOffset = cc2Xform(),
  const cc2Xform& clientFromImage = cc2Xform(),
```

```
double translationUncertainty = 0,
const ccRadian& rotationUncertainty = ccRadian(0),
double scaleUncertainty = 0) const;
```

Returns the smallest rectangular area that is guaranteed to enclose the character. The enclosing rectangle is aligned with respect to the specified image coordinates.

Parameters

clientFromModel

A transformation that maps the character model's coordinate system to the client coordinate system.

modelOffset

A transformation that maps the origin of the model to the origin of the client coordinate system.

clientFromImage

A transformation that maps the image coordinate system to the client coordinate system.

translationUncertainty

The character's translation uncertainty, which must be greater than or equal to 0.

rotationUncertainty

The character's rotation uncertainty, which must be greater than or equal to 0.

scaleUncertainty

The character's scale uncertainty, which must be greater than or equal to 0. You should not specify a value greater than 0.10 for the scale uncertainty.

Throws

ccOCDefs::BadParams

The specified value for *translationUncertainty*, *rotationUncertainty*, or *scaleUncertainty* is less than 0.

Typedefs

ccOCModelPtrh

```
typedef ccPtrHandle<ccOCModel> ccOCModelPtrh;
```

ccOCModelPtrh_const

```
typedef ccPtrHandle_const<ccOCModel> ccOCModelPtrh_const;
```

ccOCRClassifier

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifier;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRClassifier is a trainable classifier for classifying rectified images. **ccOCRClassifier** can be trained incrementally, even after **ccOCRClassifier** has been run.

Notes

There is no function called **endTrain()** because the tool is designed to be run at any time and to accept additional training instances at any time (at any time does not imply that the tool is multi-thread safe and re-entrant – it is not re-entrant – the tool follows the convention that different threads can safely run asynchronously on different tool objects, but different threads cannot safely run asynchronously on the same tool objects).

Classifier Training Instances

Typically, the OCR Classifier tool's robustness benefits from training on multiple instances of each character class, with each instance representing normal variations to be expected at run time. The OCR Classifier tool uniquely identifies each such training instance by **key.characterCode()**, **key.instance()**, **key.variant()**, and **key.fontID()**.

Collectively, these values form the identifier of the training instance.

You can provide multiple training instances with arbitrary identifiers. The OCR Classifier tool maintains the identifiers you specify as long as there is no conflict, and would automatically resolve conflicts by assigning new unique instance values when multiple training instances shared the same identifier. In other words, if a new training instance's identifier (*key.characterCode*, *key.instance*, *key.variant*, and *key.fontId*) is already present in the classifier's training instances, then the OCR Classifier tool assigns a new value for *key.instance* of its copy of the **ccOCChar** so that the resulting identifier is unique. It never changes any other part of the identifier.

It is legal to train exactly the same training instance multiple times, although this usually does not help with the tool's performance.

The OCR Classifier tool treats all as separate independent instances, each assigned a unique internal instance number.

Classifier Training

The OCR Classifier tool is designed to be incrementally trainable and to be run only after it has been trained. In addition, the tool's behavior depends on *trainParams*, and, as such, all of the training instances should reflect the same *trainParams*.

Towards this end, OCR Classifier tool training involves two steps:

1. Setting *trainParams*
2. Adding the training instances

As a corollary, the OCR Classifier tool should not accept training instances until after the train parameters have been specified.

The classifier is trained in the following way:

1. You specify the training parameters using

   ccOCRClassifier.startTrain() or **ccOCRClassifier.retrain()**

2. You specify training instances using any overload of

   ccOCRClassifier.trainIncremental().

Then, after training one or more instances, the OCR Classifier tool is able to classify rectified images.

Notes

startTrain() always calls **untrain()** as its first step.

retrain() respects (does not discard) the trained instances.

Classifier Makes Deep Copies of Training Instances

The classifier internally makes deep copies of the training instances.

Classifier Training Usage Examples

Some training usage examples are as follows:

1. You want to train a set of characters:

```
classifier.startTrain(trainParams);

classifier.trainIncremental(trainInstancesVec);
```

2. You want to incrementally train an additional character:

```
classifier.trainIncremental(trainInstance);
```

3. You want to retrain with different training parameters:

```
classifier.retrain(trainParams);
```

4. You want to start over, that is, delete all the training instances and train a new set of character instances (note that this code fragment is identical to the code fragment for case (1) because **startTrain()** internally calls **untrain()** which deletes all of the training instances).

```
classifier.startTrain(trainParams);

classifier.trainIncremental(trainInstancesVec);
```

Convenience Functions for Training

The OCR Classifier API also provides 2 convenience **train()** functions that call **startTrain()** followed by an incremental training function.

Discarding Training Instances to Conserve Memory

Nominally, **ccOCRClassifier** keeps a copy of the training instances. For memory conservation purposes, the classifier also has the ability to purge this copy of training instances. The flag **saveTrainCharacters()** controls whether training instances should be saved. The drawback of purging the training instances is that the classifier can no longer be retrained. The OCR Classifier tool throws an exception if you call **retrain()** a classifier for which the training instances have been purged.

Notes

When **untrain()** is called, **saveTrainCharacters()** is preserved.

Constructors/Destructors

ccOCRClassifier

```
ccOCRClassifier();

ccOCRClassifier(const ccOCRClassifier& rhs);
```

- `ccOCRClassifier();`

  Constructs an untrained classifier.

- `ccOCRClassifier(const ccOCRClassifier& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

ccOCRClassifier

```
~ccOCRClassifier();
```

Destructor.

Public Member Functions

isTrained

```
bool isTrained() const;
```

Gets whether this classifier has been trained with at least one training instance.

isStartTrained

```
bool isStartTrained() const;
```

Gets whether training has started, regardless of whether the classifier has received any training instances.

Notes

startTrain(), **train()**, and **retrain()** turn this to true, and **untrain()** turns this to false.

untrain

```
void untrain();
```

Untrains the classifier. Discard information of all training parameters and training instances.

Notes

Calling **untrain()** on an untrained classifier has no effect. A classifier is untrained if **isStartTrained()** == false.

After the call, **isTrained()** and **isStartTrained()** become/remain false.

This does not change the value of **saveTrainCharacters()**.

startTrain

```
void startTrain(const ccOCRClassifierTrainParams& params,
 ccDiagObject* pDiagObj = NULL,
 c_UInt32 diagFlags = 0);
```

Starts the training process with the specified parameters.

Parameters

params	The parameters.
pDiagObj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

This calls **untrain()** as the first step.

It is legal to call **startTrain()** repeatedly. Effects of earlier calls are cleared by the last call.

trainIncremental

```
void trainIncremental(const ccOCChar& trainCharacter,
 ccDiagObject* pDiagObj = NULL,
 c_UInt32 diagFlags = 0);

void trainIncremental(
 const cmStd vector<ccOCChar>& trainCharacters,
 ccDiagObject* pDiagObj = NULL,
 c_UInt32 diagFlags = 0);

void trainIncremental(
 const cmStd vector<const ccOCChar*>& trainCharacters,
 ccDiagObject* pDiagObj = NULL,
 c_UInt32 diagFlags = 0);
```

-
```
void trainIncremental(const ccOCChar& trainCharacter,
 ccDiagObject* pDiagObj = NULL,
 c_UInt32 diagFlags = 0);
```

Adds one training instance to this classifier.

Parameters

trainCharacter The additional training instance.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

This requires **isStartTrained()** be true.

After the call, **isTrained()** becomes/remains true.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained() == false.

ccOCRClassifierDefs::BadParams
trainCharacter's *cellRectImage* is not specified, or
trainCharacter.key().characterCode() ==
ccCharCode::eUnknown

ccOCRClassifierDefs::CannotTrain
trainCharacter.key().isSpace() !=
trainCharacter.metrics().isBlank() , or
saveTrainCharacters()==false for algorithms that must train on all training characters at once.

Notes

The algorithms *eBasic* and *eBasicWithValidation* can continue incremental training when **saveTrainCharacters()**==false.

- ```
  void trainIncremental(
    const cmStd vector<ccOCChar>& trainCharacters,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0);
  ```

Adds training instances to this classifier.

Parameters

trainCharacters The additional training instances.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:
  ```

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

This requires **isStartTrained()** be true.

After the call, **isTrained()** becomes/remains true.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained() == false.

ccOCRClassifierDefs::BadParams
Any of the following is true:

- **trainCharacters.size()** returns 0.
- Any element of *trainCharacters* is NULL.
- For any element of *trainCharacters*, the *trainCharacter*'s *cellRectImage* is not specified.
- For any element of *trainCharacters*, **trainCharacter.key().characterCode()** == *ccCharCode::eUnknown*
- For any element of *trainCharacters*, **trainCharacter.key().isSpace()** != **trainCharacter.metrics().isBlank()**

ccOCRClassifierDefs::CannotTrain
saveTrainCharacters()==false for algorithms that must train on all training characters at once.

Notes

The algorithms *eBasic* and *eBasicWithValidation* can continue incremental training when **saveTrainCharacters()**==false.

- ```
  void trainIncremental(
    const cmStd vector<const ccOCChar*>& trainCharacters,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0);
  ```

  Adds training instances to this classifier.
  ```

Parameters

trainCharacters The additional training instances.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

This requires **isStartTrained()** be true.

After the call, **isTrained()** becomes/remains true.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained() == false.

ccOCRClassifierDefs::BadParams
Any of the following is true:

- **trainCharacters.size()** returns 0.
- For any element of *trainCharacters*, the *trainCharacter*'s *cellRectImage* is not specified.
- For any element of *trainCharacters*, **trainCharacter.key().characterCode()** == *ccCharCode::eUnknown*
- For any element of *trainCharacters*, **trainCharacter.key().isSpace()** != **trainCharacter.metrics().isBlank()**

ccOCRClassifierDefs::CannotTrain
saveTrainCharacters()==false for algorithms that must train on all training characters at once.

Notes

The algorithms *eBasic* and *eBasicWithValidation* can continue incremental training when **saveTrainCharacters()**==false.

train

```
void train(const ccOCRClassifierTrainParams& trainParams,
  const cmStd vector<ccOCChar>& trainCharacters,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0);

void train(const ccOCRClassifierTrainParams& trainParams,
  const cmStd vector<const ccOCChar*>& trainCharacters,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0);
```

- ```
  void train(const ccOCRClassifierTrainParams& trainParams,
    const cmStd vector<ccOCChar>& trainCharacters,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0);
  ```

  Convenience function to call **startTrain()** followed by **trainIncremental()**.

  Parameters

  trainParams The training parameters.

  trainCharacters The training characters.

  pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccOCRClassifierDefs::BadParams
  if any of the following is true:

  - **trainCharacters.size()** returns 0.
  - For any element of *trainCharacters*, the *trainCharacter*'s *cellRectImage* is not specified.
  - For any element of *trainCharacters*, **trainCharacter.key().characterCode()** == *ccCharCode::eUnknown*
  ```

- For any element of *trainCharacters*, **trainCharacter.key().isSpace()** != **trainCharacter.metrics().isBlank()**

ccOCRClassifierDefs::CannotTrain
saveTrainCharacters()==false for algorithms that must train on all training characters at once.

- ```
  void train(const ccOCRClassifierTrainParams& trainParams,
    const cmStd vector<const ccOCChar*>& trainCharacters,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0);
  ```

Convenience function to call **startTrain()** followed by **trainIncremental()**.

Parameters

trainParams The training parameters.

trainCharacters The training characters.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccOCRClassifierDefs::BadParams
if any of the following is true:

- **trainCharacters.size()** returns 0.
- Any element of *trainCharacters* is NULL.
- For any element of *trainCharacters*, the *trainCharacter*'s *cellRectImage* is not specified.
- For any element of *trainCharacters*, **trainCharacter.key().characterCode()** == *ccCharCode::eUnknown*
- For any element of *trainCharacters*, **trainCharacter.key().isSpace()** != **trainCharacter.metrics().isBlank()**
  ```

ccOCRClassifierDefs::CannotTrain
saveTrainCharacters()==false for algorithms that must train on all training characters at once.

Notes

After the call, **isStartTrained()** and **isTrained()** become/remain true.

It is OK to call **train()** repeatedly. Effects of earlier calls are cleared by the last call.

The algorithms *eBasic* and *eBasicWithValidation* can continue incremental training when **saveTrainCharacters()**==false.

retrain

```
void retrain(const ccOCRClassifierTrainParams& params,
ccDiagObject* pDiagObj = NULL, c_UInt32 diagFlags = 0);
```

Re-train the classifier with the specified parameters and the training instances saved in the tool.

Parameters

params The parameters.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

It is OK to call **retrain()** repeatedly. Effects of earlier calls will be cleared by the last call.

After the call, both **isStartTrained()** and **isTrained()** remain true.

This requires that **saveTrainCharacters()** be true.

This does not change the value of **saveTrainCharacters()**.

Throws

ccOCRClassifierDefs::NotTrained
isTrained()==false.

ccOCRClassifierDefs::NoSavedData
saveTrainCharacters()==false.

run

```
void run(const ccOCChar& runCharacter,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
  ccOCRClassifierPositionResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;

void run(const cmStd vector<ccOCChar>& runCharacters,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
  ccOCRClassifierLineResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;

void run(
  const cmStd vector<const ccOCChar*>& runCharacters,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
  ccOCRClassifierLineResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;

void run(const ccOCChar& runCharacter,
  bool isSpace,
  double spaceScore,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
  ccOCRClassifierPositionResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;

void run(const cmStd vector<ccOCChar>& runCharacters,
  const cmStd vector<c_Bool>& isSpace,
  const cmStd vector<double>& spaceScore,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
  ccOCRClassifierLineResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;

void run(
  const cmStd vector<const ccOCChar*>& runCharacters,
  const cmStd vector<c_Bool>& isSpace,
  const cmStd vector<double>& spaceScore,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRClassifierRunParams& runParams,
```

```
  ccOCRClassifierLineResult& result,
  ccDiagObject* pDiagObj = NULL,
  c_UInt32 diagFlags = 0) const;
```

- ```
  void run(const ccOCChar& runCharacter,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
    ccOCRClassifierPositionResult& result,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the classifier on the input character.

  Parameters

  runCharacter The run-time character.

  swapCharacterSet
  The swap character set.

  runParams The run-time parameters.

  result The result.

  pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

- ```
  void run(const cmStd vector<ccOCChar>& runCharacters,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
    ccOCRClassifierLineResult& result,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the classifier on the input characters.

  Parameters

  runCharacters The run-time characters.

swapCharacterSet
The swap character set.

runParams The run-time parameters.

result The result.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void run(
    const cmStd vector<const ccOCChar*>& runCharacters,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
    ccOCRClassifierLineResult& result,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the classifier on the input characters.

  Parameters

  runCharacters The run-time characters.

  swapCharacterSet
  The swap character set.

  runParams The run-time parameters.

  result The result.

  pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:
  ```

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void run(const ccOCChar& runCharacter,
    bool isSpace,
    double spaceScore,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
    ccOCRClassifierPositionResult& result,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the classifier on the input character.

  Parameters

  runCharacter The run-time character.

  isSpace Whether this character is a space.

  spaceScore Space score (if this character is a space).

  swapCharacterSet
  The swap character set.

  runParams The run-time parameters.

  result The result.

  pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff
  ```

- ```
  void run(const cmStd vector<ccOCChar>& runCharacters,
    const cmStd vector<c_Bool>& isSpace,
    const cmStd vector<double>& spaceScore,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
    ccOCRClassifierLineResult& result,
    ccDiagObject* pDiagObj = NULL,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the classifier on the input characters.

  Parameters

  runCharacters The run-time characters.

  isSpace Whether this character is a space.

  spaceScore Space score (if this character is a space).

  swapCharacterSet
  The swap character set.

  runParams The run-time parameters.

  result The result.

  pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

- ```
  void run(
    const cmStd vector<const ccOCChar*>& runCharacters,
    const cmStd vector<c_Bool>& isSpace,
    const cmStd vector<double>& spaceScore,
    const ccOCSwapCharSet& swapCharacterSet,
    const ccOCRClassifierRunParams& runParams,
  ```

```
ccOCRClassifierLineResult& result,
ccDiagObject* pDiagObj = NULL,
c_UInt32 diagFlags = 0) const;
```

Runs the classifier on the input characters.

Parameters

runCharacters The run-time characters.

isSpace Whether this character is a space.

spaceScore Space score (if this character is a space).

swapCharacterSet
The swap character set.

runParams The run-time parameters.

result The result.

pDiagObj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

If the input (run-time) character is to be classified as a space, set *isSpace* to true and provide a *spaceScore* within [0, 1].

The classifier ignores *spaceScore* if *isSpace* is false.

The classifier throws an exception if the value of *isSpace* is different from **runCharacter.key().isSpace()**, or is different from **runCharacter.metrics().isBlank()**.

The overloads that do not take the *isSpace* parameter are used only for classifying nonspace characters. For each input character, both **runCharacter.metrics().isBlank()** and **runCharacter.key().isSpace()** must return false.

Throws

ccOCRClassifierDefs::NotTrained
isTrained() == false.

ccOCRClassifierDefs::BadParams
Any pointer is NULL in the overloads that take a vector of pointers.
OR
The vectors do not have the same size in the overloads that take multiple vectors.
OR
The following is true of any *runCharacter*:

- *runCharacter*'s image is unbound.
- *runCharacter*'s *cellRectImage* is not specified.
- **runCharacter.metrics().isBlank()** == true or **runCharacter.key().isSpace()** == true for the overloads that do not take the *isSpace* parameter.
- *isSpace* != **runCharacter.key().isSpace()** or *isSpace* != **runCharacter.metrics().isBlank()** for the overloads that take the *isSpace* parameter.

trainParams

```
const ccOCRClassifierTrainParams& trainParams() const;
```

Gets the training parameters specified when calling **startTrain()**, **train()**, or **retrain()**.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained() == false.

saveTrainCharacters

```
bool saveTrainCharacters() const;

void saveTrainCharacters(bool save);
```

- `bool saveTrainCharacters() const;`

  Gets whether to save all training characters.

- `void saveTrainCharacters(bool save);`

  Sets whether to save all training characters.

Parameters

save Whether to save all training characters.

Notes

When setting this to false, the setter will immediately discard any saved training characters.

After setting this to false, it is not allowed to call the following functions:

- **trainIncremental()** for algorithms needing all characters
- **retrain()**
- **trainCharacters()**
- **trainCharactersProcessed()**

The default value is true.

trainCharacters

```
const cmStd vector<ccOCChar>& trainCharacters() const;
```

Gets the training characters.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained() == false.

ccOCRClassifierDefs::NoSavedData
saveTrainCharacters()==false.

trainCharactersProcessed

```
const cmStd vector<ccOCChar>& trainCharactersProcessed()
  const;
```

Gets the training characters after processing (re-sampling and image pre-processing).

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained()==false.

ccOCRClassifierDefs::NoSavedData
saveTrainCharacters()==false.

trainCharacterKeys

```
const cmStd vector<ccOCCharKey>& trainCharacterKeys()
  const;
```

Gets the keys of all training characters.

Notes

This data is available even if **saveTrainCharacters()** == false.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained()==false.

getTrainCharacterIndices

```
cmStd vector<c_Int32> getTrainCharacterIndices(
  const ccOCCharKey& key) const;
```

Returns the indices of all training instances in **trainCharacterKeys()** that match the specified character key.

Parameters

key The character key.

Notes

This function attempts to match all specified fields of **ccOCCharKey**. If any of *key.instance*, *key.variant*, and *key.fontID* is equal to *ccOCCharKey::eUnspecified*, it is treated as *don't-care*, and this function ignores that field.

Returns an empty vector if the specified key is not found.

Throws

ccOCRClassifierDefs::NotStartTrained
isStartTrained()==false.

ccOCRClassifierDefs::BadParams
key.characterCode() == *ccCharCode::eUnknown*

Operators

operator=

```
ccOCRClassifier& operator=(const ccOCRClassifier& rhs);
```

Assignment operator.

Parameters

rhs The object to assign to this one.

ccOCRClassifierCharResult

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierCharResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains result data for one potential classification of the run-time image.

Constructors/Destructors

ccOCRClassifierCharResult

```
ccOCRClassifierCharResult();
```

Constructs an object with default values.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Gets whether this object contains valid data.

Notes

All other getters throw *NotComputed* if **isComputed()** == false.

key

```
const ccOCCharKey& key() const;
```

Gets the classification result character key.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

score

```
double score() const;
```

Gets the classification result score.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

isPrimarySwap

```
bool isPrimarySwap() const;
```

Gets whether the character in this result is a swap character of the primary character.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

Operators

operator==

```
bool operator==(const ccOCRClassifierCharResult& rhs)
const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRClassifierDefs

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierDefs;
```

This class is a namespace to declare enumerations that are shared by the classes of the OCR Classifier tool.

Enumerations

PositionStatus

```
enum PositionStatus;
```

This enumeration defines the classification status.

Value	Meaning
eRead = 1	Classified with good confidence.
eConfused = 2	Classified with poor confidence.
eFailed = 3	Failed to classify.

ConfusionExplanation

```
enum ConfusionExplanation;
```

This enumeration defines the confusion explanation.

Value	Meaning
eNotConfused = 0	No confusion.
eConfidenceScoreTooLow = 1	Low confidence score.
eClassificationValidationFailure = 2	Failed classification validation.

Algorithm

```
enum Algorithm;
```

This enumeration defines the classification algorithm to be used.

Value	Meaning
eBasic = 0x1	The basic classification algorithm.

Value	Meaning
eBasicWithValidation = 0x2	The basic classification algorithm with the classification validation step.
kDefaultAlgorithm = *eBasic*	The default classification algorithm.

ImagePreprocessing

```
enum ImagePreprocessing;
```

This enumeration defines the input image's preprocessing method.

Value	Meaning
eNormalizeHistogram = 0x1	Normalize the input image's histogram.
eSubtractMedian = 0x2	Subtract the median of a local neighborhood.
kDefaultImagePreprocessing = *eNormalizeHistogram*	The default preprocessing method.

Notes

If both histogram normalization and local neighborhood median subtraction are enabled, histogram normalization happens after median subtraction.

ccOCRClassifierLineResult

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierLineResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all result data for the classification of one line of characters.

Constructors/Destructors

ccOCRClassifierLineResult

```
ccOCRClassifierLineResult();
```

Constructs an object with default values.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Gets whether this object contains valid data.

Notes

All other getters throw **NotComputed if isComputed()**==false.

status

```
ccOCRClassifierDefs::PositionStatus status() const;
```

Gets the result status: *eRead*, *eConfused*, or *eFailed*.

Notes

This is the lowest grade among all position results in this line result.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

positionResults

```
const cmStd vector<ccOCRClassifierPositionResult>&
 positionResults() const;
```

Gets all position results in this line result.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

constrainCharacterCodes

```
ccOCRClassifierLineResult constrainCharacterCodes(
 const cmStd vector<cmStd vector<c_Char32> >
  &allowableCharacterCodes,
 const ccOCSwapCharSet &swapCharSet = ccOCSwapCharSet(),
 bool computeConfusionUsingOnlyAllowableCharacters = true)
 const;
```

Computes a new result based on the old result and a specified 2D set of allowable character codes. You also specify whether the confusion should be computed using only the allowable characters or using all the trained characters for the classifier.

If an element of the input *allowableCharacterCodes vector* is empty, then that particular input result is excluded from the output.

Parameters

allowableCharacterCodes
The allowable character codes.

swapCharSet The swap character set.

computeConfusionUsingOnlyAllowableCharacters
If true, confusion is computed using only the allowable characters.

Notes

If the confusion is not limited to only allowable characters, that is, *computeConfusionUsingOnlyAllowableCharacters* == false, then all the non-primary characters will be included as alternative characters (regardless of whether they agree with the fielding).
In other words, if *computeConfusionUsingOnlyAllowableCharacters* == false, then only the primary character is constrained to agree with the fielding.

This function respects the following reserved character codes:

- *ccCharCode::eAnyCharacter*
- *ccCharCode::eAnyNonspaceCharacter*

If the allowable characters include *ccCharCode::eAnyCharacter*, then the associated input *positionResult* is simply copied to the associated computed *positionResult* result.

For each position, if the highest scoring character that satisfies the *allowableCharacterCodes* constraints does not satisfy the accept threshold, then the status is set to *eFailed*. Correspondingly, if the status is *eFailed*, then the primary character is unknown.

If *computeConfusionUsingOnlyAllowableCharacters* == false, then for each position, the confusion character is set to the highest scoring non-primary character; consequently, for each position, *confusionCharacter* may be valid even if the primary character is unknown and the classifier status is failed.

For each position, if the primary character is the only matching character, the confusion character is set to a default constructed character.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

ccOCRDefs::BadParams
allowableCharacterCodes.size() != **positionResults().size()** or *allowableCharacterCodes* includes any Cognex reserved character codes other than *ccCharCode::eAnyCharacter* or *ccCharCode::eAnyNonspaceCharacter*.

Operators

operator==

```
bool operator==(const ccOCRClassifierLineResult& rhs)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRClassifierLineResult

ccOCRClassifierPositionResult

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierPositionResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all result data for the classification of a run-time character.

Constructors/Destructors

ccOCRClassifierPositionResult

```
ccOCRClassifierPositionResult();
```

Constructs an object with default values.

isComputed = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Gets whether this object contains valid data.

Notes

All other getters throw **NotComputed if isComputed()**==false.

primaryCharacter

```
const ccOCRClassifierCharResult& primaryCharacter() const;
```

Gets the determined classification of the input image.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

status

```
ccOCRClassifierDefs::PositionStatus status() const;
```

Gets the result status: *eRead*, *eConfused*, or *eFailed*.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

confusionExplanation

```
ccOCRClassifierDefs::ConfusionExplanation
 confusionExplanation() const;
```

Gets a reason that leads to the *eConfused* status.

Notes

This is useful only if **status()** returns *eConfused*.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

confusionCharacter

```
const ccOCRClassifierCharResult& confusionCharacter()
 const;
```

Gets the confusion character.

Notes

This is set to a default **ccOCRClassifierCharResult** if there is no confusion character (that is, when **alternativeCharacters()** returns an empty vector).

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

confidenceScore

```
double confidenceScore() const;
```

Gets the confidence score, in the range [0, 1].

Notes

The confidence score is the difference between **primaryCharacter().score()** and **confusionCharacter().score()**.

This is set to 0 if **confusionExplanation()** returns *eClassificationValidationFailure*.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

alternativeCharacters

```
const cmStd vector<ccOCRClassifierCharResult>&
  alternativeCharacters() const;
```

Gets the list of alternative classes, and optionally, their training instances, which induced scores satisfying the alternative score threshold.

Notes

This list includes at most one instance for each character code/class.

This list is sorted in the order of descending scores.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

skippedTrainCharacterIndices

```
const cmStd vector<c_Int32>&
skippedTrainCharacterIndices() const;
```

Gets the list of indices to training character instances that were skipped (that is, not considered) during classification, for example, due to violating scale/size constraints.

Notes

This vector would be empty if **runParams.reportSkippedTrainCharacterIndices()** was false for the run that generated this result.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

processedImage

```
ccPelBuffer_const<c_UInt8> processedImage() const;
```

Gets the processed image, which is generated from the rectified input image and used for classification.

Notes

This image would be unbound if **runParams.keepProcessedImage()** was false for the run that generated this result.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

constrainCharacterCodes

```
ccOCRClassifierPositionResult constrainCharacterCodes(
  const cmStd vector<c_Char32> &allowableCharacterCodes,
  const ccOCSwapCharSet &swapCharSet = ccOCSwapCharSet(),
  bool computeConfusionUsingOnlyAllowableCharacters = true)
  const;
```

Computes a new result based on the old result and a specified set of allowable character codes. You also specify whether the confusion should be computed using only the allowable characters or using all the trained characters for the classifier.

Parameters

allowableCharacterCodes
The allowable character codes.

swapCharSet The swap character set.

computeConfusionUsingOnlyAllowableCharacters
If true, confusion is computed using only the allowable characters.

Notes

This function respects the following reserved character codes:

- *ccCharCode::eAnyCharacter*
- *ccCharCode::eAnyNonspaceCharacter*

If the allowable characters include *ccCharCode::eAnyCharacter*, then the input result is simply copied to the output result.

If the confusion is not limited to only allowable characters, that is, *computeConfusionUsingOnlyAllowableCharacters* == false, then all the non-primary characters will be included as alternative characters (regardless of whether they agree with the fielding).
In other words, if *computeConfusionUsingOnlyAllowableCharacters* == false, then only the primary character is constrained to agree with the fielding.

If the highest scoring character that satisfies the *allowableCharacterCodes* constraints does not satisfy the accept threshold, then the status is set to *eFailed*. Correspondingly, if the status is *eFailed*, then the primary character is unknown.

If *computeConfusionUsingOnlyAllowableCharacters* == false, then the confusion character is set to the highest scoring non-primary character; consequently, *confusionCharacter* may be valid even if the primary character is unknown and the classifier status is failed.

If the primary character is the only matching character, the confusion character is set to a default constructed character.

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

ccOCRDefs::BadParams
allowableCharacterCodes.size() == 0
or *allowableCharacterCodes* includes any Cognex reserved character codes other than *ccCharCode::eAnyCharacter* or *ccCharCode::eAnyNonspaceCharacter*.

acceptThreshold

```
double acceptThreshold() const;
```

Returns the accept threshold used to generate this result

Throws

ccOCRClassifierDefs::NotComputed
isComputed() == false.

Operators

operator==

```
bool operator==(const ccOCRClassifierPositionResult& rhs)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRClassifierPositionResult

ccOCRClassifierRunParams

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the run-time parameters for the OCR Classifier tool.

Constructors/Destructors

ccOCRClassifierRunParams

```
ccOCRClassifierRunParams();
```

Constructs an object with default values, which are the following:

- *acceptThreshold* = 0.5
- *confidenceThreshold* = 0.0
- *xScaleFilter* = **ccRange(***0.666, 1.5***)**
- *yScaleFilter* = **ccRange(***0.666, 1.5***)**
- *reportSkippedTrainCharacterIndices* = false
- *keepProcessedImage* = false

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

acceptThreshold

```
double acceptThreshold() const;
void acceptThreshold(double thresh);
```

- `double acceptThreshold() const;`

  Gets the accept threshold.

- `void acceptThreshold(double thresh);`

  Sets the accept threshold.

  Parameters
  thresh The accept threshold.

  Throws
  ccOCRClassifierDefs::BadParams
  thresh < 0 or *thresh* > 1.0

  The default value is 0.5.

confidenceThreshold

```
double confidenceThreshold() const;
void confidenceThreshold(double thresh);
```

- `double confidenceThreshold() const;`

  Gets the confidence threshold.

- `void confidenceThreshold(double thresh);`

  Sets the confidence threshold.

  Parameters
  thresh The confidence threshold.

  Throws

ccOCRClassifierDefs::BadParams
thresh < 0 or *thresh* > 1.0

The default value is 0.0.

useXScaleFilter

```
bool useXScaleFilter() const;
void useXScaleFilter(bool use);
```

- `bool useXScaleFilter() const;`

  Gets whether to use the x-scale filter.

- `void useXScaleFilter(bool use);`

  Sets whether to use the x-scale filter.

  Parameters
  use Whether to use the x-scale filter.

  The default value is true.

xScaleFilter

```
const ccRange& xScaleFilter() const;
void xScaleFilter(const ccRange& range);
```

- `const ccRange& xScaleFilter() const;`

  Gets the x-scale filter range for skipping candidate classes/instances whose rectified training image's x-size (that is, width) is beyond the range specified here.

- `void xScaleFilter(const ccRange& range);`

  Sets the x-scale filter range for skipping candidate classes/instances whose rectified training image's x-size (that is, width) is beyond the range specified here.

  Parameters
  range The x-scale filter range.

  Throws
  ccOCRClassifierDefs::BadParams
  range is an empty range or a full range, or
  range.start() < 0

Notes

X-scale is computed as the x-size of rectified run-time image divided by the x-size of a particular training class/instance.

This is effective only if **useXScaleFilter()** returns true.

The default range is (0.666, 1.5).

useYScaleFilter

```
bool useYScaleFilter() const;
void useYScaleFilter(bool use);
```

- `bool useYScaleFilter() const;`

  Gets whether to use the y-scale filter.

- `void useYScaleFilter(bool use);`

  Sets whether to use the y-scale filter.

  Parameters

  use Whether to use the y-scale filter.

  The default value is true.

yScaleFilter

```
const ccRange& yScaleFilter() const;
void yScaleFilter(const ccRange& range);
```

- `const ccRange& yScaleFilter() const;`

  Gets the y-scale filter range for skipping candidate classes/instances whose rectified training image's y-size (that is, height) is beyond the range specified here.

- `void yScaleFilter(const ccRange& range);`

  Sets the y-scale filter range for skipping candidate classes/instances whose rectified training image's y-size (that is, height) is beyond the range specified here.

  Parameters

  range The y-scale filter range.

Throws

ccOCRClassifierDefs::BadParams

range is an empty range or a full range, or
range.start() < 0

Notes

Y-scale is computed as the y-size of rectified run-time image divided by the y-size of a particular training class/instance.

This is effective only if **useYScaleFilter()** returns true.

The default range is (0.666, 1.5).

reportSkippedTrainCharacterIndices

```
bool reportSkippedTrainCharacterIndices() const;

void reportSkippedTrainCharacterIndices(bool report);
```

- `bool reportSkippedTrainCharacterIndices() const;`

  Gets whether to include in the result object the set of train character indices that were skipped because they did not satisfy the scale constraints.

- `void reportSkippedTrainCharacterIndices(bool report);`

  Sets whether to include in the result object the set of train character indices that were skipped because they did not satisfy the scale constraints.

  Parameters

report	Whether to include in the result object the set of train character indices that were skipped because they did not satisfy the scale constraints.

  The default value is false.

keepProcessedImage

```
bool keepProcessedImage() const;

void keepProcessedImage(bool keep);
```

- `bool keepProcessedImage() const;`

  Gets whether to keep around the processed image corresponding to the run-time rectified input image.

- `void keepProcessedImage(bool keep);`

  Sets whether to keep around the processed image corresponding to the run-time rectified input image.

  This processed image is usually provided for diagnostic purposes and is usually disabled for production runs.

  Parameters

keep	Whether to keep around the processed image corresponding to the run-time rectified input image.

  The default value is false.

Operators

operator== `bool operator==(const ccOCRClassifierRunParams& rhs) const;`

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRClassifierTrainParams

```
#include <ch_cvl/ocrclass.h>

class ccOCRClassifierTrainParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains training parameters for the OCR Classifier tool.

Constructors/Destructors

ccOCRClassifierTrainParams

```
ccOCRClassifierTrainParams();
```

Constructs an object with default values, which are the following:

- *templateSize* = (10, 18)
- *maintainAspectRatio* = false
- *algorithm* = *kDefaultAlgorithm*
- *imagePreprocessing* = *kImageDefaultPreprocessing*

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

templateSize

```
ccIPair templateSize() const;

void templateSize(const ccIPair& size);
```

- ```
  ccIPair templateSize() const;
  ```

  Gets the size to which the rectified images are resampled.
  ```

- `void templateSize(const ccIPair& size);`

  Sets the size to which the rectified images are resampled.

  Parameters

  size The size.

  Throws

  ccOCRClassifierDefs::BadParams
  size.x <= 0 or *size.y* <= 0

  ccOCDefs::NotImplemented
  size.x * *size.y* > 32768

  The default size is (10, 18).

maintainAspectRatio

```
bool maintainAspectRatio() const;
void maintainAspectRatio(bool maintain);
```

- `bool maintainAspectRatio() const;`

  Gets whether to maintain the rectified images' aspect ratio when resampling the rectified image at train-time/run-time.

- `void maintainAspectRatio(bool maintain);`

  Sets whether to maintain the rectified images' aspect ratio when resampling the rectified image at train-time/run-time.

  Parameters

  maintain Whether to maintain the rectified images' aspect ratio when resampling the rectified image at train-time/run-time.

  The default value is false.

algorithm

```
ccOCRClassifierDefs::Algorithm algorithm() const;
void algorithm(ccOCRClassifierDefs::Algorithm algorithm);
```

- `ccOCRClassifierDefs::Algorithm algorithm() const;`

  Gets the algorithm used for classification.

- `void algorithm(ccOCRClassifierDefs::Algorithm algorithm);`

  Sets the algorithm used for classification.

  Parameters
  algorithm The classification algorithm.

  Throws
  ccOCRClassifierDefs::BadParams
  algorithm is not a valid value for *ccOCRClassifierDefs::Algorithm*.

  The default value is *ccOCRClassifierDefs::kDefaultAlgorithm*.

imagePreprocessing

```
c_UInt32 imagePreprocessing() const;
void imagePreprocessing(c_UInt32 preproc);
```

- `c_UInt32 imagePreprocessing() const;`

  Gets the image preprocessing methods used for classification.

- `void imagePreprocessing(c_UInt32 preproc);`

  Sets the image preprocessing methods used for classification.

  The value is a bit field from *ccOCRClassifierDefs::ImagePreprocessing*.

  Parameters
  preproc The image preprocessing methods used for classification.

  Throws
  ccOCRClassifierDefs::BadParams
  preproc is not a bitwise OR of values from *ccOCRClassifierDefs::ImagePreprocessing*.

  Notes
  The same image preprocessing methods are applied to both train-time and run-time characters.

  The result image's client coordinate transform retains any effect that the specified image preprocessing methods may have on the client transform.

  The default value is *ccOCRClassifierDefs::kDefaultImagePreprocessing*.

Operators

operator==

```
bool operator==(const ccOCRClassifierTrainParams& rhs)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRDefs

```
#include <ch_cvl/ocrdefs.h>

class ccOCRDefs;
```

The **ccOCRDefs** class contains all enumerations specific to the OCR reader supporting classes.

Enumerations

FontCharWidthType

```
enum FontCharWidthType;
```

This enumeration defines the width type of the characters in the font.

Value	Meaning
eFontCharWidthTypeUnknown = 0x1	Unknown width type; the font may be either fixed width or proportional width.
eFontCharWidthTypeFixed = 0x2	All character mark rectangles in the font have the same width.
eFontCharWidthTypeVariable = 0x4	The characters in the font may have mark rectangles with different widths.
kDefaultFontCharWidthType = *eFontCharWidthTypeUnknown*	The default width type.

FontPitchType

```
enum FontPitchType;
```

This enumeration defines the pitch type for the characters in the font.

Value	Meaning
eFontPitchTypeUnknown = 0x1	Unknown pitch type, but the type is expected to be either fixed or proportional, not variable.
eFontPitchTypeFixed = 0x2	The pitch is fixed, which means that the pitch between any pair of characters is constant, for example, regardless of the width of the mark rectangles of the characters. Thus, all characters can be considered to have cell rectangles that are the same width. How the pitch is measured for a given fixed-pitch font is specified by the pitch metric.
eFontPitchTypeProportional = 0x4	The pitch is proportional, which means that the pitch between any pair of characters depends on the particular characters. The width of a character's cell rectangle is typically approximately proportional to the width of its mark rectangle. **Note**: Although no pitch measurement is constant throughout a string, typically the intercharacter gap, which is the distance from the right side of one character's mark rectangle to the left side of the adjacent character's mark rectangle, is approximately constant.

Value	Meaning
eFontPitchTypeVariable = 0x8	No character-to-character distance metric is consistent throughout a string; character placement is erratic. The pitch is neither fixed nor proportional. **Note**: Variable pitch is different from unknown pitch, because unknown pitch means that the pitch is either fixed or proportional, but it is not known which one.
kDefaultFontPitchType = *eFontPitchTypeUnknown*	The default pitch type.

FontPitchMetric

```
enum FontPitchMetric;
```

This enumeration defines the pitch metric for characters in the font.

Value	Meaning
eFontPitchMetricUnknown = 0x1	Unknown metric; the appropriate pitch may be any of the other pitch metrics, or else there is no consistent pitch metric (as may be the case for a proportional-pitch font).
eFontPitchMetricLeftToLeft = 0x2	Measure pitch as the distance from the left side of a character's mark rectangle to the left side of the adjacent character's mark rectangle. Thus, the character's mark rectangle appears left-justified within the character's cell rectangle.
eFontPitchMetricCenterToCenter = 0x4	Measure pitch as the distance from the center of a character's mark rectangle to the center of the adjacent character's mark rectangle. Thus, the character's mark rectangle appears centered within the character's cell rectangle.

Value	Meaning
eFontPitchMetricRightToRight = 0x8	Measure pitch as the distance from the right side of a character's mark rectangle to the right side of the adjacent character's mark rectangle. Thus, the character's mark rectangle appears right-justified within the character's cell rectangle.
kDefaultFontPitchMetric = *eFontPitchMetricUnknown*	The default pitch metric.

ccOCRDictionaryChar

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryChar;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryChar represents a single character used by the OCR Dictionary Fielding tool.

Constructors/Destructors

cOCRDictionaryChar

```
explicit ccOCRDictionaryChar(
  c_Char32 characterCode = ccCharCode::eUnknown,
  double score = 0.0);
```

Constructs a character.

Parameters

characterCode The character code to construct.

score The character score, which must be in the range 0.0 through 1.0;

Throws

ccOCRDictionaryDefs::BadParams
score is less than 0.0 or greater than 1.0.

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

characterCode

```
c_Char32 characterCode() const;
void characterCode(c_Char32 characterCode);
```

- `c_Char32 characterCode() const;`

  Returns this object's character code.

- `void characterCode(c_Char32 characterCode);`

  Sets this object's character code. The character code is generally a Unicode code point, although the **ccCharCode** class defines several reserved values.

  The default value for **characterCode** is *ccCharCode::eUnknown*.

  Parameters
  characterCode The character code.

score

```
double score() const;
void score(double score);
```

- `double score() const;`

  Returns this character's score, a value in the range 0.0 through 1.0.

- `void score(double score);`

  Sets this character's score. The default value for **score** is 0.0.

  Parameters
  score The score to set.

  Throws
  ccOCRDictionaryDefs::BadParams
  score is less than 0.0 or greater than 1.0.

Operators

operator char() const;

```
operator char() const;
```

Return the **char** representation of this object.

Throws

ccCharCodeDefs::NotRepresentable
The character code cannot be represented as a **char**.

operator wchar_t() const;

```
operator wchar_t() const;
```

Return the **wchar_t** representation of this object.

Throws

ccCharCodeDefs::NotRepresentable
The character code cannot be represented as a **wchar_t**.

operator==

```
bool operator==(const ccOCRDictionaryChar& rhs) const;
```

Returns true if this **ccOCRDictionaryChar** is equal to the supplied one, false otherwise.

Parameters

rhs The **ccOCRDictionaryChar** to compare to this one.

operator!=

```
bool operator!=(const ccOCRDictionaryChar& rhs) const;
```

Returns false if this **ccOCRDictionaryChar** is equal to the supplied one, true otherwise.

Parameters

rhs The **ccOCRDictionaryChar** to compare to this one.

ccOCRDictionaryChar

ccOCRDictionaryCharMulti

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryCharMulti;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryCharMulti represents a set of characters used by the OCR Dictionary Fielding tool. This class is usually used to represent the results of the OCR Classifier tool for a single character position.

Each **ccOCRDictionaryCharMulti** includes a primary character along with 0 or more alternative characters. In the case of an OCR Classifier tool result of *eRead* or *eConfused*, the non-primary characters are the alternative characters identified by the classifier.

Constructors/Destructors

ccOCRDictionaryCharMulti

```
explicit ccOCRDictionaryCharMulti(
  const cmStd vector<ccOCRDictionaryChar>& characters=
  cmStd vector<ccOCRDictionaryChar>());

explicit ccOCRDictionaryCharMulti(
  const ccOCRDictionaryChar& c);
```

- ```
  explicit ccOCRDictionaryCharMulti(
    const cmStd vector<ccOCRDictionaryChar>& characters=
    cmStd vector<ccOCRDictionaryChar>());
  ```

  Constructs a **ccOCRDictionaryCharMulti** object from the supplied vector of **ccOCRDictionaryChar**.

  Parameters

  characters The **ccOCRDictionaryChar**s.
  ```

- ```
  explicit ccOCRDictionaryCharMulti(
    const ccOCRDictionaryChar& c);
  ```

  Constructs a **ccOCRDictionaryCharMulti** object from the supplied **ccOCRDictionaryChar**.

  Parameters

  c The character.

  Notes

  The compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

characters

```
const cmStd vector<ccOCRDictionaryChar>& characters()
   const;

void characters(
   const cmStd vector<ccOCRDictionaryChar>& c);
```

- ```
  const cmStd vector<ccOCRDictionaryChar>& characters()
     const;
  ```

  Return the individual **ccOCRDictionaryChar** objects in this object.

- ```
  void characters(
     const cmStd vector<ccOCRDictionaryChar>& c);
  ```

  Set the **ccOCRDictionaryChar** objects in this object to the supplied vector.

  Parameters

  c The **ccOCRDictionaryChar**s to set.

isEmpty

```
bool isEmpty() const;
```

Returns *true* if this object contains no individual characters, *false* otherwise.

isSingular

```
bool isSingular() const ;
```

Returns *true* if this object contains a single individual character, *false* if it contains 0 or more than 1 characters.
```

size

```
c_Int32 size() const;
```

Returns the number of individual characters in this object.

primaryCharacter

```
const ccOCRDictionaryChar& primaryCharacter() const;
```

Returns the primary character in the multicharacter class. The primary character is the first character in **ccOCRDictionaryCharMulti::characters()**.

Throws

ccOCRDictionaryDefs::NotExpressible
This **ccOCRDictionaryCharMulti** contains no characters.

Operators

operator==

```
bool operator==(const ccOCRDictionaryCharMulti& rhs) const;
```

Returns true if this **ccOCRDictionaryCharMulti** is equal to the supplied one, false otherwise.

Parameters

rhs The **ccOCRDictionaryCharMulti** to compare to this one.

operator!=

```
bool operator!=(const ccOCRDictionaryCharMulti& rhs) const;
```

Returns false if this **ccOCRDictionaryCharMulti** is equal to the supplied one, true otherwise.

Parameters

rhs The **ccOCRDictionaryCharMulti** to compare to this one.

ccOCRDictionaryCharMulti

ccOCRDictionaryDefs

```
#include <ch_cvl/ocrddefs.h>

class ccOCRDictionaryDefs;
```

This class is a namespace to declare constants and enumerations.

Enumerations

Fielding

```
enum Fielding;
```

This enumeration provides some pre-defined sets of characters for convenience in specifying the acceptable choices for a character position.

Value	Meaning
eAlphaUppercase = 0x1	Characters A through Z.
eAlphaLowercase = 0x2	Characters a through z.
eNumeric = 0x4	Characters 0 through 9.
eSpace = 0x8	The space character (UTF-32 character code 0x20).
eAnyNonspaceCharacter = 0x10	Any character not in the Cognex-reserved UTF-32 code ranges except the space character whose UTF-32 character code is 0x20. **Note**: This does include other white spaces, for example, character codes 0x09 through 0x0D.
eAnyCharacter = *eSpace* | *eAnyNonspaceCharacter*	Any character not in the Cognex-reserved UTF-32 code ranges.
eAlpha = *eAlphaUppercase* | *eAlphaLowercase*	Characters A through Z and a through z.
eAlphaNumeric = *eAlpha* | *eNumeric*	Characters A through Z, a through z, and 0 through 9.
eAlphaUppercaseNumeric = *eAlphaUppercase* | *eNumeric*	Characters A through Z and 0 through 9.

Value	Meaning
eAlphaLowercaseNumeric = *eAlphaLowercase* | *eNumeric*	Characters a through z and 0-9.
kDefaultFielding = *eAnyNonspaceCharacter*	Default fielding is any non-Cognex-reserved nonspace character.

PositionStatus

```
enum PositionStatus;
```

This enumeration defines quality ratings for characters and strings.

Value	Meaning
ePrimary = 1	Matching the primary character.
ePrimarySwap = 2	Matching a swap character of a primary character.
eSecondary = 3	Matching a secondary character.
eSecondarySwap = 4	Matching a swap character of a secondary character.
eSubstituted = 5	Replaced by a non-input character.
eSubstitutedSpace = 6	Replaced by a space.
eNoMatch = 7	No match allowed by the OCR Dictionary Fielding tool.
eInserted = 8	A character inserted by the OCR Dictionary Fielding tool.
eDeleted = 9	An input character deleted by the OCR Dictionary Fielding tool.
eDeletedIgnored = 10	An input character deleted by the OCR Dictionary Fielding tool as part of the portions to be ignored (for example, prefix).

IsGoodMetric

```
enum IsGoodMetric;
```

This enumeration defines which matches to treat as “good.”

Value	Meaning
ePrimaryMatchesAreGood = 0x3	Matching the primary character or a swap character of the primary character is acceptable.
ePrimaryAndSecondaryMatchesAreGood = 0xF	Matching the primary character or the secondary character or a swap character of the primary character or the secondary character is acceptable.
kDefaultIsGoodMetric = *ePrimaryMatchesAreGood*	The default is *ePrimaryMatchesAreGood*.

ccOCRDictionaryDefs

ccOCRDictionaryFielding

```
#include <ch_cvl/ocrfldng.h>

class ccOCRDictionaryFielding;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class specifies the set of acceptable characters at each character position in a string.

Constructors/Destructors

ccOCRDictionaryFielding

```
explicit ccOCRDictionaryFielding(
  const cmStd vector<ccOCRDictionaryPositionFielding>&
  positionFieldings =
  cmStd vector<ccOCRDictionaryPositionFielding>());
```

Constructs a fielding object from the given vector.

Parameters

positionFieldings Position fieldings vector.

Throws

ccOCRDictionaryDefs::InvalidFielding
isEmpty() is true for any element of *positionFieldings*.

ccOCRDictionaryFielding

```
ccOCRDictionaryFielding(
  const ccOCRDictionaryFielding& rhs);
```

Copy constructor.

Parameters

rhs The source of the copy.

ccOCRDictionaryFielding

```
~ccOCRDictionaryFielding();
```

Destructor.

Public Member Functions

positionFieldings

```
const cmStd vector<ccOCRDictionaryPositionFielding>&
  positionFieldings() const;

void positionFieldings(
  const cmStd vector<ccOCRDictionaryPositionFielding>&
  positionFieldings);
```

- ```
  const cmStd vector<ccOCRDictionaryPositionFielding>&
    positionFieldings() const;
  ```

  Gets the fielding for all character positions.

- ```
  void positionFieldings(
    const cmStd vector<ccOCRDictionaryPositionFielding>&
    positionFieldings);
  ```

  Sets the fielding for all character positions.

  Parameters

  positionFieldings Character positions.

  Throws

  ccOCRDictionaryDefs::InvalidFielding

  isEmpty() is true for any of the position fieldings.

size

```
c_Int32 size() const;
```

Gets the size of the position fielding vector.

positionFielding

```
const ccOCRDictionaryPositionFielding&
  positionFielding(c_Int32 index) const;

void positionFielding(c_Int32 index,
  const ccOCRDictionaryPositionFielding& fielding);
```

- ```
  const ccOCRDictionaryPositionFielding&
    positionFielding(c_Int32 index) const;
  ```

  Gets an individual character fielding.
  ```

Parameters

index The position of the character for which you are getting fielding.

Throws

ccOCRDictionaryDefs::BadParams
index < 0 or *index* >= **size()**

- ```
  void positionFielding(c_Int32 index,
    const ccOCRDictionaryPositionFielding& fielding);
  ```

Sets an individual character fielding.

Parameters

index The position of the character for which you are setting fielding.

fielding The fielding value.

Throws

ccOCRDictionaryDefs::BadParams
index < 0 or *index* >= **size()**

ccOCRDictionaryDefs::InvalidFielding
fielding.isEmpty() returned true.

run

```
void run(
  const ccOCRDictionaryStringMulti& inputStringMulti,
  const ccOCSwapCharSet& swapCharacterSet,
  const ccOCRDictionaryFieldingRunParams& runParams,
  ccOCRDictionaryResultSet& resultSet) const;
```

Checks the input string against the fielding requirements.

Parameters

inputStringMulti The input string.

swapCharacterSet
The swap character set.

runParams The run-time parameters.

resultSet The result set.

Throws

ccOCRDictionaryDefs::BadParams
inputString.size() == 0,
or
runParams.fixedLengthFielding() == false &&
runParams.minFieldLastIndex() >= **size()**,
```

or
runParams.fixedLengthFielding() == false &&
runParams.minStringLength() > **size()**,
or
any of the following is true for any element of *inputStringMulti*:

- Contains no character.
- Contains duplicate characters.
- Contains *ccCharCode::eUnknown* when the number of characters is greater than one.

Requires that all characters in *inputStringMulti* be non-Cognex-reserved, except *ccCharCode::eUnknown*, which is allowed.

Notes

If the fielding is empty, then all characters are accepted. This means that the primary character of an *inputStringMulti* character input (except for *ccCharCode::eUnknown*, which is a special case and induces unmatched) is matched as a primary match, and all the remaining characters in an *inputStringMultiCharacter* are matched as secondary matches.

Operators

operator==

```
bool operator==(const ccOCRDictionaryFielding& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCRDictionaryFielding& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for inequality.

operator=

```
ccOCRDictionaryFielding& operator=(
  const ccOCRDictionaryFielding& rhs);
```

Assignment operator.

Parameters

rhs	The object to assign to this one.

ccOCRDictionaryFielding

ccOCRDictionaryFieldingRunParams

```
#include <ch_cvl/ocrfldng.h>

class ccOCRDictionaryFieldingRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class provides run-time parameters for OCR Dictionary Fielding tool.

Constructors/Destructors

ccOCRDictionaryFieldingRunParams

```
ccOCRDictionaryFieldingRunParams();
```

Constructs an object with default values, which are the following:

- *ignoreUnfieldedSpaces*: true
- *fixedLengthFielding*: true
- *minStringLength*: 1
- *maxStringLength*: *ckMaxInt32*
- *maxFieldFirstIndex*: *ckMaxInt32*
- *minFieldLastIndex*: 0
- *ignoreFailingPrefixSuffix*: true
- *isGoodMetric*: *ccOCRDictionaryDefs::kDefaultIsGoodMetric*

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

ignoreUnfieldedSpaces

```
bool ignoreUnfieldedSpaces() const;
void ignoreUnfieldedSpaces(bool ignore);
```

- `bool ignoreUnfieldedSpaces() const;`

  Gets whether to ignore/skip spaces in the input string where the corresponding fielding settings for those character positions do not allow spaces.

- `void ignoreUnfieldedSpaces(bool ignore);`

  Sets whether to ignore/skip spaces in the input string where the corresponding fielding settings for those character positions do not allow spaces.

  Parameters

ignore	Whether to ignore/skip spaces in the input string where the corresponding fielding settings for those character positions do not allow spaces.

fixedLengthFielding

```
bool fixedLengthFielding() const;
void fixedLengthFielding(bool fixed);
```

- `bool fixedLengthFielding() const;`

  Gets whether to run the OCR Dictionary Fielding tool in the fixed-length mode or the variable-length mode.

- `void fixedLengthFielding(bool fixed);`

  Sets whether to run the OCR Dictionary Fielding tool in the fixed-length mode (or the variable-length mode).

  Parameters

fixed	Whether to run the OCR Dictionary Fielding tool in the fixed-length mode.

Notes

If set to true, the tool runs in the fixed-length mode. In this mode, the tool uses the specified fielding vector in its entirety, and ignores the parameters *minStringLength*, *maxStringLength*, *maxFieldFirstIndex*, *minFieldLastIndex*, and *ignoreFailingPrefixSuffix*.

If set to false, the tool runs in the variable-length mode. In this mode, the tool respects the following parameters in choosing a subsequence of the fielding vector that best fits the input string: *minStringLength*, *maxStringLength*, *maxFieldFirstIndex*, *minFieldLastIndex*, and *ignoreFailingPrefixSuffix*.

minStringLength

```
c_Int32 minStringLength() const;

void minStringLength(c_Int32 minStringLength);
```

- `c_Int32 minStringLength() const;`

  Gets the minimum acceptable string length, inclusive.

- `void minStringLength(c_Int32 minStringLength);`

  Sets the minimum acceptable string length, inclusive.

  Parameters

  minStringLength The minimum acceptable string length.

  Throws

  ccOCRDictionaryDefs::BadParams
  minStringLength < 1

  Notes

  This parameter has no effect if **fixedLengthFielding()** returns true.

  The **run()** function throws *ccOCRDictionaryDefs::BadParams* if *minStringLength* > *maxStringLength*, and **fixedLengthFielding()** returns false.

  The **run()** function throws *ccOCRDictionaryDefs::BadParams* if **fixedLengthFielding()** == false and **minStringLength()** > **fielding.size()**

maxStringLength

```
c_Int32 maxStringLength() const;

void maxStringLength(c_Int32 maxStringLength);
```

- `c_Int32 maxStringLength() const;`

  Gets the maximum acceptable string length, inclusive.

- `void maxStringLength(c_Int32 maxStringLength);`

  Sets the maximum acceptable string length, inclusive.

  Parameters

  maxStringLength The maximum acceptable string length.

  Throws

  ccOCRDictionaryDefs::BadParams
  maxStringLength < 1

  Notes

  This parameter has no effect if **fixedLengthFielding()** returns true.

  The **run()** function throws *ccOCRDictionaryDefs::BadParams* if *minStringLength* > *maxStringLength*, and **fixedLengthFielding()** returns false.

maxFieldFirstIndex

```
c_Int32 maxFieldFirstIndex() const;

void maxFieldFirstIndex(c_Int32 maxFirstIndex);
```

- `c_Int32 maxFieldFirstIndex() const;`

  Gets the maximum allowable start position of a subsequence of the fielding vector to be used.

- `void maxFieldFirstIndex(c_Int32 maxFirstIndex);`

  Sets the maximum allowable start position of a subsequence of the fielding vector to be used.

  Parameters

  maxFirstIndex The maximum allowable start position of a subsequence of the fielding vector to be used.

Throws

ccOCRDictionaryDefs::BadParams
maxFirstIndex < 0

Notes

For variable-length fielding, the fielding subsequences to be considered must start at a position no greater than this index.

This parameter has no effect if **fixedLengthFielding()** returns true.

minFieldLastIndex

```
c_Int32 minFieldLastIndex() const;

void minFieldLastIndex(c_Int32 minLastIndex);
```

- `c_Int32 minFieldLastIndex() const;`

Gets the minimum allowable inclusive end position of a subsequence of the fielding vector to be used.

- `void minFieldLastIndex(c_Int32 minLastIndex);`

Sets the minimum allowable inclusive end position of a subsequence of the fielding vector to be used.

Parameters

minLastIndex The minimum allowable inclusive end position of a subsequence of the fielding vector to be used.

Throws

ccOCRDictionaryDefs::BadParams
minLastIndex < 0

Notes

For variable-length fielding, the fielding subsequences to be considered must end at a position no smaller than this index.

This parameter has no effect if **fixedLengthFielding()** returns true.

The **run()** function throws *ccOCRDictionaryDefs::BadParams* if **fixedLengthFielding()** == false and **minFieldLastIndex()** >= **fielding.size()**

ignoreFailingPrefixSuffix

```
bool ignoreFailingPrefixSuffix() const;

void ignoreFailingPrefixSuffix(bool ignore);
```

- `bool ignoreFailingPrefixSuffix() const;`

  Gets whether to ignore failing prefix and suffix when supporting variable string length.

- `void ignoreFailingPrefixSuffix(bool ignore);`

  Sets whether to ignore failing prefix and suffix when supporting variable string length.

  Parameters

  ignore Whether to ignore failing prefix and suffix when supporting variable string length.

  Notes

  A failing position refers to one whose primary character is *ccCharCode::eUnknown*.

  This parameter has no effect if **fixedLengthFielding()** returns true.

isGoodMetric

```
ccOCRDictionaryDefs::IsGoodMetric isGoodMetric() const;

void isGoodMetric(
  ccOCRDictionaryDefs::IsGoodMetric isGoodMetric);
```

- `ccOCRDictionaryDefs::IsGoodMetric isGoodMetric() const;`

  Gets which matches (only primary, or either primary or secondary) are considered to be good.

- `void isGoodMetric(`
  `ccOCRDictionaryDefs::IsGoodMetric isGoodMetric);`

  Sets which matches (only primary, or either primary or secondary) are considered to be good.

  Parameters

  isGoodMetric The matches that are considered to be good.

  Throws

  ccOCRDictionaryDefs::BadParams
  isGoodMetric is not a valid enum value.

Operators

operator==

```
bool operator==(
  const ccOCRDictionaryFieldingRunParams& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

operator!=

```
bool operator!=(
  const ccOCRDictionaryFieldingRunParams& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for inequality.

ccOCRDictionaryFieldingRunParams

ccOCRDictionaryPositionFielding

```
#include <ch_cvl/ocrfldng.h>

class ccOCRDictionaryPositionFielding;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class specifies the set of acceptable characters at a position.

Notes

There are two independent methods for specifying the acceptable characters; that is, via a bit field of the *ccOCRDictionaryDefs::Fielding* enum and via listing all allowed individual characters. These two methods do not interact with each other. The OCR Dictionary Fielding tool uses the union of all characters from the two methods.

Constructors/Destructors

ccOCRDictionaryPositionFielding

```
ccOCRDictionaryPositionFielding(
  ccOCRDictionaryDefs::Fielding fielding =
  ccOCRDictionaryDefs::kDefaultFielding);

ccOCRDictionaryPositionFielding(
  const ccOCRDictionaryPositionFielding& rhs);
```

- ```
  ccOCRDictionaryPositionFielding(
    ccOCRDictionaryDefs::Fielding fielding =
    ccOCRDictionaryDefs::kDefaultFielding);
  ```

  Constructs a default object.

  Parameters

  fielding The fielding value.
  ```

- ```
  ccOCRDictionaryPositionFielding(
    const ccOCRDictionaryPositionFielding& rhs);
  ```

  Copy constructor.

  Parameters

  rhs The source of the copy.

ccOCRDictionaryPositionFielding

```
~ccOCRDictionaryPositionFielding();
```

Destructor.

Public Member Functions

fieldingBits

```
c_UInt32 fieldingBits() const;

void fieldingBits(c_UInt32 fieldingBits);
```

- ```
  c_UInt32 fieldingBits() const;
  ```

  Gets the fielding bit field.

- ```
  void fieldingBits(c_UInt32 fieldingBits);
  ```

  Sets the fielding bit field.

  Parameters

  fieldingBits The fielding bit field.

  Throws

  ccOCRDictionaryDefs::BadParams
  fieldingBits is not a bitwise OR of values from *ccOCRDictionaryDefs::Fielding*.

  Notes

  This does not interact with **fieldingCharacters()**.
  ```

fieldingCharacters

```
void fieldingCharacters(
  const cmStd vector<c_Char32>& characters);

const cmStd vector<c_Char32>& fieldingCharacters() const;
```

- ```
  void fieldingCharacters(
    const cmStd vector<c_Char32>& characters);
  ```

  Sets the fielding characters.

  Parameters

  characters The fielding characters to be set.

  Throws

  ccOCRDictionaryDefs::BadParams
  characters contain duplicates, or
  any element of *characters* is *ccCharCode::eUnknown*.

  Notes

  This is a straight setter. It does not attempt to collapse the specified characters into a minimum equivalent set of characters if the specified characters contain any special values such as *ccCharCode::eAnyCharacter*.

- ```
  const cmStd vector<c_Char32>& fieldingCharacters() const;
  ```

  Gets the fielding characters.

  Notes

  This is a straight getter. It does not attempt to collapse the set of fielding characters even if they contain special values such as *ccCharCode::eAnyCharacter*.

  This does not interact with **fieldingBits()**.

allFieldingCharacters

```
cmStd vector<c_Char32> allFieldingCharacters() const;
```

Gets the minimum equivalent set of fielding characters.

Notes

This attempts to collapse the set of fielding characters as much as possible to throw away redundant ones. For example, if **fieldingCharacters()** contained the special value *ccCharCode::eAnyNonspaceCharacter* and a value 0x20 (space) in addition to other values, **allFieldingCharacters()** would return a vector with a single element of the value *ccCharCode::eAnyCharacter*.

This does not interact with **fieldingBits()**.

fielding

```
void fielding(
  c_UInt32 fieldingBits,
  const cmStd vector<c_Char32>& fieldingCharacters);
```

Sets all allowed characters via both bit field and characters.

Parameters

fieldingBits The fielding bits.

fieldingCharacters
The fielding characters.

Notes

The fielding bits and characters are maintained independently. The tool uses their union.

multiCharacter

```
ccOCRDictionaryCharMulti multiCharacter() const;
```

Gets a multicharacter representation of the union of all characters allowed for this fielding, via either fielding bits or fielding characters.

Notes

The individual characters in the returned object are ordered in ascending order of the character code.

If **isAnyCharacter()** or **isAnyNonspaceCharacter()** returns true, the returned multicharacter object will contain exactly one element: **ccOCRDictionaryChar(***ccCharCode::eAnyCharacter***)** or **ccOCRDictionaryChar(***ccCharCode::eAnyNonspaceCharacter***)**, as appropriate.

isEmpty

```
bool isEmpty() const;
```

Gets whether this fielding allows no character.

Notes

This returns true if both of the following are true:

- **fieldingBits()** == 0
- **fieldingCharacters().size()** == 0

isSingular

```
bool isSingular() const;
```

Gets whether this fielding allows only a single character.

isAnyCharacter

```
bool isAnyCharacter() const;
```

Returns whether this fielding allows any character.

Notes

This checks the union of the bit field and the characters.

isAnyCharacter() and **isAnyNonspaceCharacter()** cannot both be true at the same time. Specifically, **isAnyNonspaceCharacter()** being true means the fielding does not allow the space character 0x20, while **isAnyCharacter()** being true allows it.

isAnyNonspaceCharacter

```
bool isAnyNonspaceCharacter() const;
```

Returns whether this fielding allows any nonspace character.

Notes

This checks the union of the bit field and the characters.

isAnyCharacter() and **isAnyNonspaceCharacter()** cannot both be true at the same time. Specifically, **isAnyNonspaceCharacter()** being true means the fielding does not allow the space character 0x20, while **isAnyCharacter()** being true allows it.

Operators

operator==

```
bool operator==(
  const ccOCRDictionaryPositionFielding& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCRDictionaryPositionFielding

operator!=

```
bool operator!=(
  const ccOCRDictionaryPositionFielding& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

operator=

```
ccOCRDictionaryPositionFielding& operator=(
  const ccOCRDictionaryPositionFielding& rhs);
```

Assignment operator.

Parameters

rhs The object to assign to this one.

ccOCRDictionaryResult

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryResult contains the results from applying the OCR Dictionary Fielding tool to the output from the OCR Classifier tool. The result includes information about each position of the input string and the result string.

Constructors/Destructors

ccOCRDictionaryResult

```
ccOCRDictionaryResult();
```

Construct a default dictionary result object. **isComputed()** returns *false* on a default-constructed **ccOCRDictionaryResult**.

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Reset this object to its default state.

isComputed

```
bool isComputed() const;
```

Returns *true* if this **ccOCRDictionaryResult** contains valid data, *false* otherwise.

Notes

All other getters will throw *ccOCRDictionaryDefs::NotComputed* if **isComputed()** returns *false*.

isGoodMetric `ccOCRDictionaryDefs::IsGoodMetric isGoodMetric() const;`

Gets whether primary and/or secondary matches are considered good.

isGood `bool isGood() const;`

If **isGoodMetric()**==*ccOCRDictionaryDefs::ePrimaryMatchesAreGood,* this function returns *true* under the following conditions:

- All result string positions have a status of *ccOCRDictionaryDefs::ePrimary* or *ccOCRDictionaryDefs::ePrimarySwap.*
- All input string positions have a status of *ccOCRDictionaryDefs::ePrimary*, *ccOCRDictionaryDefs::ePrimarySwap,* or *ccOCRDictionaryDefs::eDeletedIgnored*.

If **isGoodMetric()**==*ccOCRDictionaryDefs::ePrimaryAndSecondaryMatchesAreGood*, this function returns *true* under the following conditions:

- All result string positions have a status of *ccOCRDictionaryDefs::ePrimary*, *ccOCRDictionaryDefs::ePrimarySwap*, *ccOCRDictionaryDefs::eSecondary*, or *ccOCRDictionaryDefs::eSecondarySwap*.
- All input string positions have a status of *ccOCRDictionaryDefs::ePrimary*, *ccOCRDictionaryDefs::ePrimarySwap*, *ccOCRDictionaryDefs::eSecondary*, *ccOCRDictionaryDefs::eSecondarySwap*, or *ccOCRDictionaryDefs::eDeletedIgnored*.

inputStringMulti
```
const ccOCRDictionaryStringMulti&
   inputStringMulti() const;
```

Returns a reference to the input string used in the run that produced this result.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

inputString `ccOCRDictionaryString inputString() const;`

Returns the input string used in the run that produced this result. This function can only be used in cases where the input string includes a single character only.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

ccOCRDictionaryDefs::NotExpressible
ccOCRDictionary::inputStringMulti().isSingular() is false.

inputStringLineStatus

```
ccOCRDictionaryDefs::PositionStatus
   inputStringLineStatus() const;
```

Returns the overall status for the input string. The overall status is defined as the *lowest* status grade among all the individual position statuses. If there are no position statuses (the vector returned by the first overload of **inputStringPositionStatus()** is empty), then this function returns *ccOCRDictionaryDefs::eNoMatch*.

Throws
ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

inputStringPositionStatus

```
const cmStd vector<ccOCRDictionaryDefs::PositionStatus>&
   inputStringPositionStatus() const;

ccOCRDictionaryDefs::PositionStatus
   inputStringPositionStatus(c_Int32 pos) const;
```

- ```
  const cmStd vector<ccOCRDictionaryDefs::PositionStatus>&
     inputStringPositionStatus() const;
  ```

  Returns the position statuses for each position in the input string.

  Throws
  ccOCRDictionaryDefs::NotComputed
  This **ccOCRDictionaryResult** does not contain valid computed results.

- ```
  ccOCRDictionaryDefs::PositionStatus
     inputStringPositionStatus(c_Int32 pos) const;
  ```

  Returns the position status for the specified position in the input string.

  Parameters
  pos The string position.

  Throws
  ccOCRDictionaryDefs::NotComputed
  This **ccOCRDictionaryResult** does not contain valid computed results.

ccOCRDictionaryDefs::BadParam
pos is less than 0 or greater than or equal to the number of position statuses (**inputStringPositionStatus().size()**).

resultString

```
const ccOCRDictionaryString& resultString() const
```

Returns a reference to the result string created by the OCR Dictionary Fielding tool.

Throws
ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

resultStringLineStatus

```
ccOCRDictionaryDefs::PositionStatus
   resultStringLineStatus() const;
```

Returns the overall status for the result string. The overall status is defined as the *lowest* status grade among all the individual position statuses. If there are no position statuses (the vector returned by the first overload of **resultStringPositionStatus()** is empty), then this function returns *ccOCRDictionaryDefs::eNoMatch*.

Throws
ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

resultStringPositionStatus

```
const cmStd vector<ccOCRDictionaryDefs::PositionStatus>&
   resultStringPositionStatus() const;

ccOCRDictionaryDefs::PositionStatus
   resultStringPositionStatus(c_Int32 pos) const;
```

-
```
const cmStd vector<ccOCRDictionaryDefs::PositionStatus>&
   resultStringPositionStatus() const;
```

Returns the position statuses for each position in the result string.

Throws
ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

- ```
  ccOCRDictionaryDefs::PositionStatus
     resultStringPositionStatus(c_Int32 pos) const;
  ```

  Returns the position status for the specified position in the result string.

  Parameters

  pos The string position.

  Throws

  ccOCRDictionaryDefs::NotComputed
  This **ccOCRDictionaryResult** does not contain valid computed results.

  ccOCRDictionaryDefs::BadParam
  pos is less than 0 or greater than or equal to the number of position statuses (**resultStringPositionStatus().size()**).

numIgnoredPrefixCharacters

```
c_Int32 numIgnoredPrefixCharacters() const;
```

Return the number of prefix characters that are ignored from the beginning of the string.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

numIgnoredSuffixCharacters

```
c_Int32 numIgnoredSuffixCharacters() const;
```

Return the number of suffix characters that are ignored from the end of the string.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

numPrimaryCharacters

```
c_Int32 numPrimaryCharacters(
   bool includingSwaps = true) const;
```

Returns the number of primary characters in the result string. You can optionally include the number of their swap characters as well.

Parameters

includingSwaps Specify *true* to return the number of primary characters and their swaps, *false* to return just the number of primary characters.
```

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

numSecondaryCharacters

```
c_Int32 numSecondaryCharacters(
   bool includingSwaps = true) const;
```

Returns the number of secondary characters in the result string. You can optionally include the number of their swap characters as well.

Parameters

includingSwaps Specify *true* to return the number of secondary characters and their swaps, *false* to return just the number of secondary characters.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

inputStringIndexFromResultStringIndex

```
c_Int32 inputStringIndexFromResultStringIndex(
   c_Int32 resultStringIndex) const;
```

Returns the character index in the input string that corresponds to the specified character index in the result string.

Notes

If you specify a result string character index that refers to an inserted character, this function returns -1.

Parameters

resultStringIndex The result string character index.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

ccOCRDictionaryDefs::BadParams
resultStringIndex is less than 0 or greater than or equal to the number of position statuses (**resultStringPositionStatus().size()**).

fieldFirstIndex `c_Int32 fieldFirstIndex() const;`

Gets the position in the fielding where the fielding was matched to the input string. This parameter is only useful for variable length fielding results where the matched fielding can be a subset of the user-specified fielding.

Notes

This value is always 0 for fixed length fielding results.

This value is always greater than or equal to 0 for variable length fielding results.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

Operators

operator== `bool operator==(const ccOCRDictionaryResult& rhs) const;`

Returns true if this **ccOCRDictionaryResult** is equal to the supplied one, false otherwise.

Parameters

rhs The **ccOCRDictionaryResult** to compare to this one.

operator!= `bool operator!=(const ccOCRDictionaryResult& rhs) const`

Returns false if this **ccOCRDictionaryResult** is equal to the supplied one, true otherwise.

Parameters

rhs The **ccOCRDictionaryResult** to compare to this one.

ccOCRDictionaryResult

ccOCRDictionaryResultSet

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryResultSet contains a collection of all results from applying the OCR Dictionary Fielding tool to an input string.

Constructors/Destructors

ccOCRDictionaryResultSet

```
ccOCRDictionaryResultSet();
```

Construct a default dictionary result object. **isComputed()** returns *false* on a default-constructed **ccOCRDictionaryResultSet**.

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

reset

```
void reset();
```

Reset this object to its default state.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Returns *true* if this **ccOCRDictionaryResultSet** contains valid data, *false* otherwise.

Notes

All other getters will throw *ccOCRDictionaryDefs::NotComputed* if **isComputed()** returns *false*.

results

```
const cmStd vector<ccOCRDictionaryResult>& results() const;
```

Returns a reference to a vector containing all of the results objects.

Notes

The results are sorted in descending order of quality rating.

Throws

ccOCRDictionaryDefs::NotComputed
This **ccOCRDictionaryResult** does not contain valid computed results.

Operators

operator==

```
bool operator==(const ccOCRDictionaryResultSet& rhs) const;
```

Returns true if this **ccOCRDictionaryResultSet** is equal to the supplied one, false otherwise.

Parameters

rhs The **ccOCRDictionaryResultSet** to compare to this one.

operator!=

```
bool operator!=(const ccOCRDictionaryResultSet& rhs) const;
```

Returns false if this **ccOCRDictionaryResultSet** is equal to the supplied one, true otherwise.

Parameters

rhs The **ccOCRDictionaryResultSet** to compare to this one.

ccOCRDictionaryString

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryString;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryString represents a string of characters used by the OCR Dictionary Fielding tool (both for input and output). **ccOCRDictionaryString** contains a vector of **ccOCRDictionaryChar** objects, one for each string position.

For strings containing multicharacters, use **ccOCRDictionaryStringMulti**.

Constructors/Destructors

ccOCRDictionaryString

```
ccOCRDictionaryString(
   const cmStd vector<c_Char32>& characters, double score);

ccOCRDictionaryString(const ccCvlString& characters,
   double score);

explicit ccOCRDictionaryString(
  const cmStd vector<ccOCRDictionaryChar>& characters);
```

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

- ```
  ccOCRDictionaryString(
    const cmStd vector<c_Char32>& characters, double score);
  ```

  Constructs a **ccOCRDictionaryString** from the supplied vector of characters. All characters are assigned the supplied score value.

  Parameters

  characters The characters to place in the **ccOCRDictionaryString**.
  ```

score The score, which must be in the range 0.0 through 1.0, to assign to the characters.

Throws

ccOCRDictionaryDefs::BadParams

score is less than 0.0 or greater than 1.0.

- `ccOCRDictionaryString(const ccCvlString& characters, double score);`

Constructs a **ccOCRDictionaryString** from the supplied **ccCVLString** object. All characters are assigned the supplied score value.

Parameters

characters The string containing the characters to place in the **ccOCRDictionaryString**.

score The score, which must be in the range 0.0 through 1.0, to assign to the characters.

Throws

ccOCRDictionaryDefs::BadParams

score is less than 0.0 or greater than 1.0.

- `explicit ccOCRDictionaryString( const cmStd vector<ccOCRDictionaryChar>& characters);`

Constructs a **ccOCRDictionaryString** from the supplied vector of **ccOCRDictionaryChar** objects. The supplied characters' scores are not changed.

Public Member Functions

characters

```
const cmStd vector<ccOCRDictionaryChar>& characters()
   const;

void characters(
   const cmStd vector<ccOCRDictionaryChar>& c);

void characters(const cmStd vector<c_Char32>& characters,
   double score);

void characters(const ccCvlString& characters,
   double score);
```

- ```
  const cmStd vector<ccOCRDictionaryChar>& characters()
     const;
  ```

  Returns a reference to the characters in this **ccOCRDictionaryString**.

- ```
  void characters(
     const cmStd vector<ccOCRDictionaryChar>& c);
  ```

  Sets the characters in this **ccOCRDictionaryString** to be the supplied vector of **ccOCRDictionaryChar**. The characters' scores are not changed.

  Parameters

  c The characters to set.

  Throws

  ccOCRDictionaryDefs::BadParams
  score is less than 0.0 or greater than 1.0.

- ```
  void characters(const cmStd vector<c_Char32>& characters,
     double score);
  ```

  Sets the characters in this **ccOCRDictionaryString** to be the supplied vector of characters. All characters are assigned the supplied score value.

  Parameters

  characters The characters to set.

  score The score for the characters, in the range 0.0 through 1.0.

  Throws

  ccOCRDictionaryDefs::BadParams
  score is less than 0.0 or greater than 1.0.
  ```

- `void characters(const ccCvlString& characters, double score);`

  Sets the characters in this **ccOCRDictionaryString** to be the supplied **ccCVLString** object. All characters are assigned the supplied score value.

  Parameters

  characters The characters to set.

  score The score for the characters, in the range 0.0 through 1.0.

  Throws

  ccOCRDictionaryDefs::BadParams
  score is less than 0.0 or greater than 1.0.

size `c_Int32 size() const;`

Returns the number of characters in this **ccOCRDictionaryString**.

isEmpty `bool isEmpty() const;`

Returns *true* if there are no characters in this **ccOCRDictionaryString**, *false* otherwise.

Operators

operator ccCvlString

`operator ccCvlString() const;`

Returns the **ccCVLString** representation of this string. If either **ccOCRDictionaryChar::char()** or **ccOCRDictionaryChar::wchar_t()** throws an error for any character in the string, this function will also throw that error.

Throws

ccCharCodeDefs::NotRepresentable
A character in this string cannot be represented as a **ccCvlChar**.

---

operator[]

```
const ccOCRDictionaryChar& operator[](c_Int32 index) const;

ccOCRDictionaryChar& operator[](c_Int32 index);
```

- `const ccOCRDictionaryChar& operator[](c_Int32 index) const;`

  Return a **const** reference to the given character in the string.

  Parameters

  index The character to return.

Throws

ccOCRDictionaryDefs::BadParam

index is less than 0 or greater than or equal to the number of characters in the string.

- `ccOCRDictionaryChar& operator[](c_Int32 index);`

Return a non-**const** reference to the given character in the string.

Parameters

index The character to return.

Throws

ccOCRDictionaryDefs::BadParam

index is less than 0 or greater than or equal to the number of characters in the string.

operator== `bool operator==(const ccOCRDictionaryString& rhs) const;`

Returns *true* if this **ccOCRDictionaryString** is equal to the supplied one, *false* otherwise.

Parameters

rhs The **ccOCRDictionaryString** to compare to this one.

operator!= `bool operator!=(const ccOCRDictionaryString& rhs) const;`

Returns *false* if this **ccOCRDictionaryString** is equal to the supplied one, *true* otherwise.

Parameters

rhs The **ccOCRDictionaryString** to compare to this one.

ccOCRDictionaryString

ccOCRDictionaryStringMulti

```
#include <ch_cvl/ocrdcbas.h>

class ccOCRDictionaryStringMulti;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccOCRDictionaryStringMulti represents a string of characters used by the OCR Dictionary Fielding tool (both for input and output) where each string position contain a multicharacter. **ccOCRDictionaryStringMulti** contains a vector of **ccOCRDictionaryCharMulti** objects, one for each string position.

Constructors/Destructors

ccOCRDictionaryStringMulti

```
explicit ccOCRDictionaryStringMulti(const
   cmStd vector<ccOCRDictionaryCharMulti>& characters);

explicit ccOCRDictionaryStringMulti(
   const ccOCRDictionaryString& characters);
```

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

- ```
  explicit ccOCRDictionaryStringMulti(const
     cmStd vector<ccOCRDictionaryCharMulti>& characters);
  ```

  Constructs a **ccOCRDictionaryStringMulti** from the supplied vector of **ccOCRDictionaryCharMulti** objects.

  Parameters

characters	The characters from which to construct this **ccOCRDictionaryStringMulti**.
  ```

- ```
  explicit ccOCRDictionaryStringMulti(
     const ccOCRDictionaryString& characters);
  ```

  Constructs a **ccOCRDictionaryStringMulti** from the supplied vector of **ccOCRDictionaryString**. Each **ccOCRDictionaryChar** in the supplied string is converted to a **ccOCRDictionaryCharMulti** with a single character.

  Parameters

  characters The characters from which to construct this **ccOCRDictionaryStringMulti**.

Public Member Functions

characters

```
const cmStd vector<ccOCRDictionaryCharMulti>&
   characters() const;

void characters(const
   cmStd vector<ccOCRDictionaryCharMulti>& c);
```

- ```
  const cmStd vector<ccOCRDictionaryCharMulti>&
     characters() const;
  ```

  Returns a reference to the characters in this **ccOCRDictionaryStringMulti**.

- ```
  void characters(const
     cmStd vector<ccOCRDictionaryCharMulti>& c);
  ```

  Sets the characters in this **ccOCRDictionaryStringMulti** from the supplied vector of multicharacters.

  Parameters

  c The characters to set.

isSingular

```
bool isSingular() const;
```

Returns *true* if each character in this object contains exactly one character, false otherwise.

Notes

This function returns *true* if the string itself is empty (**size()** is 0).

size

```
c_Int32 size() const;
```

Gets the number of multicharacters in this string.
```

dictionaryString

```
ccOCRDictionaryString dictionaryString(
   bool throwIfAmbiguous = false) const;

void dictionaryString(const ccOCRDictionaryString& s);
```

- ```
  ccOCRDictionaryString dictionaryString(
     bool throwIfAmbiguous = false) const;
  ```

  Return a **ccOCRDictionaryString** that is made up of

  - A character position's primary character, if the position has multiple characters.
  - A character position's character, if the position has only a single character.

  If you supply a value of *true* for *throwIfAmbiguous*, then this function will throw an error if any character position has multiple characters.

  Parameters

  throwIfAmbiguous

  Specify a value of *true*, to force an error if any character positions have multiple characters.

  Throws

  ccCharCodeDefs::NotExpressible

  throwIfAmbiguous is *true* and at least one character position in this object has multiple characters or *throwIfAmbiguous* is false and at least one character position has multiple characters and at least one character position has no primary character.

- ```
  void dictionaryString(const ccOCRDictionaryString& s);
  ```

  Sets this **ccOCRDictionaryStringMulti**'s characters using the supplied **ccOCRDictionaryString** object. Each character position will have a single character.

  Parameters

  s The string to set.

Operators

operator[]

```
const ccOCRDictionaryCharMulti& operator[](
   c_Int32 index) const;

ccOCRDictionaryCharMulti& operator[](c_Int32 index);
```

- ```
  const ccOCRDictionaryCharMulti& operator[](
     c_Int32 index) const;
  ```

  Return a **const** reference to the given character in the string.

  Parameters

  index The character to return.

  Throws

  ccOCRDictionaryDefs::BadParam

  index is less than 0 or greater than or equal to the number of characters in the string.

- ```
  ccOCRDictionaryCharMulti& operator[](c_Int32 index);
  ```

  Return a non-**const** reference to the given character in the string.

  Parameters

  index The character to return.

  Throws

  ccOCRDictionaryDefs::BadParam

  index is less than 0 or greater than or equal to the number of characters in the string.

operator==

```
bool operator==(const ccOCRDictionaryStringMulti& rhs)
   const;
```

Returns *true* if this **ccOCRDictionaryStringMulti** is equal to the supplied one, *false* otherwise.

Parameters

rhs The **ccOCRDictionaryStringMulti** to compare to this one.

operator!=

```
bool operator!=(const ccOCRDictionaryStringMulti& rhs)
   const;
```

Returns *false* if this **ccOCRDictionaryStringMulti** is equal to the supplied one, *true* otherwise.

Parameters

rhs	The **ccOCRDictionaryStringMulti** to compare to this one.

ccOCRDictionaryStringMulti

ccOCSwapChar

```
#include <ch_cvl/ocswapch.h>

class ccOCSwapChar;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class defines a single group of swap characters. Characters within the group are swappable with each other.

Constructors/Destructors

ccOCSwapChar

```
ccOCSwapChar();

explicit ccOCSwapChar(const cmStd vector<c_Char32>&
  characterCodes);

ccOCSwapChar(c_Char32 c1, c_Char32 c2);
```

- `ccOCSwapChar();`

  Constructs an object.

- `explicit ccOCSwapChar(const cmStd vector<c_Char32>& characterCodes);`

  Constructs an object with the specified group of swap characters.

  Parameters

  characterCodes The character codes of swappable characters.

  Throws

  ccOCSwapCharDefs::BadParams

  characterCodes contains any duplicate character codes, or **characterCodes.size()** < 2;
  or
  any of the character codes are Cognex-reserved character

codes (use the **ccCharCode::isReserved()** function to determine whether it is a Cognex-reserved character code and refer to <*ch_cvl/charcode.h*>).

- `ccOCSwapChar(c_Char32 c1, c_Char32 c2);`

Constructs an object with the specified group of swap characters.

Parameters

c1 The character code of one of the swappable characters.

c2 The character code of the other swappable character.

Throws

ccOCSwapCharDefs::BadParams
c1 == *c2*, or
any of the character codes are Cognex-reserved character codes (use the **ccCharCode::isReserved()** function to determine whether it is a Cognex-reserved character code and refer to <*ch_cvl/charcode.h*>).

Notes

Compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

characters

```
const cmStd vector<c_Char32>& characters() const;

void characters(const cmStd vector<c_Char32>&
  characterCodes);

void characters(c_Char32 c1, c_Char32 c2);
```

- `const cmStd vector<c_Char32>& characters() const;`

Gets members of the swap character group.

Throws

ccOCSwapCharDefs::BadParams
characterCodes.size() < 2, or
any of the character codes are Cognex-reserved character codes (use the **ccCharCode::isReserved()** function to determine whether it is a Cognex-reserved character code and refer to <*ch_cvl/charcode.h*>)

- `void characters(const cmStd vector<c_Char32>& characterCodes);`

  Sets members of the swap character group.

  Parameters

  characterCodes

  Character codes of characters to be set as members of the swap character group.

  Throws

  ccOCSwapCharDefs::BadParams

  characterCodes contains any duplicate character codes, or *c1 == c2*;
  or
  characterCodes.size() < 2, or
  any of the character codes are Cognex-reserved character codes (use the **ccCharCode::isReserved()** function to determine whether it is a Cognex-reserved character code and refer to <*ch_cvl/charcode.h*>).

- `void characters(c_Char32 c1, c_Char32 c2);`

  Sets members of the swap character group.

  Parameters

  c1 — The first character of the character pair to be set as member of the swap character group.

  c2 — The second character of the character pair to be set as member of the swap character group

  Throws

  ccOCSwapCharDefs::BadParams

  characterCodes contains any duplicate character codes, or *c1 == c2*;
  or
  characterCodes.size() < 2, or
  any of the character codes are Cognex-reserved character codes (use the **ccCharCode::isReserved()** function to determine whether it is a Cognex-reserved character code and refer to <*ch_cvl/charcode.h*>).

Notes

The setters set, instead of append, to the group.

The setters sort the character codes in ascending order.

Setters throw an exception if *characterCodes* contains any duplicate character codes, or if *c1* == *c2*.

Operators

degen

```
bool degen() const;
```

Returns whether this group of swap character is degenerate, that is, contains less than two members.

contains

```
bool contains(c_Char32 c) const;
```

Returns whether *c* is among this group of swap characters.

Parameters

c	The character whose swap group membership is to be investigated.

operator==

```
bool operator==(const ccOCSwapChar& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCSwapChar& rhs) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for inequality.

ccOCSwapCharSet

```
#include <ch_cvl/ocswapch.h>

class ccOCSwapCharSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class defines a set of swap character groups. Characters within each group are swappable with each other.

Constructors/Destructors

ccOCSwapCharSet

```
ccOCSwapCharSet(const cmStd vector<ccOCSwapChar>&
  swapCharacters = cmStd vector<ccOCSwapChar>());

ccOCSwapCharSet(const ccOCSwapCharSet& rhs);
```

- ```
  ccOCSwapCharSet(const cmStd vector<ccOCSwapChar>&
    swapCharacters = cmStd vector<ccOCSwapChar>());
  ```

  Constructs an object with the specified set of swap character groups.

  Parameters

  swapCharacters The set of swap character groups.

  Throws

  ccOCSwapCharDefs::BadParams
  by setter if **degen()** is true for any element of *swapCharacters*.

- ```
  ccOCSwapCharSet(const ccOCSwapCharSet& rhs);
  ```

  Copy constructor.

  Parameters

  rhs The source of the copy.

ccOCSwapCharSet

```
~ccOCSwapCharSet();
```

Destructor.

Public Member Functions

swapCharacters

```
const cmStd vector<ccOCSwapChar>& swapCharacters() const;

void swapCharacters(const cmStd vector<ccOCSwapChar>&
  swapCharacters);
```

- `const cmStd vector<ccOCSwapChar>& swapCharacters() const;`

  Gets all swap character groups in this set.

- `void swapCharacters(const cmStd vector<ccOCSwapChar>& swapCharacters);`

  Sets all swap character groups in this set.

  Parameters

  swapCharacters All swap character groups in this set.

  Throws

  ccOCSwapCharDefs::BadParams
  degen() is true for any element of *swapCharacters*.

  Notes

  By transitivity, all groups that share a same member character with one another are merged into a single group.

  Calling the setter with an empty vector creates an empty set. An empty set means that there are no swappable characters.

  The setter sorts the character codes within each group in ascending order.

add

```
void add(const ccOCSwapChar& swapCharacter);
```

Adds a group of swap characters to this set.

Parameters

swapCharacter The group of swap characters to be added.

Throws

ccOCSwapCharDefs::BadParams
swapCharacter.degen() is true.

Notes

By transitivity, if any character in the group already exists in an existing group in the set, the new group is merged with that existing group.

getSwapCharacter

```
void getSwapCharacter(
  c_Char32 c,
  ccOCSwapChar& swapCharacter) const;
```

Returns the group of swap characters that contains *c*.

Parameters

c	The character to search for.
swapCharacter	The swap character.

Notes

Returns a default empty **ccOCSwapChar** object if no group in this set contains *c*.

canSwap

```
bool canSwap(c_Char32 c1, c_Char32 c2) const;
```

Returns whether *c1* and *c2* exist in the same swap character group within this set.

Parameters

c1	The first character to check.
c2	The second character to check.

contains

```
bool contains(c_Char32 c) const;
```

Returns whether any swap character group in this set contains *c*.

Parameters

c	The character to check.

Operators

operator==

```
bool operator==(const ccOCSwapCharSet& rhs) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

rhs	The object with which to compare for equality.

ccOCSwapCharSet

operator!= `bool operator!=(const ccOCSwapCharSet& rhs) const;`

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

rhs The object with which to compare for inequality.

operator= `ccOCSwapCharSet& operator=(const ccOCSwapCharSet& rhs);`

Assignment operator.

Parameters

rhs The object to assign to this one.

ccOCVDefs

```
#include <ch_cvl/ocv.h>

class ccOCVDefs;
```

A name space that holds enumerations and constants used with the OCV tool.

Enumerations

CharStatus

```
enum CharStatus ;
```

This enumeration defines verification status results for characters.

Value	Meaning
eVerified	The character passes verification. The matching score is greater than the accept threshold, and the difference between the matching score and the highest scoring confusing character is greater than the confidence threshold.
eConfused	The matching score for the character is greater than the accept threshold, however the difference between the matching score and the highest scoring confusing character is not greater than the confidence threshold.
eFailed	The character fails verification. Its matching score is less than the accept threshold.

DrawFlags

```
enum DrawFlags;
```

This enumeration determines which graphics are included when diagnostics are generated.

Value	Meaning
eDrawArrangement	Draw the final arrangement pose.
eDrawLines	Draw the final poses of each line.
eDrawPositions	Draw the final poses of each character.
eDrawArrangementBox	Draw a bounding box when drawing the final arrangement pose.

Value	Meaning
eDrawLineBoxes	Draw a bounding box when drawing the final line pose.
eDrawPositionBoxes	Draw a bounding box when drawing the final character pose.

ccOCVLineResult

```
#include <ch_cvl/ocv.h>

class ccOCVLineResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class captures information about the OCV tool's verification results for one line within a line arrangement. You should not create a **ccOCVLineResult** directly.

Constructors/Destructors

ccOCVLineResult

```
ccOCVLineResult();
```

Constructs a result object with a failed status and no character position results.

Operators

operator==

```
bool operator==(const ccOCVLineResult& other) const;
```

Returns true if this object is equal to the specified line result object.

Parameters

other The line result object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVLineResult& other) const;
```

Returns true if this object is not equal to the specified line result object.

Parameters

other The line result object with which to compare for inequality.

Public Member Functions

lineIndex

```
c_Int32 lineIndex() const;
```

Returns the index of the line within the arrangement.

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the line in client coordinates. If no characters in this line were found, the returned pose is the expected pose of the line, based on the positions of the neighboring lines within the arrangement.

arrangementPose

```
const cc2Rigid& arrangementPose() const;
```

Returns the pose of the line in arrangement coordinates. If no characters in this line were found, the returned pose is the expected pose of the line, based on the positions of the neighboring lines within the arrangement.

score

```
double score() const;
```

Returns the overall verification score for the line. This score is the average of the verification scores for all characters in the line that the tool attempted to verify.

numPosVerified

```
c_Int32 numPosVerified() const;
```

Returns the number of character positions reported as verified.

verified

```
bool verified() const;
```

Returns true if all character positions in the line passed verification.

posResults

```
const cmStd vector<ccOCVPosResult>& posResults() const;
```

Returns the results of all character positions for which the OCV tool has attempted verification.

posResult

```
const ccOCVPosResult& posResult(c_Int32 posIndex) const;
```

Returns the result for the specified character position. If no character was found, the expected position, based on the positions of nearby found characters, is returned.

Parameters

posIndex The index of the character position.

Throws

ccOCVDefs::BadIndex

posIndex is not the index of a character position for which verification was attempted.

ccOCVLineResult

ccOCVLineRunParams

```
#include <ch_cvl/ocv.h>

class ccOCVLineRunParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class defines the run-time parameters used by the OCV tool to verify a line of text.

Constructors/Destructors

ccOCVLineRunParams

```
ccOCVLineRunParams();

ccOCVLineRunParams(c_Int32 lineIndex,
  const cmStd vector<ccOCVPosRunParams>& posParams);

ccOCVLineRunParams(c_Int32 lineIndex,
  const ccOCLine& line,
  double acceptThreshold = 0.5,
  double confidenceThreshold = 0.0);
```

- `ccOCVLineRunParams();`

  Constructs a default line parameters object with no character position parameters.

- ```
  ccOCVLineRunParams(c_Int32 lineIndex,
    const cmStd vector<ccOCVPosRunParams>& posParams);
  ```

  Constructs a line run-time parameters object with the specified line index and character position parameters.

  Parameters

lineIndex	The line index for these run-time parameters.
posParams	A set of run-time parameters for each character position within this line.
  ```

Throws

ccOCVDefs::BadIndex

lineIndex is less than 0 or *posParams* contains repeated index values.

- ```
  ccOCVLineRunParams(c_Int32 lineIndex,
    const ccOCLine& line,
    double acceptThreshold = 0.5,
    double confidenceThreshold = 0.0);
  ```

Constructs a line run-time parameters object with the specified line index. The run-time parameters for all character positions in the supplied line are automatically constructed using the supplied accept and confidence thresholds.

Parameters

lineIndex The line index for these run-time parameters.

line The line for which to automatically create run-time position parameters.

acceptThreshold

The accept threshold for all character positions within the supplied line. The accept threshold specifies the matching score below which the character at the line position fails verification.

confidenceThreshold

The confidence threshold for all character positions within the supplied line. If the difference between the matching score for a character position and the highest scoring confusing character is greater than the confidence threshold, the position passes verification; otherwise, the position receives a verification status of confused.

Notes

When the OCV tool runs, it verifies all character positions in the line in sequential order.

Throws

ccOCVDefs::BadIndex

lineIndex is less than 0.

ccOCVDefs::BadParams

acceptThreshold or *confidenceThreshold* is less than 0 or greater than 1.
  ```

Operators

operator==

```
bool operator==(const ccOCVLineRunParams& other) const;
```

Returns true if this object is equal to the specified object.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVLineRunParams& other) const;
```

Returns true if this object is not equal to the specified object.

Parameters

other The object with which to compare for inequality.

Public Member Functions

lineIndex

```
void lineIndex(c_Int32 index);
c_Int32 lineIndex() const;
```

- `void lineIndex(c_Int32 index);`

  Sets the index of the line in a line arrangement for which this run-time parameters object refers.

  Parameters

  index The line index.

  Throws

  ccOCVDefs::BadIndex
  index is less than 0.

- `c_Int32 lineIndex() const;`

  Returns the index of the line in a line arrangement for which this run-time parameters object refers.

ccOCVLineRunParams

posParams

```
void posParams(
  const cmStd vector<ccOCVPosRunParams>& params);

const cmStd vector<ccOCVPosRunParams>& posParams() const;
```

- ```
  void posParams(
    const cmStd vector<ccOCVPosRunParams>& params);
  ```

  Sets the run-time parameters for each of the character positions to be verified in a line.

  Parameters

  params — The run-time parameters for each character position in a line, specified in the order that they should be verified.

  Throws

  ccOCVDefs::BadIndex — *params* contains repeated index values for character positions.

- ```
  const cmStd vector<ccOCVPosRunParams>& posParams() const;
  ```

  Returns the run-time parameters for each of the character positions to be verified in a line.

ccOCVMaxArrangement

```
#include <ch_cvl\ocmax.h>

class ccOCVMaxArrangement;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The **ccOCVMaxArrangement** class represents a spatial arrangement of paragraphs or set of character strings you want the tool to verify.

Constructors/Destructors

ccOCVMaxArrangement

```
ccOCVMaxArrangement();

ccOCVMaxArrangement(
  const cmStd vector<ccOCVMaxParagraph> &paras,
  const cmStd vector<cc2Xform> &paraPoses);

ccOCVMaxArrangement(
  const cmStd vector<ccOCVMaxParagraphPtrh_const> &paras,
  const cmStd vector<cc2Xform> &paraPoses);

ccOCVMaxArrangement(
  const cmStd vector<ccOCVMaxParagraphPtrh> &paras,
  const cmStd vector<cc2Xform> &paraPoses);
```

- `ccOCVMaxArrangement();`

  Default constructor.

- ```
  ccOCVMaxArrangement(
    const cmStd vector<ccOCVMaxParagraph> &paras,
    const cmStd vector<cc2Xform> &paraPoses);
  ```

  Constructs an arrangement using the given set of paragraphs.

  The paragraphs are arranged according to the affine poses.
  ```

Parameters

paras The set of paragraphs.

paraPoses The affine poses.

Throws

ccOCVMaxDefs::BadParams
The number of poses does not match the number of paragraphs.

- ```
  ccOCVMaxArrangement(const cmStd
    vector<ccOCVMaxParagraphPtrh_const> &paras,
    const cmStd vector<cc2Xform> &paraPoses);
  ```

  Const PtrHandle version of the constructor.

  Parameters

  paras The set of paragraphs.

  paraPoses The affine poses.

- ```
  ccOCVMaxArrangement(const cmStd
    vector<ccOCVMaxParagraphPtrh> &paras,
    const cmStd vector<cc2Xform> &paraPoses);
  ```

  PtrHandle version of the constructor.

  Parameters

  paras The set of paragraphs.

  paraPoses The affine poses.

  Notes

  The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

paragraphs

```
void paragraphs(const cmStd vector<ccOCVMaxParagraph>
 &paragraphs);

void paragraphs(const cmStd
 vector<ccOCVMaxParagraphPtrh_const> &paragraphs);

void paragraphs(const cmStd vector<ccOCVMaxParagraphPtrh>
 &paragraphs);
```

- ```
  void paragraphs(const cmStd vector<ccOCVMaxParagraph>
   &paragraphs);
  ```

  Sets the paragraphs of the arrangement.

  Parameters

  paragraphs The new paragraphs.

- ```
  void paragraphs(const cmStd
   vector<ccOCVMaxParagraphPtrh_const> &paragraphs);
  ```

  Const PtrHandle version of the setters.

  Parameters

  paragraphs The new paragraphs.

- ```
  void paragraphs(const cmStd vector<ccOCVMaxParagraphPtrh>
   &paragraphs);
  ```

  PtrHandle version of the setters.

  Parameters

  paragraphs The new paragraphs.

numParagraphs

```
const c_Int32 numParagraphs() const;
```

Returns the number of paragraphs in this arrangement.

paragraphs

```
const cmStd vector<ccOCVMaxParagraphPtrh_const>&
 paragraphs() const;
```

Gets the set of paragraphs for this arrangement.
```

Notes

Setter and getter are of different types.

paragraphPoses

```
const cmStd vector<cc2Xform>& paragraphPoses() const;

void paragraphPoses
  (const cmStd vector<cc2Xform> &paragraphPoses);
```

- `const cmStd vector<cc2Xform>& paragraphPoses() const;`

  Gets the paragraph poses for this arrangement with respect to the arrangement coordinate system.

- ```
  void paragraphPoses
    (const cmStd vector<cc2Xform> &paragraphPoses);
  ```

  Sets the paragraph poses for this arrangement with respect to the arrangement coordinate system.

  Parameters

  paragraphPoses The new paragraph poses.

origin

```
cc2Xform origin() const;

void origin(const cc2Xform& origin);
```

- `cc2Xform origin() const;`

  Gets the origin of the arrangement.

- `void origin(const cc2Xform& origin);`

  Sets the origin of the arrangement.

  Parameters

  origin The new origin.
```

encloseRect

```
ccRect encloseRect
  (const cc2Xform& clientFromArr = cc2Xform(),
  const cc2Xform& clientFromImage = cc2Xform()) const;
```

Returns the smallest rectangle aligned with the specified image coordinate system guaranteed to contain this arrangement given the transformation relating the arrangement coordinate frame plus a supplied offset to the client specified coordinate system, and the uncertainties in this transformation (translation, rotation, and scale), and the transformation relating the image coordinate system to the client coordinate system.

---

render

```
void render(ccPelBuffer<c_UInt8>& image,
  const cc2XformLinear& pose,
  c_UInt8 darkForegroundColor = 0,
  c_UInt8 lightForegroundColor = 255,
  c_UInt8 backgroundColor = 127,
  c_Int32 padding = 2) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cc2XformLinear& pose,
  const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
    displayKeys,
  c_UInt8 darkForegroundColor = 0,
  c_UInt8 lightForegroundColor = 255,
  c_UInt8 backgroundColor = 127,
  c_Int32 padding = 2) const;

void render(ccPelBuffer<c_UInt8>& image,
  ccSynFontRenderOutline& outline,
  const cc2XformLinear& pose,
  const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
    displayKeys = cmStd vector<cmStd vector<cmStd
    vector<c_Int32> > >(),
  c_UInt8 darkForegroundColor = 0,
  c_UInt8 lightForegroundColor = 255,
  c_UInt8 backgroundColor = 127,
  c_Int32 padding = 2,
  const ccColor& color = ccColor::greenColor()) const;

void render(ccSynFontRenderOutline& outline,
  const cc2XformBasePtrh_const& clientFromImageXform,
  const cc2XformLinear& pose,
  const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
```

```
  displayKeys = cmStd vector<cmStd vector<cmStd
  vector<c_Int32> > >(),
const ccColor& color = ccColor::greenColor()) const;
```

- ```
  void render(ccPelBuffer<c_UInt8>& image,
   const cc2XformLinear& pose,
   c_UInt8 darkForegroundColor = 0,
   c_UInt8 lightForegroundColor = 255,
   c_UInt8 backgroundColor = 127,
   c_Int32 padding = 2) const;
  ```

  Renders the arrangement into an image with the given pose. Padding is the number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

  Parameters

  image The image.

  pose The pose.

  darkForegroundColor
  The dark foreground color of the image.

  lightForegroundColor
  The light foreground color of the image.

  backgroundColor
  The background color of the image.

  padding The number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

  Notes

  The *clientFromImage* xform of the image is used even if the image is unbound.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
   const cc2XformLinear& pose,
   const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
    displayKeys,
   c_UInt8 darkForegroundColor = 0,
  ```

```
  c_UInt8 lightForegroundColor = 255,
  c_UInt8 backgroundColor = 127,
  c_Int32 padding = 2) const;
```

Renders the arrangement into an image with the given pose. Padding is the number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

displayKeys specifies a character code to display in the rendered image instead of using the value of one of the arrangement's keys for that position. It should either be left completely empty or else it should have an identical structure to that of the arrangement (size of the outermost vector equals the number of paragraphs, size of the next vector equals the number of lines in that paragraph, size of the innermost vector equals the number of positions in that line).

Parameters

image The image.

pose The pose.

displayKeys The display keys.

darkForegroundColor
The dark foreground color of the image.

lightForegroundColor
The light foreground color of the image.

backgroundColor
The background color of the image.

padding The number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    ccSynFontRenderOutline& outline,
    const cc2XformLinear& pose,
    const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
      displayKeys = cmStd vector<cmStd vector<cmStd
      vector<c_Int32> > >(),
    c_UInt8 darkForegroundColor = 0,
    c_UInt8 lightForegroundColor = 255,
  ```
  ```

```
c_UInt8 backgroundColor = 127,
c_Int32 padding = 2,
const ccColor& color = ccColor::greenColor()) const;
```

Renders the arrangement into an image with the given pose and an outline with the specified color. Padding is the number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

displayKeys specifies a character code to display in the rendered image or outline instead of using the value of one of the arrangement's keys for that position. It should either be left completely empty or else it should have an identical structure to that of the arrangement (size of the outermost vector equals the number of paragraphs, size of the next vector equals the number of lines in that paragraph, size of the innermost vector equals the number of positions in that line).

Parameters

image The image.

outline The outline.

pose The pose.

displayKeys The display keys.

darkForegroundColor
The dark foreground color of the image.

lightForegroundColor
The light foreground color of the image.

backgroundColor
The background color of the image.

padding The number of extra pixels to add on each side of the arrangement beyond the minimum required to render.

color The color of the rendered arrangement in the image.

- ```
  void render(ccSynFontRenderOutline& outline,
    const cc2XformBasePtrh_const& clientFromImageXform,
    const cc2XformLinear& pose,
    const cmStd vector<cmStd vector<cmStd vector<c_Int32> > >&
  ```
  ```

```
   displayKeys = cmStd vector<cmStd vector<cmStd
   vector<c_Int32> > >(),
 const ccColor& color = ccColor::greenColor()) const;
```

Renders the arrangement into an outline with the given pose and the specified color.

displayKeys specifies a character code to display in the rendered outline instead of using the value of one of the arrangement's keys for that position. It should either be left completely empty or else it should have an identical structure to that of the arrangement (size of the outermost vector equals the number of paragraphs, size of the next vector equals the number of lines in that paragraph, size of the innermost vector equals the number of positions in that line).

Parameters

outline The outline.

clientFromImageXform
A **cc2Xform** describing the transformation between image coordinates and client coordinates.

pose The pose.

displayKeys The display keys.

color The color of the rendered arrangement in the image.

clone

```
ccOCVMaxArrangementPtrh clone() const;
```

Returns a deep copy of this arrangement, where each paragraph is a clone of the corresponding paragraph of this arrangement.

operator==

```
bool operator==(const ccOCVMaxArrangement& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxArrangement& other) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

Typedefs

ccOCVMaxArrangementPtrh

```
typedef ccPtrHandle<ccOCVMaxArrangement>
  ccOCVMaxArrangementPtrh;
```

ccOCVMaxArrangementPtrh_const

```
typedef ccPtrHandle_const<ccOCVMaxArrangement>
  ccOCVMaxArrangementPtrh_const;
```

ccOCVMaxArrangementSearchKeySets

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxArrangementSearchKeySets;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is used to specify what key sets should be searched for at runtime. It requires that the structure exactly matches the structure of the trained arrangement being searched for. It also requires that the specified key sets be subsets of the trained arrangement's keysets. If an individual search key set is empty, the runtime search key set will be the full key set that was trained.

Constructors/Destructors

ccOCVMaxArrangementSearchKeySets

```
ccOCVMaxArrangementSearchKeySets();

ccOCVMaxArrangementSearchKeySets(const ccOCVMaxArrangement
  &arr);
```

- `ccOCVMaxArrangementSearchKeySets();`

- `ccOCVMaxArrangementSearchKeySets(const ccOCVMaxArrangement &arr);`

  Construct an arrangement-keysets object from an arrangement. The structure of the constructed object hierarchy will match the arrangement structure, and all key sets will be empty.

  Notes

  The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

paragraphKeySetsVect

```
const cmStd vector<ccOCVMaxParagraphSearchKeySets>
 &paragraphKeySetsVect() const;

void paragraphKeySetsVect(const cmStd
 vector<ccOCVMaxParagraphSearchKeySets>
 &paragraphKeySets);
```

- ```
  const cmStd vector<ccOCVMaxParagraphSearchKeySets>
   &paragraphKeySetsVect() const;
  ```

  Gets the entire vector of paragraph-keysets objects.

- ```
  void paragraphKeySetsVect(const cmStd
   vector<ccOCVMaxParagraphSearchKeySets>
   &paragraphKeySets);
  ```

  Sets the entire vector of paragraph-keysets objects.

  Parameters

  paragraphKeySets
  The paragraph-keysets objects.

paragraphKeySets

```
const ccOCVMaxParagraphSearchKeySets
 &paragraphKeySets(c_Int32 index) const;

void paragraphKeySets(c_Int32 index, const
 ccOCVMaxParagraphSearchKeySets &keys);
```

- ```
  const ccOCVMaxParagraphSearchKeySets
   &paragraphKeySets(c_Int32 index) const;
  ```

  Gets a single paragraph-keysets object.

  Parameters

  index The index of the paragraph-keysets object.

  Throws

  ccOCVMaxDefs::BadParams
  index is out of range.
  ```

- ```
  void paragraphKeySets(c_Int32 index, const
    ccOCVMaxParagraphSearchKeySets &keys);
  ```

  Sets a single paragraph-keysets object.

  Parameters

  index The index of the paragraph-keysets object.

  Throws

  ccOCVMaxDefs::BadParams
  index is out of range.

positionKeySets

```
const ccOCVMaxKeySet &positionKeySets(c_Int32
  paragraphIndex, c_Int32 lineIndex, c_Int32 positionIndex)
  const;

void positionKeySets(c_Int32 paragraphIndex, c_Int32
  lineIndex, c_Int32 positionIndex, const ccOCVMaxKeySet
  &keys);
```

- ```
  const ccOCVMaxKeySet &positionKeySets(c_Int32
    paragraphIndex, c_Int32 lineIndex, c_Int32 positionIndex)
    const;
  ```

  Gets a single positional keyset object. This function is a convenient way to "drill down" and get a single value deep in a hierarchy.

  Parameters

  paragraphIndex The paragraph index.

  lineIndex The line index.

  positionIndex The position index.

  Throws

  ccOCVMaxDefs::BadParams
  Any of the indices are out of range.

- `void positionKeySets(c_Int32 paragraphIndex, c_Int32 lineIndex, c_Int32 positionIndex, const ccOCVMaxKeySet &keys);`

  Sets a single positional keyset object. This function is a convenient way to "drill down" and set a single value deep in a hierarchy.

  Parameters

  paragraphIndex The paragraph index.

  lineIndex The line index.

  positionIndex The position index.

  Notes

  The setter requires that the all indices are valid. This function cannot be used to add new elements to a SearchKeySets object. For example, you cannot set position 6 on a line with only 3 position elements.

  Throws

  ccOCVMaxDefs::BadParams
  Any of the indices are out of range.

appendParagraphKeySets

```
void appendParagraphKeySets(const
 ccOCVMaxParagraphSearchKeySets &paraKeySets);
```

Adds a single paragraph-keyset object to the end of the arrangement.

Parameters

paraKeySets The paragraph-keyset object to be added.

numParagraphKeySets

```
c_Int32 numParagraphKeySets() const;
```

Returns the number of paragraph keySets stored.

Operators

operator==

```
bool operator==(const ccOCVMaxArrangementSearchKeySets&
 other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxArrangementSearchKeySets&
  other) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxArrangementSearchKeySets

ccOCVMaxDefs

```
#include <ch_cvl\ocmax.h>

class ccOCVMaxDefs;
```

A name space that holds enumerations used with the OCVMax tool.

Enumerations

PositionStatus

```
enum PositionStatus;
```

This enumeration defines verification status results for positions.

Value	Meaning
eVerified	The character passes verification. The matching score is greater than the accept threshold, and the difference between the matching score and the highest scoring confusing character is greater than the confidence threshold.
eConfused	The matching score for the character is greater than the accept threshold, however the difference between the matching score and the highest scoring confusing character is not greater than the confidence threshold.
eFailed	The character fails verification. Its matching score is less than the accept threshold.

DrawFlags

```
enum DrawFlags;
```

This enumeration determines which graphics are included when diagnostics are generated.

Value	Meaning
eDrawArrangement = 0x001	Draws the final arrangement pose.
eDrawParagraphs = 0x002	Draws the final paragraph poses.
eDrawPositions = 0x004	Draws the final character poses.
eDrawArrangementBox = 0x008	Draws the bounding box with the arrangement pose.

Value	Meaning
eDrawParagraphBoxes = 0x010	Draws the bounding box with the paragraph pose.
eDrawPositionBoxes = 0x020	Draws the bounding box with the character pose.
eDrawArrangementOutlines = 0x040	Draws character outlines with the arrangement pose.
eDrawParagraphOutlines = 0x080	Draws character outlines with the paragraph pose.
eDrawPositionOutlines = 0x100	Draws character outlines with the character pose.
eDrawArrangementText = 0x200	Draws character text with the arrangement pose.
eDrawParagraphText = 0x400	Draws character text with the paragraph pose.
eDrawPositionText = 0x800	Draws character text with the character pose.

Polarity

```
enum Polarity;
```

Polarity types for characters to specify the appearance of the character relative to its nearby background in the image.

Value	Meaning
eDarkOnLight = 0	Dark characters on light background
eLightOnDark	Light characters on dark background
eUnknown	Unknown polarity

VerificationType

```
enum VerificationType;
```

Verification type to indicate how to perform verification at a character position.

Value	Meaning
eNormal = 0	Uses standard verification.
eAlwaysVerified	Uses standard verification, but then always marks result as verified.
eIgnore	Performs no verification, but marks result as verified and having a score of 1.0.

DOF

```
enum DOF;
```

Degrees of freedom. Refer to the descriptions of the named degrees of freedom of a **cc2Matrix** for each OCVMax degree of freedom.

Value	Meaning
eAngle = 0x01	Rotation angle (**cc2Matrix::rotation()**)
eUniformScale = 0x02	Uniform scale (**cc2Matrix::scale()**)
eXScale = 0x04	xScale (**cc2Matrix::xScale()**)
eYScale = 0x08	yScale (**cc2Matrix::yScale()**)
eShear = 0x10	Shear (**cc2Matrix::shear()**)
eAspect = 0x20	Aspect (**cc2Matrix::aspect()**) Used only in reporting zone violations.
eXTranslation = 0x4000	x-translation Used only in reporting zone violations.
eYTranslation = 0x8000	y-translation Used only in reporting zone violations.

CharacterRegistration

```
enum CharacterRegistration;
```

Character registration type to specify matching technology.

Value	Meaning
eStandard = 0x01	Uses PatMax for registration.
eCorrelation = 0x08	Uses correlation for registration.

ScoreMode

```
enum ScoreMode;
```

Score mode used to compute character score when using standard (PatMax) character registration.

Value	Meaning
eScoreUsingClutter = 1	Reduces the character score if extra features (clutter) are present.
eScoreWithoutClutter = 2	Computes the score based only on the presence of expected features, ignoring any extra features (clutter).
eScoreUsingOptimizedClutter = 3	Reduces the character score if extra features (clutter) are present, but optimizes score for relatively low-contrast clutter.

PoseCompute `enum PoseCompute;`

Specifies which result poses to compute.

Value	Meaning
ePoseComputeLineLinear = 0x01	See **ccOCVMaxRunParams::computePoses()** on page 2270.
ePoseComputeParagraphLinear = 0x02	
ePoseComputeArrangementLinear = 0x04	
ePoseComputeArrangementNonlinear = 0x08	

ccOCVMaxDefs

ccOCVMaxKeySet

```
#include <ch_cvl\ocmax.h>

class ccOCVMaxKeySet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The **ccOCVMaxKeySet** class contains information about the font key values that are relevant to a particular position within an **ccOCVMaxLine** object. It contains the following information:

Keys:

The set of unique keys for characters that may be used at the position. For example, if only numbers are possible for the position, this set would contain all of the keys for numbers and none for letters. An empty keyset indicates that all keys in the owning paragraphs *alphabetKeys* vector should be considered.

Type:

The **ccOCVMaxDefs::VerificationType** value indicates how to apply optical character verification (OCV) using the keyset. *eNormal* is standard OCV, which will return values of *eVerified*, *eConfused*, or *eFailed*. *eAlwaysVerified* is also standard OCV and will score every key in the keyset at the appropriate position, but it will always return *eVerified* along with the score and ID of the highest-scoring key. *eIgnore* will not do any processing at all at the appropriate position, and will not return an ID, but will always return *eVerified* and a score of 1.

Constructors/Destructors

ccOCVMaxKeySet

```
ccOCVMaxKeySet(
  const cmStd vector<c_Int32>& theKeys =
    cmStd vector<c_Int32>(),
  ccOCVMaxDefs::VerificationType type =
    ccOCVMaxDefs::eNormal);
```

Constructs a key set using the supplied keys and verification type.

Parameters

theKeys The set of unique keys for characters that can be found at this position. For example, if only numbers are possible for this position in the paragraph, *theKeys* contains all the of the keys for numbers and none for letters.

If *theKeys* is empty, all alphabet keys for the current font are considered.

type Indicates how to apply OCV using the key set. *eNormal* is standard for OCV and returns an indication of verified, confused or failed at each position in the paragraph.

Throws

ccOCVMaxDefs::BadParams
Any of the supplied keys are the same.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

keys

```
const cmStd vector<c_Int32>& keys() const;
void keys(const cmStd vector<c_Int32>& ks);
```

- `const cmStd vector<c_Int32>& keys() const;`

Gets the vector of valid characters for this position within the paragraph.

- `void keys(const cmStd vector<c_Int32>& ks);`

Sets the vector of characters that will be considered at this particular position within the paragraph.

Parameters

ks The vector of key values, empty by default.

Throws

ccOCVMaxDefs::BadParams
More than one element of the vector has the same value.

verificationType

```
ccOCVMaxDefs::VerificationType verificationType() const;

void verificationType(
 ccOCVMaxDefs::VerificationType type);
```

- `ccOCVMaxDefs::VerificationType verificationType() const;`

  Gets the verification type performed at this character location within the paragraph.

- `void verificationType(`
  `ccOCVMaxDefs::VerificationType type);`

  Sets the verification type to perform at this character location:

Type	Description
eNormal	Default value. Returns *ccOCVMaxDefs::eFailed* if no element of the key set had a score above the accept threshold. Returns *ccOCVMaxDefs::eVerified* if an element of the key set had a score above the accept threshold and its confidence score (the difference between its score and that of its highest-scoring confusible character) is above the confidence threshold. Returns *ccOCVMaxDefs::eConfused* otherwise.
eAlwaysVerified	Returns *ccOCVMaxDefs::eVerified* regardless of the scores along with the score and ID of the highest-scoring key.
eIgnore	Returns *ccOCVMaxDefs::eVerified* regardless of the scores and a score of 1.

Parameters

type The type of verification performed at this character location.

Operators

operator==

```
bool operator==(const ccOCVMaxKeySet& other) const;
```

Returns true if and only if this key set is equal to the specified other key set.

Parameters

other The pointer to the other key set.

operator!= `bool operator!=(const ccOCVMaxKeySet& other) const;`

Returns true if this key set is not equal to the other key set and false otherwise.

Parameters

other The pointer to the other key set.

ccOCVMaxLine

```
#include <ch_cvl\ocmax.h>

class ccOCVMaxLine : public virtual ccPersistent,
                     public virtual ccRepBase
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The OCVMax Line class represents a sequential, spatial arrangement of characters chosen from a single font. In general, the character arrangement is such that each character has spatial neighbors that are the previous and next characters in the sequence.

The spatial arrangement of characters is specified with respect to a **ccOCVMaxLine** coordinate frame. For each of the specified character positions in the line, a set of possible character keys can be supplied. The more character keys per position, the more characters a particular OC vision tool (for example, OCVMax) will consider. Specifying more than one key for a position will in general require more memory for such a tool, but will allow on-the-fly replacement of characters in the line without substantial re-training.

A typical **ccOCVMaxLine** is a horizontal line of upright characters (which can easily be specified using the first constructor).

The primary difference between a **ccOCVMaxLine** and a **ccOCLine** is that a **ccOCVMaxLine** is built with a font rather than an alphabet.

Constructors/Destructors

ccOCVMaxLine `ccOCVMaxLine();`

The default constructor.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

keySetSequence

```
void keySetSequence(const cmStd vector<ccOCVMaxKeySet>
 &keySetSequence);

void keySetSequence(const cmStd vector<ccOCVMaxKeySet>
 &keySetSequence,
 const cmStd vector<c_Int32> &displayIndices);

const cmStd vector<ccOCVMaxKeySet> &keySetSequence() const;
```

- ```
  void keySetSequence(const cmStd vector<ccOCVMaxKeySet>
   &keySetSequence);
  ```

  Sets the line to use the specified sequence of character key sets.

  Parameters

  keySetSequence Sequence of character key sets.

- ```
  void keySetSequence(const cmStd vector<ccOCVMaxKeySet>
   &keySetSequence,
   const cmStd vector<c_Int32> &displayIndices);
  ```

  Sets the line to use the specified sequence of character key sets. *displayIndices* is a vector that indicates which element of each keyset should be used if the line is rendered for display purposes. The element is specified by an index, so a value of 0 will render the first element of each keyset. An index of -1 indicates that nothing should be rendered in that slot (that is, blank).

  Parameters

  keySetSequence Sequence of character key sets.

  displayIndices Element indices.

  Notes

  The one-argument version of this function assumes a vector of *displayIndices* filled with the value 0.

  If a keyset on the line has **isWildcard()** true, then its values will be rendered with the owning paragraph's current **wildcardDisplayKey()**.

  Throws

  ccOCVMaxDefs::BadParams
  The lengths of the two vectors are different.

BadIndex

The *displayIndices* vector contains any indices that are outside the range of keys in the respective **ccOCVMaxKeySet** in *keySetSequence*, and not -1.

- `const cmStd vector<ccOCVMaxKeySet> &keySetSequence() const;`

  Gets the *keySetSequence* vector.

displayIndices

```
const cmStd vector<c_Int32> &displayIndices() const;
```

Gets the *displayIndices* vectors.

numPositions `c_Int32 numPositions() const;`

Returns the number of character positions in this line.

operator== `bool operator==(const ccOCVMaxLine& other) const;`

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!= `bool operator!=(const ccOCVMaxLine& other) const;`

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

Typedefs

ccOCVMaxLinePtrh

```
typedef ccPtrHandle<ccOCVMaxLine> ccOCVMaxLinePtrh;
```

ccOCVMaxLinePtrh_const

```
typedef ccPtrHandle_const<ccOCVMaxLine>
 ccOCVMaxLinePtrh_const;
```

ccOCVMaxLine

ccOCVMaxLineResult

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxLineResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxLineResult** class contains all the result information for a single OCVMax Line.

Constructors/Destructors

ccOCVMaxLineResult

```
ccOCVMaxLineResult();
```

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

foundPose

```
bool foundPose() const;
```

Returns whether a pose was determined for this result.

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the line in client coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundPose()** operation returned false.

foundParagraphPose

```
bool foundParagraphPose() const;
```

Returns whether a paragraph pose was determined for this result.

paragraphPose

```
const cc2Xform& paragraphPose() const;
```

Returns the pose of the line in paragraph coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundParagraphPose()** operation returned false.

foundArrangementPose

```
bool foundArrangementPose() const;
```

Returns whether an arrangement pose was determined for this result.

arrangementPose

```
const cc2Xform& arrangementPose() const;
```

Returns the pose of the line in arrangement coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundArrangementPose()** operation returned false.

score

```
double score() const;
```

Returns the overall score of the line, which is the average of all of the line's position scores which have VerificationType, eNormal, or eAlwaysVerified.

numPositions

```
c_Int32 numPositions() const;
```

Returns the total number of character positions.

numPositionsVerified

```
c_Int32 numPositionsVerified() const;
```

Returns the number of character positions correctly verified.

numPositionsEmpty

```
c_Int32 numPositionsEmpty() const;
```

Returns the number of character positions that are empty.

verified

```
bool verified() const;
```

Returns true if the entire line was verified (all character positions have been verified), and false otherwise.

keyZoneViolations

```
c_UInt32 keyZoneViolations() const;
```

Returns which zones of the key search parameters were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

fullZoneViolations

```
c_UInt32 fullZoneViolations() const;
```

Return which zones of the full (that is, image or start pose) search parameters were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

positionResults

```
const cmStd vector<ccOCVMaxPositionResult>&
  positionResults() const;
```

Returns the results for all the character positions for which verification has been attempted.

Operators

operator==

```
bool operator==(const ccOCVMaxLineResult& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxLineResult& other) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxLineResult

ccOCVMaxLineSearchKeySets

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxLineSearchKeySets;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is used to specify what key sets should be searched for at runtime. It requires that the structure exactly matches the structure of the trained arrangement being searched for. It also requires that the specified key sets be subsets of the trained arrangement's keysets. If an individual search key set is empty, the runtime search key set will be the full key set that was trained.

Public Member Functions

keySetSequence

```
const cmStd vector<ccOCVMaxKeySet> &keySetSequence() const;

void keySetSequence(const cmStd vector<ccOCVMaxKeySet>
  &posKeySets);
```

- `const cmStd vector<ccOCVMaxKeySet> &keySetSequence() const;`

  Gets the entire vector of keyset objects for the line.

- `void keySetSequence(const cmStd vector<ccOCVMaxKeySet> &posKeySets);`

  Sets the entire vector of keyset objects for the line.

  Notes

  The default constructor, destructor, copy constructor, and assignment operator are used.

keySet

```
const ccOCVMaxKeySet &keySet(c_Int32 index) const;
void keySet(c_Int32 index, const ccOCVMaxKeySet &keyset);
```

- `const ccOCVMaxKeySet &keySet(c_Int32 index) const;`

  Gets a single keyset object.

  Parameters
  index The keyset object index.

  Throws
  ccOCVMaxDefs::BadParams
  index is out of range.

- `void keySet(c_Int32 index, const ccOCVMaxKeySet &keyset);`

  Sets a single keyset object.

  Parameters
  index The keyset object index.

  Throws
  ccOCVMaxDefs::BadParams
  index is out of range.

appendKeySet

```
void appendKeySet(const ccOCVMaxKeySet &keyset);
```

Add a single keyset object to the end of the line.

numKeySets

```
c_Int32 numKeySets() const;
```

Returns the number of key sets stored.

Operators

operator==

```
bool operator==(const ccOCVMaxLineSearchKeySets& other)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters
other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxLineSearchKeySets& other)
  const;
```

Return true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxLineSearchKeySets

ccOCVMaxParagraph

```
#include <ch_cvl\ocmax.h>

class ccOCVMaxParagraph : public virtual ccPersistent,
                          public virtual ccRepBase
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The OCVMax Paragraph class represents a sequential, spatial arrangement of lines chosen from a single font. The line arrangement is such that each line is directly below the previous line in the paragraph.

Constructors/Destructors

ccOCVMaxParagraph

```
ccOCVMaxParagraph();
```

Constructs a paragraph.

The lines are arranged with a uniform spacing (with respect to their origins) at position intervals given by the line spacing parameters (extraLeading, combined with the font's leading value) in the order they are specified.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

lines

```
void lines(const cmStd vector<ccOCVMaxLine> &lines);

void lines(const ccOCVMaxLine &line);
```

- ```
  void lines(const cmStd vector<ccOCVMaxLine> &lines);
  ```

  Sets the lines of the paragraph.

  Parameters

lines	The new lines.
  ```

- `void lines(const ccOCVMaxLine &line);`

  Sets the a line of the paragraph.

  Parameters
  line The new line.

numLines `c_Int32 numLines() const;`

Returns the number of lines in this paragraph.

line `const ccOCVMaxLine &line(c_Int32 posIndex) const;`

Returns the line at the specified position in the paragraph.

Parameters
posIndex The position index.

Throws
ccOCVMaxDefs::BadIndex
The specified line index is invalid.

lines `const cmStd vector<ccOCVMaxLine>& lines() const;`

Returns a vector of all the lines.

---

font `const ccSynFontPtrh_const& font() const;`

`void font(const ccSynFontPtrh_const&);`

- `const ccSynFontPtrh_const& font() const;`

  Gets the font for this paragraph.

- `void font(const ccSynFontPtrh_const&);`

  Sets the font for this paragraph.

  Parameters
  ccSynFontPtrh_const

alphabetKeys

```
const cmStd vector<c_Int32> &alphabetKeys() const;

void alphabetKeys(const cmStd vector<c_Int32>
 &alphabetKeys);
```

- `const cmStd vector<c_Int32> &alphabetKeys() const;`

  Gets the list of font characters that will be used to build the OCV alphabet for this paragraph.

- `void alphabetKeys(const cmStd vector<c_Int32> &alphabetKeys);`

  Sets the list of font characters that will be used to build the OCV alphabet for this paragraph.

  Only chars in the alphabet are considered for confusion. If *alphabetChars* is empty, all characters specified in the font will be used to build the alphabet.

  Parameters

  alphabetKeys The list of font characters.

origin

```
cc2Xform origin() const;

void origin(const cc2Xform& origin);
```

- `cc2Xform origin() const;`

  Gets the origin of the paragraph.

- `void origin(const cc2Xform& origin);`

  Sets the origin of the paragraph.

  Parameters

  origin The origin.

tracking

```
cc2Vect tracking() const;

void tracking(const cc2Vect &tracking);
```

- `cc2Vect tracking() const;`

  Gets the tracking for this paragraph with respect to the previous char in each line, in the font's coordinate system.

- `void tracking(const cc2Vect &tracking);`

  Sets the tracking for this paragraph with respect to the previous char in each line, in the font's coordinate system.

  Tracking is an amount added to the default advance between characters.

  Parameters
  tracking The new tracking.

extraLeading

```
cc2Vect extraLeading() const;
void extraLeading(const cc2Vect &extraLeading);
```

- `cc2Vect extraLeading() const;`

  Gets the extra leading for this paragraph, in the font's coordinate system.

- `void extraLeading(const cc2Vect &extraLeading);`

  Sets the extra leading for this paragraph, in the font's coordinate system.

  The origin-to-origin displacement between successive lines is equal to the sum of the font's leading [as a vector (0, leading)] and this value.

  Parameters
  extraLeading The new extra leading.

  Notes
  "Leading" is pronounced "ledding".

polarity

```
ccOCVMaxDefs::Polarity polarity() const;
void polarity(ccOCVMaxDefs::Polarity polarity);
```

- `ccOCVMaxDefs::Polarity polarity() const;`

  Gets the polarity value.

- `void polarity(ccOCVMaxDefs::Polarity polarity);`

  Sets the polarity value.

  Parameters
  polarity The new polarity value.

confusionThreshold

```
double confusionThreshold() const;

void confusionThreshold(double thresh);
```

- `double confusionThreshold() const;`

  Gets the confusion threshold for the alphabet.

  Throws
  ccOCVMaxDefs::BadParams
  The threshold is negative or greater than 1.0.

- `void confusionThreshold(double thresh);`

  Sets the confusion threshold for the alphabet.

  Parameters
  thresh The new confusion threshold value.

spotSizeFactor

```
double spotSizeFactor() const;

void spotSizeFactor(double spotSizeFactor);
```

- `double spotSizeFactor() const;`

  Gets the spot size factor, which adjusts font rendering for the paragraph by multiplying the size of the "beam" used to scribe the characters.

- `void spotSizeFactor(double spotSizeFactor);`

  Sets the spot size factor, which adjusts font rendering for the paragraph by multiplying the size of the "beam" used to scribe the characters.

  Parameters
  spotSizeFactor The new spot size factor.

  Throws
  ccOCVMaxDefs::BadParams
  spotSizeFactor is less than or equal to 0.

extraStrokeWidth

```
double extraStrokeWidth() const;

void extraStrokeWidth(double extraStrokeWidth);
```

- `double extraStrokeWidth() const;`

  Gets the *extraStrokeWidth*, which adjusts font rendering for the paragraph using morphology.

- `void extraStrokeWidth(double extraStrokeWidth);`

  Sets the *extraStrokeWidth*, which adjusts font rendering for the paragraph using morphology.

  A negative value indicates that the stroke width should be decreased.

  Parameters

  extraStrokeWidth The new *extraStrokeWidth* value.

spotSpacingXScale

```
double spotSpacingXScale() const;

void spotSpacingXScale(double xScale);
```

- `double spotSpacingXScale() const;`

  Gets the factor by which to change the x-coordinate of spots relative to each other; also changes the endpoints of strokes.

- `void spotSpacingXScale(double xScale);`

  Sets the factor by which to change the x-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Parameters

  xScale The new factor value.

  Throws

  ccOCVMaxDefs::BadParams

  xScale is less than or equal to 0.

spotSpacingYScale

```
double spotSpacingYScale() const;

void spotSpacingYScale(double yScale);
```

- `double spotSpacingYScale() const;`

  Gets the factor by which to change the y-coordinate of spots relative to each other; also changes the endpoints of strokes.

- `void spotSpacingYScale(double yScale);`

  Sets the factor by which to change the y-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Parameters

  yScale The new factor value.

  Throws

  ccOCVMaxDefs::BadParams

  yScale is less than or equal to 0.

encloseRect

```
ccRect encloseRect
  (const cc2Xform& clientFromParagraph = cc2Xform(),
  const cc2Xform& clientFromImage = cc2Xform()) const;
```

Returns the smallest rectangle aligned with the specified image coordinate system guaranteed to contain this paragraph given the transformation relating the paragraph coordinate frame and the transformation relating the image coordinate system to the client coordinate system.

markRectChar

```
ccAffineRectangle markRectChar(c_Int32 lineIndex,
  c_Int32 posIndex,
  c_Int32 keyIndex = 0) const;
```

Returns the mark rect for the given position, in the font's coordinate system.

Notes

The mark rect depends only on the character keys, not on the position within a line.

The mark rect for a blank is degenerate.

The *keyIndex* is the index of the particular key in the keyset at the given position.

Parameters

lineIndex The line index.

posIndex The position index.

keyIndex The key index.

Throws

ccOCVMaxDefs::BadParams
Any index is negative or larger than the number of lines/positions/keys present in the paragraph.

encloseRectChar

```
ccRect encloseRectChar(c_Int32 lineIndex,
 c_Int32 posIndex,
 const cc2Xform& clientFromParagraph = cc2Xform(),
 const cc2Xform& clientFromImage = cc2Xform()) const;
```

Returns the smallest rectangle aligned with the specified image coordinate system guaranteed to contain the specified char given the transform relating the paragraph coordinate frame and the transformation relating the image coordinate system to the client coordinate system.

Parameters

lineIndex The line index.

posIndex The position index.

Throws

ccOCVMaxDefs::BadParams
lineIndex is greater than or equal to *numLines, or* *posIndex* is greater than or equal to lines[*lineIndex*].*numPositions*

nextLine

```
cc2Vect nextLine() const;
```

Returns the location of the origin of the next line of text beyond those specified in the paragraph. For example, if the paragraph has three lines, this is where the fourth line would start.

nextChar

```
cc2Vect nextChar() const;
```

Returns the location of the origin of the next character of text beyond those specified in the paragraph, based on the longest line in the paragraph. However, the x coordinate is set as if the character was part of the paragraph's first line. For example, if the paragraph consists of the lines "123" and "12345", the given location would be six characters out from the first line (the star in this diagram):

123..*

12345

Motivation: this is where another adjacent paragraph might start.

wildcardDisplayKey

```
void wildcardDisplayKey(c_Int32 wcDisplayKey);

c_Int32 wildcardDisplayKey() const;
```

- `void wildcardDisplayKey(c_Int32 wcDisplayKey);`

  Sets the font key value that is used to display wildcards (that is, keysets consisting of an empty list) when the paragraph's **render()** method is called.

  Parameters

  wcDisplayKey The new font key value.

- `c_Int32 wildcardDisplayKey() const;`

  Gets the font key value that is used to display wildcards (that is, keysets consisting of an empty list) when the paragraph's **render()** method is called.

clone

```
ccOCVMaxParagraphPtrh clone() const;
```

Returns a copy of this paragraph.

fontAvailableChars

```
const cmStd vector<c_Int32>& fontAvailableChars() const;
```

Gets the available characters in the font.

Notes

This differs from **font()**->**availableChars(false)** if the keys in the keys sets contain blanks with different keys.

operator== `bool operator==(const ccOCVMaxParagraph& other) const;`

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

Notes

The fonts in the two lines are considered equal if and only if they are *ptrHandles* to the same underlying object.

operator!= `bool operator!=(const ccOCVMaxParagraph& other) const;`

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

Typedefs

ccOCVMaxParagraphPtrh

```
typedef ccPtrHandle<ccOCVMaxParagraph>
  ccOCVMaxParagraphPtrh;
```

ccOCVMaxParagraphPtrh_const

```
typedef ccPtrHandle_const<ccOCVMaxParagraph>
  ccOCVMaxParagraphPtrh_const;
```

ccOCVMaxParagraphResult

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxParagraphResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxParagraphResult** class contains result information for a single paragraph.

Constructors/Destructors

ccOCVMaxParagraphResult

```
ccOCVMaxParagraphResult();
```

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

foundPose

```
bool foundPose() const;
```

Returns whether a pose was determined for this result.

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the paragraph in client coordinates.

Throws

ccOCVMaxDefs::NotFound

The **foundPose()** operation returned false.

foundArrangementPose

```
bool foundArrangementPose() const;
```

Returns whether an arrangement pose was determined for this result.

arrangementPose

```
const cc2Xform& arrangementPose() const;
```

Returns the pose of the paragraph in arrangement coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundArrangementPose()** operation returned false.

score

```
double score() const;
```

Returns the overall score of the paragraph (the average of the scores of all of the characters in the paragraph).

numPositions

```
c_Int32 numPositions() const;
```

Returns the total number of character positions (on all lines).

numPositionsVerified

```
c_Int32 numPositionsVerified() const;
```

Returns the number of character positions (on all lines) correctly verified.

numPositionsEmpty

```
c_Int32 numPositionsEmpty() const;
```

Returns the number of character positions that are empty.

numLines

```
c_Int32 numLines() const;
```

Returns the total number of lines.

numLinesVerified

```
c_Int32 numLinesVerified() const;
```

Returns the number of lines correctly verified.

verified

```
bool verified() const;
```

Returns true if the entire paragraph was verified (all character positions have been verified), and false otherwise.

keyZoneViolations

```
c_UInt32 keyZoneViolations() const;
```

Returns which zones of the key search parameters were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

fullZoneViolations

```
c_UInt32 fullZoneViolations() const;
```

Returns which zones of the full (that is, image or start pose) search parameters were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

lineResults

```
const cmStd vector<ccOCVMaxLineResult>& lineResults()
  const;
```

Returns the results for all the lines in the paragraph.

Operators

operator==

```
bool operator==(const ccOCVMaxParagraphResult& other)
  const;
```

Returns true if this object is equal to to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxParagraphResult& other)
const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxParagraphResult

ccOCVMaxParagraphRunParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxParagraphRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax paragraph runtime parameters class encapsulates all of the parameters for a particular paragraph within an arrangement that are required for character verification, including:

confusionThreshold

Each paragraph builds a "confusion matrix" when it's trained. This matrix has a number for every pair of keys in the paragraph's font alphabet. The number indicates how confusable the two keys are, with values near one being very confusable (e.g. '5' and 'S') and values near zero being not confusable (e.g. '5' and '1'). The *confusionThreshold* parameter specifies the value below which other keys are not considered by the tool for confusion purposes. For example, if the tool is expecting to find a '5', it will also check other potentially confusing keys to see if they are also good matches. With a confusion threshold of 0.9, the keys for 'S' and '6' might be tried, but '1' would not. With a threshold of 0.4, many somewhat-similar keys would be tried, such as 'E' or '8'. With a threshold of 0, all keys would be tried.

confidenceThreshold

It specifies the amount that the score of the highest-scoring character in the current key set must be above the highest-scoring character that has a non-zero confusion score with any character in the key set.
Note that if a potentially confusing character has a higher score than the highest-scoring key set member, then the status result will always be "confused", but the returned key will still be the one from the key set, not the confusing key.
Note that only keys that pass the *confusionThreshold* test, above, are considered for this scoring/verification step.

Constructors/Destructors

ccOCVMaxParagraphRunParams

```
ccOCVMaxParagraphRunParams(double confusionThreshold =
  0.5, double confidenceThreshold = 0.0);
```

Constructs a runtime parameters object with the supplied parameters.

Parameters

confusionThreshold The confusion threshold.

confidenceThreshold The confidence threshold.

Throws

ccOCVMaxDefs::BadParams
The confusion threshold value is less than 0 or greater than 1 or the confidence threshold value is less than 0 or greater than 1.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

confidenceThreshold

```
double confidenceThreshold() const;

void confidenceThreshold(double t);
```

- `double confidenceThreshold() const;`

Gets the confidence threshold.

Throws

ccOCVMaxDefs::BadParams
t is less than 0 or greater than 1.

- `void confidenceThreshold(double t);`

Sets the confidence threshold.

Parameters

t The new confidence threshold value.

confusionThreshold

```
double confusionThreshold() const;

void confusionThreshold(double t);
```

- `double confusionThreshold() const;`

  Gets the confusion threshold

  Throws

  ccOCVMaxDefs::BadParams
  : *t* is less than 0 or greater than 1.

- `void confusionThreshold(double t);`

  Sets the confusion threshold.

  Parameters

t	The new confusion threshold value.

Operators

operator==

```
bool operator==(const ccOCVMaxParagraphRunParams& other)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxParagraphRunParams& other)
  const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxParagraphRunParams

ccOCVMaxParagraphSearchKeySets

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxParagraphSearchKeySets;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is used to specify what key sets should be searched for at runtime. It requires that the structure exactly matches the structure of the trained arrangement being searched for. It also requires that the specified key sets be subsets of the trained arrangement's keysets. If an individual search key set is empty, the runtime search key set will be the full key set that was trained.

Public Member Functions

lineKeySetsVect

```
const cmStd vector<ccOCVMaxLineSearchKeySets>
  &lineKeySetsVect() const;

void lineKeySetsVect(const cmStd
  vector<ccOCVMaxLineSearchKeySets> &lineKeySets);
```

- ```
  const cmStd vector<ccOCVMaxLineSearchKeySets>
    &lineKeySetsVect() const;
  ```

  Gets the entire vector of line-keysets objects.

- ```
  void lineKeySetsVect(const cmStd
    vector<ccOCVMaxLineSearchKeySets> &lineKeySets);
  ```

  Sets the entire vector of line-keysets objects.

  Notes

  The default constructor, destructor, copy constructor, and assignment operator are used.

ccOCVMaxParagraphSearchKeySets

lineKeySets

```
const ccOCVMaxLineSearchKeySets &lineKeySets(c_Int32
  index) const;

void lineKeySets(c_Int32 index, const
  ccOCVMaxLineSearchKeySets &keys);
```

- ```
  const ccOCVMaxLineSearchKeySets &lineKeySets(c_Int32
    index) const;
  ```

  Gets a single line-keysets object.

  Parameters

  index The line-keyset object index.

  Throws

  ccOCVMaxDefs::BadParams
  index is out of range.

- ```
  void lineKeySets(c_Int32 index, const
    ccOCVMaxLineSearchKeySets &keys);
  ```

  Sets a single line-keysets object.

  Parameters

  index The line-keyset object index.

  Throws

  ccOCVMaxDefs::BadParams
  index is out of range.

positionKeySets

```
const ccOCVMaxKeySet &positionKeySets(c_Int32 lineIndex,
  c_Int32 positionIndex) const;

void positionKeySets(c_Int32 lineIndex, c_Int32
  positionIndex, const ccOCVMaxKeySet &keys);
```

- ```
  const ccOCVMaxKeySet &positionKeySets(c_Int32 lineIndex,
    c_Int32 positionIndex) const;
  ```

  Gets a single positional keyset object. This function is a convenient way to "drill down" and get a single value deep in a hierarchy.

  Parameters

  lineIndex The index of the line.
  ```

positionIndex The index of the position.

Throws

ccOCVMaxDefs::BadParams
Any of the indices are out of range.

- `void positionKeySets(c_Int32 lineIndex, c_Int32 positionIndex, const ccOCVMaxKeySet &keys);`

Sets a single positional keyset object. This function is a convenient way to "drill down" and set a single value deep in a hierarchy.

Parameters

lineIndex The index of the line.

positionIndex The index of the position.

Notes

The setter requires that the all indices are valid. This function cannot be used to add new elements to a SearchKeySets object. For example, you cannot set position 6 on a line with only 3 position elements.

Throws

ccOCVMaxDefs::BadParams
Any of the indices are out of range.

appendLineKeySets

```
void appendLineKeySets(const ccOCVMaxLineSearchKeySets &lineKeySets);
```

Adds a single line-keyset object to the end of the paragraph.

numLineKeySets

```
c_Int32 numLineKeySets() const;
```

Returns the number of line keySets stored.

Operators

operator==

```
bool operator==(const ccOCVMaxParagraphSearchKeySets& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxParagraphSearchKeySets&
  other) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxParagraphTrainParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxParagraphTrainParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxParagraphTrainParams** class encapsulates all of the parameters for a particular paragraph within an arrangement that are required for character verification.

Constructors/Destructors

Notes

The default constructor, destructor, copy constructor, and assignment operator are used.

Operators

operator==

```
bool operator==(const ccOCVMaxParagraphTrainParams& other)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxParagraphTrainParams& other)
  const;
```

Returns true if this object is not equal to the specified object.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxParagraphTuneParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxParagraphTuneParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax paragraph tune parameters specify which aspects of a given paragraph within an arrangement should be modified by tuning.

Enumerations

TuneFlags `enum TuneFlags;`

Enumeration for the tune flags.

Value	Meaning
eTuneNone = 0x0000	Does not tune anything.
eTuneSpotSizeFactor = 0x0001	These flags each tune the corresponding value of the **ccOCVMaxParagraph** object.
eTuneTrackingX = 0x0002	
eTuneTrackingY = 0x0004	
eTuneExtraLeadingX = 0x0008	
eTuneExtraLeadingY = 0x0010	
eTuneExtraStrokeWidth = 0x0020	
eTuneSpotSpacingXScale = 0x0040	
eTuneSpotSpacingYScale = 0x0080	
eTunePolarity = 0x0100	

Value	Meaning
eTunePoseUniformScale = 0x0200	These flags each tune the corresponding value of the arrangement's **paragraphPose()** for the paragraph.
eTunePoseAspect = 0x0400	
eTunePoseRotation = 0x0800	
eTunePoseShear = 0x1000	
eTuneAll = (*eTuneSpotSizeFactor* | *eTuneTrackingX* | *eTuneTrackingY* | *eTuneExtraLeadingX* | *eTuneExtraLeadingY* | *eTuneExtraStrokeWidth* | *eTuneSpotSpacingXScale* | *eTuneSpotSpacingYScale* | *eTunePolarity* | *eTunePoseUniformScale* | *eTunePoseAspect* | *eTunePoseRotation* | *eTunePoseShear*)	All values are tuned.
eTuneDefault = (*eTuneAll* & ~(*eTuneTrackingY* | *eTuneExtraLeadingX* | *eTunePoseAspect* | *eTunePoseShear* | *eTuneSpotSpacingXScale* | *eTuneSpotSpacingYScale* | *eTuneExtraStrokeWidth*))	The default values corresponding to the specified flags are tuned.

Constructors/Destructors

ccOCVMaxParagraphTuneParams

```
ccOCVMaxParagraphTuneParams();
```

Constructs a default tune parameters object.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

flags

```
c_UInt32 flags() const;

void flags(c_UInt32 f);
```

- `c_UInt32 flags() const;`

  Gets a bitfield of TuneFlags specifying what to tune.

- `void flags(c_UInt32 f);`

  Sets a bitfield of TuneFlags specifying what to tune.

  The default value is *eTuneDefault*.

  Parameters

f	The bitfield value of TuneFlags.

ccOCVMaxParagraphTuneParams

ccOCVMaxPositionResult

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxPositionResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax Position Result class contains all the result information for an instance of a single character position within a particular line within a particular paragraph within a particular arrangement. This information includes the status of the search at that position (verified, confused, or failed), the key of the detected character (if any), the pose of the character in various coordinate systems, the score of the character, the keys and scores for any characters that may be confused with the found character, and the confidence score, which is the score of the found character minus the score of the highest-scoring confusion character (but not less than zero).

Constructors/Destructors

ccOCVMaxPositionResult

```
ccOCVMaxPositionResult();
```

Constuct a result object with a failed status.

Notes

The default destructor, copy constructor, and assignment operators are used.

Public Member Functions

key

```
c_Int32 key() const;
```

Returns the key of the character found at this position.

Notes

Returns -1 if status is *eFailed* or if the verification type for the search was *eIgnore*.

ccOCVMaxPositionResult

status

```
ccOCVMaxDefs::PositionStatus status() const;
```

Returns the verification status: verified, confused, or failed.

VerificationType *eNormal*:

Standard verification. Returns failed if no element of the key set had a score above the accept threshold. Returns verified if an element of the key set had a score above the accept threshold, and its confidence score (the difference between its score and that of its highest-scoring confusable key) is above the confidence threshold. Otherwise returns confused.

VerificationType *eAlwaysVerified*:

Standard verification. Returns verified regardless of the scores. Scores are computed.

VerificationType *eIgnore*:

No verification. Returns verified regardless of the scores. Scores are not computed, they are set to 1.0.

foundPose

```
bool foundPose() const;
```

Returns whether a pose was determined for this result.

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the found character in client coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundPose()** operation returned false.

foundParagraphPose

```
bool foundParagraphPose() const;
```

Returns whether a paragraph pose was determined for this result.

paragraphPose

```
const cc2Xform& paragraphPose() const;
```

Returns the pose of the found character in paragraph coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundPose()** operation returned false.

foundArrangementPose

```
bool foundArrangementPose() const;
```

Returns whether an arrangement pose was determined for this result.

arrangementPose

```
const cc2Xform& arrangementPose() const;
```

Returns the pose of the found character in arrangement coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundPose()** operation returned false.

score

```
double score() const;
```

Returns the verification score of the found character. If the verification type is *eIgnore*, this will be 1.0.

matchScore

```
double matchScore() const;
```

Returns the match component of the verification score.

zoneScore

```
double zoneScore() const;
```

Returns the zone component of the verification score.

fitError

```
double fitError() const;
```

Returns the *fitError* of the found character.

fitError ranges from 0.0 (best) to infinity (worst).

Notes

Value will be -1.0 if not available.

Although fitError has no theoretical upper limit, it is typically less than 10 in practical use.

isEmpty

```
bool isEmpty() const;
```

Returns whether the position is empty; that is, failed and with no match or zone violation information.

keyZoneViolations

```
c_UInt32 keyZoneViolations() const;
```

Returns which zones of the key search parameters were violated and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

fullZoneViolations

```
c_UInt32 fullZoneViolations() const;
```

Returns which zones of the full (that is, image or start pose) search params were violated and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

confusionKeys

```
const cmStd vector<c_Int32>& confusionKeys() const;
```

Returns the keys of the characters causing confusion, if the status is *eConfused*. Otherwise the vector is empty. The vector contains the confusing characters in order from most confusing (highest-scoring) to least confusing (lowest scoring).

confusionMatchScores

```
const cmStd vector<double>& confusionMatchScores() const;
```

Returns the confusion match scores corresponding to the *confusionKeys*, if the status is *eConfused*. Otherwise the vector is empty.

confidenceScore

```
double confidenceScore() const;
```

Returns the confidence score, which is the score minus the score of the best *confusionMatchScore*, but not less than zero. If the verification type is *eIgnore*, this will be 1.0.

hasResultRegion

```
bool hasResultRegion() const;
```

Gets whether the result contains a result region. See **resultRegion()** below.

resultRegion

```
ccAffineRectangle resultRegion() const;
```

Return the affine rectangle that describes the boundary of the matched character in the runtime image, in client coordinates.

Throws

ccOCVMaxDefs::NotFound
The **hasResultRegion()** operation returned false.

Operators

operator==

```
bool operator==(const ccOCVMaxPositionResult& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxPositionResult& other) const;
```

Return true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxPositionResult

ccOCVMaxPositionResultStats

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxPositionResultStats;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxPositionResultStats** class computes cumulative statistics over a set of position results. These statistics can be helpful for determining optimal score accept thresholds for later runs or for process control.

Constructors/Destructors

ccOCVMaxPositionResultStats

```
ccOCVMaxPositionResultStats();
```

Constructs a default position result statistics object.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Resets the statistics.

add

```
void add(const ccOCVMaxPositionResult& result);
```

Adds the position result to the set of statistics.

Parameters

result	The statistical result.

numPositionResults

```
c_Int32 numPositionResults() const;
```

Gets the number of position results that have been added.

numVerified `c_Int32 numVerified() const;`

Gets the number of position results whose status was *eVerified*.

numConfused `c_Int32 numConfused() const;`

Gets the number of position results whose status was *eConfused*.

numFailed `c_Int32 numFailed() const;`

Gets the number of position results whose status was *eFailed*.

numNonFailed `c_Int32 numNonFailed() const;`

Gets the number of position results whose status was not *eFailed*; that is, the number of position results that were either *eVerified* or *eConfused*.

hasScores `bool hasScores() const;`

Gets whether any score statistics are available.

minNonFailedScore

`double minNonFailedScore() const;`

Gets the minimum score of all the position results whose status was not *eFailed*. Typically, one should expect that setting a score accept threshold somewhat lower than this value would allow finding all such results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

maxNonFailedScore

`double maxNonFailedScore() const;`

Gets the maximum score of all the position results whose status was not *eFailed*.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

meanNonFailedScore

`double meanNonFailedScore() const;`

Gets the mean score of all the position results whose status was not *eFailed*.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

ccOCVMaxPositionResultStats

ccOCVMaxProgress

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxProgress;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxProgress** class provides information about how much progress has been made by OCVMax towards completion of a potentially time-consuming task such as training or tuning a tool.

Enumerations

Type

```
enum Type;
```

The type of operation whose progress is being reported.

Value	Meaning
eTrain	Progress is for **ccOCVMaxTool::train()**
eTune	Progress is for **ccOCVMaxTool::tune()**

Constructors/Destructors

ccOCVMaxProgress

```
ccOCVMaxProgress(): progress_(0.), userParams_(NULL) {}
```

Constructs a progress object.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

type

```
Type type() const;
void type(Type t);
```

- `Type type() const;`

  Gets the type of function whose progress is measured.

- `void type(Type t);`

  Sets the type of function whose progress is measured.

  Parameters

  t — The function type. Must be one of:
  ccOCVMaxProgress::eTrain
  ccOCVMaxProgress::eTune

progress

```
double progress() const;
void progress(double p);
```

- `double progress() const;`

  Gets progress, in the range [0, 1].

- `void progress(double p);`

  Sets progress, in the range [0, 1].

  The task has just started when progress is 0, and the task is complete when the progress is 1.

  Parameters

  p — The progress value.

  Throws

  ccOCVMaxDefs::BadParams
  Progress value is less than 0 or greater than 1.

  The default progress value is 0.

userParams

```
const void* userParams() const;
void* userParams();
void userParams(void* u);
```

- `const void* userParams() const;`

  Gets the user parameters.

- `void* userParams();`

  Sets the user parameters.

- `void userParams(void* u);`

  Sets the user parameters.

  Typically, the user parameters are the parameters passed as the *userParams* to the tool's **train()** or **tune()** function. As an example, this might be a GUI object that implements a progress bar.

  Parameters

u	The user parameter.

  Notes

  The pointer is not owned by this object.

  userParams are not serialized.

  The default user parameters value is NULL.

ccOCVMaxProgress

ccOCVMaxProgressCallback

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxProgressCallback;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccOCVMaxProgressCallback** class allows the user to implement custom behavior based on how much progress has been made by OCVMax towards completion of a potentially time-consuming task such as training or tuning a tool. One example of callback function might be to provide a GUI progress bar whose state indicates the amount of progress made.

Constructors/Destructors

ccOCVMaxProgressCallback

```
ccOCVMaxProgressCallback(Function f = NULL, void*
  userParams = NULL): callback_(f), userParams_(userParams)
  {}

ccOCVMaxProgressCallback(const ccOCVMaxProgressCallback&
  rhs): callback_(NULL), userParams_(NULL) {}
```

- ```
  ccOCVMaxProgressCallback(Function f = NULL, void*
    userParams = NULL): callback_(f), userParams_(userParams)
    {}
  ```

  Constructs a progress callback object that will execute the specified function when OCVMax reports a progress update. A shallow copy of *userParams* will be contained in the **ccOCVMaxProgress** object passed to the callback function.

  Parameters

f	The specified function.
userParams	The user parameters.
  ```

- `ccOCVMaxProgressCallback(const ccOCVMaxProgressCallback& rhs): callback_(NULL), userParams_(NULL) {}`

  Copy constructor; copies actually nothing, since there would usually be lifetime issues.

  Parameters

  rhs The source of the copy.

  Notes

  The default destructor is used.

Operators

operator=

```
ccOCVMaxProgressCallback& operator=(const
 ccOCVMaxProgressCallback& rhs);
```

Assignment operator; assigns actually nothing, since there would usually be lifetime issues.

Parameters

rhs The assignment source.

Public Member Functions

callback

```
void callback(Function f);

Function callback() const;
```

- `void callback(Function f);`

  Sets the function to be used.

  Parameters

  f The function to be used.

- `Function callback() const;`

  Gets the function to be used.

  The default function value is NULL.

userParams

```
const void* userParams() const;

void* userParams();

void userParams(void* u);
```

- `const void* userParams() const;`

  Gets the user parameters, which will be passed to the callback function whenever it is invoked.

- `void* userParams();`

  Sets the user parameters, which will be passed to the callback function whenever it is invoked.

- `void userParams(void* u);`

  Sets the user parameters, which will be passed to the callback function whenever it is invoked.

  Parameters

u	The new user parameters.

  Notes

  The pointer is not owned by this object. The user is responsible for ensuring that the object pointed to continues to exist for the entire duration of the train/tune call.

  The default user parameters value is NULL.

assignFull

```
void assignFull(const ccOCVMaxProgressCallback& rhs)
 {
  if (this != &rhs)
    {
     callback_ = rhs.callback_;
     userParams_ = rhs.userParams_;
    }
 }
```

Full assignment, typically for short-lived copies.

Typedefs

```
typedef c_Int32 (*Function)(ccOCVMaxProgress& progress);
```

A function pointer type for user-specified callback functions.

ccOCVMaxProgressCallback

ccOCVMaxResult

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxResult** class contains all the result information for a single application of the OCVMax tool.

Constructors/Destructors

ccOCVMaxResult

```
ccOCVMaxResult();
```

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

foundPose

```
bool foundPose() const;
```

Returns whether a pose was determined for this result.

clientPose

```
cc2XformBasePtrh_const clientPose() const;
```

Returns the pose of the arrangement in client coordinates.

Throws

ccOCVMaxDefs::NotFound
The **foundPose()** operation returned false.

foundPoseLinear

```
bool foundPoseLinear() const;
```

Returns whether a linear pose was determined for this result.

clientPoseLinear

```
const cc2XformLinear &clientPoseLinear() const;
```

Returns the pose of the arrangement in client coordinates, but linearized over the area covered by the arrangement.

Throws

ccOCVMaxDefs::NotFound
The **foundPoseLinear()** operator returned false.

score

```
double score() const;
```

Returns the overall score of the arrangement (the average of the scores of all of the paragraphs that the tool attempted to verify).

numParagraphs

```
c_Int32 numParagraphs() const;
```

Returns the total number of paragraphs.

numParagraphsVerified

```
c_Int32 numParagraphsVerified() const;
```

Returns the number of paragraphs correctly verified.

verified

```
bool verified() const;
```

Returns true if the tool passed (all character positions have been verified), and false otherwise.

numPositionsEmpty

```
c_Int32 numPositionsEmpty() const;
```

Returns the number of character positions that are empty.

keyZoneViolations

```
c_UInt32 keyZoneViolations() const;
```

Returns which zones of the key search params were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

fullZoneViolations

```
c_UInt32 fullZoneViolations() const;
```

Returns which zones of the full (i.e. image or start pose) search params were violated by at least one position and thus decreased the zone score, as a bitwise-OR of values from **ccOCVMaxDefs::DOF**.

paragraphResults

```
const cmStd vector<ccOCVMaxParagraphResult>&
  paragraphResults() const;
```

Returns the paragraph results for all paragraphs on which verification has been attempted.

timeoutOccurred

```
bool timeoutOccurred() const;
```

Gets whether a timeout occurred during the run.

Notes

The other information in the result represents the best result obtained as of the time when the timeout occurred; it is possible that a better result might have been obtained if the run had been allowed to run to completion without a timeout.

Operators

operator==

```
bool operator==(const ccOCVMaxResult& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxResult& other) const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxResult

ccOCVMaxResultDOFStats

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxResultDOFStats;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxResultDOFStats** class computes cumulative statistics over a set of run results. These statistics can be helpful for determining optimal DOF ranges for later runs or for process control.

Constructors/Destructors

ccOCVMaxResultDOFStats

```
ccOCVMaxResultDOFStats();
```

Constructs a default statistics object.

Notes

The default copy constructor, assignment operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Resets the statistics.

add

```
void add(const ccOCVMaxResult& result);
```

Adds the result to the set of statistics to measure the observed range of DOFs.

Parameters

result	The result to be added.

numResults

```
c_Int32 numResults() const;
```

Gets the number of results that have been added to the statistics.

numFullPositionResults

```
c_Int32 numFullPositionResults() const;
```

Gets the cumulative number of position results contained within all the results that have been added.

Notes

The term "full" is meant to indicate that the statistics for the position results affects the full initial search parameters for a run, which might be specified as either image search parameters or as start pose search parameters.

numKeyPositionResultPairs

```
c_Int32 numKeyPositionResultPairs() const;
```

Gets the cumulative number of pairs of position results contained within all the results that have been added. A pair of position results consists of two adjacent position results, which are thus representative of DOFs for key search parameters.

hasKeyStats

```
bool hasKeyStats() const;
```

Gets whether any statistics relevant for key search parameters are available.

keyUniformScaleRange

```
ccRange keyUniformScaleRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

keyXScaleRange

```
ccRange keyXScaleRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

keyYScaleRange

```
ccRange keyYScaleRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

keyAspectRange

```
ccRange keyAspectRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

keyRotationRange

```
ccAngleRange keyRotationRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

keyShearRange

```
ccAngleRange keyShearRange() const;
```

Gets the observed range of the specific DOF obtained by comparing the DOFs of adjacent position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the key search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyStats()** operation returned false.

hasKeyXyStats

```
bool hasKeyXyStats() const;
```

Gets whether pairwise xy (translation) statistics are available.

keyMaxXyDiff

```
cc2Vect keyMaxXyDiff() const;
```

Gets the maximum xy (translation) difference between a position result and its expected position, where the expected position is based on an adjacent position result and the advance. This value can be useful for setting the **xyUncertainty()** of key search run parameters.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasKeyXyStats()** operation returned false.

hasFullStats

```
bool hasFullStats() const;
```

Gets whether full (image or start pose) statistics are available.

fullUniformScaleRange

```
ccRange fullUniformScaleRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullXScaleRange

```
ccRange fullXScaleRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullYScaleRange

```
ccRange fullYScaleRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullXyScaleRatioRange

```
ccRange fullXyScaleRatioRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullAspectRange

```
ccRange fullAspectRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullRotationRange

```
ccAngleRange fullRotationRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullShearRange

```
ccAngleRange fullShearRange() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

fullXyRect

```
ccRect fullXyRect() const;
```

Gets the observed range of the specific DOF obtained over all position results. Typically, one should expect that setting a DOF range slightly larger than the observed range in the full (that is, image or start pose) search run parameters would allow finding all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasFullStats()** operation returned false.

ccOCVMaxResultStats

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxResultStats;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax result statistics object contains statistics computed over a set of results. The statistics include scores, DOF ranges, and status values.

Constructors/Destructors

ccOCVMaxResultStats

```
ccOCVMaxResultStats();
```

Constructs a default result statistics object.

Notes

The default copy constructor, assign operator, and destructor are used.

Public Member Functions

reset

```
void reset();
```

Resets the statistics.

add

```
void add(const ccOCVMaxResult& result);
```

Adds the result to the set of statistics to measure the observed range of DOFs.

Parameters

result	The result to be added.

numResults

```
c_Int32 numResults() const;
```

Gets the number of results that were added.

ccOCVMaxResultStats

numVerified `c_Int32 numVerified() const;`

Gets the number of results that were verified.

numFailed `c_Int32 numFailed() const;`

Gets the number of results that were not verified.

numTimedOut `c_Int32 numTimedOut() const;`

Gets the number of results that timed out.

hasScores `bool hasScores() const;`

Gets whether any score statistics are available.

minScore `double minScore() const;`

Gets the minimum score over all the results.

Throws
ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

maxScore `double maxScore() const;`

Gets the maximum score over all the results.

Throws
ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

meanScore `double meanScore() const;`

Gets the mean score over all the results.

Throws
ccOCVMaxDefs::StatisticNotComputed
The **hasScores()** operation returned false.

dofStats `const ccOCVMaxResultDOFStats& dofStats() const;`

Gets the DOF statistics accumulated over all the results.

combinedPositionStats

```
const ccOCVMaxPositionResultStats& combinedPositionStats()
  const;
```

Gets the position result statistics accumulated over all the positions over all the results.

hasPositionStats

```
bool hasPositionStats() const;
```

Gets whether position result statistics are available.

numParagraphs

```
c_Int32 numParagraphs() const;
```

Gets the total number of paragraphs in all the results.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasPositionStats()** operation returned false.

numLines

```
c_Int32 numLines(c_Int32 paragraphIndex) const;
```

Gets the total number of lines in all the results.

Parameters

paragraphIndex The paragraph index.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasPositionStats()** operation returned false.

numPositions

```
c_Int32 numPositions(c_Int32 paragraphIndex, c_Int32
lineIndex) const;
```

Gets the total number of positions in all the results.

Parameters

paragraphIndex The paragraph index.

lineIndex The line index.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasPositionStats()** operation returned false.

positionStats

```
const ccOCVMaxPositionResultStats& positionStats(c_Int32
paragraphIndex, c_Int32 lineIndex, c_Int32 positionIndex)
const;
```

Gets the statistics computed over only those position results at the specified paragraph index, line index, and position index.

Parameters

paragraphIndex The paragraph index.

lineIndex The line index.

positionIndex The position index.

Throws

ccOCVMaxDefs::StatisticNotComputed
The **hasPositionStats()** operation returned false.

dump

```
void dump(ccCvlOStream& out, c_Int32 indent = 0) const;
```

Outputs a text representation of all the statistics to the stream.

Parameters

out The stream to which the descriptive text is output.

indent The indent.

Throws

ccOCVMaxDefs::BadParams
indent is less than 0.

ccOCVMaxRunParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxRunParams** class encapsulates all of the OCVMax tool run-time parameters required for running the tool.

Constructors/Destructors

ccOCVMaxRunParams

```
ccOCVMaxRunParams (
  const cmStd vector<ccOCVMaxParagraphRunParams>&
                     paragraphParams = cmStd
                     vector<ccOCVMaxParagraphRunParams>(),
  const ccOCVMaxSearchRunParams &imageSearchRunParams =
                                  ccOCVMaxSearchRunParams(),
  const ccOCVMaxSearchRunParams &keySearchRunParams =
                                  ccOCVMaxSearchRunParams(),
  const ccOCVMaxSearchRunParams &startPoseSearchRunParams =
                                ccOCVMaxSearchRunParams());

ccOCVMaxRunParams
  (const ccOCVMaxArrangement &arr,
  const ccOCVMaxSearchRunParams &imageSearchRunParams =
                                  ccOCVMaxSearchRunParams(),
  const ccOCVMaxSearchRunParams &keySearchRunParams =
                                  ccOCVMaxSearchRunParams(),
  const ccOCVMaxSearchRunParams &startPoseSearchRunParams =
                                ccOCVMaxSearchRunParams());
```

-
```
ccOCVMaxRunParams (
  const cmStd vector<ccOCVMaxParagraphRunParams>&
                     paragraphParams = cmStd
                     vector<ccOCVMaxParagraphRunParams>(),
  const ccOCVMaxSearchRunParams &imageSearchRunParams =
                                  ccOCVMaxSearchRunParams(),
```

```
  const ccOCVMaxSearchRunParams &keySearchRunParams =
                                    ccOCVMaxSearchRunParams(),
  const ccOCVMaxSearchRunParams &startPoseSearchRunParams =
                                  ccOCVMaxSearchRunParams());
```

Constructs a runtime parameter object using the supplied parameters.

Parameters

paragraphParams
Paragraph parameters.

imageSearchRunParams
Image search run-time parameters.

keySearchRunParams
Key search run-time parameters.

startPoseSearchRunParams
Start pose search run-time parameters.

- ```
  ccOCVMaxRunParams(
    const ccOCVMaxArrangement &arr,
    const ccOCVMaxSearchRunParams &imageSearchRunParams =
                                    ccOCVMaxSearchRunParams(),
    const ccOCVMaxSearchRunParams &keySearchRunParams =
                                    ccOCVMaxSearchRunParams(),
    const ccOCVMaxSearchRunParams &startPoseSearchRunParams =
                                  ccOCVMaxSearchRunParams());
  ```

  Constructs with a default-constructed paragraph parameters for each paragraph in the given arrangement.

  Parameters

  arr The arrangement.

  imageSearchRunParams
  Image search run-time parameters.

  keySearchRunParams
  Key search run-time parameters.

  startPoseSearchRunParams
  Start pose search run-time parameters.

  Notes

  The default destructor, copy constructor, and assignment operator are used.
  ```

Public Member Functions

imageSearchRunParams

```
const ccOCVMaxSearchRunParams& imageSearchRunParams()
  const;

void imageSearchRunParams
  (const ccOCVMaxSearchRunParams &searchRunParams);
```

- ```
  const ccOCVMaxSearchRunParams& imageSearchRunParams()
    const;
  ```

  Gets the search run-time parameters to use for pattern alignment in the image.

- ```
  void imageSearchRunParams
    (const ccOCVMaxSearchRunParams &searchRunParams);
  ```

  Sets the search run-time parameters to use for pattern alignment in the image.

  Parameters

  searchRunParams Search run-time parameters.

keySearchRunParams

```
const ccOCVMaxSearchRunParams& keySearchRunParams() const;

void keySearchRunParams
  (const ccOCVMaxSearchRunParams &keySearchRunParams);
```

- ```
  const ccOCVMaxSearchRunParams& keySearchRunParams() const;
  ```

  Gets the search run-time parameters to use for alignment of each keyset relative to its neighbor.

  Throws

  ccOCVMaxDefs::BadParams

  The *keySearchRunParams* value has an angle DOF for which it is not true that low is less than or equal to 0 and high is greater than or equal to 0; or the *keySearchRunParams* value has a scale DOF for which it is not true that low is less than or equal to 1 and high is greater than or equal to 1. In other words, the "neutral" DOF value must be within the specified range.
  ```

- ```
  void keySearchRunParams
    (const ccOCVMaxSearchRunParams &keySearchRunParams);
  ```

  Sets the search run-time parameters to use for alignment of each keyset relative to its neighbor.

  Parameters

  keySearchRunParams Key search run-time parameters.

  Throws

  ccOCVMaxDefs::BadParams

  The *keySearchRunParams* value has an angle DOF for which it is not true that low is less than or equal to 0 and high is greater than or equal to 0; or the *keySearchRunParams* value has a scale DOF for which it is not true that low is less than or equal to 1 and high is greater than or equal to 1. In other words, the "neutral" DOF value must be within the specified range.

startPoseSearchRunParams

```
const ccOCVMaxSearchRunParams& startPoseSearchRunParams()
  const;

void startPoseSearchRunParams
  (const ccOCVMaxSearchRunParams
  &startPoseSearchRunParams);
```

- ```
  const ccOCVMaxSearchRunParams& startPoseSearchRunParams()
    const;
  ```

  Gets the search run-time parameters to use for pattern alignment in the image when a *startPose* is specified at run-time.

- ```
  void startPoseSearchRunParams
    (const ccOCVMaxSearchRunParams
    &startPoseSearchRunParams);
  ```

  Sets the search run-time parameters to use for pattern alignment in the image when a *startPose* is specified at run-time.

  Parameters

  startPoseSearchRunParams

  The start pose search run-time parameters.
  ```

paragraphParams

```
const cmStd vector<ccOCVMaxParagraphRunParams>&
  paragraphParams() const;

void paragraphParams(const cmStd
  vector<ccOCVMaxParagraphRunParams>& params);
```

- `const cmStd vector<ccOCVMaxParagraphRunParams>& paragraphParams() const;`

  Gets the run-time parameters for the paragraphs to be verified.

- `void paragraphParams(const cmStd vector<ccOCVMaxParagraphRunParams>& params);`

  Sets the run-time parameters for the paragraphs to be verified.

  Parameters

  params The run-time parameters.

earlyAcceptThreshold

```
double earlyAcceptThreshold() const;

void earlyAcceptThreshold(double eat);
```

- `double earlyAcceptThreshold() const;`

  Gets the threshold for early acceptance of a potential line match as the true instance of the line in the image.

- `void earlyAcceptThreshold(double eat);`

  Sets the threshold for early acceptance of a potential line match as the true instance of the line in the image.

  If the percentage of keys in the line that match (that is, are verified or confused) is above this threshold, no further searching for the line is performed. This speeds up the search process when the user knows that there will not be spurious characters in the run-time image (for example, when it is known that the only text in the image will be the string to be verified).

  The default value is 0.75.

Parameters

eat Early acceptance threshold.

Throws

ccOCVMaxDefs::BadParams
The setter is given a value not between 0 and 1.

earlyFailThreshold

```
double earlyFailThreshold() const;
void earlyFailThreshold(double eft);
```

- `double earlyFailThreshold() const;`

  Gets the threshold for early failure of a potential line match as the true instance of the line in the image.

- `void earlyFailThreshold(double eft);`

  Sets the threshold for early failure of a potential line match as the true instance of the line in the image.

  If the percentage of keys in the line that match (that is, are verified or confused) is below this threshold, the section of the image containing the potential line will not be considered any further. This speeds up the search process when the user knows that the image should be clean, with no missing or badly damaged characters allowed.

  The default value is 1.0 (that is, stop as soon as one character fails).

  Parameters

  eft Early failure threshold.

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a value not between 0 and 1.

computePoses

```
c_UInt32 computePoses() const;
void computePoses(c_UInt32 sel);
```

- `c_UInt32 computePoses() const;`

  Gets which result poses to compute, as a bitwise-OR of values from **ccOCVMaxDefs::PoseCompute**.

- `void computePoses(c_UInt32 sel);`

  Sets which result poses to compute, as a bitwise-OR of values from **ccOCVMaxDefs::PoseCompute**.

  Computing poses takes additional execution time and may not be needed in all applications; *ePoseComputeArrangementNonlinear* in particular can be expensive.

  Note that the poses of individual character positions are always computed. Poses that are not computed will cause the relevant **foundPose()** getter to return false and the relevant pose getters to throw **ccOCVMaxDefs::NotFound()**.

  The following table shows which bits must be set in order to make a given type of pose result valid.

  Bits:

  ePoseComputeLineLinear = L

  ePoseComputeParagraphLinear = P

  ePoseComputeArrangementLinear = A

  ePoseComputeArrangementNonlinear = AN

  Flags are set (X = valid).

	Bits			
Pose result type	L	P	A	AN
positionResult.clientPose				
positionResult.paragraphPose		X		
positionResult.arrangementPose			X	
lineResult.clientPose	X			
lineResult.paragraphPose	X	X		
lineResult.arrangementPose	X		X	
paragraphResult.clientPose		X		
paragraphResult.arrangementPose		X	X	

Pose result type	Bits L	P	A	AN
result.clientPoseLinear			X	
result.clientPose				X

Parameters

sel

The default value is 0 (only position result poses computed).

Throws

ccOCVMaxDefs::BadParams

sel is not a valid bitwise-OR of values from **ccOCVMaxDefs::PoseCompute**.

nonlinearXformType

```
ccOCVMaxDefs::NonlinearXformType nonlinearXformType()
  const;

void nonlinearXformType(ccOCVMaxDefs::NonlinearXformType
  type);
```

- `ccOCVMaxDefs::NonlinearXformType nonlinearXformType()
  const;`

  Gets the type of xform to use when computing the nonlinear arrangement pose.

- `void nonlinearXformType(ccOCVMaxDefs::NonlinearXformType
  type);`

  Sets the type of xform to use when computing the nonlinear arrangement pose.

  Parameters

  type Type of xform.

Operators

operator== `bool operator==(const ccOCVMaxRunParams& other) const;`

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!= `bool operator!=(const ccOCVMaxRunParams& other) const;`

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxRunParams

ccOCVMaxSearchRunParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxSearchRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxSearchRunParams** class encapsulates all the parameters used to run the arrangement and/or character searches during the course of processing. This object is conceptually similar to a **ccPMAlignRunParams** object in how it is used to control the search space.

Constructors/Destructors

ccOCVMaxSearchRunParams

```
ccOCVMaxSearchRunParams();
```

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

acceptThreshold

```
double acceptThreshold() const;

void acceptThreshold(double a);
```

- `double acceptThreshold() const;`

  Gets the threshold used to locate character shapes in the run-time image.

- `void acceptThreshold(double a);`

  Sets the threshold used to locate character shapes in the run-time image.

  The default value is 0.5.

Parameters

a The threshold value.

Throws

ccOCVMaxDefs::BadParams
The setter is given a value not between 0 and 1.

contrastThreshold

```
double contrastThreshold() const;

void contrastThreshold(double c);
```

- `double contrastThreshold() const;`

  Gets the amount of contrast (in run-time image grey levels) that a result must have to be accepted.

- `void contrastThreshold(double c);`

  Sets the amount of contrast (in run-time image grey levels) that a result must have to be accepted.

  The default value is 10.

  Parameters

  c The contrast amount.

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a negative value.

xyUncertainty

```
cc2Vect xyUncertainty() const;

void xyUncertainty(const cc2Vect& xyUnc);
```

- `cc2Vect xyUncertainty() const;`

  Gets the uncertainty of the starting pose in the x and y dimensions, in client coordinates.

- `void xyUncertainty(const cc2Vect& xyUnc);`

  Sets the uncertainty of the starting pose in the x and y dimensions, in client coordinates.

  This value has no effect when used in the *imageSearchRunParams* parameter of **ccOCVMaxRunParams**. It only has an effect on the keySearchRunParams parameter and the *startPoseSearchRunParams* parameter.

  The default value is 5,5.

  Parameters

  xyUnc The uncertainty of the starting pose in the x and y dimensions.

  Throws

  ccOCVMaxDefs::BadParams
  Either element of the *cc2Vect* is negative.

zoneEnable

```
c_UInt32 zoneEnable() const;
void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

  Gets the zone enable for each degree of freedom.

- `void zoneEnable(c_UInt32 enable);`

  Sets the zone enable for each degree of freedom.

  Non-zero bits in the value indicates degrees of freedom to be searched. If *zoneEnable* is set for a given DOF, the search will be performed between that DOF's *zoneLow* and *zoneHigh* values; otherwise, it will use the single nominal value.

  Parameters

  enable The zone enable parameter.

  Requires that the value be 0 or a bitwise OR of values from the **ccOCVMaxDefs::DOF** enumeration.

  The default value is *ccOCVMaxDefs::eAngle* bitwise OR *ccOCVMaxDefs::eUniformScale*

nominal

```
double nominal(ccOCVMaxDefs::DOF dof) const;
void nominal(ccOCVMaxDefs::DOF dof, double val);
```

- `double nominal(ccOCVMaxDefs::DOF dof) const;`

  Gets the nominal value for the given DOF.

  Parameters

  dof The DOF.

- `void nominal(ccOCVMaxDefs::DOF dof, double val);`

  Sets the nominal value for the given DOF.

  The nominal value is only used if the given DOF is not enabled by **zoneEnable()**.

  Parameters

  dof The DOF.

  val The nominal value.

  Notes

  Angle and shear are specified in degrees.

  If this object is used in the *keySearchRunParams* parameter of **ccOCVMaxRunParams**, then the **ccOCVMaxRunParams** object will throw *BadParams* if for a disabled angle or shear DOF, nominal is not equal to 0; or if for a disabled scale DOF, nominal is not equal to 1. In other words, the "identity" DOF value must be the nominal value. default Angle: 0.0, Scales: 1.0, Shear: 0.0

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a zero or negative scale value.

zoneLow

```
double zoneLow(ccOCVMaxDefs::DOF dof) const;
```

Gets the low zone parameter for the given DOF.

Parameters

dof The DOF.

zoneHigh

```
double zoneHigh(ccOCVMaxDefs::DOF dof) const;
```

Gets the high zone parameter for the given DOF.

Parameters

dof The DOF.

zone

```
void zone(ccOCVMaxDefs::DOF dof, double low, double high);
```

Sets the low and high zone parameters for the given DOF.

Parameters

dof The DOF.

low The low zone parameter.

high The high zone parameter.

Notes

Angle and shear are specified in degrees, and the search is performed from the low value to the high value.

If this object is used in the *keySearchRunParams* parameter of **ccOCVMaxRunParams**, then the **ccOCVMaxRunParams** object will throw *BadParams* if for an enabled angle or shear DOF, it is not true that low is less than or equal to 0 and high is greater than or equal to 0, or if for an enabled scale DOF, it is not true that low is less than or equal to 1 and high is greater than or equal to 1. In other words, the "identity" DOF value must be within the specified range.

The default values: Angle: -5 to 5. Scales: 0.95 to 1.05. Shear: 0 to 0.

Throws

ccOCVMaxDefs::BadParams
The setter is given a zero or negative scale value, or *zoneLow* is greater than *zoneHigh* for a scale DOF.

---

zoneOverlap

```
double zoneOverlap(ccOCVMaxDefs::DOF dof) const;

void zoneOverlap(ccOCVMaxDefs::DOF dof, double
overlapThresh);
```

- `double zoneOverlap(ccOCVMaxDefs::DOF dof) const;`

Gets the required zone overlap to consider two instances to be the same result.

Parameters

dof The DOF.

- `void zoneOverlap(ccOCVMaxDefs::DOF dof, double overlapThresh);`

  Sets the required zone overlap to consider two instances to be the same result.

  Two results are considered overlapping if the overlap amount is greater than overlapThresh.

  Parameters

  dof The DOF.

  overlapThresh The required zone overlap.

  Notes

  Angle and shear are specified in degrees.

  The default values: Angle: 30. Scales: 1.4. Shear: 30.

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a scale value less than 1 or an angle value less than 0.

xyOverlap

```
double xyOverlap() const;

void xyOverlap(double overlapThresh);
```

- `double xyOverlap() const;`

  Gets the required xy overlap to consider two instances to be the same result.

- `void xyOverlap(double overlapThresh);`

  Sets the required xy overlap to consider two instances to be the same result.

  Two results are considered overlapping if the overlap amount is greater than *overlapThresh*.

  The default value is 0.8.

  Parameters

  overlapThresh The overlap threshold.

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a negative value or a value greater than 1.

Operators

operator==

```
bool operator==(const ccOCVMaxSearchRunParams& other)
  const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVMaxSearchRunParams& other)
  const;
```

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxSearchRunParams

ccOCVMaxTool

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxTool;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxTool** class contains all the methods necessary to train and run the OCVMax tool.

Constructors/Destructors

ccOCVMaxTool

```
ccOCVMaxTool();

ccOCVMaxTool(const ccOCVMaxTool &from);
```

- `ccOCVMaxTool();`

  Constructor.

- `ccOCVMaxTool(const ccOCVMaxTool &from);`

  Copy-constructor.

  Parameters

  from The source of the copy.

operator=

```
ccOCVMaxTool &operator=(const ccOCVMaxTool &from);
```

Assignment operator.

Parameters

from Source of the assignment.

The default destructor is used.

Public Member Functions

train

```
void train(
  const ccOCVMaxArrangement &arrangement,
  const cc2XformBase& clientFromImage,
  const ccOCVMaxTrainParams &trainParams,
  ccDiagObject* diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Trains the tool using the supplied arrangement.

Parameters

arrangement The supplied arrangement.

clientFromImage The client space from image space transform.

trainParams Train parameters.

diagObject An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccOCVMaxDefs::BadParams
There are no paragraphs in the arrangement,
or any of the lines in the arrangement contain no characters besides wildcards and spaces.

ccOCVMaxDefs::BadKey
Any paragraph contains keys that are not present in that paragraph's font,
or any paragraph's *alphabetKeys* contain keys that are not present in that paragraph's font.

Notes

Part of the training process is converting fonts into "alphabets" for use by the lower level tools. Depending on the sizes of these alphabets (that is, the number of possible characters in the search process), the training time can be quite large.

untrain

```
void untrain();
```

Untrains the tool. Releases memory required for training.

Notes

No effect if **isTrained()** == false.

isTrained

```
bool isTrained() const;
```

Returns true if this tool is trained and false otherwise.

arrangement

```
const ccOCVMaxArrangement& arrangement() const;
```

Returns the trained arrangement to be verified by the tool.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

trainParams

```
const ccOCVMaxTrainParams& trainParams() const;
```

Returns the train parameters used to train this tool.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

trainClientFromImage

```
cc2XformBasePtrh_const trainClientFromImage() const;
```

Returns the train client from image xform used to train this tool.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

confusionMatrixKeys

```
void confusionMatrixKeys(
  c_Int32 paragraphIndex,
  cmStd vector<c_Int32>& searchKeys,
  cmStd vector<c_Int32>& confusionKeys) const;
```

Returns the set of keys for which confusion has been computed for the given paragraph.

Parameters

paragraphIndex The paragraph index.

searchKeys The search keys.

confusionKeys The confusion keys.

confusion

```
double confusion(
  c_Int32 paragraphIndex,
  c_Int32 searchKey,
  c_Int32 confusionKey) const;
```

Returns the computed confusion value between the two specified keys, in the range [0, 1]. Value will be negative if the tool did not compute the given confusion score.

Parameters

paragraphIndex The paragraph index.

searchKey The search keys.

confusionKey The confusion keys.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

cellRectKey

```
ccAffineRectangle cellRectKey(
  c_Int32 paragraphIndex,
  c_Int32 key,
  const cc2Xform& clientFromParagraph = cc2Xform()) const;
```

Returns the cell rect for the given key at the specified pose.

Parameters

paragraphIndex The paragraph index.

key The key.

clientFromParagraph
The client transformation of the paragraph.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

ccOCVMaxDefs::BadKey
The key was not trained.

tune

```
void tune(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);

void tune(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);
```

-

```
void tune(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Tunes the tool using the supplied image, tune parameters, and run-time parameters, and places results in the supplied result object.

Parameters

image	The supplied image.
tuneParams	The supplied tune parameters.
runParams	The supplied run-time parameters.
keysets	The key sets.
startPose	The start pose.
result	The supplied result object in which results are placed.
**diagObject*	An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void tune(
    const ccPelBuffer_const<c_UInt8> &image,
    const ccOCVMaxTuneParams& tuneParams,
    const ccOCVMaxRunParams &runParams,
    const ccOCVMaxArrangementSearchKeySets &keysets,
    ccOCVMaxTuneResult &result,
    ccDiagObject *diagObject = 0,
    c_UInt32 diagFlags = 0);
  ```

  Tunes the tool using the supplied image, tune parameters, and runtime parameters, and places results in the supplied result object.

  Tuning modifies the tool's arrangement to more closely match the instance found in the image. The initial arrangement must be reasonably close match to allow tuning to improve the arrangement.

  Parameters

image	The supplied image.
tuneParams	The supplied tune parameters.
runParams	The supplied run-time parameters.
keysets	The key sets.
result	The supplied result object in which results are placed.
*diagObject	An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values:
  ```

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

The search is restricted to the specified search keysets. If the overload that specifies *startPose* is used, the search process begins with the assumption that the string will be found very close to the given pose. If this is indeed the case, the tool can tune much faster than when it needs to search the entire image first.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

ccOCVMaxDefs::BadImage
The image is unbound.

ccOCVMaxDefs::BadParams
The paragraph/line/position/keyset structure specified by the **ccOCVMaxArrangementSearchKeySets** object does not match the trained arrangement structure. For example, the keysets object must have the same number of **ccOCVMaxParagraphSearchKeysets** as the trained arrangement has paragraphs.

If the tool was trained with *characterRegistration* mode of *eCorrelation*, then the following throws may also occur:

Throws

ccOCVMaxDefs::DOFNotTrained

The run-time parameters enable a DOF that was not enabled during **train()**.

OR

Run-time parameters (together with the *startPose*, if any) specify a DOF nominal value other than the value specified during **train()**.

OR

The size of an enabled DOF range is larger than the size of the trained range for that DOF, in any of the relevant search parameters (image, start pose, or key).

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrained

The *startPose* contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

If the tool was trained with *characterRegistration* mode of *eCorrelation*, then the following throws may also occur in a future release (but are not yet implemented):

Throws

ccOCVMaxDefs::DOFNotTrainedImageCoords

Run-time parameters (together with the *startPose*, if any) specify a DOF nominal value in image coords other than the value specified during **train()**.

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value in image coords outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrainedImageCoords

The *startPose* in image coords contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

Requires that *diagObject* point to a valid diagnostic object or be NULL.

tuneRunParams

```
void tuneRunParams(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);

void tuneRunParams(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);
```

-
```
void tuneRunParams(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxTuneParams& tuneParams,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxTuneResult &result,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Tunes the run params using the supplied image, tune parameters, and run-time parameters, and places results in the supplied result object.

Parameters

image	The supplied image.
tuneParams	The supplied tune parameters.
runParams	The supplied run-time parameters.
keysets	The key sets.
startPose	The start pose.
result	The supplied result object in which results are placed.
**diagObject*	An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void tuneRunParams(
    const ccPelBuffer_const<c_UInt8> &image,
    const ccOCVMaxTuneParams& tuneParams,
    const ccOCVMaxRunParams &runParams,
    const ccOCVMaxArrangementSearchKeySets &keysets,
    ccOCVMaxTuneResult &result,
    ccDiagObject *diagObject = 0,
    c_UInt32 diagFlags = 0);
  ```

  Tunes the run params using the supplied image, tune parameters, and run-time parameters, and places results in the supplied result object.

  Runs parameter tuning is cumulative with previous calls to **tuneRunParams()**, so that previous images should also work with the new parameters; the state is stored in *result*. To make tuning non-cumulative, call **resetHistory()** on *result* before calling **tuneRunParams()**. The arrangement and initial params must be a reasonably close match to allow tuning to improve the run params.

  Parameters

  image The supplied image.

  tuneParams The supplied tune parameters.

  runParams The supplied run-time parameters.

  keysets The key sets.

  result The supplied result object in which results are placed.

  *diagObject An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

  diagFlags The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values:
  ```

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

The search is restricted to the specified search keysets. If the overload that specifies *startPose* is used, the search process begins with the assumption that the string will be found very close to the given pose. If this is indeed the case, the tool can tune much faster than when it needs to search the entire image first.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

ccOCVMaxDefs::BadImage
The image is unbound.

ccOCVMaxDefs::BadParams
The paragraph/line/position/keyset structure specified by the **ccOCVMaxArrangementSearchKeySets** object does not match the trained arrangement structure. For example, the keysets object must have the same number of **ccOCVMaxParagraphSearchKeysets** as the trained arrangement has paragraphs.

OR

The **ccOCVMaxTuneParams** object has any "max" value less than its corresponding "min" value.

If the tool was trained with the *characterRegistration* mode of *eCorrelation*, then the following throws may also occur:

Throws

ccOCVMaxDefs::DOFNotTrained

The run-time parameters enable a DOF that was not enabled during **train()**.

OR

The run-time parameters (together with the *startPose*, if any) specify a DOF nominal value other than the value specified during **train()**.

OR

The size of an enabled DOF range is larger than the size of the trained range for that DOF, in any of the relevant search params (image, start pose, or key).

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrained

The *startPose* contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

If the tool was trained with *characterRegistration* mode of *eCorrelation*, then the following throws may also occur in a future release (but are not yet implemented):

Throws

ccOCVMaxDefs::DOFNotTrainedImageCoords

Run-time parameters (together with the *startPose*, if any) specify a DOF nominal value in image coords other than the value specified during **train()**.

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value in image coords outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrainedImageCoords

The *startPose* in image coords contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

Requires that *diagObject* point to a valid diagnostic object or be NULL.

run

```
void run(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxResult &results,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0) const;

void run(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  ccOCVMaxResult &results,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0) const;
```

-
```
void run(
  const ccPelBuffer_const<c_UInt8> &image,
  const ccOCVMaxRunParams &runParams,
  const ccOCVMaxArrangementSearchKeySets &keysets,
  const cc2XformBasePtrh_const &startPose,
  ccOCVMaxResult &results,
  ccDiagObject *diagObject = 0,
  c_UInt32 diagFlags = 0) const;
```

Runs the tool using the supplied image and run-time parameters, and places results in the supplied result object.

Parameters

image	The supplied image.
runParams	The supplied run-time parameters.
keysets	The key sets.
startPose	The start pose.
results	The supplied result object in which results are placed.
**diagObject*	An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults*

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void run(
    const ccPelBuffer_const<c_UInt8> &image,
    const ccOCVMaxRunParams &runParams,
    const ccOCVMaxArrangementSearchKeySets &keysets,
    ccOCVMaxResult &results,
    ccDiagObject *diagObject = 0,
    c_UInt32 diagFlags = 0) const;
  ```

  Runs the tool using the supplied image and run-time parameters, and places results in the supplied result object.

  The search is restricted to the specified search keysets. If the overload that specifies *startPose* is used, the search process begins with the assumption that the string will be found very close to the given pose. If this is indeed the case, the tool can run much faster than when it needs to search the entire image first.

  Parameters

image	The supplied image.
runParams	The supplied run-time parameters.
keysets	The key sets.
results	The supplied result object in which results are placed.
*diagObject	An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. diagFlags must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*
  ```

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

ccOCVMaxDefs::BadImage
The image is unbound.

ccOCVMaxDefs::BadParams
The paragraph/line/position/keyset structure specified by the **ccOCVMaxArrangementSearchKeySets** object does not match the trained arrangement structure. For example, the keysets object must have the same number of **ccOCVMaxParagraphSearchKeysets** as the trained arrangement has paragraphs.

ccOCVMaxDefs::NoAlignableChars
All of the positions in any line consist of only blanks, ignored key sets, and/or very poorly alignable characters (typically small punctuation such as periods).

If the tool was trained with the *characterRegistration* mode of *eCorrelation*, then the following throws may also occur:

Throws

ccOCVMaxDefs::DOFNotTrained
The run-time parameters enable a DOF that was not enabled during **train()**.

OR

The run-time parameters (together with the *startPose*, if any) specify a DOF nominal value other than the value specified during **train()**.

OR

The size of an enabled DOF range is larger than the size of the trained range for that DOF, in any of the relevant search params (image, start pose, or key).

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrained
The *startPose* contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

If the tool was trained with characterRegistration mode of *eCorrelation*, then the following throws may also occur in a future release (but are not yet implemented):

Throws

ccOCVMaxDefs::DOFNotTrainedImageCoords
The run-time parameters (together with the *startPose*, if any) specify a DOF nominal value in image coords other than the value specified during **train()**.

OR

The relevant full (that is, image or start pose) search params (together with the start pose, if any) contains a DOF value in image coords outside the trained range.

ccOCVMaxDefs::StartPoseDOFNotTrainedImageCoords
The *startPose* in image coords contains a non-identity value for aspect and the training DOFs did not have a non-identity *xScale* or *yScale*.

Requires that *diagObject* point to a valid diagnostic object or be NULL.

draw

```
void draw(const ccOCVMaxResult &result, c_UInt32 drawFlags,
ccGraphicList &graphList) const;
```

Append graphics for the specified result to *graphList* according to the specified flags:

- *eDrawArrangement* : draw final arrangement pose.
- *eDrawParagraphs* : draw final paragraph poses.
- *eDrawPositions* : draw final character poses.
- *eDrawArrangementBox* : draw arrangement bounding box when drawing arrangement pose.
- *eDrawParagraphBoxes* : draw paragraph bounding boxes when drawing paragraph poses.
- *eDrawPositionBoxes* : draw character regions when drawing character poses.

Parameters

result The specified result.

drawFlags The specified flags.

graphList The graph list to which graphics is appended.

Notes

The following color scheme is used for poses and boxes:

Color	Status of Arrangement/Line/Position
Green	Passed.
Red	Failed.
Blue	Confused.

All graphics are drawn in client coordinates.

Throws

ccOCVMaxDefs::NotTrained
This tool is not currently trained.

Requires that the result specified was generated by calling **run()** from this tool in its current trained state.

operator==

```
bool operator==(const ccOCVMaxTool& other) const;
```

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other The object with which to compare for equality.

operator!= `bool operator!=(const ccOCVMaxTool& other) const;`

Returns true if this object is not equal to the specified object and false otherwise.

Parameters

other The object with which to compare for inequality.

ccOCVMaxTrainParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxTrainParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax training parameters class encapsulates all of the parameters required to run the OCVMax Tool.

Constructors/Destructors

ccOCVMaxTrainParams

```
ccOCVMaxTrainParams();

ccOCVMaxTrainParams(const ccOCVMaxArrangement &arr);
```

- `ccOCVMaxTrainParams();`

  Notes

  The default destructor, copy constructor, and assignment operator are used.

- `ccOCVMaxTrainParams(const ccOCVMaxArrangement &arr);`

  Constructs with a default-constructed paragraph parameters for each paragraph in the given arrangement.

  Parameters

  arr The given arrangement.

Public Member Functions

paragraphParams

```
const cmStd vector<ccOCVMaxParagraphTrainParams>&
  paragraphParams() const;

void paragraphParams(
  const cmStd vector<ccOCVMaxParagraphTrainParams>&
  params);
```

- ```
  const cmStd vector<ccOCVMaxParagraphTrainParams>&
    paragraphParams() const;
  ```

  Gets the training parameters for the paragraphs to be verified.

  There must be one training parameter object for each paragraph in the arrangement, in order.

  Notes

  Training throws *BadParams* if the size of the vector is not the same as the number of paragraphs in the arrangement.

- ```
  void paragraphParams(
    const cmStd vector<ccOCVMaxParagraphTrainParams>&
    params);
  ```

  Sets the training parameters for the paragraphs to be verified.

  Parameters

  params The training parameters.

characterRegistration

```
ccOCVMaxDefs::CharacterRegistration
  characterRegistration() const;

void
characterRegistration(ccOCVMaxDefs::CharacterRegistration
  regType);
```

- ```
  ccOCVMaxDefs::CharacterRegistration
    characterRegistration() const;
  ```

  Gets the type of registration (fitting) done for each character found.
  ```

- ```
  void
  characterRegistration(ccOCVMaxDefs::CharacterRegistration
    regType);
  ```

  Sets the type of registration (fitting) done for each character found.

  - If *eStandard* is selected, the registration is done using PatMax technology with up to six degrees of freedom.
  - If *eCorrelation* is selected, the registration is done using the correlation technology with at most translation, rotation, and uniform scale. The maximum possible runtime ranges for rotation and uniform scale must be specified at training time.

  eStandard usually takes longer to run than *eCorrelation* in the cases where both modes apply (that is, at most rotation and uniform scale are used).

  The default value is *ccOCVMaxDefs::eStandard*

  Parameters

  regType The type of registration.

---

scoreMode

```
ccOCVMaxDefs::ScoreMode scoreMode() const;

void scoreMode(ccOCVMaxDefs::ScoreMode s);
```

- ```
  ccOCVMaxDefs::ScoreMode scoreMode() const;
  ```

  Gets the score mode used to compute the score for each character.

- ```
  void scoreMode(ccOCVMaxDefs::ScoreMode s);
  ```

  Sets the score mode used to compute the score for each character.

  - *ScoreUsingClutter* - reduces the character score if extra features (clutter) are present.
  - *ScoreUsingOptimizedClutter* - reduces the character score if extra features (clutter) are present, but optimizes score for relatively low-contrast clutter.
  - *ScoreWithoutClutter* - computes the score based only on the presence of expected features, ignoring any extra features (clutter).

  Parameters

  s The score mode.
  ```

Notes

ScoreUsingClutter is usually preferable to allow confusion to be computed more reliably, whereas *ScoreWithoutClutter* may be necessary in noisy images. Ignored if *characterRegistration* is *eCorrelation*.

The default value is *ScoreUsingOptimizedClutter*

zoneEnable

```
c_UInt32 zoneEnable() const;

void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

  Gets the zone enable for each degree of freedom.

- `void zoneEnable(c_UInt32 enable);`

  Sets the zone enable for each degree of freedom.

  Non-zero bits in the value indicates degrees of freedom that may be searched at runtime. If *zoneEnable* is set for a given DOF, the search will be performed between that DOF's *zoneLow* and *zoneHigh* values; otherwise, it will use the single nominal value.

  Parameters

  enable The zone enable.

  Requires that the value be 0 or a bitwise OR of values from the **ccOCVMaxDefs::DOF** enumeration.

  Notes

  This value is used only in *eCorrelation* registration mode. Other modes do not need to specify DOF ranges during training.

  The default value is
  ccOCVMaxDefs::eAngle bitwise OR *ccOCVMaxDefs::eUniformScale*

nominal

```
double nominal(ccOCVMaxDefs::DOF dof) const;

void nominal(ccOCVMaxDefs::DOF dof, double val);
```

- `double nominal(ccOCVMaxDefs::DOF dof) const;`

  Gets the nominal value for the given DOF.

  Parameters

  dof The given DOF.

- `void nominal(ccOCVMaxDefs::DOF dof, double val);`

  Sets the nominal value for the given DOF.

  The nominal value is only used if the given DOF is not enabled by **zoneEnable()**.

  Parameters

  dof The given DOF.

  val The nominal value.

  Notes

  Angle and shear are specified in degrees.
  This value is used only in the *eCorrelation* registration mode. Other modes do not need to specify DOF ranges during training.

  The default values: Angle: 0.0, Scales: 1.0, Shear: 0.0

  Throws

  ccOCVMaxDefs::BadParams
  The setter is given a zero or negative scale value.

zoneLow `double zoneLow(ccOCVMaxDefs::DOF dof) const;`

Gets the low zone parameters for the given DOF.

Parameters

dof The given DOF.

zoneHigh `double zoneHigh(ccOCVMaxDefs::DOF dof) const;`

Gets the high zone parameters for the given DOF.

Parameters

dof The given DOF.

zone `void zone(ccOCVMaxDefs::DOF dof, double low, double high);`

Sets the low and high zone parameters for the given DOF.

Parameters

dof The given DOF.

low The low zone parameter.

high The high zone parameter.

Notes

Angle and shear are specified in degrees, and the search is performed from the low value to the high value.

If this object is used in the *keySearchRunParams* parameter of **ccOCVMaxRunParams**, then the **ccOCVMaxRunParams** object will throw *BadParams* if for an enabled angle or shear DOF, it is not true that low is less than or equal to 0 and high is greater than or equal to 0; or if for an enabled scale DOF, it is not true that low is less than or equal to 1 and high is greater than or equal to 1. In other words, the "neutral" DOF value must be within the specified range.

This value is used only in *eCorrelation* registration mode. Other modes do not need to specify DOF ranges during training.

The default values: Angle: -10 to 10. Scales: 0.9 to 1.1. Shear: 0 to 0.

Throws

ccOCVMaxDefs::BadParams
The setter is given a zero or negative scale value, or *zoneLow* is greater than *zoneHigh* for a scale DOF.

---

callback

```
const ccOCVMaxProgressCallback& callback() const;
void callback(const ccOCVMaxProgressCallback& c);
```

- `const ccOCVMaxProgressCallback& callback() const;`

Gets a callback function for training.

- `void callback(const ccOCVMaxProgressCallback& c);`

Sets a callback function for training.

The callback function will be called at various points during the tool's **train()** function to indicate the amount of progress made to allow implementing functionality such as a progress bar.

The callback will initially be called with a progress value of 0.0, and near the end of training it will be called with a value of 1.0; it may be called with several increasing values in between.

Parameters

c The callback function.

Notes

The callback object is not serialized.

computeConfusionMatrix

```
bool computeConfusionMatrix() const;
void computeConfusionMatrix(bool c);
```

- `bool computeConfusionMatrix() const;`

  Gets whether to compute the confusion matrix during training.

- `void computeConfusionMatrix(bool c);`

  Sets whether to compute the confusion matrix during training.

  If the confusion matrix is not computed, then characters will never be considered to be confused. This parameter should be used only in unusual circumstances.

  Parameters

c	Boolean parameter: if true, the confusion matrix is calculated during training.

Operators

operator== `bool operator==(const ccOCVMaxTrainParams& other) const;`

Returns true if this object is equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for equality.

operator!= `bool operator!=(const ccOCVMaxTrainParams& other) const;`

Return true if this object is not equal to the specified object and false otherwise.

Parameters

other	The object with which to compare for inequality.

ccOCVMaxTrainParams

ccOCVMaxTuneParams

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxTuneParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The OCVMax tune parameters specify which aspects of each paragraph within an arrangement should be modified by tuning, and they also allow specifying a callback so that the user can track the progress of a tune operation, which can be time consuming.

Constructors/Destructors

ccOCVMaxTuneParams

```
ccOCVMaxTuneParams();

ccOCVMaxTuneParams(const ccOCVMaxArrangement& arr);
```

- `ccOCVMaxTuneParams();`

  Constructs a default tune parameters object.

- `ccOCVMaxTuneParams(const ccOCVMaxArrangement& arr);`

  Constructs a tune parameters object with one paragraph tune parameters object for each paragraph of the arrangement.

  Parameters

  arr The arrangement.

  Notes

  The default copy constructor, assignment operator, and destructor are used.

Public Member Functions

paragraphIndices

```
const cmStd vector<c_Int32>& paragraphIndices() const;

void paragraphIndices(const cmStd vector<c_Int32>& p);
```

- `const cmStd vector<c_Int32>& paragraphIndices() const;`

  Gets which paragraphs to tune.

- `void paragraphIndices(const cmStd vector<c_Int32>& p);`

  Sets which paragraphs to tune.

  An empty vector indicates that all paragraphs should be tuned.

  Parameters

  p The paragraphs to be tuned.

paragraphParams

```
const cmStd vector<ccOCVMaxParagraphTuneParams>
 &paragraphParams() const;

void paragraphParams(const cmStd
 vector<ccOCVMaxParagraphTuneParams> &pparams);
```

- `const cmStd vector<ccOCVMaxParagraphTuneParams> &paragraphParams() const;`

  Gets the parameters for each paragraph to be tuned.

- `void paragraphParams(const cmStd vector<ccOCVMaxParagraphTuneParams> &pparams);`

  Sets the parameters for each paragraph to be tuned.

  The vector is referenced using the indices specified by paragraphIndices. The vector should have the same number of elements as the tuned arrangement has paragraphs.

  Parameters

  pparams The paragraph parameters.

callback

```
const ccOCVMaxProgressCallback& callback() const;
void callback(const ccOCVMaxProgressCallback& c);
```

- `const ccOCVMaxProgressCallback& callback() const;`

  Gets a callback function for tuning.

- `void callback(const ccOCVMaxProgressCallback& c);`

  Sets a callback function for tuning.

  The callback function will be called at various points during the tool's **tune()** function to indicate the amount of progress made, to allow implementing functionality such as a progress bar. The callback will initially be called with a progress value of 0.0, and near the end of tuning it will be called with a value of 1.0; it may be called with several increasing values in between.

  Parameters

  c The callback function.

  Notes

  The callback object is not serialized.

ccOCVMaxTuneParams

ccOCVMaxTuneResult

```
#include <ch_cvl/ocvmax.h>

class ccOCVMaxTuneResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccOCVMaxTuneResult** class contains information obtained by tuning an OCVMax tool.

Constructors/Destructors

ccOCVMaxTuneResult

```
ccOCVMaxTuneResult();
```

Constructs a default tune result.

Notes

The default copy constructor, assignment operator, and destructor are used.

Public Member Functions

result

```
const ccOCVMaxResult& result() const;
```

Gets the result, which represents the run result obtained for the final tuned arrangement.

runParams

```
const ccOCVMaxRunParams &runParams() const;
```

Gets a *runParams* object which is a tightly restricted set of params that is sufficiently open to find the tuned arrangement in the tuning image.

runTimeout

```
double runTimeout() const;
```

Gets a timeout value which is sufficiently large to allow a run to complete.

ccOCVMaxTuneResult

startPose

```
const cc2XformBasePtrh_const& startPose() const;
```

Gets a start pose that is appropriate to find the tuned arrangement in the tuning image.

resetHistory

```
void resetHistory();
```

Resets the history so that previous tuning data is not used to tune the output run parameters.

Notes

This affects only **ccOCVMaxTool::tuneRunParams()**.

ccOCVPosResult

```
#include <ch_cvl/ocv.h>

class ccOCVPosResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class captures information about the OCV tool's verification results for a character position within a line of text. You should not create a **ccOCVPosResult** directly.

Constructors/Destructors

ccOCVPosResult

```
ccOCVPosResult();
```

Constructs a position result object with a verification status of failed.

Operators

operator==

```
bool operator==(const ccOCVPosResult& other) const;
```

Returns true if this object is equal to the specified position results object.

Parameters

other The position results object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVPosResult& other) const;
```

Returns true if this object is not equal to the specified position results object.

Parameters

other A position results object with which to compare for inequality.

Public Member Functions

posIndex

```
c_Int32 posIndex() const;
```

Returns the index of the character position within the line.

key

```
c_Int32 key() const;
```

Returns the key of the character found at the position. A value of -1 is returned if no character was found at this position or if a wildcard key is part of the current key set.

status

```
ccOCVDefs::CharStatus status() const;
```

Returns the verification status for this character position: verified, confused, or failed.

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the character in client coordinates.

If no character was found at this position, a blank character was defined for this position, or a wildcard key is part of the current key set, then the returned pose is estimated from the found poses of adjacent characters.

linePose

```
const cc2Xform& linePose() const;
```

Returns the pose of the character in line coordinates.

If no character was found at this position, a blank character was defined for this position, or a wildcard key was part of the current key set, then the returned pose is estimated from the found poses of adjacent characters.

score

```
double score() const;
```

Returns the verification score, which indicates how well the character found at this position matched the expected character.

A value of 0.0 is returned if no character was found. If a wildcard key is part of the current key set, a value of 1.0 is returned. In all cases, the returned value is greater than the accept threshold if the character was found.

confidenceScore

```
double confidenceScore() const;
```

Returns the confidence score for the character. The confidence score indicates the amount that the verification score for this character is greater than the next-highest scoring character that has a non-zero confusion score with the character at the indexed position. Characters corresponding to the current key indices are not able to be confused with the position.

A value of 0.0 is returned if no character was found or the highest-scoring confusion character's score exceeded this character's score.

For blank characters, this score indicates the tool's confidence that the tool has that no features are present.

confusionKeys

```
const cmStd vector<c_Int32>& confusionKeys() const;
```

Returns the keys of all the characters that were confused at this position.

confusionMatchScores

```
const cmStd vector<double>& confusionMatchScores() const;
```

Returns the verification scores received by the characters that were confused at this position. The order of the scores matches the order of the keys returned by **confusionKeys()**.

ccOCVPosResult

ccOCVPosRunParams

```
#include <ch_cvl/ocv.h>

class ccOCVPosRunParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class defines the run-time parameters used by the OCV tool to verify a character position within a line of text.

Constructors/Destructors

ccOCVPosRunParams

```
ccOCVPosRunParams(c_Int32 posIndex = 0,
  double acceptThreshold = 0.5,
  double confidenceThreshold = 0.0);
```

Constructs a run-time parameters object for the specified position within a line.

Parameters

posIndex The index of the character position for which these run-time parameters apply.

acceptThreshold The matching score below which the character at this line position fails verification.

confidenceThreshold
The confidence threshold determines whether the character position receives a verification status of verified or confused. If the difference between the matching score for the position and the highest scoring confusing character is greater than the confidence threshold, the position passes verification; otherwise, the verification status of the position is confused.

Throws

ccOCVDefs::BadIndex
posIndex is less than 0.

ccOCVDefs::BadParams
acceptThreshold or *confidenceThreshold* is less than 0 or greater than 1.

Operators

operator==

```
bool operator==(const ccOCVPosRunParams& other) const;
```

Returns true if this object is equal to the specified object.

Parameters

other The run-time parameters object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVPosRunParams& other) const;
```

Returns true if this object is not equal to the specified object.

Parameters

other The run-time parameters object with which to compare for inequality.

Public Member Functions

posIndex

```
void posIndex(c_Int32 index);
c_Int32 posIndex() const;
```

- `void posIndex(c_Int32 index);`

Sets the character position index for these run-time parameters.

Parameters

index A position index.

Throws

ccOCVDefs::BadIndex
posIndex is less than 0.

- `c_Int32 posIndex() const;`

Returns the character position index for these run-time parameters.

acceptThreshold

```
void acceptThreshold(double t);
double acceptThreshold() const;
```

- `void acceptThreshold(double t);`

  Sets the accept threshold for this character position. The accept threshold specifies the matching score below which the character at this position fails optical verification.

  Parameters

  t The accept threshold. This value must be between 0 and 1.

  Throws

  ccOCVDefs::BadParams
  t is less than 0 or greater than 1.

- `double acceptThreshold() const;`

  Returns the accept threshold for this line position.

confidenceThreshold

```
void confidenceThreshold(double t);
double confidenceThreshold() const;
```

- `void confidenceThreshold(double t);`

  Sets the confidence threshold for the character position. The confidence threshold determines whether a character position receives a verification status of verified or confused. If the difference between the matching score for the position and the highest scoring confusing character is greater than the confidence threshold, the position passes verification; otherwise, the verification status of the position is confused.

  Parameters

  t The confidence threshold. This value must be between 0 and 1.

  Throws

  ccOCVDefs::BadParams
  t is less than 0 or greater than 1.

- `double confidenceThreshold() const;`

  Returns the confidence threshold for the character position.

ccOCVPosRunParams

ccOCVResult

```
#include <ch_cvl/ocv.h>

class ccOCVResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class captures the result information obtained by using the OCV tool to verify a line arrangement.

Constructors/Destructors

ccOCVResult

```
ccOCVResult();
```

Constructs a result object with a failed status and no line results.

Operators

operator==

```
bool operator==(const ccOCVResult& other) const;
```

Returns true if this object is equal to the specified result object.

Parameters

other	The OCV tool result object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVResult& other) const;
```

Returns true if this object is not equal to the specified result object.

Parameters

other	The OCV tool result object with which to compare for inequality.

Public Member Functions

clientPose

```
const cc2Xform& clientPose() const;
```

Returns the pose of the line arrangement in client coordinates.

fixturePose

```
const cc2Xform& fixturePose() const;
```

Returns the pose of the arrangement fixture in client coordinates.

score

```
double score() const;
```

Returns the overall verification score for the line arrangement. This score is the average of the verification scores for the lines that the tool attempted to verify.

numLinesVerified

```
c_Int32 numLinesVerified() const;
```

Returns the number of lines that passed verification.

verified

```
bool verified() const;
```

Returns true if all lines in the line arrangement passed verification. A line passes verification if all character positions in the line receive a status of verified.

lineResults

```
const cmStd vector<ccOCVLineResult>& lineResults() const;
```

Returns the results for all lines in the arrangement for which verification has been attempted.

lineResult

```
const ccOCVLineResult& lineResult(c_Int32 lineIndex) const;
```

Returns the result for the specified line.

Parameters

lineIndex The index of the line.

Throws

ccOCVDefs::BadIndex
lineIndex is not the index of a line for which verification was attempted.

time

```
double time() const;
```

Returns the time in milliseconds that the tool takes to complete its run.

ccOCVRunParams

```
#include <ch_cvl/ocv.h>

class ccOCVRunParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class encapsulates the parameters required to run the OCV tool.

Constructors/Destructors

ccOCVRunParams

```
ccOCVRunParams();

ccOCVRunParams (
  const cmStd vector<ccOCVLineRunParams>& lineParams,
  const cc2Xform& expectedPose = cc2Xform(),
  const cc2Rigid& fixtureOffset = cc2Rigid(),
  double translationUncertainty = 0,
  const ccRadian & rotationUncertainty = ccRadian(0),
  double scaleUncertainty = 0,
  double timeout = HUGE_VAL);

ccOCVRunParams (
  const ccOCLineArrangement& lineArrangement,
  const cc2Xform& expectedPose,
  const cc2Rigid& fixtureOffset,
  double translationUncertainty = 0,
  const ccRadian & rotationUncertainty = ccRadian(0),
  double scaleUncertainty = 0,
  double acceptThreshold = 0.5,
  double confidenceThreshold = 0.0,
  double timeout = HUGE_VAL);

ccOCVRunParams (
  const ccOCLineArrangement& lineArrangement,
  const cc2Xform& expectedPose = cc2Xform(),
  c_Int32 lineIndex = 0,
  c_Int32 posIndex = 0,
  double translationUncertainty = 0,
```

```
  const ccRadian & rotationUncertainty = ccRadian(0),
  double scaleUncertainty = 0,
  double acceptThreshold = 0.5,
  double confidenceThreshold = 0.0,
  double timeout = HUGE_VAL);
```

- `ccOCVRunParams();`

  Constructs a default run-time parameters object with an identity expected pose, no offset, and no uncertainty factors.

- ```
  ccOCVRunParams (
    const cmStd vector<ccOCVLineRunParams>& lineParams,
    const cc2Xform& expectedPose = cc2Xform(),
    const cc2Rigid& fixtureOffset = cc2Rigid(),
    double translationUncertainty = 0,
    const ccRadian & rotationUncertainty = ccRadian(0),
    double scaleUncertainty = 0,
    double timeout = HUGE_VAL);
  ```

  Constructs a run-time parameters object with the specified expected pose, offset, and uncertainties.

  Parameters

  lineParams The line run-time parameters for each of the lines in the arrangement to be verified.

  expectedPose The nominal pose of the fixture, specified in the client coordinates of the input image.

  fixtureOffset The rigid offset from arrangement coordinates to the fixture.

  translationUncertainty
  The translation uncertainty of the line arrangement.

  rotationUncertainty
  The rotation uncertainty of the line arrangement.

  scaleUncertainty
  The scale uncertainty of the line arrangement. You should not specify a value greater than 0.10 for the scale uncertainty.

  timeout The maximum time in seconds for the tool to run.

  Throws

  ccOCVDefs::BadParams
  translationUncertainty, *rotationUncertainty*, *scaleUncertainty,* or *timeout* is less than 0.
  ```

ccOCVDefs::BadIndex
lineParams contains repeated position indices.

- ```
  ccOCVRunParams (
    const ccOCLineArrangement& lineArrangement,
    const cc2Xform& expectedPose,
    const cc2Rigid& fixtureOffset,
    double translationUncertainty = 0,
    const ccRadian & rotationUncertainty = ccRadian(0),
    double scaleUncertainty = 0,
    double acceptThreshold = 0.5,
    double confidenceThreshold = 0.0,
    double timeout = HUGE_VAL);
  ```

  Constructs a run-time parameters object with the specified expected pose, offset, and uncertainties. The run-time parameters for each line and character position in the supplied arrangement are automatically constructed using the given accept and confidence thresholds.

  Parameters

  lineArrangement The line arrangement with lines to be verified.

  expectedPose The nominal pose of the fixture, specified in the client coordinates of the input image.

  fixtureOffset The rigid offset from arrangement coordinates to the fixture.

  translationUncertainty
  The translation uncertainty of the line arrangement.

  rotationUncertainty
  The rotation uncertainty of the line arrangement.

  scaleUncertainty
  The scale uncertainty of the line arrangement. You should not specify a value greater than 0.10 for the scale uncertainty.

  acceptThreshold The accept threshold, which specifies the matching score below which a character position fails verification. This value applies to all character positions in the line arrangement.

  confidenceThreshold
  The confidence threshold, which determines whether a character position receives a verification status of verified or confused. If the difference between the matching score for the position and the highest scoring confusing character is greater than the confidence threshold, the position passes verification; otherwise,
  ```

the verification status of the position is confused. The confidence threshold value applies to all character positions in the line arrangement.

timeout The maximum time in seconds for the tool to run.

Throws

ccOCVDefs::BadParams

translationUncertainty, *rotationUncertainty*, *scaleUncertainty*, or *timeout* is less than 0; or the *acceptThreshold* or *confidenceThreshold* is less than 0 or greater than 1.

Notes

When the tool runs, it verifies all character positions in all lines.

- ```
  ccOCVRunParams (
    const ccOCLineArrangement& lineArrangement,
    const cc2Xform& expectedPose = cc2Xform(),
    c_Int32 lineIndex = 0,
    c_Int32 posIndex = 0,
    double translationUncertainty = 0,
    const ccRadian & rotationUncertainty = ccRadian(0),
    double scaleUncertainty = 0,
    double acceptThreshold = 0.5,
    double confidenceThreshold = 0.0,
    double timeout = HUGE_VAL);
  ```

Constructs a run-time parameters object with the specified expected pose and uncertainties, and computes the offset from the fixture to the specified character position. Run-time parameters for line and character positions in the line arrangement are automatically constructed using the supplied accept and confidence thresholds.

Parameters

lineArrangement The line arrangement with lines to be verified.

expectedPose The nominal pose of the fixture, specified in the client coordinates of the input image.

lineIndex The index of the line that contains the character from which to calculate the fixture offset.

posIndex The index of the character position from which to calculate the fixture offset.

translationUncertainty

The translation uncertainty of the line arrangement.
  ```

rotationUncertainty
The rotation uncertainty of the line arrangement.

scaleUncertainty
The scale uncertainty of the line arrangement. You should not specify a value greater than 0.10 for the scale uncertainty.

acceptThreshold The accept threshold, which specifies the matching score below which a character position fails verification. This value applies to all character positions in the line arrangement.

confidenceThreshold
The confidence threshold, which determines whether a character position receives a verification status of verified or confused. If the difference between the matching score for the position and the highest scoring confusing character is greater than the confidence threshold, the position passes verification; otherwise, the verification status of the position is confused. The confidence threshold value applies to all character positions in the line arrangement.

timeout The maximum time in seconds for the tool to run.

Throws

ccOCVDefs::BadParams
translationUncertainty, *rotationUncertainty*, *scaleUncertainty*, or *timeout* is less than 0; or the *acceptThreshold* or *confidenceThreshold* is less than 0 or greater than 1.

ccOCVDefs::BadIndex
The *lineIndex* or *posIndex* value is not valid for the given arrangement.

Notes

When the tool runs, it verifies all characters in all lines.

Operators

operator==

```
bool operator==(const ccOCVRunParams& other) const;
```

Returns true if this object is equal to the specified run-time parameters object.

Parameters

other The object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVRunParams& other) const;
```

Returns true if this object is not equal to the specified run-time parameters object.

Parameters

other The object with which to compare for inequality.

Public Member Functions

expectedPose

```
void expectedPose(const cc2Xform& pose);

const cc2Xform& expectedPose() const;
```

- `void expectedPose(const cc2Xform& pose);`

  Sets the expected pose of the fixture, specified in the client coordinates of the input image.

  Parameters

  pose The expected pose of the arrangement fixture.

- `const cc2Xform& expectedPose() const;`

  Returns the expected pose of the fixture, specified in the client coordinates of the input image.

fixtureOffset

```
void fixtureOffset(const cc2Rigid& offset);

const cc2Rigid& fixtureOffset() const;

void fixtureOffset(const ccOCLineArrangement& lineArr,
  c_Int32 lineIndex, c_Int32 posIndex);
```

- `void fixtureOffset(const cc2Rigid& offset);`

  Sets the offset from the arrangement coordinates to the fixture.

  Parameters

  offset The offset from the line arrangement to the fixture.

- `const cc2Rigid& fixtureOffset() const;`

  Returns the offset from the arrangement coordinates to the fixture.

- `void fixtureOffset(const ccOCLineArrangement& lineArr, c_Int32 lineIndex, c_Int32 posIndex);`

  Sets the offset from the line arrangement to a fixture that is defined by the coordinate system of the specified character within the line arrangement.

  Parameters

  lineArr The line arrangement for which to set the fixture offset.

  lineIndex The index of the line that contains the character position to act as the fixture.

  posIndex The index of the character position to act as the fixture.

  Throws

  ccOCVDefs::BadIndex
  The *lineIndex* or *posIndex* value is not valid for the given arrangement.

translationUncertainty

```
void translationUncertainty(double unc);

double translationUncertainty() const;
```

- `void translationUncertainty(double unc);`

  Sets the translation uncertainty for the expected pose of the line arrangement.

  Parameters

  unc The translation uncertainty. This must be greater than or equal to 0.

  Throws

  ccOCVDefs::BadParams
  unc is less than 0.

- `double translationUncertainty() const;`

  Returns the translation uncertainty for the expected pose of the line arrangement.

rotationUncertainty

```
void rotationUncertainty(const ccRadian& unc);
const ccRadian& rotationUncertainty() const;
```

- `void rotationUncertainty(const ccRadian& unc);`

  Sets the rotation uncertainty for the expected pose of the line arrangement.

  Parameters

  unc The rotation uncertainty. This must be greater than or equal to 0.

  Throws

  ccOCVDefs::BadParams
  unc is less than 0.

- `const ccRadian& rotationUncertainty() const;`

  Returns the rotation uncertainty for the expected pose of the line arrangement.

scaleUncertainty

```
void scaleUncertainty(double unc);
double scaleUncertainty() const;
```

- `void scaleUncertainty(double unc);`

  Sets the scale uncertainty for the expected pose of the line arrangement.

  Parameters

  unc The scale uncertainty. This must be greater than or equal to 0. You should not specify a value greater than 0.10 for the scale uncertainty.

  Throws

  ccOCVDefs::BadParams
  unc is less than 0.

- `double scaleUncertainty() const;`

  Returns the scale uncertainty for the expected pose of the line arrangement.

lineParams

```
void lineParams(
  const cmStd vector<ccOCVLineRunParams>& params);

const cmStd vector<ccOCVLineRunParams>& lineParams() const;
```

- ```
  void lineParams(
    const cmStd vector<ccOCVLineRunParams>& params);
  ```

  Sets the run-time parameters for the lines to be verified.

  Parameters

  params The line run-time parameters.

  Throws

  ccOCVDefs::BadIndex

  params contains repeated line indices.

- ```
  const cmStd vector<ccOCVLineRunParams>& lineParams() const;
  ```

  Returns the run-time parameters for the lines to be verified.

timeout

```
void timeout(double timeInSeconds);

double timeout() const;
```

- ```
  void timeout(double timeInSeconds);
  ```

  Sets the maximum time in seconds allowed for the tool to run.

  Parameters

  timeInSeconds The maximum time in seconds for the tool's run.

  Throws

  ccOCVDefs::BadParams

  timeInSeconds is less than 0.

  ccTimeout::Expired

  The tool's **run()** function has not completed before the timeout period elapses. As a consequence, the tool does not yield valid results.
  ```

Notes

This value is intended as an approximate upper limit. The actual execution time may exceed the maximum timeout value by up to 0.02 seconds on a 200 Mhz Pentium, however typical latencies for faster CPU machines are much lower.

User-created **ccTimeout** objects can also terminate the tool's **run()** function.

If you did not specify a timeout for the run-time parameters object at construction-time, it defaults to *HUGE_VAL*.

- `double timeout() const;`

Returns the maximum time in seconds allowed for the tool to run.

ccOCVTool

```
#include <ch_cvl/ocv.h>

class ccOCVTool;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class contains methods for training and running the OCV tool. You use the OCV tool to perform optical character verification of a text area.

Constructors/Destructors

ccOCVTool

```
ccOCVTool();

~ccOCVTool();

ccOCVTool(const ccOCVTool& t);
```

- `ccOCVTool();`

  Constructs an untrained OCV tool.

- `~ccOCVTool();`

  Destroys the tool.

- `ccOCVTool(const ccOCVTool& t);`

  Creates a copy of the specified OCV tool.

  Parameters

t	The tool to copy.

operator=

```
ccOCVTool& operator=(const ccOCVTool& t);
```

Assigns the values of the specified OCV tool to this tool.

Parameters

t The tool from which to assign values.

Operators

operator==

```
bool operator==(const ccOCVTool& other) const;
```

Returns true if this object is equal to the specified tool object.

Parameters

other The OCV tool object with which to compare for equality.

operator!=

```
bool operator!=(const ccOCVTool& other) const;
```

Returns true if this object is not equal to the specified tool object.

Parameters

other The OCV tool object with which to compare for inequality.

Public Member Functions

train

```
void train(
  const ccOCLineArrangementPtrh_const& lineArrangement,
  ccDiagObject* diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Trains the tool using the supplied line arrangement.

If alphabets referenced by the lines in the line arrangement have not yet been compiled, they are automatically compiled as a result of calling **train()**. This may cause the training operation to take substantially longer and may also affect other clients of the alphabets.

Parameters

lineArrangement The line arrangement with which to train the tool.

diagObject A valid diagnostic object or null.

diagFlags Diagnostic flags.

Throws

ccOCVDefs::CanNotTrain

The arrangement contains no lines; or any line in the arrangement has wildcard or blank characters in all positions.

retrain

```
void retrain(
  const ccOCLineArrangementPtrh_const& lineArrangement,
  ccDiagObject* diagObject = 0,
  c_UInt32 diagFlags = 0);
```

Retrains the tool using the specified line arrangement. Only tool information that has changed since the last training operation is retrained.

Parameters

lineArrangement The line arrangement with which to retrain the tool.

diagObject A valid diagnostic object or null.

diagFlags Diagnostic flags.

Throws

ccOCVDefs::CanNotTrain
The arrangement contains no characters.

ccOCVDefs::NotTrained
The tool is not trained.

untrain

```
void untrain();
```

Untrains the tool, releasing any memory that was allotted by training.

Notes

Calling this function has no effect if the tool is not trained.

isTrained

```
bool isTrained() const;
```

Returns true if this tool is trained.

lineArrangement

```
const ccOCLineArrangementPtrh_const&
  lineArrangement() const;
```

Returns the trained line arrangement to be verified by the tool.

Throws

ccOCVDefs::NotTrained
The tool is not trained.

run

```
void run(const ccPelBuffer_const<c_UInt8> image,
  const ccOCVRunParams& runParams,
  ccOCVResult& results,
  ccDiagObject* diagObject = 0,
  c_UInt32 diagFlags = 0) const;
```

Runs the OCV tool using the supplied image and runtime parameters, and records tool results in the supplied result object.

The tool tries to verify all characters specified by its run-time parameters. However, following a verification failure, the tool may not be able to locate remaining characters. In this case, the tool reports the results of those characters verified up to and including the verification failure.

Parameters

image The image that contains the text area to verify.

runParams Parameters for the tool that specify the run-time arrangement of lines and characters and the pose and uncertainties of these.

results The tool stores information about the verification run in the *results* object.

diagObject A valid diagnostic object or null.

diagFlags Any diagnostic flags.

Throws

ccOCVDefs::NotTrained
tool is not currently trained.

ccOCVDefs::BadImage
The image is unbound.

ccOCVDefs::BadIndex
The run-time parameters specify a line or character position index that does not correspond to a valid line or character position in the supplied arrangement.

ccTimeout::Expired
The tool timeout period elapsed.

draw

```
void draw(const ccOCVResult& result, c_UInt32 drawFlags,
  ccGraphicList& graphList) const;
```

Appends the specified graphics associated with the supplied result to the supplied graphics list. The graphics are colored as follows: green for passed, red for failed, blue for confused, and yellow for not run.

Notes

The supplied result must have been generated by calling **run()** while the tool was in its current trained state.

Parameters

result	The result for which to create graphics.
drawFlags	A value formed by ORing together zero or more of the values defined in **ccOCVDefs::DrawFlags**.

Throws

ccOCVDefs::NotTrained
This tool is not trained.

ccOCVTool

ccOutputLine

```
#include <ch_cvl/pio.h>

class ccOutputLine;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

ccOutputLine describes a single output line. You obtain a **ccOutputLine** by calling the **outputLine()** member of the class that describes your hardware platform.

You can set any output line to **true** or **false** using **ccOutputLine::set**. For TTL output or TTL bidirectional lines, **true** means TTL high (+5V). For opto-isolated lines, **true** enables the no-current-flowing state (the LED inside the opto-isolator is OFF, and thus the circuit is open). For opto-isolated lines, **false** sets the current-flowing state (the LED inside the opto-isolator is ON, thus the circuit is closed). Refer to the circuit diagram for opto-isolated parallel I/O lines in the hardware manual for your MVS-8000 product.

Notes

Do not attempt to construct a **ccOutputLine** directly.

Public Member Functions

get

```
bool get() const;
```

Retrieves the current state of the output line associated with this **ccOutputLine**. The meanings of **true** and **false** are defined in *Class Properties* above.

This function does not indicate the actual state of the line. Instead, it indicates the state that the software is attempting to set. An improper connection or hardware failure can cause the actual state of the output line to be different than the value returned by this function.

Throws

ccParallelIO::NotEnabled

The output line associated with this **ccOutputLine** is not enabled. You must enable the output line by calling **enable()** before you can examine its state.

set `void set(bool value);`

Sets the output line associated with this **ccOutputLine** to the specified state.

Parameters

value Set *value* to **true** to set the output line to TTL high (for TTL output or bidirectional lines) or to the no-current-flowing state (for opto-isolated lines). Set *value* to **false** to set the output line to TTL low (for TTL lines) or to current-flowing state (for opto-isolated lines).

Throws

ccParallelIO::NotEnabled
The output line associated with this **ccOutputLine** is not enabled. You must enable the output line by calling **enable()** before you can set its state.

lineNumber `c_Int32 lineNumber() const;`

Returns the logical line number of the output line associated with this **ccOutputLine**. The returned value is in the range determined by the configuration set by **ccParallelIO::setIOConfig()**.

Throws

ccParallelIO::NotEnabled
The output line object was not constructed correctly.

Notes

See the documentation for the class that describes your hardware platform for the equivalence between logical line numbers and signal names.

enable `void enable(bool value);`

Enables or disables the output line associated with this **ccOutputLine**.

Parameters

value Set *value* to **true** to enable the line, **false** to disable it.

Throws

ccParallelIO::CannotEnable
This **ccOutputLine** cannot be enabled. On some hardware platforms, all bidirectional TTL lines must be enabled as a group to be input or output lines. In these cases, it may not be possible to enable an output line if other lines in the same group have been configured as input lines.

enabled

```
bool enabled() const;
```

Returns **true** if the output line associated with this is **ccOutputLine** enabled and **false** otherwise.

Throws

ccParallelIO::NotEnabled
The output line object was not constructed correctly.

canEnable

```
bool canEnable() const;
```

Returns **true** if the output line associated with this **ccOutputLine** can be enabled. Returns **false** if **enable()** would throw an error.

Throws

ccParallelIO::NotEnabled
The output line object was not constructed correctly.

toggle

```
void toggle();
```

Sets the line to the opposite of its current state.

Throws

ccParallelIO::NotEnabled
The output line associated with this **ccOutputLine** is not enabled. You must enable the output line by calling **enable()** before you can set its state.

pulse

```
void pulse(bool polarity, double width,
  bool blocking=true);
```

Toggles the line to the specified polarity for the specified number of seconds.

Parameters

polarity — True means a zero-to-one transition; false means a one-to-zero transition.

width — The number of seconds to wait before complementing the line.

blocking — Specifies how you want this function to behave. True makes it a blocking function, false makes it a non-blocking function.

Throws

ccParallelIO::NotEnabled
The output line associated with this **ccOutputLine** is not enabled. You must enable the output line by calling **enable()** before you can set its state.

Notes

1. If the pulse is disabled or the program exits in the middle of a pulse, the line retains its last state.
2. If the polarity argument specified is the same as the current state, the pulse function does not toggle on the initial transition. For example, if the state of the output line is already high (one) and the user attempts to pulse high (*polarity* = **true**), the line will remain high on what would have been the initial pulse transition, and after the pulse duration expires, it will toggle low.
3. The first call that your program makes to this function may result in a pulse that is from ten to several hundred milliseconds longer than you specified. This additional time only occurs the first time you call **pulse()**; subsequent pulses will be the correct length, subject to the granularity limits described above.
4. The **pulse()** function has a granularity of 1 ms for embedded applications running on the MVS-82400. For frame grabber-based applications running on a PC host, the pulse granularity is approximately 10 ms, although the exact timing is controlled by the Windows OS. In this case, you can improve the resolution of the pulse by changing the granularity of the operating system's multimedia timer, using the Win32 function **timeBeginPeriod()**.

   However, be aware that changing the operating system's timer resolution affects the timing of all programs running on that system. Changing the resolution may adversely affect the timing of CVL image acquisition or vision tool operations. Carefully test all aspects of your CVL application if you change the operating system timer resolution.
5. For PC-based frame grabber applications, the actual pulse width can be longer than the width you specify depending on the host PC processor speed, the amount of memory, and the operating environment when the **pulse()** call is made. For example, the number of background tasks, amount of background activity, and so on can increase the pulse width beyond what you specify.

   When using non-blocking pulses with PC-based frame grabber applications, the actual pulse width can be slightly shorter than that specified due to known limitations with Windows OS timers. The problem is exacerbated by making multiple non-blocking **pulse()** calls on multiple lines simultaneously. If you need an absolute minimum pulse width, increase the specified pulse width a small amount. Please note, however, that this will increase the average width for all pulses. This problem does not occur for blocking **pulse()** calls.
6. Calling the **pulse()** function again replaces any pulse in progress on the same physical line.

ccOverrunCallbackProp

```
#include <ch_cvl/prop.h>

class ccOverrunCallbackProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

As of CVL 6.1, this class is one of two ways to register a callback class for the overrun state:

Method	Features	See
ccAcqFifo:: overrunInfoCallback()	Calls your callback function, passing a **ccAcquireInfo** class.	*overrunInfoCallback* on page 234
ccOverrunCallbackProp	Calls your callback function.	this section

If you are writing a new CVL application, consider using **ccAcqFifo::overrunInfoCallback()** to register your move-part callback function.

This class describes the overrun callback property of an acquisition FIFO queue. The class contains a pointer to a function you write that is called by the acquisition software when an overrun occurs. The acquisition software calls the overrun callback function when an overrun occurs.

The callback function you write should set flags or semaphores in your application that allow your program to handle the overrun condition the next time it executes. Your callback function is executed internally by the acquisition software, which cannot proceed until your callback function returns. Callback functions should be short and quick, and *must not block*. Callback functions should not call CVL routines such as **start()** and **complete()**. The time taken to execute your callback function blocks the acquisition engine.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccOverrunCallbackProp

```
ccOverrunCallbackProp();

explicit ccOverrunCallbackProp(
  const ccCallbackPtrh &callback);
```

- `ccOverrunCallbackProp();`

  Creates a new overrun callback property not associated with any FIFO. The default callback function is an unbound handle, meaning no callback function is invoked.

- `explicit ccOverrunCallbackProp(`
  `const ccCallbackPtrh &callback);`

  Creates a new overrun callback function not associated with any FIFO, registering the function pointed to by *callback* as the overrun callback function.

  Parameters

  callback — Effectively, the callback function to be invoked when the acquisition process detects an overrun error or an **isMissed()** error. Generally, overrun errors and **isMissed()** errors occur when triggers are occurring too fast. See **ccAcqFailure::isOverrun()** and **ccAcqFailure::isMissed()** for more information. An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

Public Member Functions

overrunCallback

```
void overrunCallback(const ccCallbackPtrh& callback);

const ccCallbackPtrh& overrunCallback() const;
```

- `void overrunCallback(const ccCallbackPtrh& callback);`

  callback points to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

Parameters

callback — Effectively, the callback function to be invoked when the acquisition process detects an overrun error or an **isMissed()** error. Generally, overrun errors and **isMissed()** errors occur when triggers are occurring too fast. See **ccAcqFailure::isOverrun()** and **ccAcqFailure::isMissed()** for more information. An unbound handle means no callback will occur. Technically, *callback* is a pointer handle to an instance of **ccCallback** that contains the callback function you have defined as an override of **operator()()**.

- `const ccCallbackPtrh& overrunCallback() const;`

  Returns the callback function to be invoked when the acquisition overruns.

ccOverrunCallbackProp

ccPackedRGB16Pel

```
#include <ch_cvl/colorpel.h>

class cmImport_cogstd ccPackedRGB16Pel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccPackedRGB16Pel** class describes an RGB pixel whose values are packed in a single 16-bit word. This format is also called 565 because of the way the values for each component are packed into 16 bits:

```
rrrr rggg gggb bbbb
```

Constructors/Destructors

ccPackedRGB16Pel

```
ccPackedRGB16Pel(c_UInt16 ppel=0);

ccPackedRGB16Pel(c_UInt8 pr, c_UInt8 pg, c_UInt8 pb);
```

- `ccPackedRGB16Pel(c_UInt16 ppel=0);`

  Creates a new 16-bit RGB pixel with the specified value.

  Parameters

  ppel — The value of the pixel. The default is 0 or black.

- `ccPackedRGB16Pel(c_UInt8 pr, c_UInt8 pg, c_UInt8 pb);`

  Creates a new 16-bit RGB pixel with the specified values for each of the RGB components.

  Parameters

  pr — The value for the red component. Must be a value from 0 through 31.

  pg — The value for the green component. Must be a value from 0 through 63.

pb The value of the blue component. Must be a value from 0 through 33.

Notes

Values outside the appropriate range are clipped to zero.

Public Member Functions

r

```
c_UInt8 r() const;
void r(c_UInt8 rv);
```

- `c_UInt8 r() const;`

Returns the red component of the pixel.

- `void r(c_UInt8 rv);`

Sets the red component of the pixel.

Parameters

rv The value for the red component. Must be a value from 0 through 31.

g

```
c_UInt8 g() const;
void g(c_UInt8 gv);
```

- `c_UInt8 g() const;`

Returns the green component of the pixel.

- `void g(c_UInt8 gv);`

Sets the green component of the pixel.

Parameters

gv The value for the red component. Must be a value from 0 through 63.

b

```
c_UInt8 b() const;
void b(c_UInt8 bv);
```

- `c_UInt8 b() const;`

  Returns the blue component of the pixel.

- `void b(c_UInt8 bv);`

  Sets the blue component of the pixel.

  Parameters

bv	The value for the red component. Must be a value from 0 through 31.

Operators

operator const c_UInt16&

```
operator const c_UInt16& () const;
```

Casts this pixel to a **const c_UInt16**.

operator c_UInt16&

```
operator c_UInt16& ();
```

Casts this pixel to a non-const **c_UInt16**.

operator==

```
bool operator==(const ccPackedRGB16Pel& p) const;
```

Compares this pixel to the specified pixel. Returns true if the two have the same RGB value, false otherwise.

Parameters

p	Pixel to compare to the current one.

operator!=

```
bool operator==(const ccPackedRGB16Pel& p) const;
```

Compares this pixel to the specified pixel. Returns true if the two have the same RGB value, false otherwise.

Parameters

p	Pixel to compare to the current one.

ccPackedRGB16Pel

ccPackedRGB32Pel

```
#include <ch_cvl/colorpel.h>

class cmImport_cogstd ccPackedRGB32Pel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccPackedRGB32Pel** class describes an RGB pixels whose values are packed into four 8-bit bytes. The three low order bytes contain the red, green, and blue information. The remaining byte contains an alpha value. When you acquire a 32-bit image through a 32-bit acquisition FIFO, you can specify how the alpha value is calculated with the FIFO's **ccAlphaColorProp** property.

Constructors/Destructors

ccPackedRGB32Pel

```
ccPackedRGB32Pel(c_UInt32 ppel=0);

ccPackedRGB32Pel(c_UInt8 pr, c_UInt8 pg, c_UInt8 pb,
  c_UInt8 pa);
```

- `ccPackedRGB32Pel(c_UInt32 ppel=0);`

  Creates a new 32-bit RGB pixel with the specified value.

  Parameters

ppel	The value of the pixel. The default is 0 or black.

- `ccPackedRGB32Pel(c_UInt8 pr, c_UInt8 pg, c_UInt8 pb, c_UInt8 pa);`

  Creates a new 32-bit RGB pixel with the specified values for each of the RGB components. Each value must be from 0 to 255.

  Parameters

pr	The value for the red component.
pg	The value for the green component.

pb The value of the blue component.

pa The value of the alpha component. This value is not used.

Public Member Functions

a

```
c_UInt8 a() const;
void a(c_UInt8 aval);
```

- `c_UInt8 a() const;`

  Returns the value of the alpha component.

- `void a(c_UInt8 aval);`

  Sets the value of the alpha component.

  Parameters

  aval The value of the alpha component.

r

```
c_UInt8 r() const;
void r(c_UInt8 rval);
```

- `c_UInt8 r() const;`

  Returns the value of the red component.

- `void r(c_UInt8 rval);`

  Sets the value of the red component.

  Parameters

  rval The value of the red component.

g

```
c_UInt8 g() const;
void g(c_UInt8 gval);
```

- `c_UInt8 g() const;`

  Gets the value of the green component.

- `void g(c_UInt8 gval);`

  Sets the value of the green component.

  Parameters

  gval The value of the green component.

b

`c_UInt8 b() const;`

`void b(c_UInt8 bval);`

- `c_UInt8 b() const;`

  Gets the value of the blue component.

- `void b(c_UInt8 bval);`

  Sets the value of the blue component.

  Parameters

  bval The value of the blue component.

Operators

operator const c_UInt32&

`operator const c_UInt32& () const;`

Casts this pixel to a **const c_UInt32**.

operator c_UInt32&

`operator c_UInt32& ();`

Casts this pixel to a non-const **c_UInt32**.

operator== `bool operator==(const ccPackedRGB32Pel& p) const;`

Compares this pixel to the specified pixel. Returns true if the two have the same values for their RGB and alpha components, false otherwise.

Parameters

p Pixel to compare to the current one.

operator!= `bool operator==(const ccPackedRGB32Pel& p) const;`

Compares this pixel to the specified pixel. Returns true if the two have the same values for their RGB and alpha components, false otherwise.

Parameters

p	Pixel to compare to the current one.

ccPair

```
#include <ch_cvl/pair.h>

template <class T> class ccPair : public cmStd pair<T,T>;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	yes

This class, derived from the standard template library's **pair** class, is used to describe pairs and arithmetic operations on the pairs. However, unlike the standard template library's class, both components of the pair must be of the same type. In the CVL, **ccPair** is often used to describe points.

T Template parameter specifying the type of the components. *T* must provide the following.

T()
T(const T&)
~T()
T& operator= (const T&)
operator+ (T, T)
operator+= (T)
operator- (T)
operator- (T, T)
operator-= (T)
operator* (T, T)
operator*= (T)
operator/ (T, T)
operator/= (T)
operator== (T, T)
operator!= (T, T)
T(c_Int16)
T(c_Int32)
T(float)
T(double)

Note that all builtin arithmetic types support these operations.

Typedefs are provided for **ccPair** for **c_Int32**, **c_Int16**, **double**, and **float**. See page 2361.

Constructors/Destructors

ccPair

```
ccPair();
ccPair(T x, T y);
```

- `ccPair();`

  Creates a new pair with components of type *T*. Both components are set to zero.

- `ccPair(T x, T y);`

  Crates a new pair with components of type *T* with initial values *x* and *y*.

  Parameters

x	Value of the x component.
y	Value of the y component.

Operators

operator+

```
ccPair<T> operator+ (const ccPair<T>& r) const;
```

Returns a new pair whose *x* and *y* components are added to the *x* and y components of *r*.

Parameters

r	The pair whose *x* and *y* values will be used in the addition.

operator+=

```
ccPair<T>& operator+= (const ccPair<T>& r);
```

Returns this pair after adding the *x* and *y* components or *r*.

Parameters

r	The pair whose *x* and *y* values will be used in the addition.

operator-

```
ccPair<T> operator- () const;
ccPair<T> operator- (const ccPair<T>& r) const;
```

- `ccPair<T> operator- () const;`

  Returns a new pair with the values of the *x* and *y* components negated. (Unary minus.)

- `ccPair<T> operator- (const ccPair<T>& r) const;`

  Returns a new pair with the x and y components of r subtracted from this pair's x and y components.

  Parameters

  r The pair whose *x* and *y* values will be used in the subtraction.

operator-= `ccPair<T>& operator-= (const ccPair<T>& r);`

Returns this pair after subtracting the *x* and *y* components of *r*.

Parameters

r The pair whose *x* and *y* values will be used in the subtraction.

operator* `ccPair<T> operator* (const ccPair<T>& r) const;`

Returns a new pair whose *x* and *y* components are multiplied by the *x* and y components of *r*.

Parameters

r The pair whose *x* and *y* values will be used in the multiplication.

operator*= `ccPair<T>& operator*= (const ccPair<T>& r);`

Returns this pair after multiplying the *x* and *y* components by the *x* and *y* components of *r*.

Parameters

r The pair whose *x* and *y* values will be used in the multiplication.

operator/ `ccPair<T> operator/ (const ccPair<T>& r);`

Returns a new pair with the *x* and *y* components divided by the *x* and *y* components of *r*.

r The pair whose *x* and *y* values will be used in the division.

operator/= `ccPair<T>& operator/= (const ccPair<T>& r);`

Returns this pair after dividing the *x* and *y* components by the *x* and *y* components of *r*.

Parameters

r The pair whose *x* and *y* values will be used in the division.

operator== `bool operator== (const ccPair<T>& r) const;`

Returns true if this pair and *r* are equal.

Parameters

r The pair to use in the comparison.

operator!= `bool operator!= (const ccPair<T>& r) const;`

Returns true if this pair and *r* are not equal.

Parameters

r The pair to use in the comparison.

Public Member Functions

x

```
const T& x() const;
T& x();
```

- `const T& x() const;`

  Returns a constant reference to the *x* component of the pair.

- `T& x();`

  Returns a reference to the *x* component of the pair.

y

```
const T& y() const;
T& y();
```

- `const T& y() const;`

  Returns a constant reference to the *y* component of the pair.

- `T& y();`

  Returns a reference to the *x* component of the pair.

Typedefs

ccSPair `typedef ccPair<c_Int16> ccSPair;`

ccIPair `typedef ccPair<c_Int32> ccIPair;`

ccFPair `typedef ccPair<float> ccFPair;`

ccDPair `typedef ccPair<double> ccDPair;`

ccPair

ccParallelIO

```
#include <ch_cvl/pio.h>

class ccParallelIO;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only.
Archiveable	No

ccParallelIO is an abstract base class for parallel input and output (I/O) from which are derived classes to represent specific Cognex hardware platforms.

When used with any member of the MVS-8100 frame grabber family, all member functions of **ccParallelIO** can throw *ccBoard::FpgaLoadFailure* on first use, if the external camera power cable is not connected to the frame grabber.

Constructors/Destructors

Constructors are automatically created for this class.

Public Member Functions

inputLine

```
virtual ccInputLine inputLine(c_Int32 line) = 0;
```

Returns a **ccInputLine** object that represents the specified logical input line.

Parameters

line The logical line number. *line* must be a valid value for the configuration set by **ccParallelIO::setIOConfig()**.

Throws

ccParallelIO::BadParams
line is not a valid value for the configuration set by **ccParallelIO::setIOConfig()**.

ccParalleIIO::NotImplemented
Input lines are not supported on the host side.

Notes

See the documentation for the derived class that describes your specific hardware platform for the equivalence between logical line numbers and physical lines.

outputLine `virtual ccOutputLine outputLine(c_Int32 line) = 0;`

Returns a **ccOutputLine** object that represents the specified logical output line.

Parameters

line The logical line. *line* must be a valid value for the configuration set by **ccParallelIO::setIOConfig()**.

Throws

ccParallelIO::BadParams
line is not a valid value for the hardware and the configuration set by **ccParallelIO::setIOConfig()**.

ccParalleIIO::NotImplemented
Output lines are not supported on the host side.

Notes

See the documentation for the derived class that describes your specific hardware platform for the equivalence between logical line numbers and physical lines.

numInputLines `virtual c_Int32 numInputLines() = 0;`

Returns the number of total input lines for this hardware. The total depends upon the configuration set by **ccParallelIO::setIOConfig()**.

Notes

Some platforms have bidirectional input/output lines. Refer to your hardware documentation for additional information on using bidirectional lines.

numOutputLines `virtual c_Int32 numOutputLines() = 0;`

Returns the number of total output lines for this hardware.

Notes

Some platforms have bidirectional input/output lines. Refer to your hardware documentation for additional information on using bidirectional lines.

getIOConfig `virtual ccIOConfig& getIOConfig()= 0;`

Returns the parallel I/O board configuration.

setIOConfig `virtual void setIOConfig(ccIOConfig& config)= 0;`

Sets the parallel I/O board configuration. See **ccIOConfig** and related classes in *ch_cvl/pioconfg.h*.

Parameters

config The I/O board configuration.

Example

This example sets the I/O configuration for an MVS-8120 frame grabber with a Standard Option Parallel I/O board. See **cc8120** for information about Parallel I/O board options.

```
cc8120& fg = cc8120::get(0);
ccParallelIO* pio = dynamic_cast<ccParallelIO*> (&fg);
pio-> setIOConfig(ccIOStandardOption());
```

Global Exceptions

A number of hardware-related global exceptions are defined as nested classes of **ccBoard**. These exceptions can be thrown by any member function in this class, or in classes derived from this class. These global exceptions include the following.

Throws

ccBoard::HardwareNotResponding

The frame grabber did not respond to the current access request. This can be the result of a problem with the hardware or the hardware's driver. Check that the board is installed and powered on correctly according to its hardware manual. Make sure there are no overcurrent conditions on parallel I/O lines. Check that the board's driver is running; check the Windows Event Log for any messages from the device driver.

ccBoard::HardwareInUse

The current process tried to access frame grabber hardware that is already owned by another running process. To avoid this error, a process that touches the hardware (such as a CVM ID query, number of camera ports query, or image acquisition request) must exit before another process can access the same hardware.

ccBoard::HardwareNotInitialized

The current access request received a response from the board's driver, but the board reports itself as not yet initialized. Make sure the current process has instantiated the right frame grabber class (**cc8100m**, **cc8504**, and so on). Power the host PC all the way off and back on and try the request again.

ccBoard::BadEERAMContents

The EERAM chip on the board that contains the board's serial number and other information could not be read.

ccBoard::FpgaLoadFailure

An error occured while loading the FPGA on the board. On some frame grabbers, including the MVS-8100M and MVS-8100C, this error can occur if external camera power is incorrectly applied to the board. Check the setting of the jumper that determines whether camera power is to be pulled from the PCI bus or from an external power cable, as described in the frame grabber's hardware manual. Make sure the external power cable, if used, is plugged into the board and the PC's power supply.

ccPDF417Result

```
#include <ch_cvl/pdf417.h>

class ccPDF417Result;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccPDF417Result** class contains a single result returned by the PDF417 decoder. It has const accessors for all available data.

Constructors/Destructors

ccPDF417Result

```
ccPDF417Result();
```

Constructs a **ccPDF417Result** with the following default values:

Parameter	Value
isDecoded_	False
decodedString_	“”
time_	0.0
rows_	-1
cols_	-1
numErrors_	-1
unusedErrorFraction_	-1

Public Member Functions

isDecoded

```
bool isDecoded () const;
```

Returns true if the result was both found and decoded, false otherwise. A result is decoded if the information encoded in the symbol under consideration was found and successfully decoded. To ensure a secure and valid decode, the return value of **ccPDF417Result::unusedErrorFraction()** should be a nonnegative value.

decodedString

```
ccCvlString decodedString () const;
```

Returns the decoded string.

Throws

ccPDF417Defs::BadString
The isDecoded() operation returned false.

time

```
double time () const;
```

Returns the time (in seconds) required to decode the symbol.

rows

```
c_Int32 rows () const;
```

Returns the number of data rows in the data region. A row is a lateral set of elements made up of a start pattern, codewords, and a stop pattern. The returned value ranges from 3 to 90. Returns -1 if this information is not available.

cols

```
c_Int32 cols () const;
```

Returns the number of data columns in the data region. In each row of a PDF417 symbol, between left and right row indicators, there may be from 1 to 30 data codewords. Collectively, among all rows, these codewords form data columns. The returned value ranges from 1 to 30. Returns -1 if this information is not available

numErrors

```
c_Int32 numErrors () const;
```

Returns the number of errors (both rejection and substitution) in data words encountered and corrected while decoding the symbol. Returns -1 if this information is not available.

unusedErrorFraction

```
double unusedErrorFraction () const;
```

Returns the ratio of the unused error correction codewords to the total number of error correction codewords specified by the error correction level encoded in the symbol. Among the total number of error correction codewords, two are needed for error detection. Any additional error correction codewords provide error correction capability, with one such codeword needed to recover each erasure (rejection) and two needed to correct each error (substitution).

Notes

The return value is in the range -1.0 through 1.0, inclusive. When the return value is -1.0, the decode procedure failed. When the return value is other negative values, the number of erasures and errors is beyond the limit for a safe correction. The closer a negative value is to 0.0, the lower the probability of a misread becomes.

In applications where a high decode rate is desired at the risk of low-probability misreads, you can use **ccPDF417Result::isDecoded()** as the sole indication of a successful decode. When a slightly lower but more secure decode rate is preferred to a high decode rate with possible misreads, check that the return value is nonnegative before considering the decode successful and valid.

operator==

```
bool operator== (const ccPDF417Result&) const;
```

Returns true if the ccPDF417 result passed in is equal to the current one, false otherwise.

Parameters

ccPDF417Result

PDF417 result object to compare.

Notes

Two ccPDF417Result objects are considered equal if all their corresponding data members except time_ are identical.

ccPDF417Result

ccPelBuffer

```
#include <ch_cvl/pelbuf.h>

template <class P> class ccPelBuffer :
  public ccPelBuffer_const<P>;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccPelBuffer** class is a template class for creating rectangular windows into root images with pixels of type *P* (**ccPelRoot<P>**).This class allows read/write access to the underlying pixels. The class **ccPelBuffer_const** allows read-only access to the pixels. Any number of windows may refer to the same root image.

P — Template parameter specifying the value associated with each pixel. CVL provides instantiations of **ccPelRoot** for the types **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, and **ccPackedRGB32Pel**.

Functions that take pointers of type **P** as parameters or that return pointers of type **P** use the **pointer** or **const_pointer typedef** defined by **ccPelTraits** instead of **P***. See **ccPelTraits** on page 2403.

Constructors/Destructors

ccPelBuffer

```
ccPelBuffer();

ccPelBuffer(c_Int32 width, c_Int32 height,
  c_Int32 alignModulus=32);

ccPelBuffer(ccPelRoot<P>* pelroot);
```

- `ccPelBuffer();`

  Creates an unbound window, that is, one that is not associated with any root image. Height and width are set to 0 and all offsets are set to (0,0). The window's transform is set to identity.

- `ccPelBuffer(c_Int32 width, c_Int32 height, c_Int32 alignModulus=32);`

  Allocates contiguous storage for a root image of *width* x *height* pixels of type *P* and a window that encompasses the entire root image. The pixels are default-constructed. This storage will be freed by the destructor. The byte address of the first row's first pixel is zero modulo the *alignModulus*. The allocated row width (in pixels) is increased if necessary to make the row size (in bytes) a multiple of the specified *alignModulus*. Up to (*alignModulus*-1) pad pixels may be allocated for each row. Pad pixels, if any, occur to the right (greater x) of the pixels that belong to the root image. Pixel processing routines are permitted to overwrite pad pixels.

  Parameters

width	The width, in pixels, of the root image. (*width* > 0)
height	The height, in rows, of the root image. (*height* > 0)
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 means that memory is aligned on byte boundaries, 16 aligns on word boundaries, 32 aligns on long word boundaries, and so on. (*alignModulus* >= 1)

- `ccPelBuffer(ccPelRoot<P>* pelroot);`

  Creates a window bound to the root image *pelroot*. Height and width are set to encompass the entire root image. Offset is set to (0,0) and the transform is set to identity.

  Parameters

pelroot	The root image the window is bound to.

  Notes

  If *pelroot* is *NULL*, the effect is the same as **ccPelBuffer()**; this window becomes unbound.

Public Member Functions

put

```
void put(const ccIPair&, P pelVal) const;
void put(c_Int32 x, c_Int32 y, P pelVal) const;
```

- `void put(const ccIPair& point, P pelVal) const;`

  Sets the value of the pixel at location *point* in image coordinates to *pelval*.

  Parameters

point	The location of the pixel in image coordinates.

pelVal The new value of the selected pixel.

Throws

ccPel::BadCoord
Argument does not correspond to a pixel within this window.

ccPel::UnboundWindow
This window is not bound to any root image.

- `void put(c_Int32 x, c_Int32 y, P pelVal) const;`

Sets the value of the pixel at location *(x, y)* in image coordinates to *pelVal*.

Parameters

x The x-coordinate of the pixel in image coordinates.

y The y-coordinate of the pixel in image coordinates.

pelVal The new value of the selected pixel.

Throws

ccPel::BadCoord
Argument does not correspond to a pixel within this window.

ccPel::UnboundWindow
This window is not bound to any root image.

pointToRow `ccPelTraits<P>::pointer pointToRow(c_Int32 y) const;`

Returns a pointer to the first pixel in row *y*, in image coordinates, of the window.

Parameters

y The row in image coordinates.

Throws

ccPel::BadCoord
Y does not correspond to a row within this window. The x value in the thrown exception object is set to 0.

ccPel::UnboundWindow
This window is not bound to any root image.

pointToPel

```
ccPelTraits<P>::pointer pointToPel(c_Int32 x, c_Int32 y)
  const;

ccPelTraits<P>::pointer pointToPel(const ccIPair& point)
  const;
```

- `ccPelTraits<P>::pointer pointToPel(c_Int32 x, c_Int32 y) const;`

  Returns a pointer to the pixel at location *(x, y)* in image coordinates.

  Parameters

  x — The x-coordinate of the pixel in image coordinates.

  y — The y-coordinate of the pixel in image coordinates.

  Throws

  ccPel::BadCoord — Argument does not correspond to a pixel within this window.

  ccPel::UnboundWindow — This window is not bound to any root image.

- `ccPelTraits<P>::pointer pointToPel(const ccIPair& point) const;`

  Returns a pointer to the pixel located at location *point* in image coordinates.

  Parameters

  point — The location of the pixel in image coordinates.

  Throws

  ccPel::BadCoord — Argument does not correspond to a pixel within this window.

  ccPel::UnboundWindow — This window is not bound to any root image.

copyFromBuffer

```
void copyFromBuffer(const P* buf) const;
```

Copies the pixels from *buf*, an array of pixels, to this window.

Buf is addressed as follows:

```
this->put(x, y, buf[x-offset().x() + (y-offset().y()) *
                    this->width()])
```

`buf[0]` corresponds to `this->put(offset())`

Notes

The parameter is **P*** rather than **ccPelTraits<P>::pointer** to allow simple pointer or array manipulation of the buffer.

Parameters

buf The array to receive the copied pixels. Must be width() * height() pixels.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

mutating

```
void mutating() const;
```

Informs the persistence system that this image's pixel values are about to be changed (or have been changed already).

Notes

Most operations that modify pixel values automatically call this function. The only time you would need to call **mutating()** explicitly is if you modify pixel values through a non-const pointer returned by **pointToRow()** or **pointToPel()**. Note that the act of obtaining such a pointer automatically calls **mutating()**.

root

```
ccPelRoot<P>* root() const;
```

Returns a pointer to this window's root image. Make sure you do not cache the returned pointer.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

disconnectRoot

```
ccPelRoot<P>* disconnectRoot();
```

Disconnects this window from its root image, causing the window to become unbound, but does not delete root image. Returns the disconnected root image.

bind

```
bool bind(const ccPelBuffer<P>& pelbuf, bool clip=false,);
```

Makes this window have the same root image as *pelbuf*. *Pelbuf*'s root offset, offset, transform, and size are ignored. If *pelbuf* is unbound, this window becomes unbound. Returns true if the result was clipped to fit within the new image; false otherwise.

This window's root offset, offset and size are not modified unless clipping is required. If *clip* is true, the result is clipped to the extent of the new root image (possibly resulting in a null window result if the window's location is entirely outside of the new root image). This window's transform is not changed.

Parameters

pelbuf The window whose root image you want to bind this window to.

clip If true, clip to the extent of the new root image.

Throws

ccPel::BadWindow

The window's location does not fit entirely within this window's new root image, and *clip* is false.

ccPelBuffer_const

```
#include <ch_cvl/pelbuf.h>

template <class P> class ccPelBuffer_const : public cc_PelBuffer;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccPelBuffer_const** class is a template class for creating rectangular windows into root images with pixels of type *P* (**ccPelRoot<P>**).This class allows read-only access to the underlying pixels. The class **ccPelBuffer** allows read/write access to the pixels. Any number of windows may refer to the same root image.

P — Template parameter specifying the value associated with each pixel. CVL provides instantiations of **ccPelRoot** for the types **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, and **ccPackedRGB32Pel**.

The class **cc3PlanePelBuffer** on page 147 implements a pel buffer that uses three-plane pixels (see **cc3PlanePel** on page 145).

Functions that take pointers of type **P** as parameters or that return pointers of type **P** use the **pointer** or **const_pointer typedef** defined by **ccPelTraits** instead of **P***. See **ccPelTraits** on page 2403.

Constructors/Destructors

ccPelBuffer_const

```
ccPelBuffer_const();

ccPelBuffer_const(const ccPelRoot<P>* pelroot);
```

- `ccPelBuffer_const();`

  Creates an unbound window, that is, one that is not associated with any root image. Height and width are set to 0 and all offsets are set to (0,0). The window's transform is set to identity.

- `ccPelBuffer_const(const ccPelRoot<P>* pelroot);`

  Creates a window bound to the root image *pelroot*. Height and width are set to encompass the entire root image. Offset is set to (0,0) and the transform is set to identity.

  Parameters

  pelroot The root image the window is bound to.

  Notes

  If *pelroot* is *NULL*, the effect is the same as **ccPelBuffer_const()**; this window becomes unbound.

Public Member Functions

get

```
P get(const ccIPair& point) const;
P get(c_Int32 x, c_Int32 y) const;
```

- `P get(const ccIPair& point) const;`

  Returns the pixel at location *point* in image coordinates.

  Parameters

  point The location of the pixel in image coordinates.

  Throws

  ccPel::BadCoord
  Argument does not correspond to a pixel within this window.

  ccPel::UnboundWindow
  This window is not bound to any root image.

- `P get(c_Int32 x, c_Int32 y) const;`

  Returns the pixel at location *(x, y)* in image coordinates.

  Parameters

  x The x-coordinate of the pixel in image coordinates.

  y The y-coordinate of the pixel in image coordinates.

  Throws

  ccPel::BadCoord
  Argument does not correspond to a pixel within this window.

  ccPel::UnboundWindow
  This window is not bound to any root image.

pointToRow

```
ccPelTraits<P>::const_pointer pointToRow(c_Int32 y) const;
```

Returns a pointer to the first pixel in row *y*, in image coordinates, of the window.

Parameters

y The row in image coordinates.

Throws

ccPel::BadCoord

Y does not correspond to a row within this window. The x value in the thrown exception object is set to 0.

ccPel::UnboundWindow

This window is not bound to any root image.

---

pointToPel

```
ccPelTraits<P>::const_pointer pointToPel(
  const ccIPair& point) const;

ccPelTraits<P>::const_pointer pointToPel(
  c_Int32 x, c_Int32 y) const;
```

- ```
  ccPelTraits<P>::const_pointer pointToPel(
    const ccIPair&) const;
  ```

  Returns a pointer to the pixel located at location *point* in image coordinates.

  Parameters

  point The location of the pixel in image coordinates.

- ```
  ccPelTraits<P>::const_pointer pointToPel(
    c_Int32 x, c_Int32 y) const;
  ```

  Returns a pointer to the pixel at location *(x, y)* in image coordinates.

  Parameters

  x The x-coordinate of the pixel in image coordinates.

  y The y-coordinate of the pixel in image coordinates.

  Throws

  ccPel::BadCoord

  Argument does not correspond to a pixel within this window.

  ccPel::UnboundWindow

  This window is not bound to any root image.

pointToOffset `ccPelTraits<P>::const_pointer pointToOffset() const;`

Returns a pointer to the pixel in the upper left-hand corner of this window. Equivalent to calling **pointToPel(offset())** but more efficient.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

copyToBuffer `void copyToBuffer(P* buf) const;`

Copies the pixels from this window to *buf*, an array of pixels.

Buf is addressed as follows:

```
buf[x - offset().x() + (y - offset().y())* this->width()] =
  this->get(x, y)
```

`buf[0]` corresponds to `this->get(offset())`

Notes

The parameter is **P*** rather than **ccPelTraits<P>::pointer** to allow simple pointer or array manipulation of the buffer.

Parameters

buf The array to receive the copied pixels. Must be width() * height() pixels.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

contains `bool contains(ccPelTrait<P>::pointer ppixel) const;`

Returns true if the pixel pointed to by *ppixel* is a pixel in this window. If the window is unbound, this function returns false.

Parameters

ppixel A pointer to a pixel.

root `const ccPelRoot<P>* root() const;`

Returns a pointer to this window's root image. Do not cache the returned pointer.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

bind

```
bool bind(const ccPelBuffer_const<P>& pelbuf,
  bool clip=false);
```

Makes this window have the same root image as *pelbuf*. *Pelbuf*'s root offset, offset, transform, and size are ignored. If *pelbuf* is unbound, this window becomes unbound. Returns true if the result was clipped to fit within the new image; false otherwise.

This window's root offset, offset and size are not modified unless clipping is required. If *clip* is true, the result is clipped to the extent of the new root image (possibly resulting in a null window result if the window's location is entirely outside of the new root image). This window's transform is not changed.

Parameters

pelbuf The window whose root image you want to bind this window to.

clip If true, clip to the extent of the new root image.

Throws

ccPel::BadWindow

The window's location does not fit entirely within this window's new root image, and *clip* is false.

ccPelBuffer_const

ccPelFunc

```
#include <ch_cvl/pelfunc.h>

class ccPelFunc;
```

A name space class for global pixel-processing (**cfPel***) functions.

Enumerations

sub_mode

```
enum sub_mode;
```

This enumeration defines the ways that **cfPelSub()** can handle overflow conditions when subtracting pixel values.

Value	Meaning	8-bit Example
eSubDefault	Result wraps around.	0 - 6 ⇒ 250(-6)
eSubAbsDefault	Result is truncated and converted to signed value, then absolute value is returned.	255 - 2 ⇒ 3
eSubAbs	Yields absolute value of result.	0 - 6 ⇒ 6
eSubZero	Negative results are clamped at zero.	0 - 6 ⇒ 0
eSubShft	Result divided by 2.	0 - 6 ⇒ 253(-3)
eSubNabs	Yields negative of absolute value of result.	6 - 0 ⇒ 250(-6)
eSubLimit	Result is clamped to minimum or maximum signed value. Results greater than 127 are clamped to 127; results less than -128 are clamped to -128.	0 - 255 ⇒ -128

add_mode `enum add_mode;`

This enumeration defines the ways that **cfPelAdd()** can handle overflow conditions when adding pixel values.

Value	Meaning	8 -bit Example
eAddDefault	Result wraps around.	250 + 6 ⇒ 0
eAddAbs	Yields absolute value of result.	0 + 6 ⇒ 6
eAddClamp	Clamp to maximum pixel value.	200 + 100 ⇒ 255
eAddShft	Result divided by 2.	200 + 100 ⇒ 150
eAddLimit	Result is clamped to minimum or maximum signed value. Results greater than 127 are clamped to 127; results less than -128 are clamped to -128.	200 + 100 ⇒ 127

mult_mode `enum mult_mode;`

This enumeration defines the ways that **cfPelMult()** handles the result of multiplying pixel values.

Value	Meaning	8-bit Example
eMultDefault	In case of overflow, result wraps around.	250 * 3 ⇒ 238 (-18)
eMultShft	In all cases, the result is shifted right by 8 bits.	128 * 11 ⇒ 5

mult_add_mode `enum mult_add_mode;`

This enumeration defines the ways that **cfPelMultAdd()** handles the result of multiplying and adding pixel values.

Value	Meaning	8-bit Example
eMultAddDefault	In case of overflow, the result wraps around.	250 * 3 + 3 ⇒ 241 (-15)
eMultAddShft	In all cases, the values are multiplied, the result is shifted right by 8 bits, then the third value is added.	128 * 11 + 3 ⇒ 8

ccPelFunc

ccPelRect

```
#include <ch_cvl/pelrect.h>

class ccPelRect : public ccRectangle<c_Int32>;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes rectangular regions of pel buffers. See **ccRectangle** on page 2699 for functions to access the components of a **ccPelRect**.

Constructors/Destructors

ccPelRect

```
ccPelRect();
ccPelRect(c_Int32 w, c_Int32 h);
ccPelRect(c_Int32 x, c_Int32 y, c_Int32 w, c_Int32 h);
ccPelRect(const ccIPair& v1, const ccIPair& v2);
ccPelRect(const ccRectangle<c_Int32>& r);
```

- `ccPelRect();`

  Makes this rectangle have origin (0,0), with width and height both equal to zero.

- `ccPelRect(c_Int32 w, c_Int32 h);`

  Makes this rectangle have width *w* and height *h*. If *w* and *h* are both non-negative, the origin is (0,0).

  Parameters

w	The width of the rectangle.
h	The height of the rectangle.

Notes

If *w* is negative, the rectangle's origin x-component is *w* (negative), and its width is *-w* (positive). Similarly, if *h* is negative, the rectangle's origin y-component is *h* (negative), and its height is *-h* (positive).

- `ccPelRect(c_Int32 x, c_Int32 y, c_Int32 w, c_Int32 h);`

Makes this rectangle have the indicated origin, width, and height.

Parameters

x	The origin's x-component.
y	The origin's y-component.
w	The width of the rectangle.
h	The height of the rectangle.

Notes

If *w* is negative, the rectangle's origin x-component is *x+w*, and its width is *-w* (positive). Similarly, if *h* is negative, the rectangle's origin y-component is *y+h,* and its height is *-h* (positive).

- `ccPelRect(const ccIPair& v1, const ccIPair& v2);`

Makes this rectangle the minimum enclosing rectangle of the indicated two points.

Parameters

v1	The origin (upper left component)
v2	The lower right component

- `ccPelRect(const ccRectangle<c_Int32>& r)`

Copies the upper left and bottom right values of rectangle *r* into this rectangle.

Parameters

r	The rectangle whose values will be copied into this rectangle.

Operators

operator= `ccPelRect& operator=(const ccRectangle<c_Int32>& r);`

Copies the upper left and lower right values of rectangle *r* into this rectangle.

Parameters

r The rectangle whose values will be copied into this rectangle.

operator+ `ccPelRect operator+ (const ccPelRect& se) const;`

Returns a rectangle dilated by the amount specified in the structuring element *se*. The dilation of a region by a structuring element is the union of all points covered by the structuring element over all positions of its origin within the region.

The identity structuring element has an upper left value of (0,0) and a size of (1,1). Dilating a rectangle by this structuring element leaves the rectangle unchanged.

Parameters

se The structuring element.

Notes

Dilation by a null structuring element is always null.

operator+= `ccPelRect& operator+= (const ccPelRect& se);`

Dilate this rectangle by the structuring element *se*.

Parameters

se The structuring element.

operator- `ccPelRect operator- (const ccPelRect& se) const;`

Returns a rectangle eroded by the amount specified in the structuring element *se*. The erosion of a region by a structuring element *se* is the set of all positions of the origin of *se* over all the positions of *se* that fit within the region.

The identity structuring element has an upper left value of (0,0) and a size of (1,1). Eroding a rectangle by this structuring element leaves the rectangle unchanged.

Parameters

se The structuring element.

Notes

Erosion by a null structuring element is undefined.

operator-= `ccPelRect& operator-= (const ccPelRect& se);`

Erode this rectangle by the structuring element *se*.

Parameters

se The structuring element.

Notes

Erosion by a null structuring element is undefined.

ccPelRoot

```
#include <ch_cvl/pelbuf.h>
#include <ch_cvl/coloroot.h>

template <class P> class ccPelRoot : public cc_PelRoot;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

The **ccPelRoot** class is a template class for creating root images with pixels of type **P**.

P — Template parameter specifying the value associated with each pixel. CVL provides instantiations of **ccPelRoot** for the types **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, **ccPackedRGB32Pel**, and **cc3PlanePel**.

Functions that take pointers of type **P** as parameters or that return pointers of type **P** use the **pointer** or **const_pointer typedef** defined by **ccPelTraits** instead of **P***. See **ccPelTraits** on page 2403.

The file *coloroot.h* contains a specialization for **cc3PlanePel** that treats the image buffer as an RGB-like image in which the three channels are expected to be in three different planes.

Constructors/Destructors

ccPelRoot

```
ccPelRoot();

ccPelRoot(c_Int32 width, c_Int32 height,
  c_Int32 alignModulus=32);

ccPelRoot(c_Int32 width, c_Int32 height,
  ccPelTraits<P>::pointer pelArray,
  c_Int32 alignModulus=1);

ccPelRoot(c_Int32 width, c_Int32 height, c_Int32 pitch,
  ccPelTraits<P>::pointer pelArray,
  c_int32 alignModulus = 1);

virtual ~ccPelRoot();
```

- `ccPelRoot();`

  Initializes this root image to a null state with no associated pixels. The only things that you can do with a null root image are load it from a persistent archive and destroy it.

- `ccPelRoot(c_Int32 width, c_Int32 height, c_Int32 alignModulus=32);`

  Allocates contiguous storage for a root image of *width* x *height* pixels of type *P*. The pixels are default-constructed. This storage will be freed by the destructor. The byte address of the first row's first pixel is zero modulo *alignModulus*. The allocated row width (in pixels) is increased if necessary to make the row size (in bytes) a multiple of the specified *alignModulus*. Up to (*alignModulus*-1) pad pixels may be allocated for each row. Pad pixels, if any, occur to the right (greater x) of the pixels that belong to the root image. Pixel processing routines are permitted to overwrite pad pixels.

  Parameters

width	The width, in pixels, of the root image. (*width* > 0)
height	The height, in rows, of the root image. (*height* > 0)
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 aligns on byte boundaries, 2 aligns on word boundaries, 4 aligns on long word boundaries, 16 aligns on 16-byte boundaries, 32 aligns on 32-byte boundaries, and so on. (*alignModulus* >= 1)

- ```
  ccPelRoot(c_Int32 width, c_Int32 height,
    ccPelTraits<P>::pointer pelArray,
    c_Int32 alignModulus=1);
  ```

  Uses *pelArray* as contiguous storage to store pixels of type *P*. *Width* and *height* refer to the logical size of the root image. The *pelArray* must have been allocated with alignment and padding as described above. You are responsible for freeing *pelArray* if necessary.

  Parameters

width	The width, in pixels, of the root image. (*width* > 0)
height	The height, in rows, of the root image. (*height* > 0)
pelArray	An array to hold width x height pixels of type *P*. (*pelArray != NULL*)
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 aligns on byte boundaries, 2 aligns on word boundaries, 4 aligns on long word boundaries, 16 aligns on 16-byte boundaries, 32 aligns on 32-byte boundaries, and so on. (*alignModulus* >= 1)

- ```
  ccPelRoot(c_Int32 width, c_Int32 height, c_Int32 pitch,
    ccPelTraits<P>::pointer pelArray,
    c_int32 alignModulus = 1);
  ```

  Uses *pelArray* as contiguous storage to store pixels of type *P*. *Width* and *height* refer to the logical size of the root image. The *pelArray* must have been allocated with *pitch* pixels per row aligned by *alignModulus*. You are responsible for freeing *pelArray* if necessary.

  Parameters

width	The width, in pixels, of the root image. (*width* > 0)
height	The height, in rows, of the root image. (*height* > 0)
pitch	The number of pixels per row.
pelArray	An array to hold width x height pixels of type *P*. (*pelArray != NULL*) If *P* is **cc3PlanePel**, the three pointers in *pelArray* are assumed to be pointing to the first byte of their respective planes.
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 aligns on byte boundaries, 2 aligns on word boundaries, 4 aligns on long word boundaries, 16 aligns on 16-byte boundaries, 32 aligns on 32-byte boundaries, and so on. (*alignModulus* >= 1)

- `virtual ~ccPelRoot();`

  Frees the pixel storage, if it was automatically allocated.

Public Member Functions

pels

```
ccPelTraits<P>::pointer pels() const;
```

Returns a pointer to the first pixel in the first row. See also, **ccPelBuffer::pointToRow()**.

Static Functions

padPelsNeeded

```
static c_Int32 padPelsNeeded(c_Int32 width,
  c_Int32 alignModulus);
```

Returns the number of pad pixels needed to make the row size *width* (in bytes) a multiple of *alignModulus*.

Parameters

width	The width in pixel of a root image. (*width* > 0)
alignModulus	A value that determines how memory used for the image is aligned. A value of 1 aligns on byte boundaries, 2 aligns on word boundaries, 4 aligns on long word boundaries, 16 aligns on 16-byte boundaries, 32 aligns on 32-byte boundaries, and so on. (*alignModulus* >= 1)

ccPelRootPool

```
#include <ch_cvl/pelpool.h>

class ccPelRootPool : public ccRepBase;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

The **ccPelRootPool** class is an abstract class used to work with root image pools (pel root pools). See **ccPelRoot** on page 2391 to learn more about root images.

Constructors/Destructors

This is an abstract class. To obtain a root image pool, see the global function **cfDefaultPelRootPool()()** on page 3619.

Public Member Functions

size

```
virtual size_t size() const = 0;

virtual void size(size_t bytes) = 0;
```

- `virtual size_t size() const = 0;`

  Returns the number of bytes occupied by the root image pool. This value is equal to the last value passed to **size(size_t bytes)** or to the default value (see **cfDefaultPelRootPoolSize()()** on page 3621) if it has never been called.

- `virtual void size(size_t bytes) = 0;`

  Changes the size of the of the root image pool.

  Parameters

  bytes The size of the root image pool in bytes.

  Throws

  ccPelRootPool::NotSupported
  This root image pool does not support resizing.

ccPelRootPool::Outstanding
At least one pel root is currently allocated from this pool.

flush

```
void flush();
```

Frees all of the cached **ccPelRoot** objects. When a root image is returned to its pool, the memory it occupies is cached rather than released so that later requests for a same-sized root image can be performed quickly. **flush()** releases all of the cached root images, effectively returning the pool to its initial size. **size()** invokes **flush()** before resizing the pool.

videoPelRoots

```
virtual bool videoPelRoots() const;
```

Returns true if this root image pool contains root images in video memory.

Typedefs

ccPelRootPoolPtrh

```
typedef ccPtrHandle<ccPelRootPool> ccPelRootPoolPtrh;
```

A pointer handle to a **ccPelRootPool** object.

ccPelRootPoolProp

```
#include <ch_cvl/prop.h>

class ccPelRootPoolProp;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

The pel root pool property lets you specify the source (or pool) of memory for root images (**ccPelRoot** objects).

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccPelRootPoolProp

```
ccPelRootPoolProp();

explicit ccPelRootPoolProp(
  const ccPelRootPoolPtrh& pelRootPool);
```

- `ccPelRootPoolProp();`

  Creates a new pel root pool property not associated with any FIFO. The default pel root pool is used.

- ```
  explicit ccPelRootPoolProp(
    const ccPelRootPoolPtrh& pelRootPool);
  ```

  Creates a new pel root pool property not associated with any FIFO. The specified pel root pool is used.
  ```

Parameters

pelRootPool The pool from which the acquisition FIFO gets its **ccPelRoot** objects

Public Member Functions

pelRootPool

```
const ccPelRootPoolPtrh& pelRootPool() const;
void pelRootPool(const ccPelRootPoolPtrh& pelRootPool);
```

- `const ccPelRootPoolPtrh& pelRootPool();`

  Returns the current pool from which the acquisition FIFO gets its **ccPelRoot** objects.

- `void pelRootPool(const ccPelRootPoolPtrh& pelRootPool);`

  Selects the pool from which the acquisition FIFO gets its **ccPelRoot** objects. The default pool is **cfDefaultPelRootPool()**.

  Parameters

  pelRootPool The pool from which the acquisition FIFO gets its **ccPelRoot** objects.

ccPelSpan

```
#include <ch_cvl/pelspan.h>

class ccPelSpan;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a linear region in an integer coordinate system. It is analogous to a **ccPelRect** with a height (or width) of 1. It is used to specify the destination span for the 1D image unwarp tool.

Constructors/Destructors

ccPelSpan

```
ccPelSpan();

ccPelSpan(c_Int32 origin, c_Int32 size);
```

- `ccPelSpan();`

  Constructs a zero-length **ccPelSpan**.

- `ccPelSpan(c_Int32 origin, c_Int32 size);`

  Constructs a **ccPelSpan** with the specified origin and size

  Parameters

  origin The origin.

  size The size.

  Throws

  ccRectErrors::NegativeSize
  size is less than 0.

Public Member Functions

origin

```
c_Int32 origin() const;
```

Returns the origin of this span.

size

```
c_Int32 size() const;
```

Returns the size of this span.

end

```
c_Int32 end() const;
```

Returns the end of this span.

Notes

The pel span does not "contain" the end of this span; it only contains "end()-1" (if end()-1 >= origin()).

isNull

```
bool isNull(void) const;
```

Returns true if this span is empty.

contains

```
bool contains(const ccPelSpan &that) const;
bool contains(c_Int32 val) const;
```

- `bool contains(const ccPelSpan &that) const;`

Returns true if the supplied **ccPelSpan** is contained within this **ccPelSpan**.

Parameters

that The **ccPelSpan** to evaluate.

Notes

A **ccPelSpan** always contains itself.

- `bool contains(c_Int32 val) const;`

Returns true if the indicated position is contained within this **ccPelSpan**.

Parameters

val The position to evaluate.

Operators

operator+

```
ccPelSpan operator+ (const ccPelSpan& se) const;
```

Returns a **ccPelSpan** that is the dilation of this **ccPelSpan** by the supplied structuring element (a **ccPelSpan**).

The new object's origin will be equal to the sum of the origins of the supplied objects, and the new object's size will be equal to the sum of the sizes of the supplied objects minus 1.

Parameters

se	The **ccPelSpan** to use as a structuring element. *se* must be non-null.

Notes

If either of the **ccPelSpan**s is empty, then the sum will be the default constructed **ccPelSpan**.

operator+=

```
ccPelSpan& operator+= (const ccPelSpan& se);
```

Dilates this **ccPelSpan** by the supplied structuring element (a **ccPelSpan**).

The dilated object's origin will be equal to the sum of the origins of the supplied objects, and the dilated object's size will be equal to the sum of the sizes of the supplied objects minus 1.

Parameters

se	The **ccPelSpan** to use as a structuring element. *se* must be non-null.

Notes

If either of the **ccPelSpan**s is empty, then the sum will be the default constructed **ccPelSpan**.

operator-

```
ccPelSpan operator- (const ccPelSpan& se) const;
```

Returns a **ccPelSpan** that is the erosion of this **ccPelSpan** by the supplied structuring element (a **ccPelSpan**).

The new object's origin will be equal to the difference of the origins of the supplied objects, and the new object's size will be equal to the differences of the sizes of the supplied objects plus 1.

Parameters

se	The **ccPelSpan** to use as a structuring element. *se* must be non-null.

Notes

If this **ccPelSpan** is smaller than the supplied **ccPelSpan**, the result is a default-constructed **ccPelSpan**.

operator-= `ccPelSpan& operator-= (const ccPelSpan& se);`

Erodes this **ccPelSpan** by the supplied structuring element (a **ccPelSpan**).

The eroded object's origin will be equal to the difference of the origins of the supplied objects, and the erorded object's size will be equal to the difference of the sizes of the supplied objects plus 1.

Parameters

se	The **ccPelSpan** to use as a structuring element. *se* must be non-null.

Notes

If this **ccPelSpan** is smaller than the supplied **ccPelSpan**, the result is a default-constructed **ccPelSpan**.

Erode this pelspan by the specified structuring element.

operator== `bool operator== (const ccPelSpan& that) const;`

Returns true if the supplied object is equal to this one, false otherwise

Parameters

that	The object to compare.

ccPelTraits

```
#include <ch_cvl/peltrait.h>

template <class P> class ccPelTraits;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	No

The **ccPelTraits** class is a template class used to describe pointer and reference types for all of the different pixel types used by **ccPelBuffer** and its related classes. For example, **ccPelRoot<P>::pels()** returns a pointer to the first pixel in the first row of the pel root. Instead of returning **P***, which may not be appropriate for types P, the function returns a value of type **ccPelTraits<P>::pointer** which is guaranteed to be a pointer for any support pixel type.

CVL provides instantiations of **ccPelTraits** for the following classes:

- **c_UInt8**
- **c_UInt16**
- **c_UInt32**
- **ccPackedRGB16Pel**
- **ccPackedRGB32Pel**
- **cc3PlanePel**

Static Functions

isColor

```
static bool isColor();
```

Returns true if the pixel class represents color information

isPacked

```
static bool isPacked();
```

Returns true if the storage for a single pixel is guaranteed to be contiguous.

Typedefs

pointer

```
typedef P* pointer;
```

A pointer to a non-const object

reference

```
typedef P& reference;
```

A reference to a non-const object

const_pointer

```
typedef const P *const_pointer;
```

A pointer to a const object

const_reference

```
typedef const P & const_reference;
```

A reference to a const object

ccPerimPos

```
#include <ch_cvl/shapbase.h>

class ccPerimPos;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class implements perimeter positions. Perimeter positions represent arbitrary and unique points along a **ccShape** in terms of a distance (arc length) along the shape from the *first point*. Both the first point on the shape and the manner in which the shape is traversed as a function of arc length, are consistent with the way the **sample()** operation is defined to work on the shape.

Perimeter ranges, which comprise a perimeter position and a signed distance, can be used to delineate arbirtrary portions of a shape. See **ccPerimRange** on page 2406.

See the *Shapes* chapter of the *CVL User's Guide* for more information on perimeter positions.

Note You never need to construct **ccPerimPos** objects explicitly. They are created internally when you call certain **ccShapeInfo** and **ccShape** methods.

Operators

operator==

```
bool operator==(const ccPerimPos& other) const;
```

Returns true if and only if this perimeter position is exactly equal to the given perimeter position.

Parameters

other The other perimeter position.

operator!=

```
bool operator==(const ccPerimPos& other) const;
```

Returns true if and only if this perimeter position is not exactly equal to the given perimeter position.

Parameters

other The other perimeter position.

operator< `bool operator<(const ccPerimPos& other) const;`

Returns true if and only if the given perimeter position is further along the perimeter of a shape than this perimeter position, in the direction of shape traversal.

Parameters

other The other perimeter position.

operator> `bool operator>(const ccPerimPos& other) const;`

Returns true if and only if this perimeter position is further along the perimeter of a shape than the given perimeter position, in the direction of shape traversal.

Parameters

other The other perimeter position.

Typedefs

ccPerimRange `typedef cmStd pair<ccPerimPos, double> ccPerimRange;`

This type definition specifies a perimeter range. Perimeter ranges, which comprise a perimeter position and a signed distance, can be used to delineate arbirtrary portions of a shape.

Notes

A perimeter range begins at the given perimeter position, and extends the given distance along the perimeter of the shape. The range may extend in either direction, depeding on the sign of the distance.

ccPersistent

```
#include <ch_cvl/persist.h>

class ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Not applicable

The **ccPersistent** class is a base class from which you derive complex-persistent objects. To implement a complex-persistent class, you must follow these guidelines:

1. Your class must be derived using the **virtual** keyword from **ccPersistent**. (In a complex derivation hierarchy there must be only a single instance of the **ccPersistent** base class.)
2. Your class declaration must begin with the **cmPersistentDcl** macro. (Use the **cmPersistentDclTemplate** macro for template classes and the **cmPersistentDclAbstract** macro for abstract base classes.)
3. Your class implementation must begin with the **cmPersistentDef** macro. (Use the **cmPersistentDefTemplate** macro for template classes and the **cmPersistentDefAbstract** macro for abstract base classes.)
4. Your class must override the **ccPersistent::serialize_()** function. This function takes a **ccArchive** as its first argument. Your implementation of this function must persist the state of the object to the supplied **ccArchive**.
5. Whenever your class's state changes, the class must call the **ccPersistent::mutating()** function.

For more information on writing complex-persistent objects, refer to the files *ch_cvl\persist.h* and *sample\persist.cpp*.

Constructors/Destructors

ccPersistent

```
ccPersistent();

virtual ~ccPersistent();

ccPersistent(const ccPersistent&);
```

Do not instantiate this class directly.

Operators

operator=

```
ccPersistent& operator= (const ccPersistent& rhs);
```

Assignment operator.

Parameters

rhs The **ccPersistent** to assign from.

operator||

```
ccArchive& operator|| (ccArchive& arc, ccPersistent& obj);

template <class T>
 ccArchive& operator|| (ccArchive& arc, T *& ptr);

template <class T>
 ccArchive& operator|| (ccArchive& arc, const T * ptr);
```

- `ccArchive& operator|| (ccArchive& arc, ccPersistent& obj);`

  This overload of **operator||** performs non-polymorphic serialization of the supplied object. This supports serialization of complex-persistent objects embedded as members of other persistent objects but does not support serialization through a pointer.

  When you load a complex-persistent object using this overload of **operator||**, the object into which you are loading the persisted object must already exist (since you pass a reference to it to this function). The persistence system calls the object's **reInit()** function before it serializes the data. Since you can override **reInit()** in your complex-persistent class, you can use your implementation of **reInit()** to place the object in a known state before the data is serialized.

  This behavior is different than the **operator||** overloads that support pointer-based serialization (listed below). When you load a complex-persistent operator using the pointer-based **operator||** overload, an instance of the object is created using the **new** operator, then it is serialized.

  You can ensure that the results of pointer-based and reference-based loading of complex-persistent objects are identical by having your object's default constructor call your override of **reInit()**.

  Parameters

  arc The archive into which the object is serialized.

  obj The **ccPersistent**-derived object being serialized.

Throws

ccArchive::BadType

The **ccArchive** loaded an invalid dynamic object type (loading only). The archive's position is unspecified after this error.

ccArchive::UnknownType

The **ccArchive** did not recognize the loaded dynamic object type (loading only). The archive's position is unspecified after this error.

ccArchive::UnknownVersion

A persistent object's serialization code did not recognize a data version number (loading only).

ccArchive::Eof

No more input data (loading only). The archive is left positioned at the end of the input stream.

ccArchive::BadBuffer

The **ccArchive** is broken and is unusable (loading or storing).

Notes

When storing, this function may only be called in the context of sequential stores onto the end of this archive. When loading, the object being loaded must have been stored through a reference serialization (rather than by use of pointer serialization or **ccArchive::storeObject()**).

Your override of the **serialize_()** function in your **ccPersistent**-derived class can assume that whenever the object is being loading from an archive, it is loaded into a default-constructed object or an object upon which **reInit()** has been called.

- ```
  template <class T>
  ccArchive& operator|| (ccArchive& arc, const T * ptr);
  ```

  This overload of **operator||** performs polymorphic serialization of the supplied object through a pointer. This overload is intended for use in *storing* a complex-persistent object through a pointer; you pass the pointer to the **operator||** function.

  Complex-persistent objects stored through a pointer are annotated with type information allowing subsequent loading through a pointer to dynamically allocate an object of the appropriate dynamic type. The archive tracks what objects have been serialized through pointers in order to properly handle structural sharing of dynamically allocated complex-persistent objects.

  When storing, the pointed-to object is stored immediately (if it has not been stored already).

  When storing, this function may only be called in the context of sequential stores onto the end of this archive.
  ```

Parameters

arc The archive into which the object is serialized

ptr A pointer to the **ccPersistent**-derived object being serialized.

Throws

ccArchive::NotFound
A pointed-to object could not be located in this archive (loading only). The archive is positioned after the pointer.

ccArchive::UnknownType
The **ccArchive** did not recognize the loaded dynamic object type (loading only). The archive is positioned after the pointer.

ccArchive::UnknownVersion
The loaded persistent object's serialization code did not recognize a data version number (loading only). The archive is positioned after the pointer.

ccArchive::Eof
No more input data (loading only). The archive is left positioned at the end of the input stream.

ccArchive::BadBuffer
The **ccArchive** is broken and is unusable (loading or storing).

If one of the above errors occurs when loading the pointed-to object, the loaded pointer is set to null.

Notes

Serializing a pointer to a complex-persistent member sub-object of another persistent object is not well supported; when storing a pointer to a complex-persistent member sub-object of another object, only the referenced sub-object is stored. The entire parent object is not stored. When the pointer is loaded, only the pointed-to sub-object is loaded.

When storing through a pointer, the pointed-to complex persistent object need not be dynamically allocated. In such cases, be aware that the stored object will be dynamically allocated when it is loaded. Therefore, storing a pointer to an object that is not dynamically allocated should be done with care.

- ```
  template <class T>
  ccArchive& operator|| (ccArchive& arc, T *& ptr);
  ```

  This overload of **operatorII** performs polymorphic serialization through a reference to a pointer to the object. This overload is primarily intended for use in *loading* a complex-persistent object through a pointer; you pass a reference to the pointer to the **operatorII** function. (The overload will store the object if the archive's mode is storing.)

  When you load a complex-persistent object using this overload of **operatorII**, an instance of the object is dynamically allocated using the **new** operator, then the stored data is serialized into the new object, and the pointer that you supplied is set to point to the new object.

  This behavior is different than the **operatorII** overload that supports reference-based (non-polymorphic) serialization. When you load a complex-persistent operator using the non-polymorphic **operatorII** overload, the object instance already exists. The persistence system calls that object's overload of **reInit()** to allow you to initialize the object to a known state before serialization.

  You can ensure that the results of pointer-based and reference-based loading of complex-persistent objects are identical by having your object's default constructor call your override of **reInit()**.

  When loading, the object being loaded must have been stored through pointer serialization (rather than by use of reference serialization or **ccArchive::storeObject()**).

  Parameters

  arc — The archive into which the object is serialized

  ptr — A pointer to the **ccPersistent**-derived object being serialized.

  Throws

  ccArchive::NotFound
  A pointed-to object could not be located in this archive (loading only). The archive is positioned after the pointer.

  ccArchive::UnknownType
  The **ccArchive** did not recognize the loaded dynamic object type (loading only). The archive is positioned after the pointer.

  ccArchive::UnknownVersion
  The loaded persistent object's serialization code did not recognize a data version number (loading only). The archive is positioned after the pointer.

  ccArchive::Eof
  No more input data (loading only). The archive is left positioned at the end of the input stream.
  ```

ccArchive::BadBuffer
The **ccArchive** is broken and is unusable (loading or storing).

If one of the above errors occurs when loading the pointed-to object, the loaded pointer is set to null.

Notes

When storing a pointer, the pointed-to complex persistent object need not be dynamically allocated. In such cases, be aware that the stored object will be dynamically allocated when it is loaded. Therefore, storing a pointer to an object that is not dynamically allocated should be done with care.

operator<<

```
friend ccArchive& operator<< (ccArchive& ar,
  ccPersistent const& obj);

template <class T>
friend ccArchive& operator<< (ccArchive& ar,
  const T * ptr);
```

These overloads of the **operator<<** function are identical to the corresponding **operator||** functions except that the **ccArchive** must be storing.

operator>>

```
friend ccArchive& operator>> (ccArchive& ar,
  ccPersistent& obj);

friend ccArchive& operator>> (ccArchive& ar,
  T *& ptr);
```

These overloads of the **operator>>** function are identical to the corresponding **operator||** functions except that the **ccArchive** must be loading.

Protected Member Functions

reInit

```
virtual void reInit();
```

This function is called prior to loading into an existing complex-persistent object.

This function can be overridden to prepare an object to be loaded. Typically, this function will be overridden to put the object back into its default-constructed state, so that the object's **serialize_()** implementation may assume that it is always loading into a object with a known state.

The base class implementation has no effect.

Notes

In general, a derivation's **reInit()** override should also call its direct base class's **reInit()** function.

loadSimple

```
virtual bool loadSimple(ccArchive& ar);
```

If this class used to be simple persistent, then this function should be overridden to do the following:

1) Call **reInit()**.

2) Perform the old simple persistent loading.

3) Return true.

The base class implementation simply returns false.

Parameters

ar The archive to load.

Notes

The persistence mechanism will call this function only if it has already determined that the object was stored in its old simple persistent form. Thus the override does not need to do any special checking, and it may throw as appropriate.

haveVisited

```
static bool haveVisited(void*, size_t);
```

Called by **dispatchSerialize()**. Queries whether the indicated base sub-component of the currently serializing **ccPersistent** object has been visited.

Returns 0 if this component has already been visited while traversing the currently serializing **ccPersistent** object.

Returns 1 if this component has not yet been visited. Requires the indicated sub-component to be within the currently serializing **ccPersistent** object.

Notes

This function is for Cognex internal use only.

setVisited

```
static void setVisited(void*, size_t);
```

Called by **dispatchSerialize()**. Records that the indicated base sub-component of the currently serializing **ccPersistent** object has been visited.

Requires the indicated sub-component to be within the currently serializing **ccPersistent** object.

Notes

This function is for Cognex internal use only.

mutating

```
void mutating();
```

Notifies any archives that may care about this instance that this instance is either being destroyed or is about to have its state altered.

Notes

This function should not be called by **serialize_()**.

Private Member Functions

serialize_

```
void serialize_(ccArchive& ar, c_UInt8 dataVersion);
```

Each complex-persistent class that you derive from **ccPersistent** must define an implementation for this function (the derivation macros provide the declaration). Your implementation should perform the following steps:

- For each direct base class derived (directly or indirectly) from **ccPersistent**, call that class's **dispatchSerialize()** function.
- For each direct base class *not* derived from **ccPersistent**, serialize that base class (using that class's override of **operator||**).
- Serialize each member of your class using **operator||**.

Parameters

ar	The archive to or from which the data is serialized.
dataVersion	The data version. You specify the data version as an argument to the derivation macro. Whenever your persistent class changes, you should increment this value. Keep in mind that your **serialize_()** function must be prepared to handle both current and older data versions.

Notes

The base class implementation does nothing.

Your implementation of this function must *not* call **mutating()**.

When storing, *dataVersion* is always the current data version number for this class; when loading, *dataVersion* might be different from the current data version number. In such cases, your **serialize_** implementation must either correctly process the different (presumably older) data format, or it should throw *ccArchive::UnknownVersion*.

This function must not call any protected functions of **ccPersistent** other than **dispatchSerialize()**.

ccPersistent

ccPMAlignDefs

```
#include <ch_cvl/pmalign.h>

class ccPMAlignDefs : public cc_PMDefs;
```

A name space that holds enumerations and constants used with PatMax.

Enumerations

TrainMethod `enum TrainMethod`

This enumeration defines the training methods supported by PatMax.

Value	Meaning
kImageTrainMethod = 1	Train using an image model.
kSyntheticTrainMethod = 2	Train using a synthetic model. **Note**: This method had been deprecated.
kShapeTrainMethod = 3	Train using a geometric shape.
kFeatureTrainMethod = 4	Train using edge features.

DrawMode `enum DrawMode`

This enumeration defines the types of result graphics you can draw for PatMax results.

Value	Meaning
eDrawOrigin = 0x1	Draws a cross at the location of the result. The cross is aligned to the angle at which the pattern is found.
eDrawLabel = 0x2	Draws a text label at the result location.
eDrawBoundingBox = 0x4	Draws a box around the region of the image that corresponds to the trained pattern.
eDrawWireFrame = 0x8	Draws a wireframe representation of the found pattern.
eDrawMatchInfo = 0x10	Draws the matched feature boundary points.
eDrawMatchInfoPattern = *eDrawMatchInfo*	Draws the matched feature boundary points.

Value	Meaning
eDrawMatchInfoImage = 0x20	Draws the run-time image feature match info.
eDrawStandard = 0xf	Draws a labeled, pattern-aligned cross at the pattern location along with a box that corresponds to the trained pattern and a wireframe representation of the trained pattern.

ccPMAlignPattern

```
#include <ch_cvl/pmalign.h>

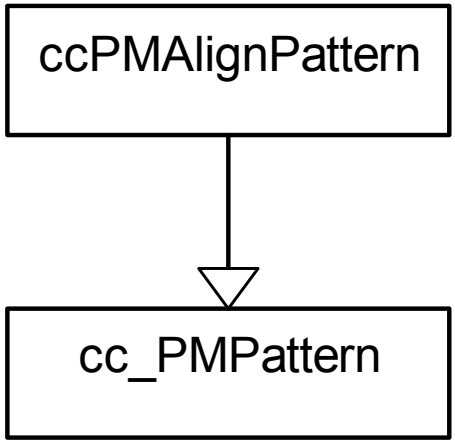
class ccPMAlignPattern : public cc_PMPattern;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single trained PatMax pattern. This class includes functions to set the training parameters and a function to locate the pattern in an image.

The following figure shows the **ccPMAlignPattern** class inheritance hierarchy.



Note See the **cc_PMPattern** class for information on additional functions common to all PatMax pattern classes.

Constructors/Destructors

ccPMAlignPattern

```
ccPMAlignPattern();
~ccPMAlignPattern();
ccPMAlignPattern(const ccPMAlignPattern& rhs);
```

- `ccPMAlignPattern();`

  Construct an untrained patmax alignment pattern with default values

- `~ccPMAlignPattern();`

  Destructor.

- `ccPMAlignPattern(const ccPMAlignPattern& rhs);`

  Copy constructor. Constructs an object equal to *rhs*.

  If **rhs.trainMethod()** = **ccPMAlignDefs::ImageTrainMethod()** and **rhs.saveImage()** is false, the resulting pattern is not trained regardless of whether *rhs* is currently trained.

Operators

operator= `ccPMAlignPattern& operator=(const ccPMAlignPattern& rhs);`

Assignment operator. Set this object equal to *rhs*.

If **rhs.trainMethod()** is equal to *ccPMAlignDefs::kImageTrainMethod* and **rhs.saveImage()** is false, the resulting pattern is not trained regardless of whether *rhs* is currently trained.

Public Member Functions

ignorePolarity

```
virtual bool ignorePolarity() const;
virtual void ignorePolarity(bool t);
```

- `virtual bool ignorePolarity() const;`

  Retrieves the *ignorePolarity* flag.

Notes

Overrides the virtual method inherited from the **cc_PMPattern** base class.

- `virtual void ignorePolarity(bool t);`

Sets the *ignorePolarity* flag.

Parameters

t If true, PatMax will not use polarity as one of the search criteria.

Throws

ccPMAlignDefs::NotImplemented

The parameter *t* is false, and any portion of the shape on which this pattern was trained has an effective ignore polarity setting of true.

Notes

This function overrides the virtual function inherited from the **cc_PMPattern** base class. Its behavior is the same as that of the base class method, with the exception of the throw.

See also **cc_PMPattern::ignorePolarity()**.

---

saveImage

```
bool saveImage() const;

void saveImage(bool save);
```

Used with image training. If you are training PatMax with an image, this function controls whether a copy of the training image pixels are stored in this pattern during training (default = true).

This function is ignored unless the tool is trained with an image.

- `bool saveImage() const;`

Returns true if this **ccPMAlignPattern** is currently configured to save an internal copy of the pattern training image, otherwise false. If this function returns false when **train()** is called, image pixels are not saved.

Returned values are valid only if you are working with an image model.

- `void saveImage(bool save);`

  Control whether a copy of the training image pixels are stored in this pattern when it is trained with an image. If this function returns false when **train()** is called, image pixels are not saved.

  If you change **saveImage()** from true to false on a trained pattern, saved image pixels are discarded. **saveImage()** cannot be changed from false to true on a pattern that has been trained with an image. Any attempts to do this are ignored.

  Calls to this function are ignored if the object is trained with a **ccShape**.

  Parameters

  save Set to true to save a copy of the pattern training image (default = true).

  Throws

  ccPMAlignDefs::BadParams
  If **saveImage(true)** is called on a trained pattern for which **isImageTrainMethod()** is true and **saveImage()** is currently false.

  Notes

  Setting **saveImage()** to false has limitations with respect to copying, assigning, and archiving. See the comments of those functions for details.

---

train

```
void train(
 const ccPelBuffer_const<c_UInt8>& image,
 c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
 ccDiagObject* diagobj = 0,
 c_UInt32 diagFlags=0);

void train(
 const ccPelBuffer_const<c_UInt8>& image,
 const ccPelBuffer_const<c_UInt8>& mask,
 c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
 ccDiagObject* diagobj=0,
 c_UInt32 diagFlags=0);

void train(
 const ccShape& trainShape,
 const cc2XformBase& clientFromImage,
 const ccPelRect& trainRegion = ccPelRect(0,0),
```

```
c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
ccDiagObject* diagobj = 0,
c_UInt32 diagFlags = 0);
```

- ```
  void train(
    const ccPelBuffer_const<c_UInt8>& image,
    c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

  Trains this **ccPMAlignPattern** using the supplied pattern training image and the supplied algorithms. You can perform a search using only an algorithm for which the **ccPMAlignPattern** has been trained.

  Parameters

  image — The pattern training image. Unless you have previously called **saveImage()** with the *save* argument set to false, this function saves an internal copy of *image*.

  algorithms — The algorithms for which to train this **ccPMAlignPattern**. *algorithms* must be formed by ORing together one or more of the following values. Note that neither *kPatflex* nor *kPatpersp* can be used with another algorithm.

  ccPMAlignDefs::kPatquick
  ccPMAlignDefs::kPatmax
  ccPMAlignDefs::kPatflex
  ccPMAlignDefs::kPatpersp

  diagobj — An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

  diagFlags — The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccPMAlignDefs::BadParams
  If *algorithms* is invalid, or if *algorithms* has selected both the *cc_PMDefs::kPatflex* flag and another flag. When PatFlex is
  ```

trained the pattern cannot be used to train another algorithm.
OR
If *algorithms* has both the *cc_PMDefs::kPatpersp* flag and another flag. When PatPersp is trained, the pattern cannot be used to train another algorithm.

ccPMAlignDefs::CanNotTrain
If *image* is not bound,
or if *image* does not contain any features,
or if *image* contains a NULL window,

Call the exception's **message()** function to determine the specific problem.

ccEdgeletDefs::CoordOutOfRange
If the pattern size is greater than 32769 pixels in width or height.

Notes

If this **ccPMAlignPattern** is already trained, it is automatically untrained and retrained.

This function supports the use of a **ccTimeout**-based timeout.

- ```
  void train(
    const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

Trains this **ccPMAlignPattern** using the supplied pattern training image, the supplied algorithms, and the supplied mask. You can perform a search using only an algorithm for which the **ccPMAlignPattern** has been trained.

The mask image must have the same dimensions and offset as the pattern training image. The pixels in the mask image are interpreted as follows:

- All pixels in *image* that correspond to pixels in *mask* with values greater than or equal to 192 are considered 'care' pixels. All feature boundary points detected within 'care' pixels are included in the trained pattern.
- All pixels in *image* that correspond to pixels in *mask* with values from 0 through 63 are considered 'don't care but score' pixels. Feature boundary points detected within 'don't care but score' pixels are not included in the trained pattern.

  When the trained pattern is located in a run-time image, features within the 'don't care but score' part of the trained pattern are treated as clutter features.
  ```

- All pixels in *image* that correspond to pixels in *mask* with values from 64 through 127 are considered 'don't care and don't score' pixels. Feature boundary points detected within 'don't care and don't score' pixels are not included in the trained pattern.

  When the trained pattern is located in a run-time image, features within the 'don't care and don't score' part of the trained pattern are ignored and not treated as clutter features.

- Mask pixel values from 128 through 191 are reserved for future use by Cognex.

Parameters

image — The pattern training image. Unless you have previously called **saveImage()** with the *save* argument set to false, this function saves an internal copy of *image*.

mask — The mask image.

algorithms — The algorithms for which to train this **ccPMAlignPattern**. *algorithms* must be formed by ORing together one or more of the following values. Note that neither *kPatflex* nor *kPatpersp* can be used with another algorithm.

ccPMAlignDefs::kPatquick
ccPMAlignDefs::kPatmax
ccPMAlignDefs::kPatflex
ccPMAlignDefs::kPatpersp

diagobj — An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

diagFlags — The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMAlignDefs::BadParams
If *algorithms* is invalid, or if *algorithms* has selected both the *cc_PMDefs::kPatflex* flag and another flag. When PatFlex is trained the pattern cannot be used to train another algorithm.
OR

If *algorithms* has both the *cc_PMDefs::kPatpersp* flag and another flag. When PatPersp is trained, the pattern cannot be used to train another algorithm.

ccPMAlignDefs::CanNotTrain
If *image* or *mask* is not bound,
or if *image* does not contain any features,
or if *image* contains a NULL window,
or it *mask* contains reserved grey levels,
or if *mask* does not have the same offset and dimensions as *image*.

Call the exception's **message()** function to determine the specific problem.

ccEdgeletDefs::CoordOutOfRange
If the pattern size is greater than 32769 pixels in width or height.

Notes

If this **ccPMAlignPattern** is already trained, it is automatically untrained and retrained.

This function supports the use of a **ccTimeout**-based timeout.

- ```
  void train(
    const ccShape& trainShape,
    const cc2XformBase& clientFromImage,
    const ccPelRect& trainRegion = ccPelRect(0,0),
    c_UInt32 algorithms = ccPMAlignDefs::kPatquick,
    ccDiagObject* diagobj = 0,
    c_UInt32 diagFlags = 0);
  ```

Trains this pattern from the given shape, defined in training client coordinates. The relationship between the client and image space of the pattern at train time is specified by the *clientFromImage* transform. The specified *trainRegion* rectangle indicates the effective extent of the trained pattern in training image coordinates. If a null rectangle is specified (the default), the tool will automatically compute the effective training image region as the bounding box of the trained pattern (which may actually be larger than the specified train shape) in training image coordinates. If the trained pattern in training image coordinates does not lie completely within the specified image region, it will be clipped. Otherwise, as long as the trained pattern lies completely within the specified region, the exact rectangle is only important if *scoreUsingClutter* is true when the tool is run, since it represents the region over which the clutter will be computed. All of the algorithms specified by *algorithms* are trained. *algorithms* is the bit-wise OR of one or more of *ccPMAlignDefs::Algorithms*. Only algorithms that are trained are available at run time.
  ```

Parameters

trainShape The shape to train.

clientFromImage
The client space from image space transform.

trainRegion The rectangular region in training image coordinates where the training takes place.

algorithms The algorithms for which to train this **ccPMAlignPattern**. *algorithms* must be formed by ORing together one or more of the following values. Note that neither *kPatflex* nor *kPatpersp* can be used with another algorithm.

ccPMAlignDefs::kPatquick
ccPMAlignDefs::kPatmax
ccPMAlignDefs::kPatflex
ccPMAlignDefs::kPatpersp

diagobj An optional **ccDiagObject**. If you supply a value, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMAlignDefs::CanNotTrain
The shape contains too few features when mapped into image space by the supplied client transform and within the effective training region.

ccPMAlignDefs::BadParams
If *algorithms* is invalid, or if *algorithms* has selected both the *cc_PMDefs::kPatflex* flag and another flag. When PatFlex is trained the pattern cannot be used to train another algorithm.
OR

If *algorithms* has both the *cc_PMDefs::kPatpersp* flag and another flag. When PatPersp is trained, the pattern cannot be used to train another algorithm.

ccPMAlignDefs::BadWeights
None of the effective weights within the supplied shape and within the effective train region are > 0.

ccPMAlignDefs::ModelTooLarge
shape.isFinite() is false, and **trainRegion.isNull()** is true.

ccPMAlignDefs::NotImplemented
The effective ignore polarity flag for any portion of the supplied shape is true, and the **ignorePolarity()** setting for this pattern is false.

ccEdgeletDefs::CoordOutOfRange
If the pattern size is greater than 32769 pixels in width or height.

Notes

If this pattern is already trained, it is automatically untrained and then retrained using the given parameters.

When polarity is not ignored, dark to light transitions are expected when moving from *negative* to *positive* sides of shape boundaries, as defined by the effective polarity of the shape, after the pattern has been aligned with the run-time image. In other words, negative means dark and positive means light.

All portions of the shape (including those with 0 weight) are used to automatically compute the training region, if unspecified. At run time, however, portions are treated differently depending on their weight. Note that the weights within a shape are relative. That is, scaling each of the weights by the same factor does not affect runtime behavior, as they are internally normalized.

Weights are treated as follows:

- **Positive effective weight:** Results favor those poses for which the portion matches the image features with high accuracy, although the particular value of the weight has no effect on accuracy. The portion contributes positively to the PatQuick result score in an amount proportional to the normalized weight,

to the perimeter of the portion, and to the degree of match at the result pose. Image features that match the portion are not considered clutter. Such features instead contribute to the coverage score, but the particular value of the weight is not used when computing coverage.

- **Negative effective weight:** Results favor those poses for which the portion does not match the image at all. The portion has no effect on the accuracy of the returned pose. The portion contributes negatively to a PatQuick result score in an amount proportional to the normalized weight, to the perimeter of that portion, and to the degree of match at the result pose. Image features that match the portion do not contribute to the coverage score. Such features are considered clutter.
- **Zero effective weight:** The portion has no effect on the result pose or its accuracy, and contributes nothing to the PatQuick result score, regardless of the degree of match. Image features that match the portion do not contribute to the coverage score. Such features are instead considered clutter.

As the particular value of a weight does not affect the coverage or clutter scores, a PatMax algorithm result score is only affected by the sign of a weight. Only the sign determines whether matched features contribute to clutter or coverage. Therefore, if you want to experiment with weighting schemes to optimize performance with respect to the acceptance threshold, the PatMax algorithm (if used) should be temporarily disabled. The returned score will then be the PatQuick result score, which is affected by the particular values of the weights, and not just their signs. When the PatMax algorithm is again enabled, the PatQuick score will continue to be internally computed and compared to the acceptance threshold, but will generally no longer be returned as the score of the result. Instead, the PatMax algorithm score will be returned.

See the **ccShapeModel** and **ccShapeModelProps** reference pages for information about model boundaries and polarities. See the *PatMax* and *Shape Models* chapters of the *CVL Vision Tools Guide* for more information about the weight property.

Notes

PatMax ignores the *magnitude* properties of the supplied shape.

trainAdvanced

```
void trainAdvanced(
   const ccPelBuffer_const<c_UInt8>& image,
   c_UInt32 algorithms = ccPMAlignDefs::kPatmax,
   ccDiagObject* diagobj=0, c_UInt32 diagFlags=0);

void trainAdvanced(
   const ccPelBuffer_const<c_UInt8>& image,
   const ccPelBuffer_const<c_UInt8>& mask,
   c_UInt32 algorithms = ccPMAlignDefs::kPatmax,
   ccDiagObject* diagobj=0, c_UInt32 diagFlags=0);
```

-
```
void trainAdvanced(
   const ccPelBuffer_const<c_UInt8>& image,
   c_UInt32 algorithms = ccPMAlignDefs::kPatmax,
   ccDiagObject* diagobj=0, c_UInt32 diagFlags=0);
```

The usage, parameters, and throws of this function are identical to those of the first overload of **train()**, as described on on page 2423, with the following amendment for the selected algorithm:

Throws

ccPMAlignDefs::NotImplemented
If the selected algorithm is not *cc_PMDefs::kPatmax*

This function performs additional processing to optimize the selection of the coarse granularity limit. The optimized training can produce better results when used with pattern training images that contain repeating features.

-
```
void trainAdvanced(
   const ccPelBuffer_const<c_UInt8>& image,
   const ccPelBuffer_const<c_UInt8>& mask,
   c_UInt32 algorithms = ccPMAlignDefs::kPatmax,
   ccDiagObject* diagobj=0, c_UInt32 diagFlags=0);
```

The usage, parameters, and throws of this function are identical to those of the second overload of **train()**, as described on on page 2424, with the following amendment for the selected algorithm:

Throws

ccPMAlignDefs::NotImplemented
If the selected algorithm is not *cc_PMDefs::kPatmax*

This function performs additional processing to optimize the selection of the coarse granularity limit. The optimized training can produce better results when used with pattern training images that contain repeating features.

untrain

```
void untrain();
```

Untrains this **ccPMAlignPattern**. Discards any saved pattern training image. If this **ccPMAlignPattern** is not trained, this function has no effect.

run

```
void run(const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPMAlignRunParams& params,
  class ccPMAlignResultSet& resultSet,
  ccDiagObject* diagobj = 0, c_UInt32 diagFlags = 0) const;

void run(const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPMAlignRunParams& params,
  const cc2XformBasePtrh_const& startPose,
  class ccPMAlignResultSet& resultSet,
  ccDiagObject* diagobj=0, c_UInt32 diagFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPMAlignRunParams& params,
  class ccPMAlignResultSet& resultSet,
  ccDiagObject* diagobj = 0, c_UInt32 diagFlags = 0) const;

void run(const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPMAlignRunParams& params,
  const cc2XformBasePtrh_const& startPose,
  class ccPMAlignResultSet& resultSet,
  ccDiagObject* diagobj=0, c_UInt32 diagFlags=0) const;
```

-
```
void run(const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPMAlignRunParams& params,
  class ccPMAlignResultSet& resultSet,
  ccDiagObject* diagobj = 0,
  c_UInt32 diagFlags=0) const;
```

Locate this **ccPMAlignPattern** in the supplied image using the parameters in the supplied **ccPMAlignRunParams**. The supplied **ccPMAlignResultSet** is cleared and then filled with the results of the search, in decreasing order of score.

Parameters

inputImage	The image in which to locate this pattern.
params	The search parameters to use.
resultSet	A reference to a **ccPMAlignResultSet** into which to place the results of this search.
diagobj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

ccPMAlignDefs::BadImage
If *inputImage* is unbound.

ccPMAlignDefs::BadParams
params specifies an algorithm for which this **ccPMAlignPattern** is not trained.

ccTimeout::Expired
The tool did not find a pattern instance within the timeout specified.

ccPMAlignDefs::InternalError
This error can occur if the tool locates a pattern in *inputImage* that is displaced by more than 10,000 client units or is less than one tenth the size or greater than ten times the size of the trained pattern. If this is the case, this exception's **message()** function returns the string **Scale and/or Offset out of range**.

ccPMAlignDefs::NotImplemented
If *algorithm* is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp* and *sensitivityMode* is *kSensitivityModeHigh*.

ccPMAlignDefs::NotImplemented
If *algorithm* is *cc_PMDefs::kPatflex* and *outsideRegionThreshold* is > 0.

Notes

This function terminates if it runs longer than the timeout specified in *params*. If this occurs, the tool results are invalid.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& inputImage,
    const ccPMAlignRunParams& params,
    const cc2XformBasePtrh_const& startPose,
    class ccPMAlignResultSet& resultSet,
    ccDiagObject* diagobj=0, c_UInt32 diagFlags=0) const;
  ```

  Locate this **ccPMAlignPattern** in the supplied image using the parameters in the supplied **ccPMAlignRunParams**.

  The search is started at the pose specified by *startPose*. The supplied pose is refined in each degree of freedom that is enabled and has a nonzero range in the supplied **ccPMAlignRunParams** object. This override is intended for use in cases where you already have an accurate coarse location for the pattern instance.

  The supplied **ccPMAlignResultSet** is cleared and then filled with the results of the search, in decreasing order of score.

  Parameters

  inputImage — The image in which to locate this pattern.

  params — The search parameters to use.

  startPose — A reference to a **cc2Xform** indicating where to start the search.

  resultSet — A reference to a **ccPMAlignResultSet** into which to place the results of this search.

  diagobj — An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

  diagFlags — The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccPMAlignDefs::NotTrained
  This model is not trained.

  ccPMAlignDefs::BadImage
  If *inputImage* is unbound,.
  ```

ccPMAlignDefs::BadParams
: *params* specifies an algorithm for which this **ccPMAlignPattern** is not trained or *params* specifies an algorithm of *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatmax* and *startPose* is a nonlinear transform.

ccTimeout::Expired
: The tool did not find a pattern instance within the timeout specified.

ccPMAlignDefs::NotImplemented
: If *algorithm* is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp* and *sensitivityMode* is *kSensitivityModeHigh*.

Notes

This function terminates if it runs longer than the timeout specified in *params*. If this occurs, the tool results are invalid.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& inputImage,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccPMAlignRunParams& params,
    class ccPMAlignResultSet& resultSet,
    ccDiagObject* diagobj = 0,
    c_UInt32 diagFlags = 0) const;
  ```

  Locate this **ccPMAlignPattern** in the supplied image using the parameters in the supplied **ccPMAlignRunParams**. The image is masked using the supplied mask image. Pixels in the mask image with values less than 128 are *don't care* pixels. Pixels in the mask image with values greater than or equal to 128 are *care* pixels. All feature boundary points in the supplied image that lie within pixels that correspond to *don't care* pixels in the mask image are discarded.

  The supplied **ccPMAlignResultSet** is cleared and then filled with the results of the search, in decreasing order of score.

  Parameters

  inputImage — The image in which to locate this pattern.

  mask — The mask image. *mask* must have the same dimensions and image offset as *inputImage.*

  params — The search parameters to use.

  resultSet — A reference to a **ccPMAlignResultSet** into which to place the results of this search.

  diagobj — An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
  ```

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

ccTimeout::Expired
The tool did not find a pattern instance within the timeout specified.

ccPMAlignDefs::BadParams
params specifies an algorithm for which this **ccPMAlignPattern** is not trained.

ccPMAlignDefs::BadImage
inputImage or *mask* is unbound or *inputImage* and *mask* do not have the same dimensions and image offset.

ccPMAlignDefs::InternalError
This error can occur if the tool locates a pattern in *inputImage* that is displaced by more than 10,000 client units or is less than one tenth the size or greater than ten times the size of the trained pattern. If this is the case, this exception's **message()** function returns the string **Scale and/or Offset out of range**.

ccPMAlignDefs::NotImplemented
If *algorithm* is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp* and *sensitivityMode* is *kSensitivityModeHigh*.

ccPMAlignDefs::NotImplemented
If *algorithm* is *cc_PMDefs::kPatflex* and *outsideRegionThreshold* is > 0.

Notes

This function terminates if it runs longer than the timeout specified in *params*. If this occurs, the tool results are invalid.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& inputImage,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccPMAlignRunParams& params,
    const cc2XformBasePtrh_const& startPose,
    class ccPMAlignResultSet& resultSet,
    ccDiagObject* diagobj=0, c_UInt32 diagFlags=0) const;
  ```

  Locate this **ccPMAlignPattern** in the supplied image using the parameters in the supplied **ccPMAlignRunParams**. The image is masked using the supplied mask image. Pixels in the mask image with values less than 128 are *don't care* pixels. Pixels in the mask image with values greater than or equal to 128 are *care* pixels. All feature boundary points in the supplied image that lie within pixels that correspond to *don't care* pixels in the mask image are discarded.

  The search is started at the pose specified by *startPose*. The supplied pose is refined in each degree of freedom that is enabled and has a nonzero range in the supplied **ccPMAlignRunParams** object. This override is intended for use in cases where you already have an accurate coarse location for the pattern instance.

  The supplied **ccPMAlignResultSet** is cleared and then filled with the results of the search, in decreasing order of score.

  Parameters

inputImage	The image in which to locate this pattern.
mask	The mask image. *mask* must have the same dimensions and image offset as *inputImage.*
params	The search parameters to use.
startPose	A reference to a **cc2Xform** indicating where to start the search.
resultSet	A reference to a **ccPMAlignResultSet** into which to place the results of this search.
diagobj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*
  ```

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

ccPMAlignDefs::BadImage
inputImage or *mask* is unbound or *inputImage* and *mask* do not have the same dimensions and image offset.

ccPMAlignDefs::BadParams
params specifies an algorithm for which this **ccPMAlignPattern** is not trained or *params* specifies an algorithm of *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatmax* and *startPose* is a nonlinear transform.

ccTimeout::Expired
The tool did not find a pattern instance within the timeout specified.

ccPMAlignDefs::NotImplemented
If *algorithm* is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp* and *sensitivityMode* is *kSensitivityModeHigh*.

Notes

This function terminates if it runs longer than the timeout specified in *params*. If this occurs, the tool results are invalid.

trainImage

```
ccPelBuffer_const<c_UInt8> trainImage() const;
```

Returns the pattern training image used to train this **ccPMAlignPattern**.

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

ccPMAlignDefs::NoImage
The pattern training image was not saved when this **ccPMAlignPattern** was trained, or was discarded because you called **saveImage()** with the *save* argument set to false after training.

ccPMAlignDefs::WrongTrainMethod
trainMethod() is not equal to *ccPMAlignDefs::kImageTrainMethod*.

maskImage

```
ccPelBuffer_const<c_UInt8> maskImage() const;
```

Returns the mask image used to train this **ccPMAlignPattern**.

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

ccPMAlignDefs::NoImage
saveImage() was not called with a value of true for this **ccPMAlignPattern**.

ccPMAlignDefs::WrongTrainMethod
trainMethod() is not equal to *ccPMAlignDefs::kImageTrainMethod*.

Notes

Only the training time mask is saved. The run-time mask is not available.

trainShape

```
const ccShape& trainShape() const;
```

Returns the geometric shape used to train this pattern.

Throws

ccPMAlignDefs::NotTrained
This pattern is not trained.

ccPMAlignDefs::WrongTrainMethod
trainMethod() is not equal to *ccPMAlignDefs::kShapeTrainMethod*.

trainRegion

```
ccPelRect trainRegion() const;
```

Returns image region used to train this pattern.

Throws

ccPMAlignDefs::NotTrained
This pattern is not trained.

ccPMAlignDefs::WrongTrainMethod
trainMethod() is equal to *ccPMAlignDefs::kSyntheticTrainMethod*. (*kSyntheticTrainMethod* is deprecated)

trainMethod

```
ccPMAlignDefs::TrainMethod trainMethod() const;
```

Returns the training method used to train this **ccPMAlignPattern**.

Throws

ccPMAlignDefs::NotTrained
This model is not trained.

isImageTrainMethod

```
bool isImageTrainMethod() const;
```

Returns true if **trainMethod()** is equal to *ccPMAlignDefs::kImageTrainMethod*, otherwise false.

Throws

ccPMAlignDefs::NotTrained
This pattern is not trained.

Protected Member Functions

assignUntrainedPatternData_

```
void assignUntrainedPatternData_(ccPMAlignUntrainedData&
ptmxUtData) const;

ccPMAlignResult

```
#include <ch_cvl/pmalign.h>

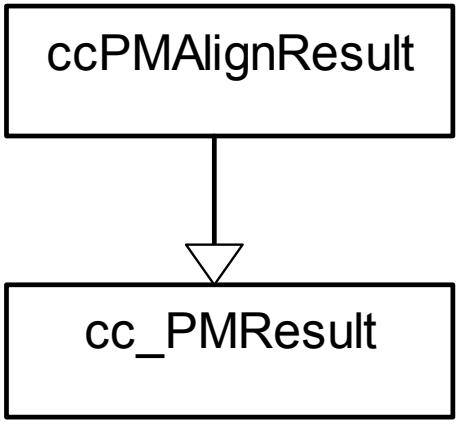
class ccPMAlignResult : public cc_PMResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single PatMax/Align search result. You should not create a **ccPMAlignResult** directly.

The following figure shows the ccPMAligResult class inheritance hierarchy.



Note See the **cc_PMResult** class for additional functions common to all PatMax result classes.

Constructors/Destructors

ccPMAlignResult

```
ccPMAlignResult();
```

Default constructor. Constructs a **ccPMAlignResult** containing no meaningful information.

Public Member Functions

draw

```
void draw(ccGraphicList& graphList,
  const ccPMAlignResultSet& set,
  c_UInt32 drawMode=ccPMAlignDefs::eDrawStandard,
  const ccCvlString& label=ccCvlString()) const;
```

Appends result graphics for this **ccPMAlignResult** to the supplied **ccGraphicList**.

Parameters

graphList — The graphics list to append the graphics to.

set — You must supply a reference to a **ccPMAlignResultSet** that contains this **ccPMAlignResult**.

drawMode — The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccPMAlignDefs::eDrawOrigin
ccPMAlignDefs::eDrawLabel
ccPMAlignDefs::eDrawBoundingBox
ccPMAlignDefs::eDrawWireFrame
ccPMAlignDefs::eDrawMatchInfo
ccPMAlignDefs::eDrawMatchInfoPattern
ccPMAlignDefs::eDrawStandard

label — If you include *ccPMAlignDefs::eDrawLabel* in *drawMode*, then the contents of *label* are used to label the center of mass.

Notes

Graphics are drawn in **ccColor::greenColor()** if the result met your acceptance threshold, **ccColor::redColor()** if it did not.

All graphics are drawn in client coordinates.

ccPMAlignResultSet

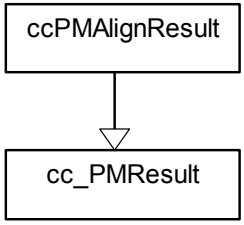
```
#include <ch_cvl/pmalign.h>

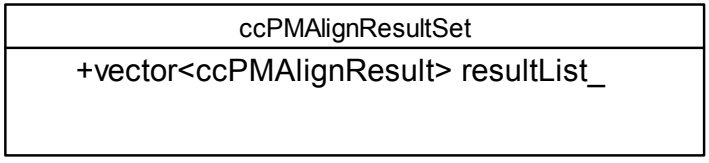
class ccPMAlignResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all of the **ccPMAlignResult** objects returned by a PatMax alignment.





Constructors/Destructors

ccPMAlignResultSet

```
ccPMAlignResultSet();

virtual ~ccPMAlignResultSet();

ccPMAlignResultSet(const ccPMAlignResultSet&);
```

- `ccPMAlignResultSet();`

  Creates a **ccPMAlignResultSet** with no results. **numFound()** and **time()** both return 0 when called on a default-constructed **ccPMAlignResultSet**.

Public Member Functions

time

```
double time() const;
```

Returns the amount of time in seconds required to perform this alignment.

numFound

```
c_Int32 numFound() const;
```

Returns the number of **ccPMAlignResult**s in this **ccPMAlignResultSet**.

algorithm

```
ccPMAlignDefs::Algorithm algorithm() const;
```

Returns the algorithm which was used to locate the results in this **ccPMAlignResultSet**. This function returns one of the following values:

ccPMAlignDefs::kPatquick
ccPMAlignDefs::kPatmax

getResult

```
void getResult(c_Int32 index, ccPMAlignResult& result)
  const;
```

Places the contents of the requested result in the supplied **ccPMAlignResult** reference.

Parameters

index	The index of the result to retrieve.
result	A reference to a **ccPMAlignResult** into which to place the result.

Throws

ccPMAlignDefs::BadParams
index is equal or greater than **numFound()** or *index* is less than 0.

results

```
const cmStd vector<ccPMAlignResult>& results() const;
```

Returns a vector of **ccPMAlignResult**s that contains all the results from this alignment. The results in the returned vector are sorted in decreasing order of score.

infoStrings

```
cmStd vector<cccVlString> infoStrings() const;
```

Returns a vector of run-time diagnostic message strings. For additional information about the diagnostic messages, see the *CVL Vision Tools Guide*.

infoIds

```
cmStd vector<c_UInt32> infoIds() const;
```

Returns a vector of run-time diagnostic message IDs. For a list and description of the diagnostic message IDs, see the *CVL Vision Tools Guide*.

draw

```
void draw(ccGraphicList& graphList,
  c_UInt32 drawMode = ccPMAlignDefs::eDrawStandard,}
  bool drawOnlyAccepted = false) const;
```

Appends result graphics for this **ccPMAlignResultSet** to the supplied **ccGraphicList**.

Parameters

graphList The graphics list to append the graphics to.

drawMode The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccPMAlignDefs::eDrawOrigin
ccPMAlignDefs::eDrawLabel
ccPMAlignDefs::eDrawBoundingBox
ccPMAlignDefs::eDrawWireFrame
ccPMAlignDefs::eDrawMatchInfo
ccPMAlignDefs::eDrawStandard

drawOnlyAccepted
If true, only results which met your accept threshold are drawn. If false, all results are drawn.

ccPMAlignResultSet

ccPMAlignRunParams

```
#include <ch_cvl/pmalign.h>

class ccPMAlignRunParams : public cc_PMRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters used to control a Patmax alignment.

Note See the **cc_PMRunParams** class for additional functions common to all PatMax run-time parameter classes.

Constructors/Destructors

ccPMAlignRunParams

```
ccPMAlignRunParams();

~ccPMAlignRunParams();

ccPMAlignRunParams(const ccPMAlignRunParams&);
```

- `ccPMAlignRunParams();`

  Constructs a **ccPMAlignRunParams** with default parameter values.

Public Member Functions

algorithm

```
ccPMAlignDefs::Algorithm algorithm() const;

void algorithm(ccPMALignDefs::Algorithm alg);
```

- `ccPMAlignDefs::Algorithm algorithm() const;`

  Returns the algorithm that this **ccPMAlignRunParams** is configured to use. The function returns one of the following values:

  ccPMAlignDefs::kPatquick
  ccPMAlignDefs::kPatmax

- `void algorithm(ccPMALignDefs::Algorithm alg);`

  Sets the algorithm that this **ccPMAlignRunParams** uses to perform alignments.

  Parameters

  alg The algorithm to use. *alg* must be one of the following values:

  ccPMAlignDefs::kPatquick
  ccPMAlignDefs::kPatmax

saveMatchInfoModes

```
void saveMatchInfoModes (c_UInt32 modes);

c_UInt32 saveMatchInfoModes () const;
```

- `void saveMatchInfoModes (c_UInt32 modes);`

  Sets modes indicating whether to save information necessary to generate a match display, modes are set as a bitwise-OR of values from *ccPMAlignDefs::SaveMatchInfoMode*

  The following modes are available (described in **cc_PMDefs**):

  ccPMAlignDefs::kSaveMatchInfoModeNone

  ccPMAlignDefs::kSaveMatchInfoModeClassic

  ccPMAlignDefs::kSaveMatchInfoModePattern

  ccPMAlignDefs::kSaveMatchInfoModeImage

  The default is *ccPMAlignDefs::kSaveMatchInfoModeNone*

  Notes

  If the modes contain anything other than *kSaveMatchInfoModeNone*, some extra time and significant extra memory is used for each result returned. The modes are ignored if the algorithm is *kPatquick*, in which case no information is saved.

  Parameters

  modes The modes to set.

- `c_UInt32 saveMatchInfoModes () const;`

  Returns modes indicating whether to save information necessary to generate a match display, modes are returned as a bitwise-OR of values from *ccPMAlignDefs::SaveMatchInfoMode*

Deprecated Members

saveMatchInfo

```
void saveMatchInfo (bool save);
bool saveMatchInfo () const;
```

- `void saveMatchInfo (bool save);`

  Determines whether this **ccPMAlignRunParams** is configured to generate and store match information.

  Parameters

  save — If save is true, match information is generated; if save is false, no match information is generated.

  Notes

  Match information is not saved when you archive a **ccPMAlignResult**.

  Saving match information greatly increases PatMax's memory usage. Alignments where match information is generated and stored take somewhat longer than alignments where match information is not generated and stored.

  Match information is only generated and stored if the alignment is performed using the *ccPMAlignDefs::kPatmax* algorithm.

  Notes

  This function has been deprecated and is provided for backwards compatibility only. New code should use **saveMatchInfoModes()** instead.

  saveMatchInfo(*false***)** is equivalent to **saveMatchInfoModes(***kSaveMatchInfoModeNone***)**, and **saveMatchInfo(***true***)** is equivalent to **saveMatchInfoModes(***kSaveMatchInfoModeClassic***)**.

- `bool saveMatchInfo () const;`

  Returns true if this **ccPMAlignRunParams** is configured to generate and store match information. Match information is required to produce a diagnostic display showing which pattern features were matched in the run-time image. The function **ccPMAlignResult::displayMatch()** produces this diagnostic display.

  Notes

  This function has been deprecated and is provided for backwards compatibility only. New code should use **saveMatchInfoModes()** instead.

  This function returns true if **saveMatchInfoModes()** has the *kSaveMatchInfoModeClassic* and/or *kSaveMatchInfoModePattern* bits set, and false otherwise.

ccPMCompositeModelDefs

```
#include <ch_cvl/pmcmpmod.h>

class ccPMCompositeModelDefs;
```

A name space that holds an enumeration used with the Composite Model of the PatMax tool.

Enumerations

TrainInstanceOverflowHandling

```
enum TrainInstanceOverflowHandling;
```

This enumeration defines the train instance overflow handling policy. That is, if additional instances are added beyond *maxNumTrainInstances*, this property determines the behavior of **ccPMCompositeModelManager::addTrainInstance()** and **ccPMCompositeModelManager::addTrainInstances()**.

Value	Meaning
eThrow = 0	The **ccPMCompositeModelManager::addTrainInstance()** or **ccPMCompositeModelManager::addTrainInstances()** function throws *ccPMAlignDefs::CanNotTrain* if the total number of train instances would become greater than *maxNumTrainInstances*
eIgnore = 1	Train instances beyond *maxNumTrainInstances* are silently ignored.
eFIFO = 2	The least-recently-added train instance(s) are discarded in favor of the most-recently-added train instance(s) to maintain a total of no more than *maxNumTrainInstances* For *eFIFO* to operate as intended, **saveImages()** must be true.

ccPMCompositeModelDefs

ccPMCompositeModelManager

```
#include <ch_cvl/pmcmpmod.h>

class ccPMCompositeModelManager;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class is used to manage, create, train, and incrementally train Composite Models for PatMax.

Constructors/Destructors

ccPMCompositeModelManager

```
ccPMCompositeModelManager();
```

Default constructor.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

saveImages

```
bool saveImages() const;

void saveImages(bool save);
```

- `bool saveImages() const;`

  Returns whether train images and related information are saved in the model manager.

- `void saveImages(bool save);`

  Sets whether train images and related information are saved in the model manager.

  When set to true, the original images and pose transforms from all **addTrainInstance()** or **addTrainInstances()** calls are saved in the model manager and can be retrieved using **getTrainInstances()**.

  When set to false, only the data that is required for producing Composite Models is saved, and **getTrainInstances()** will return empty vectors.

  The default is true.

  Parameters

  save If true, train images and related information are saved in the model manager.

  Notes

  Changing the value of **saveImages()** removes all train instances, but does not change parameter values.
  It is recommended that **saveImages()** only be set before training has begun.

  If you wish to be able to manually adjust grain limits in the future (by calling **retrainGrainLimits()**), **saveImages()** must be set to true.

maxNumTrainInstances

```
c_Int32 maxNumTrainInstances() const;

void maxNumTrainInstances(c_Int32 maxInstances);
```

- `c_Int32 maxNumTrainInstances() const;`

  Returns the maximum number of training instances.

- `void maxNumTrainInstances(c_Int32 maxInstances);`

  Sets the maximum number of training instances.

  Parameters

  maxInstances The maximum number of training instances.

  The default is 8.

Notes

If additional instances are added beyond this number, the resulting behavior is defined by **ccPMCompositeModelDefs::trainInstanceOverflowHandling**.

The run-time of **produceCompositeModel()** grows more than linearly in the number of train instances, so setting this value too large may result in extremely slow performance.

maxNumTrainInstances cannot be changed if the training has started.

Throws

ccPMCompositeModelDefs::BadParams
maxInstances is less than 2.

ccPMAlignDefs::NotImplemented
The setter would change the value and **isTrainStarted()** is true.

trainInstanceOverflowHandling

```
ccPMCompositeModelDefs::TrainInstanceOverflowHandling
trainInstanceOverflowHandling() const;

void trainInstanceOverflowHandling(
ccPMCompositeModelDefs::TrainInstanceOverflowHandling
policy);
```

- ```
  ccPMCompositeModelDefs::TrainInstanceOverflowHandling
  trainInstanceOverflowHandling() const;
  ```

  Returns the train instance overflow handling policy.

- ```
  void trainInstanceOverflowHandling(
  ccPMCompositeModelDefs::TrainInstanceOverflowHandling
  policy);
  ```

  Sets the train instance overflow handling policy.

  Parameters

  policy The train instance overflow handling policy.

  The default is *ccPMCompositeModelDefs::eThrow*

  Notes

  trainInstanceOverflowHandling can be changed even if training has started, and will take effect the next time instances are added.

Throws

ccPMCompositeModelDefs::BadParams

policy is not a valid enum value for **ccPMCompositeModelDefs::TrainInstanceOverflowHandling** or *ccPMCompositeModelDefs::eFIFO* (for **ccPMCompositeModelDefs::TrainInstanceOverflowHandling**) is attempted while **saveImages()** is false.

startTrain

```
void startTrain(
const ccPMAlignPattern& initialTrainedModel,
ccDiagObject* diagobj = 0,
c_UInt32 diagFlags = 0);
```

Initializes training with a trained PatMax model.

Parameters

initialTrainedModel
The initial trained model.

diagobj A diagnostic object.

diagFlags Diagnostic flags.

Notes

Some of the settings on this model are used throughout Composite Model training, such as granularities.
Composite Model will not perform well if *initialTrainedModel* is trained with the *kPatquick* algorithm only.

isTrainStarted

```
bool isTrainStarted() const;
```

Returns true if there is currently an *initialTrainedModel* from a call to **startTrain()**.

The default is false.

addTrainInstance

```
void addTrainInstance(
const ccPelBuffer_const<c_UInt8>& image,
const cc2XformLinear& modelFromClient,
ccDiagObject* diagobj = 0,
c_UInt32 diagFlags = 0);
```

Processes a single train instance to be used by the next call to **produceCompositeModel()**.

The *image* parameter is the input image containing an instance of the desired model.

The *modelFromClient* parameter specifies the pose that maps the image's client coordinates to a common model space.

Parameters

image The input image.

modelFromClient The pose that maps the image's client coordinates to a common model space.

diagobj A diagnostic object.

diagFlags Diagnostic flags.

Throws

ccPMAlignDefs::CanNotTrain
Any of the images contains no usable features,
or **isTrainStarted()** is false,
or the number of train instances would become greater than *maxNumTrainInstances* and **trainInstanceOverflowHandling()** is equal to *ccPMCompositeModelDefs::eThrow,*
or the number of train instances would become greater than *maxNumTrainInstances* and **trainInstanceOverflowHandling()** is equal to *ccPMCompositeModelDefs::eFIFO* and **saveImages()** is false.

Notes

The edge extraction parameters and granularities used are from the *ccPMAlignPattern* passed into **startTrain()**.

addTrainInstances

```
void addTrainInstances(
const cmStd vector<ccPelBuffer_const<c_UInt8> >& imageVec,
const cmStd vector<cc2XformLinear>& modelFromClientVec,
ccDiagObject* diagobj = 0,
c_UInt32 diagFlags = 0);
```

Processes train instances to be used by the next call to **produceCompositeModel()**.

The *imageVec* parameter is the set of input images containing instances of the desired model.

The *modelFromClientVec* parameter corresponds by index to *imageVec* and specifies the poses that map each image's client coordinates to a common model space.

Parameters

imageVec The set of input images.

modelFromClientVec
The poses that map each image's client coordinates to a common model space.

diagobj A diagnostic object.

diagFlags Diagnostic flags.

Throws

ccPMAlignDefs::CanNotTrain
Any of the images contains no usable features,
or **isTrainStarted()** is false,
or the number of train instances would become greater than *maxNumTrainInstances* and **trainInstanceOverflowHandling()** is equal to *ccPMCompositeModelDefs::eThrow*,
or the number of train instances would become greater than *maxNumTrainInstances* and **trainInstanceOverflowHandling()** is equal to *ccPMCompositeModelDefs::eFIFO* and **saveImages()** is false.

ccPMCompositeModelDefs::BadParams
imageVec and *modelFromClientVec* are not the same size or if either is empty.

Notes

The edge extraction parameters and granularities used are from the *ccPMAlignPattern* passed into **startTrain()**.

getTrainInstances

```
void getTrainInstances(
cmStd vector<ccPelBuffer_const<c_UInt8> >& imageVec,
cmStd vector<cc2XformLinear>& modelFromClientVec);
```

Fills the supplied vectors with all train images and transforms, including from the model used for **startTrain()**.

Parameters

imageVec The set of train images.

modelFromClientVec
The transforms.

Notes

Empty vectors are returned if **saveImages()** is false.

reset

```
void reset();
```

Removes all train instances, including the **startTrain()** data, and frees all associated memory. All parameters are restored to default-constructed state.

Notes

Consecutive calls to **reset()** have no effect.

produceCompositeModel

```
void produceCompositeModel(
const ccPMCompositeModelParams& params,
ccPMAlignPattern& resultCompositeModel,
ccDiagObject* diagobj = 0,
c_UInt32 diagFlags = 0);
```

Produces a trained *resultCompositeModel* from all accumulated train instances, guided by the Composite Model parameters.

Parameters

params Composite Model parameters.

resultCompositeModel
The result Composite Model.

diagobj A diagnostic object.

diagFlags Diagnostic flags.

Notes

The last (highest index of most recently added) train instance image is used to determine some image-related parameters for the result model.

resultCompositeModel.ignorePolarity() is set to match *params.ignorePolarity*. A model produced with *params.ignorePolarity* value of true cannot be usefully run with *params.ignorePolarity* value of false, because the original direction information is lost.

The *params* parameter provides Composite-Model-specific parameters.

The *resultCompositeModel* parameter is output as the trained model that is a composite of information from the supplied instances.

The *diagobj* and *diagFlags* are the same as the parameters used by any **ccPMAlignPattern::train()** overload.

Throws

ccPMAlignDefs::CanNotTrain
isTrainStarted() is false.

retrainGrainLimits

```
void retrainGrainLimits(
double coarseGran,
double fineGran);
```

Retrains the internal data to use the new specified grain limits.

The next call to **produceCompositeModel()** will produce a result model trained with these grain limits. This requires the original images, so it throws if they have not been saved.

Parameters

coarseGran Coarse grain limit.

fineGran Fine grain limit.

Throws

ccPMAlignDefs::CanNotTrain
isTrainStarted() is false,
or **saveImages()** is false.

coarseGrainLimit

```
double coarseGrainLimit();
```

Returns the current coarse grain limit.

fineGrainLimit

```
double fineGrainLimit();
```

Returns the current fine grain limit.

ccPMCompositeModelManager

ccPMCompositeModelParams

```
#include <ch_cvl/pmcmpmod.h>

class ccPMCompositeModelParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains parameters to guide the process of creating a Composite Model.

Constructors/Destructors

ccPMCompositeModelParams

```
ccPMCompositeModelParams();
```

Default constructor.

Notes

The default destructor, copy constructor, and assignment operator are used.

Public Member Functions

minImagesFrac

```
double minImagesFrac() const;

void minImagesFrac(double frac);
```

- `double minImagesFrac() const;`

  Returns the minimum images fraction.

- `void minImagesFrac(double frac);`

  Sets the minimum images fraction.

  Parameters

  frac The minimum images fraction.

The default is 0.75.

Notes

To be considered for the final model, an edgelet must be present in at least this fraction of the images. See *ch_cvl/edge.h* for the definition of edgelet.

Be aware of how discretization works here. For example, if we have 5 images and **minImagesFrac()** is set to 50%, then a feature will actually have to be present in 60% of the images; 2 would be 40% and therefore below the threshold.

Throws

ccPMCompositeModelDefs::BadParams
frac is less than 0 or greater than 1.

matcherDistanceTolerancePels

```
double matcherDistanceTolerancePels() const;

void matcherDistanceTolerancePels(double distTolPels);
```

- `double matcherDistanceTolerancePels() const;`

Returns the internal feature matcher's maximum capture distance, in pels.

- `void matcherDistanceTolerancePels(double distTolPels);`

Sets the internal feature matcher's maximum capture distance, in pels.

Parameters

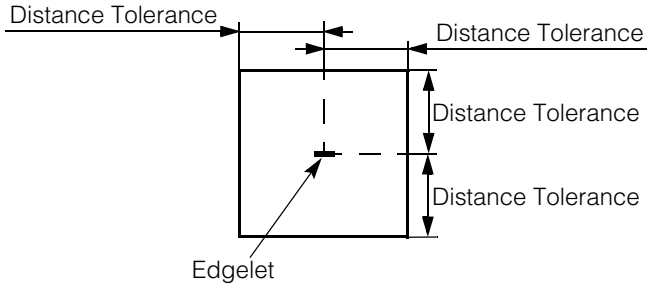
distTolPels	The internal feature matcher's maximum capture distance, in pels.

The default is 5.0.

Notes

matcherDistanceTolerancePels() forms a capture range rectangle aligned to a given edgelet.

For example, with an edgelet shown below, the capture range would look like this:



This parameter is mainly for speed, reducing the number of correspondences to consider. The internal feature matcher will always prefer closer correspondences.

It is far more convenient to specify this value in pels, so that a standard default can be meaningful for many applications. Pel units from the most recently added training instances are used.

Throws

ccPMCompositeModelDefs::BadParams
distTolPels is less than 0.

ignorePolarity

```
bool ignorePolarity() const;

void ignorePolarity(bool ignorePol);
```

- `bool ignorePolarity() const;`

  Returns the internal feature matcher's treatment of polarity.

- `void ignorePolarity(bool ignorePol);`

  Sets the internal feature matcher's treatment of polarity.

Parameters

ignorePol Internal feature matcher's treatment of polarity.

The default is false.

Notes

If *ignorePolarity* is false, then angle similarity is measured as the raw difference in edgelet angle. If *ignorePolarity* is true, then angle similarity is measured such that an opposite direction is also a perfect match. This allows a Composite Model to be built from instances whose boundaries are not of the same polarity.

If *ignorePolarity* is true, then the *ccPMAlignPattern* produced by **ccPMCompositeModelManager::produceCompositeModel()** will have its *ignorePolarity* set to true. A model produced with *ignorePolarity* value of true cannot be usefully run with *ignorePolarity* value of false, because the original direction information is lost. If *ignorePolarity* is false, then the *ccPMAlignPattern* produced by **ccPMCompositeModelManager::produceCompositeModel()** will have its *ignorePolarity* set to match that of the initial *ccPMAlignPattern* supplied to **ccPMCompositeModelManager::startTrain()**.

ccPMFlexResult

```
#include <ch_cvl/pmpbase.h>

class ccPMFlexResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single PatFlex result. You should not instantiate objects of this class in your programs. **ccPMFlexResult** objects are created for you as needed.

A description of how to run the PatFlex algorithm with PatMax is included in the introduction of the **ccPMFlexRunParams** reference page. Please see that reference.

When PatMax runs using the PatFlex algorithm it produces a PatFlex result along with its normal results. You access the PatFlex result with the getter **cc_PMResult::flexResult()**. The PatFlex result contains a deformation transform that you can apply to the run-time image to transform it into an image that matches the trained model. Cognex provides the global function **cfSampledImageWarp()** you can use for this transformation.

Constructors/Destructors

ccPMFlexResult

```
ccPMFlexResult();
```

Default constructor. Do not instantiate this class in your programs. Objects are created for you as needed.

Public Member Functions

xform

```
cc2XformBasePtrh_const xform() const;
```

Returns a transform that approximately maps the training image to the client coordinates of the run-time image.

Notes

If **computeXform()** was set to *kFitNone* in the run-time parameters, this function returns a null pointer-handle.

ccPMFlexResult

ccPMFlexRunParams

```
#include <ch_cvl/pmpbase.h>

class ccPMFlexRunParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class holds the run-time parameters used by PatFlex, a special algorithm you can run on the PatMax tool. The parameters are defaulted at construction but setters and getters are provided for you to read and write the parameters if you wish.

To run PatFlex prepare PatMax using the *kPatflex* algorithm. Add the PatFlex run-time parameters to the PatMax run-time parameters using the setter **cc_PMRunParams::flexRunParams()**. You run PatFlex by calling **ccPMAlignPattern::run()** as you would for other PatMax algorithms.

PatMax runs using the PatFlex algorithm and produces a PatFlex result along with its normal results. You access the PatFlex result with the getter **cc_PMResult::flexResult()**. See the **ccPMFlexResult** reference page for information about PatFlex results.

Constructors/Destructors

ccPMFlexRunParams

```
ccPMFlexRunParams();
```

Default constructor. The default values are:

Parameter	Default value
deformationRate	0.3
smoothness	3.0
refinement	*cc_PMDefs::kRefinementCoarse*
partialMatchMode	false
coverageThreshold	0.5

Parameter	Default value
controlPoints	(6, 6)
controlPointsExplicit	An empty vector
computeXform	*kFitDeformation*

Public Member Functions

deformationRate

```
double deformationRate() const;
void deformationRate(double rate);
```

Specifies the maximum deformation rate permitted in PatFlex alignment. The valid range is 0 through 1.0. Higher values increase the alignment time and may result in spurious matches due to the large amount of freedom the tool has to deform parts of the training image to fit the run-time image.

The default is 0.3.

- `double deformationRate() const;`

  Returns the maximum deformation rate.

- `void deformationRate(double rate);`

  Sets a new maximum deformation rate.

  Parameters

  rate The new maximum deformation rate.

  Throws

  cc_PMDefs::BadParams
  If *rate* < 0, or *rate* > 1.0.

smoothness

```
double smoothness() const;
void smoothness(double smoothness);
```

Specifies the smoothness value used to create the **cc2XformDeform** deformation transform.

The default is 3.0.

- `double smoothness() const;`

  Returns the smoothness.

- `void smoothness(double smoothness);`

  Sets the smoothness.

  Parameters

  smoothness The new smoothness.

  Throws

  cc_PMDefs::BadParams
  If *smoothness* < 0.

refinement

```
cc_PMDefs::Refinement refinement() const;
void refinement(cc_PMDefs::Refinement refinement);
```

Specifies the amount of refinement done on the deformation transform. See the following:

Refinement value	Description
kRefinementNone	No refinement. There may be small errors in the transform's mapping.
kRefinementCoarse	The computed transformation is refined so that it has no more residual error than the specified coarse granularity limit.
kRefinementMedium	The same as coarse refinement, except that certain types of high-level inaccuracy are removed.
kRefinementFine	Same as medium refinement, except that the transformation is refined so that it has no more residual error than the specified fine granularity limit.

The default is *cc_PMDefs::kRefinementCoarse*

- `cc_PMDefs::Refinement refinement() const;`

  Returns the refinement value.

- `void refinement(cc_PMDefs::Refinement refinement);`

  Sets a new refinement.

  Parameters
  refinement The new refinement.

partialMatchMode

```
bool partialMatchMode() const;
void partialMatchMode(bool partialMatchMode);
```

Specifies whether or not to use *partialMatchMode*, which accepts any candidate match for which it can match a proportion at least equal to the *coverageThreshold* with a score on those sections of the pattern greater than or equal to the *acceptThreshold*.

The default is false.

- `bool partialMatchMode() const;`

  Returns whether or not to use *partialMatchMode.*

- `void partialMatchMode(bool partialMatchMode);`

  Sets whether or not to use *partialMatchMode.*

  Parameters
  partialMatchMode
  If true, *partialMatchMode* is used.

coverageThreshold

```
double coverageThreshold() const;
void coverageThreshold(double coverageThreshold);
```

Specifies the minimum proportion of the pattern that must be matched in order to accept the match as a valid result. Has no effect if unless *partialMatchMode* is true.

The default is 0.5.

- `double coverageThreshold() const;`

  Returns the minimum proportion of the pattern that must be matched in order to accept the match as a valid result.

- `void coverageThreshold(double coverageThreshold);`

  Sets the minimum proportion of the pattern that must be matched in order to accept the match as a valid result.

  Parameters

  coverageThreshold
  The coverage threshold.

controlPoints

```
ccIPair controlPoints() const;
void controlPoints(const ccIPair &controlPoints);
```

Specifies the number of control points used in the x- and y-dimensions to define the returned deformation transform. While these points are internal to the transform, having more points allows the transform to better match sharp and more heavily deformed areas of the pattern image.

The default is (6, 6).

Notes

The returned transform is not guaranteed to have exactly the number of control points specified, nor to place them on a regular grid. The provided values are considered a guideline, but characteristics of the pattern or of the deformation may cause the tool to modify control point placement to more accurately represent the transform.

- `ccIPair controlPoints() const;`

  Returns the control points.

- `void controlPoints(const ccIPair &controlPoints);`

  Sets the control points.

  Parameters

  controlPoints The new control points.

  Throws

  cc_PMDefs::BadParams
  If either element of *controlPoints* has value less than 2.

controlPointsExplicit

```
const cmStd vector<cc2Vect> &controlPointsExplicit() const;

void controlPointsExplicit(
  const cmStd vector<cc2Vect> &pointList);
```

Specifies the exact positions of all control points used to define the returned deformation transform. An empty vector indicates that **controlPoints()** values should be used instead.

The default is an empty vector.

Notes

The control points are specified in the client coordinate system of the training image.

The control points must not all be colinear, and no two control points can have the same position.

No more than 64 control points can be specified.

- `const cmStd vector<cc2Vect> &controlPointsExplicit() const;`

  Returns the explicit control points.

- ```
  void controlPointsExplicit(
    const cmStd vector<cc2Vect> &pointList);
  ```

  Sets the explicit control points.

  Parameters

  pointList The new control points.

  Throws

  cc_PMDefs::BadParams
  If *pointList* has fewer than three elements and is not empty, or if *pointList* has more than 64 elements.
  ```

computeXform

```
cc_PMDefs::DeformationFit computeXform() const;
void computeXform(cc_PMDefs::DeformationFit computeXform);
```

Specifies the type of transform PatMax computes and returns in the PatFlex result. (See **ccPMFlexResult**). The transform type must be one of the **DeformationFit** enums as follows:

Computed transform type	Description
kFitNone	No transform is computed.
kFitDeformation	A deformation transform is computed. See **cc2XformDeformation**.
kFitPerspective	A perspective transform is computed. See **cc2XformPerspective**.

The default is *kFitDeformation*.

Notes

If you know you don't need the deformation transform from the result, you can save significant time and memory by setting **computeXform()** to *kFitNone*.

Using *kFitPerspective* can result in a more accurate transform if the run-time image is known to have only perspective deformation, or if you only want to have the perspective part of the deformation mapped.

- `cc_PMDefs::DeformationFit computeXform() const;`

  Returns the transform type.

- `void computeXform(cc_PMDefs::DeformationFit computeXform);`

  Sets the transform type. Must be one of the **DeformationFit** enums.

  Parameters

  computeXform The new transform type.

ccPMFlexRunParams

ccPMInspectAbsenceData

```
#include <ch_cvl/pminspct.h>

class ccPMInspectAbsenceData;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class stores the inspection results for the blank scene inspection mode. The boundary features stored by the class are defects in a region that is supposed to be blank (see *PatInspect* in *Vision Tools Guide*).

Constructors/Destructors

ccPMInspectAbsenceData

```
ccPMInspectAbsenceData();
```

Constructs an empty **ccPMInspectAbsenceData** object.

Public Member Functions

extra

```
const cmStd vector<ccPMInspectUnmatchedFeature>& extra()
  const;
```

Returns a reference to a vector whose elements contain defect boundary features.

Throws

ccPMInspectDefs::BadResultSetup
The function is called prior to initialization by the **ccPMInspectResult::getBlankSceneMeasurement()**.

displayFeatures

```
void displayFeatures(ccGraphicList& displayList,
  const cc2Xform& pose = cc2Xform::I,
  const ccColor& extraColor = ccColor::redColor()) const;
```

Draws the defect boundary features on *displayList*.

Parameters

displayList The graphic list used to draw the defect boundary features

pose A **cc2Xform** object used to transform the displayed boundary features

extraColor The color used to draw the defect boundary features.

Throws

ccPMInspectDefs::BadResultSetup
The function is called prior to a successful run

ccPMInspectBoundaryData

```
#include <ch_cvl/pminspct.h>

class ccPMInspectBoundaryData;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that stores boundary feature differences information. Boundary feature differences are grouped in three categories.

- Matched Features. These are boundary features that are present in both run-time and template image
- Extra Features. These are boundary features that are present in the run-time image but not in the template image.
- Missing Features. These are features that are present in the template image but not in the run-time image.

Constructors/Destructors

ccPMInspectBoundaryData

```
ccPMInspectBoundaryData();
```

Creates an empty **ccPMInspectBoundaryData** object.

Public Member Functions

match

```
const cmStd vector <ccPMInspectMatchedFeature>& match()
  const;
```

Returns the list of matched features.

Throws

ccPMInspectDefs::BadResultSetup
The function has been called prior to initialization by **ccPMInspectResult::getBoundaryDiff()**.

missing

```
const cmStd vector <ccPMInspectUnmatchedFeature>& missing()
  const;
```

Returns the list of missing features.

Throws

ccPMInspectDefs::BadResultSetup
The function has been called prior to initialization by **ccPMInspectResult::getBoundaryDiff()**.

extra

```
const cmStd vector <ccPMInspectUnmatchedFeature>& extra()
  const;
```

Returns the list of extra features.

Throws

ccPMInspectDefs::BadResultSetup
The function has been called prior to initialization by **ccPMInspectResult::getBoundaryDiff()**.

minDeformation

```
double minDeformation() const;
```

Returns the smallest deformation in client coordinates computed across all the matched boundary features.

maxDeformation

```
double maxDeformation() const;
```

Returns the biggest deformation in client coordinates computed across all the matched boundary features.

displayFeatures

```
void displayFeatures(
  ccGraphicList& displayList,
  const cc2Xform& pose = cc2Xform::I,
  bool showMatch = true,
  bool showExtra = true,
  bool showMissing = true,
  bool showConnect = true,
  ccColor matchColor = ccColor::blueColor(),
  const ccColor extraColor& = ccColor::redColor(),
  const ccColor missingColor& = ccColor::yellowColor(),
```

```
const ccColor connectColor& = ccColor::whiteColor(),
const ccColor patternColor& = ccColor::greenColor())
const;
```

Draws the difference boundary feature data (match, extra and missing) on the graphic list *displayList* using the color specified by *matchColor*, *extraColor*, *missingColor*, *connectColor*, *patternColor*.

Parameters

displayList	The graphic list to be used for drawing
pose	A **cc2Xform** object used to transform the displayed boundary features
showMatch	If true the matching boundary features are shown
showExtra	If true the extra boundary features are shown
showMissing	If true the missing boundary features are shown
showConnect	If true the connections between neighboring points on the boundary features are shown
matchColor	The color of the matching boundary features
extraColor	The color of the extra boundary features
missingColor	The color of the missing boundary features
connectColor	The color of the connections between neighboring points
patternColor	The color of the boundary features in this region

Throws

ccPMInspectDefs::BadResultSetup
The function has been called prior to initialization by **ccPMInspectResult::getBoundaryDiff()**.

Notes

This member function replaces the global function **cfPMInspectDisplayFeatures()** which will be deprecated after CVL 5.5.

Typedefs

ccPMInspectSimpleBoundaryDiffData

```
typedef ccPMInspectBoundaryData
 ccPMInspectSimpleBoundaryDiffData;
```

The class **ccPMInspectSimpleBoundaryDiffData** will be deprecated after CVL 5.5.

ccPMInspectBP

```
#include <ch_cvl/bndpnts.h>

class ccPMInspectBP;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that describes a single PatInspect feature boundary point.

Note You should not instantiate this class directly.

Constructors/Destructors

ccPMInspectBP

```
ccPMInspectBP();
```

Construct an uninitialized **ccPMInspectBP**.

Public Member Functions

pos

```
cc2Vect pos() const;
```

Returns the position of this feature boundary point in the alignment training image client coordinate system.

dir

```
ccRadian dir() const;
```

Returns the direction of this feature boundary point in the alignment training image client coordinate system. The direction is defined as the angle between the client coordinate system x-axis and the positive gradient direction of the boundary point (dark-to-light).

weight

```
double weight() const;
```

Returns the weight of this feature boundary point in the range 0.0 to 1.0. The weight is a measure of the relative strength of the boundary point in the image. The stronger the boundary point, the higher the weight.

matchQuality

```
double matchQuality() const;
```

Returns the match quality of this feature boundary point in the range -1.0 to 1.0. Match quality is a measure of the degree to which this feature boundary point matched the corresponding feature boundary point in the inspection training image and an indication of the feature boundary point's weight.

A match quality of 1.0 means that there was perfect match and that the feature boundary point had a high weight. A match quality of -1.0 means that there was a complete mismatch and that the feature boundary point had a high weight.

Match qualities close to 0 indicate that the feature boundary point had a low weight.

ccPMInspectDefs

```
#include <ch_cvl/pminspct.h>

class ccPMInspectDefs : public cc_PMDefs;
```

A name space that holds enumerations and constants used with PatInspect.

Enumerations

NormalizationMethod

```
enum NormalizationMethod
```

This enumeration defines the image normalization methods used by PatInspect (for more details see *Normalizing Run-Time Images* in *PatInspect* chapter of *Vision Tools Guide*).

Value	Meaning
eIdentity	No normalization
eHistogramEqualize	Normalize to match histograms
eMeanAndStdDev	Normalize to match mean and standard deviation
eMatchTails	Normalize to match tails

DiffMode

```
enum DiffMode
```

The difference mode specifies the pel sign handling of the difference operator.

Value	Meaning
eAbs	Absolute value of the difference pels
eClampNeg	Negative difference pels are clamped to zero. This discards negative difference pels.
eClampPos	Positive difference pels are clamped to zero and negative pels are negated. This discards positive difference pels.

Value	Meaning
eClampAdd128	Positive values are clamped to +127 and negative values are clamped to -127, after which 128 is added to all values. This preserves both positive and negative difference pels.
eDiv2Add128	All values are divided by two, then incremented by 128. This preserves both positive and negative difference pels.

InspectMode

```
enum InspectMode
```

This enumeration defines the inspection modes supported by PatInspect (to learn about each of these inspection modes see *PatInspect* chapter in *Vision Tools Guide*).

Value	Meaning
eBPDifference = 0x01	Feature difference mode
eIntensityDifference = 0x02	Intensity difference mode
eBlankScene = 0x04	Blank scene inspection mode

InspectModeModifier

```
enum InspectModeModifier
```

This enumeration defines the modifiers that can be applied to the feature difference inspection mode (for more information see *Fine Alignment for Boundary Feature Inspection* in *PatInspect* chapter of *Vision Tools Guide*).

Value	Meaning
eSoftwareZoomTrain = 0x1000	Software zoom applied only during training
eSoftwareZoomTrainRun = 0x2000	Software zoom applied during training and runtime
eFineAlign = 0x4000	Alignment to local inspection features

Valid combinations:

Inspection mode	Inspection mode modifiers
eBPDifference	*eSoftwareZoomTrain, eSoftwareZoomTrainRun, eFineAlign*
eIntensityDifference	None
eBlankScene	None

DrawMode `enum DrawMode`

Drawing modes

Value	Meaning
eDrawDefectBoundary = 0x1	Draw defect boundary features of result set when using *eBlankScene* inspection mode
eDrawMatchingBoundary = 0x2	Draw matching boundary features of result set when using *eBPDifference* inspection mode
eDrawExtraBoundary = 0x4	Draw extra boundary features of result set when using *eBPDifference* inspection mode
eDrawMissingBoundary = 0x8	Draw missing boundary features of result set when using *eBPDifference* inspection mode

ccPMInspectDefs

ccPMInspectMatchedBP

```
#include <ch_cvl/bndpnts.h>

class ccPMInspectMatchedBP : public ccPMInspectBP;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single matched PatInspect feature boundary point.

Note You should not instantiate this class directly.

Constructors/Destructors

ccPMInspectMatchedBP

```
ccPMInspectMatchedBP();
```

Construct an uninitialized **ccPMInspectMatchedBP**.

Public Member Functions

hasPatternBP

```
bool hasPatternBP() const;
```

Returns true if this feature boundary point has a corresponding feature boundary point in the inspection training image. If this function returns false, then **patternPos()**, **patternDir()**, and **patternWeight()** will not return valid information.

patternPos

```
cc2Vect patternPos() const;
```

Returns the position of this feature boundary point in the alignment training image's client coordinate system.

patternDir

```
ccRadian patternDir() const;
```

Returns the direction of this feature boundary point in the alignment training image's client coordinate system.

patternWeight `double patternWeight() const;`

Returns the weight of this feature boundary point in the inspection training image. The returned value is in the range 0.0 to 1.0.

ccPMInspectMatchedFeature

```
#include <ch_cvl/bndpnts.h>

class ccPMInspectMatchedFeature :
  public cc_PMInspectFeature<ccPMInspectMatchedBP>;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a feature that is present in both the trained PatInspect pattern and the run-time image.

Note You should not instantiate this class directly.

Constructors/Destructors

ccPMInspectMatchedFeature

```
ccPMInspectMatchedFeature();
```

Construct an uninitialized **ccPMInspectMatchedFeature**.

Operators

operator==

```
bool operator== (const ccPMInspectMatchedFeature&) const;
```

Returns true if the location, direction, weight, match quality, and matched state are equal.

Public Member Functions

minDeformation

```
double minDeformation() const;
```

Returns the minimum deformation over all feature boundary points in this feature in alignment training image client coordinate system units. Feature boundary points in the run-time image that were not present in the inspection training image are ignored.

maxDeformation `double maxDeformation() const;`

Returns the maximum deformation over all feature boundary points in this feature in alignment training image client coordinate system units. Feature boundary points in the run-time image that were not present in the inspection training image are ignored.

ccPMInspectPattern

```
#include <ch_cvl/pminspct.h>

class ccPMInspectPattern : public cc_PMPattern;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class implements a PatInspect pattern. This is the class upon which the operation of the PatInspect vision tool is based. The two main components of a PatInspect pattern are:

- An alignment region that is used to align training and run-time inspection images
- An array of inspection regions that can be different from the alignment region and can be inspected according to the following inspection modes:

  intensity difference
  feature difference
  blank scene inspection

The member functions of **ccPMInspectPattern** allow you to:

- Train an inspection image
- Align an inspection image
- Run an inspection
- Return the results of the inspection

For more information on PatInspect training and run-time operation see *PatInspect* in *Vision Tools Guide*.

Notes

See the **cc_PMPattern** class for additional functions common to all PatMax pattern classes.

If you attempt to persist a **ccPMInspectPattern** before calling **endTrain()**, the archive operator will throw *ccPMInspectDefs::NotTrained*.

Constructors/Destructors

ccPMInspectPattern

```
ccPMInspectPattern();
```

Constructs an untrained **ccPMInspectPattern**.

Public Member Functions

compatibilityMode

```
void compatibilityMode(bool beCompatible);

bool compatibilityMode() const;
```

- `void compatibilityMode(bool beCompatible);`

  Causes this **ccPMInspectPattern** to be trained in CVL 5.4 backward compatibility mode. If *beCompatible* is set to true, all default values and behaviors are set according to CVL 5.4 conventions. The default values of *beCompatible* is false (the tool is not CVL 5.4 backward compatible by default).

  Parameters

  beCompatible If *true* PatInspect operates in CVL 5.4 backward compatibility mode. If *false* PatInspect is not CVL 5.4 backward compatible.

  Throws

  ccPMInspectDefs::BadParams
  The function is called after **ccPMInspectPattern::startTrain()**.

  Notes

  This function must be called only once (you cannot switch back and forth between compatibility modes) and immediately after the construction of this **ccPMInspectPattern**. Setting *beCompatible* to *true* prevents you from performing multiple region inspections.

- `bool compatibilityMode() const;`

  Returns true if this **ccPMInspectPattern** is configured to be CVL 5.4 backward compatible.

customizeInspect

```
ccCvlString customizeInspect(const ccCvlString& pcp);
```

Uses a Cognex-supplied customization string to modify internal PatInspect parameters. This function returns a string containing diagnostic information for use by Cognex Corporation.

Parameters

pcp A PatInspect customization string provided by Cognex Corporation.

Throws

cc_PMDefs::BadParams
This function is not supported in compatibility mode.

ccParamCompileError
pcp is invalid.

customizeInspectFromFile

```
ccCvlString customizeInspectFromFile(
  const ccCvlString& filename);
```

Uses a Cognex-supplied customization file to modify internal PatInspect parameters. This function returns a string containing diagnostic information for use by Cognex Corporation.

Parameters

filename A PatInspect customization file provided by Cognex Corporation.

Throws

cc_PMDefs::BadParams
This function is not supported in compatibility mode.

ccParamCompileError
filename contains invalid data or *filename* could not be opened.

customizeInspectString

```
ccCvlString customizeInspectString() const;
```

Returns the customization string most recently supplied to **customizeInspect()** or **customizeInspectFromFile()**.

Throws

cc_PMDefs::BadParams
This function is not supported in compatibility mode.

ignorePolarity

```
bool ignorePolarity() const;

void ignorePolarity(bool doIgnore);
```

- `bool ignorePolarity() const;`

  Returns true if this **ccPMInspectPattern** is configured to ignore polarity changes when searching for the pattern during alignment.

- `virtual void ignorePolarity(bool doIgnore);`

  Controls whether this **ccPMInspectPattern** is configured to ignore polarity changes when searching for the pattern during alignment. You can call this function without needing to retrain this **ccPMInspectPattern**. The default value of *doIgnore* is false.

  Parameters

doIgnore	If *true*, pattern polarity is ignored. If *false*, only patterns with matching polarity are found.

sobelCoeffs

```
void sobelCoeffs(const ccDPair& coeffs,
  c_Int32 index = 0);

ccDPair sobelCoeffs(c_Int32 index = 0) const;
```

- ```
  void sobelCoeffs(const ccDPair& coeffs,
    c_Int32 index = 0);
  ```

  Sets the coefficients used to compute the synthetic standard deviation image for the inspection region *index*. Each pixel in the standard deviation image is set to the following value:

  $$xM + y$$

  where:

  x is the value returned by *coeffs.x()*.

  M is the Sobel edge magnitude value of the pixel (see *Edge Tool* in *Vision Tools Guide* for more details).

  y is the value returned by *coeffs.y()*.

  The default values for x and y are 1.0 and 0.0. If you operate in CVL 5.4 backward compatibility mode the default values are 1.2 and 19.3.
  ```

Parameters

coeffs A **ccDPair** containing the x and y coefficients.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode.

Notes

This function will have an effect only if **ccPMInspectPattern::endTrain()** is called in *ccPMInspectDefs::eIntensityDifference* mode with a single prior call to **ccPMInspectPattern::statisticTrain()**. You can call this function anytime before calling **ccPMInspectPattern::run()**. If you are working in CVL 5.4 backward compatibility mode and you want to set the values of x and y, you should call this function only after **ccPMInspectPattern::compatibilityMode(true)** has been called.

- ```
  ccDPair sobelCoeffs(c_Int32 index = 0) const;
  ```

Returns the coefficients used to compute the standard deviation region from the single inspection region *index*.

Parameters

index The index for the inspection region.

thresholdCoeffs

```
void thresholdCoeffs(const ccDPair& coeffs,
  c_Int32 index = 0);

ccDPair thresholdCoeffs(c_Int32 index = 0) const;
```

- ```
  void thresholdCoeffs(const ccDPair& coeffs,
    c_Int32 index = 0);
  ```

Sets the coefficients used to compute the threshold from the standard deviation for the inspection region *index*. Each pixel in the threshold region is set to the following value:

$$xS + y$$

where

x is the value returned by *coeffs.x()*.

S is the value of the pixel in the standard deviation region.

y is the value returned by *coeffs.y()*.

The default values for x and y are1.0 and 0.0. If you operate in CVL 5.4 backward compatibility mode the default values are 3.0 and 10.0.

Parameters

coeffs A **ccDPair** containing the x and y coefficients.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode

Notes

You can call this function anytime before calling **ccPMInspectPattern::run()**. If you are working in CVL 5.4 backward compatibility mode and you want to set the values of x and y, you should call this function only after **ccPMInspectPattern::compatibilityMode(true)** has been called.

- `ccDPair thresholdCoeffs(c_Int32 index = 0) const;`

Returns the coefficients x and y used to compute the threshold image from the standard deviation image for the inspection region *index*.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode.

tailFractions

```
void tailFractions(const ccDPair& fracs,
  c_Int32 index = 0);

ccDPair tailFractions(c_Int32 index = 0) const;
```

- ```
  void tailFractions(const ccDPair& fracs,
    c_Int32 index = 0);
  ```

  Sets the tail percentages used for tail matching for the inspection region *index*. The fraction of tail pixels below the value supplied in *fracs.x()* and above the value supplied in *fracs.y()* are discarded before the run-time region is mapped. Legal values for *fracs.x()* and *fracs.y()* are between 0.0 and 1.0.

  The following figure shows how the tail fractions are interpreted, given fractions of 0.10 and 0.90:

  The default values for the left and right tail values are 0.1 and 0.9.

  Parameters

  fracs — A **ccDPair** containing the left and right tail lengths. Whichever value is higher is used as the right tail length.

  index — The index for the inspection region.

  Throws

  ccPMInspectDefs::BadParams

  fracs contains values less than 0.0 or greater than 1.0.
  The index for the inspection region is not valid.
  Region *index* does not support intensity difference mode.

  Notes

  You can call this function anytime before calling **ccPMInspectPattern::run()**.
  ```

```
ccDPair tailFractions(c_Int32 index = 0) const;
```

Returns the tail percentages used for tail matching for the inspection region *index*.

Throws

ccPMInspectDefs::BadParams

fracs contains values less than 0.0 or greater than 1.0.
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode.

interpolationQuality

```
void interpolationQuality(
  ccAffineSamplingParams::Interpolation value,
  c_Int32 index = 0);

ccAffineSamplingParams::Interpolation
  interpolationQuality(c_Int32 index = 0) const;
```

- ```
  void interpolationQuality(
    ccAffineSamplingParams::Interpolation value,
    c_Int32 index = 0);
  ```

Sets the interpolation method used to affine-transform the training and run-time inspection region *index*.

Parameters

value — A valid sampling method as defined in *ccAffineSamplingParams::Interpolation*.

index — The index for the inspection region.

Throws

ccPMInspectDefs::BadParams

value is not one of the enumerated values defined in *ccAffineSamplingParams::Interpolation*.
index is not valid for the inspection region.

Notes

Interpolation quality is relevant for intensity difference and blank scene modes and does not affect boundary difference mode.

This function must be called before **ccPMInspectPattern::statisticTrain()**.
  ```

- ```
  ccAffineSamplingParams::Interpolation
    interpolationQuality(c_Int32 index = 0) const;
  ```

  Returns the sampling method used to affine-transform the run-time inspection region *index* before computing the intensity difference image.

  Throws

  ccPMInspectDefs::BadParams
  index is not valid for the inspection region.

  Notes

  Interpolation quality is relevant for intensity difference and blank scene modes and does not affect boundary difference mode.

templateImage

```
const ccPelBuffer_const<c_UInt8>& templateImage(
  c_Int32 index = 0) const;
```

Returns the template region used for intensity difference inspection of the region *index*.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode.

Notes

This function returns an unbound image if this **ccPMInspectPattern** has not completed statistical training for intensity difference mode.

thresholdImage

```
const ccPelBuffer_const<c_UInt8>& thresholdImage(c_Int32
  index = 0) const;
```

Returns the threshold image used for intensity difference inspection of the region *index*.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support intensity difference mode.

Notes

This function returns an unbound image if this **ccPMInspectPattern** has not completed statistical training for intensity difference mode.
```

maskImage `const ccPelBuffer_const<c_UInt8>& maskImage() const;`

Returns the mask image used for alignment and for inspection region 0 when operating in CVL 5.4 backward compatibility mode.

Notes

This function returns an unbound image if training of this **ccPMInspectPattern** has not started or if a mask image was not supplied.

ignoreInspectPolarity

```
void ignoreInspectPolarity(bool doIgnore, c_Int32 index);
bool ignoreInspectPolarity(c_Int32 index);
```

- `void ignoreInspectPolarity(bool doIgnore, c_Int32 index);`

Controls whether to ignore the polarity of the inspection region *index* when inspecting in feature difference mode.

Parameters

doIgnore If *true*, the polarity of the region *index* is ignored during feature difference inspection. If *false*, polarity is taken into account.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

- `bool ignoreInspectPolarity(c_Int32 index);`

Returns true if the polarity of the inspection region *index* is ignored when inspecting in feature difference mode.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

matchQualityThresholds

```
void matchQualityThresholds(double low, double high,
  c_Int32 index = 0);
```

Sets the low and high thresholds for match quality for the inspection region *index*. Only features with average match quality greater than the high threshold are treated as matching features. Features with match quality between the low and high thresholds are discarded. Features with match quality below the low threshold are treated as either missing or extraneous.

If the two thresholds are equal (which is the default), then no features are discarded, and all features appear in one of the three feature lists (matched, missing, or extra).

Valid values are in the range -1.0 through 1.0. The default values are 0.0 for both the low threshold and the high threshold.

Parameters

low The low threshold.

high The high threshold.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams

low is greater than *high*.
The inspection region index is not valid.
Region *index* does not support feature difference mode.

matchQualityThresholdLow

```
double matchQualityThresholdLow(c_Int32 index = 0) const;
```

Returns the match quality low threshold assigned to the inspection region *index*.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams

The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

matchQualityThresholdHigh

```
double matchQualityThresholdHigh(c_Int32 index = 0) const;
```

Returns the match quality high threshold of the inspection region *index*.

Parameters

index The index for the inspection region

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

boundaryDeformation

```
void boundaryDeformation(double value, c_Int32 index);

double boundaryDeformation(c_Int32 index) const;
```

- `void boundaryDeformation(double value, c_Int32 index);`

Sets the distance in pixels within which feature boundary points can be matched for the inspection region *index*. This parameter indicates how far away a feature boundary point in the run-time region can be from a feature boundary point in the template region and still be considered for a match. The default value is 0.0. The maximum value is 5.0.

Parameters

value The distance in pixels within which feature boundary points can be matched.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
value is less than 0.0 or greater than 5.0.
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

Notes

Calling this function has no effect in this release.

- `double boundaryDeformation(c_Int32 index) const;`

Returns the distance in pixels within which feature boundary points can be matched for the inspection region *index*.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

Notes
Calling this function has no effect in this release.

background

```
void background(double back, c_Int32 index);
double background(c_Int32 index) const;
```

- `void background(double back, c_Int32 index);`

Overrides the standard deviation value computed during blank scene training of the region *index* and sets it to *back* (see *Training for Blank Scene Inspection* in the *Vision Tools Guide* for a description of how the standard deviation value is computed during blank scene training).

Parameters
back The value the standard deviation region is set to.

index The index for the inspection region.

Throws
ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support blank scene inspection mode.

Notes
The value of *back* is automatically generated during training but you can use this function to override it.

- `double background(c_Int32 index) const;`

Returns the standard deviation value used for blank scene inspection training of the region *index*.

Parameters
index The index for the inspection region.

Throws
ccPMInspectDefs::BadParams
The index for the inspection region is not valid.
Region *index* does not support blank scene inspection mode.

backgroundRange

```
void backgroundRange(double backRange, c_Int32 index);
double backgroundRange(c_Int32 index) const;
```

- `void backgroundRange(double backRange, c_Int32 index);`

  Sets the coefficient used to compute the blank scene threshold from the standard deviation of the region *index (*see *Training for Blank Scene Inspection* in the *Vision Tools Guide* for a description of how the threshold region is obtained during blank scene training). Each pixel in the threshold region is set to the following value:

  $$backRange \times S$$

  where S is the standard deviation value of the region *index*. The value of *backRange* must be from 0.0 through 5.0.

  Parameters

  backRange — The coefficient used to compute the threshold for blank scene inspection of region *index*.

  index — The index for the inspection region.

  Throws

  ccPMInspectDefs::BadParams

  backRange is either less than 0.0 or greater than 5.0.
  The index for the inspection region is not valid.
  Region *index* does not support blank scene inspection mode.

- `double backgroundRange(c_Int32 index) const;`

  Returns the coefficient used to compute the blank scene threshold from the standard deviation of the region *index.*

  Parameters

  index — The index for the inspection region.

  Throws

  ccPMInspectDefs::BadParams

  The index for the inspection region is not valid.

minimumFeatureSize

```
void minimumFeatureSize(c_Int32 minSize, c_Int32 index);

c_Int32 minimumFeatureSize(c_Int32 index) const;
```

- `void minimumFeatureSize(c_Int32 minSize, c_Int32 index);`

  Sets the minimum boundary feature size in pixels for the region *index*. Features with sizes that are less than *minSize* are not considered defects. The default value is 1.0.

  Throws

  ccPMInspectDefs::BadParams

  The index for the inspection region is not valid.
  Region *index* does not support either feature difference or blank scene inspection mode.

  Notes

  This function can be used for both blank scene and feature difference inspection mode.

- `c_Int32 minimumFeatureSize(c_Int32 index) const;`

  Returns the minimum boundary feature size in pixels for the region *index*.

  Throws

  ccPMInspectDefs::BadParams

  The index for the inspection region is not valid.
  Region *index* does not support either feature difference or blank scene inspection mode.

  Notes

  This function can be used for both blank scene and feature difference inspection mode.

minimumFeatureContrast

```
void minimumFeatureContrast(double contrastThresh,
  c_Int32 index);

double minimumFeatureContrast(c_Int32 index) const;
```

- `void minimumFeatureContrast(double contrastThresh, c_Int32 index);`

  Sets the minimum feature contrast in grey levels for the region *index*. Features with contrast levels that are less than *contrastThresh* are not considered defects. The default value of *contrastThresh* is 10.0 grey levels.

Throws

ccPMInspectDefs::BadParams

contrastThresh is either less than 0 or greater than 255
The index for the inspection region is not valid.
Region *index* does not support either feature difference or blank scene inspection mode.

Notes

This function can be used for both blank scene and feature difference inspection mode.

- ```
  void minimumFeatureContrast(double contrastThresh,
    c_Int32 index);
  ```

Returns the minimum feature contrast in grey levels for the region *index.*

Throws

ccPMInspectDefs::BadParams

The index for the inspection region is not valid.
Region *index* does not support either feature difference or blank scene inspection mode.

Notes

This function can be used for both blank scene and feature difference inspection mode.

trainFeatureContrast

```
void trainFeatureContrast(double contrastThresh,
  c_Int32 index);

double trainFeatureContrast(c_Int32 index) const;
```

- ```
  void trainFeatureContrast(double contrastThresh,
    c_Int32 index);
  ```

Sets the minimum feature contrast in grey levels for the region *index* at training time. Features with contrast levels that are less than *contrastThresh* are not included in the trained **ccPMInspectPattern**. The default value of *contrastThresh* is 10.0 grey levels.

Throws

ccPMInspectDefs::BadParams

contrastThresh is either less than 0 or greater than 255; the index for the inspection region is not valid; or the region *index* does not support either feature difference or blank scene inspection mode.

Notes

This function can be used for both blank scene and feature difference inspection mode.

- ```
  void trainFeatureContrast(double contrastThresh,
    c_Int32 index);
  ```

Returns the minimum feature contrast in grey levels for the region *index* at training time. Features with contrast levels that are less than *contrastThresh* are included in the trained **ccPMInspectPattern**. The default value of *contrastThresh* is 10.0 grey levels.

Throws

ccPMInspectDefs::BadParams

The index for the inspection region is not valid or region *index* does not support either feature difference or blank scene inspection mode.

Notes

This function can be used for both blank scene and feature difference inspection mode.

---

startTrain

```
void startTrain(ccDiagObject* dObj=0,
  c_UInt32 diagFlags=0);

void startTrain(
  const ccPelBuffer_const<c_UInt8>& alignModel,
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);

void startTrain(
  const ccPelBuffer_const<c_UInt8>& alignModel,
  const ccPelBuffer_const<c_UInt8>& mask
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
```

- ```
  void startTrain(ccDiagObject* dObj=0,
    c_UInt32 diagFlags=0);
  ```

Starts training when alignment is performed by using a pose. You supply the pose when you call the appropriate overload of **ccPMInspectPattern::statisticTrain()**.

Parameters

dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMInspectDefs::BadParams
PatInspect operates in backward compatibility mode.

ccPel::BadWindow
Any inspection region defined with the **ccAffineRectangle** overload of **addInspectRegion()** is out of the image.

Notes

To avoid *ccPel::BadWindow* being thrown from **startTrain()** when using affine rectangular regions that are clipped by the root image, test for a bad **ccAffineRectangle** before calling **addInspectRegion()**. For example, the following code performs such a test:

```
ccAffineRectangle affRect(cc2Xform(cc2Vect(267,123),
  ccRadian(ccDegree(-27)), ccRadian(ccDegree(-27)), 300,
  150));
// Test affine rectangle before calling addInspectRegion()
ccPelBuffer <c_UInt8> foo(trainImage);
try
{
  foo.window(affRect.encloseImageRect());
}
catch(ccPel::BadWindow &e)
{
  // bad ccAffineRectangle, try again!
  throw;
}
pat.addInspectRegion(model, ccPMInspectDefs::eBPDifference,
  cmT("BFC"));
```

See **ccPMInspectPattern::addInspectRegion()** for more information.

- ```
  void startTrain(
    const ccPelBuffer_const<c_UInt8>& alignModel,
    ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
  ```

  Performs alignment training using the alignment region *alignModel*. When operating in backward compatibility mode, *alignModel* is also inspection region 0. PatInspect uses the pattern information trained from *alignModel* to locate the alignment region in both training and run-time images. All previously trained information is discarded after the call to this function.

  Parameters

  alignModel — The region to use for alignment training.

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccPel::BadWindow

  Any inspection region defined with the **ccAffineRectangle** overload of **addInspectRegion()** is out of the image. See notes in first overload for details.
  ```

- ```
  void startTrain(
    const ccPelBuffer_const<c_UInt8>& alignModel,
    const ccPelBuffer_const<c_UInt8>& mask,
    ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
  ```

  Performs alignment training using the alignment region *alignModel* and the masking image *mask*.

  The mask image must have the same dimensions and offset as the alignment region. The pixels in the mask image are interpreted as follows:

  - All pixels in *alignModel* that correspond to pixels in *mask* with values greater than or equal to 192 are considered 'care' pixels. All feature boundary points detected within 'care' pixels are included in the trained pattern.
  - All pixels in *alignModel* that correspond to pixels in *mask* with values from 0 through 63 are considered 'don't care but score' pixels. Feature boundary points detected within 'don't care but score' pixels are not included in the trained pattern.

    When the trained pattern is located in a run-time image, features within the 'don't care but score' part of the trained pattern are treated as clutter features and they contribute to the feature difference list.
  - All pixels in *alignModel* that correspond to pixels in *mask* with values from 64 through 127 are considered 'don't care and don't score' pixels. Feature boundary points detected within 'don't care and don't score' pixels are not included in the trained pattern.

    When the trained pattern is located in a run-time image, features within the 'don't care and don't score' part of the trained pattern are ignored and not treated as clutter features and they do not contribute to the feature difference list.
  - Mask pixel values from 128 through 191 are reserved for future use by Cognex.

  Parameters

alignModel	The region to be used for alignment training.
mask	The mask image. *mask* must have the same dimensions and offset as *alignModel*. The client coordinate system of *mask* is ignored.
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults*
  ```

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

All results produced before this call become invalid. *alignModel* is used for alignment training only.

Throws

ccPMInspectDefs::CanNotTrain

The pattern could not be trained or *mask* does not have the same dimensions and offset as *alignModel*.

ccPMInspectDefs::BadImage

PatInspect could not locate a pattern instance with a score greater than the acceptance threshold within the image.

ccPel::BadWindow

Any inspection region defined with the **ccAffineRectangle** overload of **addInspectRegion()** is out of the image. See notes in first overload for details.

statisticTrain

```
cc2Xform statisticTrain(
  const ccPelBuffer_const<c_UInt8>& trainScene,
  const ccPMInspectStatTrainParams& params,
  c_Int32 inspectModes =
  ccPMInspectDefs::eIntensityDifference,
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);

cc2Xform statisticTrain(
  const ccPelBuffer_const<c_UInt8>& trainScene,
  const ccPMInspectStatTrainParams& params,
  const cc2Xform& pose,
  c_Int32 inspectModes =
  ccPMInspectDefs::eIntensityDifference,
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
```

-
```
cc2Xform statisticTrain(
  const ccPelBuffer_const<c_UInt8>& trainScene,
  const ccPMInspectStatTrainParams& params,
  c_Int32 inspectModes =
  ccPMInspectDefs::eIntensityDifference,
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
```

Adds an iteration to the statistical training of all the enabled regions in *trainScene* and returns the pose at which the alignment region was found. The parameters controlling the search of the alignment region are defined in *params*. If you are in CVL 5.4 backward

compatibility mode, the *inspectModes* parameter is applied to inspection region 0. If you are not in backward compatibility mode the value of *inspectModes* is ignored and need not be supplied.

Parameters

trainScene The image to use for inspection training.

params A **ccPMInspectStatTrainParams** object containing the parameters used to locate the alignment region in the training image.

inspectModes The inspection mode to be used for inspection region 0 when in backward compatibility mode. *inspectModes* must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference

If you supply 0 for *inspectModes*, the function returns **cc2Xform::I()** and performs no training.

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMInspectDefs::NotTrained
The **ccPMInspectPattern::startTrain()** function has not been called on this **ccPMInspectPattern**.

ccPMInspectDefs::BadImage
PatInspect cannot locate the alignment region within the training image with a score greater than the acceptance threshold.
The alignment region is not fully in the field if view.
One or more regions to be trained for blank scene inspection contain too many edge features to be considered blank.

ccPMInspectDefs::CanNotTrain
ccPMInspectPattern::endTrain() has been called with the *saveState* parameter set to *false;* the no argument overload of **ccPMInspect::startTrain()** has been called; or one or more of the regions to be trained for boundary mode has too many features.

Notes

You must have already called the appropriate overload of **ccPMInspect::startTrain()** before calling this function, and you must call **ccPMInspect::statisticTrain()** at least once between calls to **ccPMInspect::startTrain()** and **ccPMInspect::endTrain()** for correct operation. *trainScene* must span all the window regions supplied as arguments to **addInspectRegion()**. If you are not in backward compatibility mode the value of *inspectMode* is ignored. If a throw occurs, training terminates for all inspection regions regardless of the region that caused the throw.

- ```
  cc2Xform statisticTrain(
    const ccPelBuffer_const<c_UInt8>& trainScene,
    const ccPMInspectStatTrainParams& params,
    const cc2Xform& pose,
    c_Int32 inspectModes =
    ccPMInspectDefs::eIntensityDifference,
    ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
  ```

  Adds an iteration to the statistical training of all the enabled regions in *trainScene. trainScene* is aligned by using *pose* and the function returns *pose*. If you are in CVL 5.4 backward compatibility mode, the *inspectModes* parameter is applied to inspection region 0. If you are not in backward compatibility mode the value of *inspectModes* is ignored.

  Parameters

  trainScene — The image to use for inspection training.

  params — A **ccPMInspectStatTrainParams** object. This parameter is a place holder reserved for future use by Cognex. The value of this parameter is ignored in this release.

  pose — The transformation used to align *trainScene*.

  inspectModes — The inspection mode to be used for inspection region 0 when in backward compatibility mode. *inspectModes* must be formed by ORing together one or more of the following values:

  ccPMInspectDefs::eIntensityDifference
  ccPMInspectDefs::eBPDifference
  ```

If you supply 0 for *inspectModes*, the function returns **cc2Xform::I()**, and it performs no training.

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMInspectDefs::NotTrained
The **startTrain()** function has not been called on this **ccPMInspectPattern**.

ccPMInspectDefs::BadImage
One or more regions to be trained for blank scene inspection contain too many edge features to be considered blank.

ccPMInspectDefs::CanNotTrain
ccPMInspectPattern::endTrain() has been called with the *saveState* parameter set to *false;* the no argument overload of **ccPMInspect::startTrain()** has been called; or one or more of the regions to be trained for boundary mode has too many features.

Notes

You must have already called the appropriate overload of **ccPMInspect::startTrain()** before calling this function, and you must call **ccPMInspect::statisticTrain()** at least once between calls to **ccPMInspect::startTrain()** and **ccPMInspect::endTrain()** for correct operation. *trainScene* must span all the window regions supplied as arguments to **addInspectRegion()**.

endTrain

```
void endTrain(bool saveState,
  c_Int32 inspectModes =
  ccPMInspectDefs::eIntensityDifference,
  ccDiagObject* dObj=0, c_UInt32 diagFlags=0);
```

Completes the training process for this **ccPMInspectPattern**. If *saveState* is true then intermediate state information is saved and you can call **ccPMInspect::statisticTrain()** later to add more training images. If *saveState* is false, then the memory taken up by the state is freed, but the ability to further train the pattern is lost. If you are in CVL 5.4 backward compatibility mode, the *inspectModes* parameter is applied to inspection region 0. If you are not in backward compatibility mode the value of *inspectModes* is ignored.

Parameters

saveState — If *true*, then internal state information is saved. If *false*, then internal state information is discarded.

inspectModes — The inspection mode of inspection region 0 when in backward compatibility mode. *inspectModes* must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference

dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccPMInspectDefs::NotTrained
ccPMInspect::startTrain() has not been called.
One of the difference patterns has not been trained.
The pattern has not been previously trained with the specified method.

ccPMInspectDefs::CanNotTrain
ccPMInspect::endTrain() has been previously called with *saveState* set to false or an inspection region using boundary

feature comparison mode is not trainable. Note that you can disable an individual untrainable region without discarding all regions.

Notes

For blank scene inspection mode this function is only meant as a mechanism to recompute and update internal statistical information. When in this inspection mode, the value of *saveState* has no effect and you can continue training even after the function is called.

untrain

```
void untrain(bool alignOnly = false);
```

Frees the memory allocated for the internal data. If *alignOnly* is true only the memory allocated for the alignment pattern is freed. If *alignOnly* is false the memory allocated for the alignment pattern and the inspection regions is freed. This function can be called on an untrained pattern with no effect.

Parameters

alignOnly — If *true*, then the memory allocated for the alignment pattern is freed. If *false*, the memory for the inspection regions is also freed.

Notes

All the results produced before the call to this function became invalid.

addInspectRegion

```
c_Int32 addInspectRegion(
  const ccPelBuffer_const<c_UInt8>& inspReg,
  c_UInt32 inspectModes, const ccCvlString& name = cmT(""));

c_Int32 addInspectRegion(const ccAffineRectangle& inspReg,
  c_UInt32 inspectModes, const ccCvlString& name = cmT(""));
```

-
```
c_Int32 addInspectRegion(
  const ccPelBuffer_const<c_UInt8>& inspReg,
  c_UInt32 inspectModes, const ccCvlString& name = cmT(""));
```

Adds the inspection region *inspReg* to the current inspection region list and returns the total number of regions after the addition. The region is added in the enabled state and is identified by the case-sensitive string *name*. *inspectModes* specifies the inspection mode of *inspReg, a combination of the* enums *ccPMInspectDefs::InspectMode* and *ccPMInspectDefs::InspectModeModifier*. If *inspReg* is inspected for blankness, it cannot be also inspected for intensity or feature difference. The inspection modifiers

apply only to feature difference modes. The combinations of inspection base modes and modifiers that can be applied to an inspection region are summarized in the following table.

Base Mode	Valid additional base mode	Modifiers
eBPDifference	*eIntensityDifference*	*eSoftwareZoomTrain* *eSoftwareZoomTrainRun* *eFineAlign*
eIntensityDifference	*eBPDifference*	*eSoftwareZoomTrain* *eSoftwareZoomTrainRun* *eFineAlign*
eBlankScene	None	None

This function must be called before **ccPMInspect::startTrain()**.

Parameters

inspReg The region added to the list of inspection regions.

inspectModes The inspection mode of *inspReg*. This parameter must be formed by ORing together valid combinations of the base modes and modifiers as show in the table above.

name An optional string that identifies *inspReg*.

Throws

ccPMInspectDefs::NotTrained
ccPMInspect::startTrain() has been called first.

ccPMInspectDefs::BadParams
The region could not be added to the list.
A region with the same name already exists.
An invalid bit is asserted in *inspectModes*.
PatInspect operates in CVL 5.4 backward compatibility mode.

- ```
  c_Int32 addInspectRegion(const ccAffineRectangle& inspReg,
    c_UInt32 inspectModes, const ccCvlString& name = cmT(""));
  ```

  Same as above, except it adds the inspection region specified by the supplied **ccAffineRectangle** to the current inspection region list.

  Parameters

  inspReg The **ccAffineRectangle** added to the list of inspection regions.
  ```

inspectModes The inspection mode of *inspReg*. This parameter must be formed by ORing together valid combinations of the base modes and modifiers as show in the table above.

name An optional string that identifies *inspReg.*

Throws

ccPMInspectDefs::NotTrained
ccPMInspect::startTrain() has been called first.

ccPMInspectDefs::BadParams
The region could not be added to the list; a region with the same name already exists; an invalid bit is asserted in *inspectModes.*; PatInspect is being operated in CVL 5.4 backward compatibility mode; or *inspReg* specifies a non-zero skew component.

inspectRegion

```
const ccPMInspectRegion& inspectRegion(
  c_Int32 index)const;

ccPMInspectRegion& inspectRegion(c_Int32 index);
```

- ```
  const ccPMInspectRegion& inspectRegion(
    c_Int32 index) const;
  ```

  Returns a read-only reference to the inspection region *index*.

  Parameters

  index The index for the inspection region.

- ```
  ccPMInspectRegion& inspectRegion(c_Int32 index);
  ```

  Returns a reference to the inspection region *index*.

  Parameters

  index The index for the inspection region.

  Throws

  ccPMInspectDefs::BadParams
  The index for the inspection region is not valid.

inspectRegionIndex

```
c_Int32 inspectRegionIndex(const ccCvlString& name) const;
```

Returns the index for the inspection region identified by the string *name.*

Parameters

name The string that identifies the inspection region

Throws

ccPMInspectDefs::BadParams
There is no region identified by *name.*

numInspectRegions

```
c_Int32 numInspectRegions(c_UInt32 mask = 0,
  bool onlyIfEnabled = false) const;
```

Returns the total number of inspection regions whose inspection mode is *mask*. If *onlyIfEnabled* is true only the regions enabled for inspection are counted.

Parameters

mask The inspection mode. This parameter must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference
ccPMInspectDefs::InspectModeModifier

You can assign *cPMInspectDefs::eBlankScene* to *inspReg* but you cannot OR *cPMInspectDefs::eBlankScene* with any of the previous enumerations.

onlyIfEnabled If *true* only the enabled regions are counted. If *false* all the regions are counted.

Throws

ccPMInspectDefs::BadParams
The inspection modality specified by *mask* is not valid.

inspectRegionType

```
void inspectRegionType(cmStd vector<c_UInt32>& codes,
  bool enableMode=false) const;
```

Resizes and initializes the vector *codes*. Each element of the vector contains the bitwise OR of values from the *ccPMInspectDefs::InspectMode* and *ccPMInspectDefs::InspectModeModifier* enumerations. If *enableMode* is true then the vector elements corresponding to the inspection regions that are not enabled are set to zero.

Parameters

codes The vector containing the information on the inspection mode of each region.

enableMode If *true*, the vector elements corresponding to the inspection regions that are not enabled are set to zero. If *false,* the inspection mode of each region is reported.

enableAllRegions

```
void enableAllRegions();
```

Enables all inspection regions.

disableAllRegions

```
void disableAllRegions();
```

Disables all inspection regions.

displayInspectConfig

```
void displayInspectConfig(ccGraphicList& displayList)
 const;
```

Initializes the specified *displayList* with a graphical and text rendering of the current inspection configuration using default colors.

Parameters

displayList The graphic list used to display the current inspection configuration.

Notes

Before training, this function returns the region windows and annotations configured for this pattern. After training, this function returns the region windows and annotations as well as the trained model feature graphics. Note that incomplete results will be obtained when displaying inspection regions configured in boundary feature mode if this function is called before training has completed.

timesStatTrained

```
c_Int32 timesStatTrained(c_UInt32 mask, c_Int32 index)
 const;
```

Returns the number of iterations of statistical training that were performed for the inspection region *index* in the inspection mode specified by *mask*. Returns 0 if the alignment region has not been trained.

Parameters

mask The inspection mode. This parameter must be formed by ORing together 0 or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference

ccPMInspectDefs::InspectModeModifier

You can assign *cPMInspectDefs::eBlankScene* to *inspReg* but you cannot OR *cPMInspectDefs::eBlankScene* with any of the previous enumerations.

index The index for the inspection region

Throws

ccPMInspectDefs::BadParams
The inspection mode specified by *mask* is not valid.
The index for the inspection region is not valid

isModeTrained

```
bool isModeTrained(ccPMInspectDefs::InspectMode mode,
 c_Int32 index) const;

bool isModeTrained(ccPMInspectDefs::InspectMode mode,
 const ccCvlString& name) const;
```

- ```
  bool isModeTrained(ccPMInspectDefs::InspectMode mode,
   c_Int32 index) const
  ```

Returns true if the inspection region *index* has completed training in the inspection mode specified by *mode*.

Parameters

mode The inspection mode. This parameter must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference
ccPMInspectDefs::eBlankScene

Note: When you set an inspection region to *ccPMInspectDefs::eBlankScene* you cannot OR this mode with any of the other modes. See *addInspectRegion* on page 2518 for valid combinations. The mode modifiers shown there are not required for this function.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams
The inspection modality specified by *mode* is not valid.
The index for the inspection region is not valid.
  ```

- `bool isModeTrained(ccPMInspectDefs::InspectMode mode, const ccCvlString& name) const;`

  Returns true if the inspection region identified by *name* has completed training in the inspection mode specified by *mode*.

  Parameters

  mode The inspection mode. This parameter must be formed by ORing together one or more of the following values:

  ccPMInspectDefs::eIntensityDifference
  ccPMInspectDefs::eBPDifference
  ccPMInspectDefs::eBlankScene

  Note: When you set an inspection region to *ccPMInspectDefs::eBlankScene* you cannot OR this mode with any of the other modes. See *addInspectRegion* on page 2518 for valid combinations. The mode modifiers shown there are not required for this function.

  name The string that identifies the inspection region

  Throws

  ccPMInspectDefs::BadParams
  The inspection modality specified by *mode* is not valid. There is no inspection region identified by *name*.

isAlignmentTrained

```
bool isAlignmentTrained() const;
```

Returns true if the training of the alignment region is completed, false otherwise.

run

```
void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
  ccPMInspectResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 diagFlags=0);

void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
```

```
const cmStd vector<cc2Xform>& poses,
ccPMInspectResultSet& resultSet, ccDiagObject* dObj=0,
c_UInt32 diagFlags=0);
```

- ```
  void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
  ccPMInspectResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 diagFlags=0);
  ```

  Performs the inspection on *image* using the parameters specified by *params* and stores the inspection results in *resultSet*. When this function is called all the enabled regions are inspected according to their inspection mode.

  Parameters

  image — The image to inspect.

  params — A **ccPMInspectRunParams** object containing the inspection parameters.

  resultSet — A **ccPMInspectResultSet** object into which the inspection results are placed.

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccPMInspectDefs::NotTrained
  This **ccPMInspectPattern** is not trained.
  This **ccPMInspectPattern** was trained without an alignment region.

  ccPMInspectDefs::BadImage
  The inspection image is unbound.
  ```

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
    const ccPMInspectRunParams& params,
    const cmStd vector<cc2Xform>& poses,
    ccPMInspectResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 diagFlags=0);
  ```

  Performs the inspection on *image* using the parameters specified by *params* and stores the inspection results in *resultSet*. The function uses the vector of poses to perform region alignment. When this function is called all the enabled regions are inspected according to their inspection mode.

  Parameters

  image — The image to inspect.

  params — A **ccPMInspectRunParams** containing the inspection parameters.

  poses — A vector of **cc2Xform**s containing the poses to be used for aligning the inspection regions.

  *result*Set — A **ccPMInspectResultSet** object into which the inspection results are placed

  dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:

  ccDiagDefs::eRecordOn
  ccDiagDefs::eRecordOff

  Throws

  ccPMInspectDefs::NotTrained
  This **ccPMInspectPattern** is not trained.

  ccPMInspectDefs::BadImage
  The inspection image is unbound.

  Notes

  The length of the poses vector argument determines the number of results returned.
  ```

Deprecated Members

The following member functions are deprecated in CVL 5.5.1. They are provided for backward compatibility only and will not cause compilation errors in CVL 5.5.1. It is recommended to update your code to use the newer versions. These functions will be obsoleted after CVL 5.5.1, at which time they will cause compilation errors.

deformation

```
void deformation(double value);

double deformation() const;
```

```
void deformation(double value);
```

Sets the distance in pixels within which boundary points can be matched. This parameter indicates how far away a boundary point in the run-time region can be from a boundary point in the template region and still be considered for a match. The default value is 0.0. The maximum value is 5.0. This function applies only to inspection region 0 when in CVL 5.4 backward compatibility mode.

Parameters

value The distance in pixels within which image and pattern boundary points can be matched.

Throws

ccPMInspectDefs::BadParams

value is less than 0 or greater than 5.0
The index for the inspection region is not valid

- `double deformation() const;`

Returns the distance in pixels within which boundary points can be matched. This function applies only to inspection region 0 when in CVL 5.4 backward compatibility mode.

Notes

Calling this function has no effect.

minFeatureContrast

```
void minFeatureContrast(double contrastThresh);

double minFeatureContrast() const;
```

- `void minFeatureContrast(double contrastThresh);`

  Sets the minimum feature contrast. Only feature boundary points in the run-time image with contrast greater than or equal to the minimum feature contrast are considered as defects. Feature boundary points which do not have the minimum contrast level are discarded before the features are assembled. This function applies only to inspection region 0 when in CVL 5.4 backward compatibility mode.

  Parameters

  contrastThresh The minimum feature contrast, expressed as the number of grey levels.

  Throws

  ccPMInspectDefs::BadParams

  contrast is greater than 255.0 or less than 0.0.
  The index for the inspection region is not valid.

  Notes

  The default minimum feature contrast is 10.0.

- `double minFeatureContrast() const;`

  Returns the minimum feature contrast expressed in grey levels. This function applies only to inspection region 0 when in CVL 5.4 backward compatibility mode.

minFeatureSize

```
void minFeatureSize(c_Int32 minSize);

c_Int32 minFeatureSize() const;
```

- `void minFeatureSize(c_Int32 minSize);`

  Sets the minimum boundary feature size in pixels. This function applies only to inspection region 0.

- `c_Int32 minFeatureSize() const;`

  Returns the minimum boundary feature size in pixels. This function applies only to inspection region 0.

timesStatTrained

```
int timesStatTrained(
  ccPMInspectDefs::InspectMode mode) const;
```

Returns the number of iterations of statistical training performed on the inspection region 0. The inspection mode is defined by *mode*. This function applies only to inspection region 0 when in CVL 5.4 backward compatibility mode.

Parameters

mode — The inspection mode. This parameter must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference

You cannot OR *ccPMInspectDefs::eBlankScene* with any of the previous enumerations.

isDifferenceTrained

```
bool isDifferenceTrained(
  ccPMInspectDefs::InspectMode mode) const;
```

Returns true if this **ccPMInspectPattern** can be used to perform inspections of the specified inspection mode. This is determined by whether or not **endTrain()** has been successfully called for the specified difference type.

Parameters

mode — The inspection mode. This parameter must be formed by ORing together one or more of the following values:

ccPMInspectDefs::eIntensityDifference
ccPMInspectDefs::eBPDifference

Throws

ccPMInspectDefs::BadParams
The inspection modality specified by *mode* is not valid.

run

```
void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
  cmStd vector<ccPMInspectResult>& results);

void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
  const cmStd vector<cc2Xform>& poses,
  cmStd vector<ccPMInspectResult>& results);
```

-
```
void run(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccPMInspectRunParams& params,
  cmStd vector<ccPMInspectResult>& results);
```

Performs the inspection on *image* using the parameters specified by *params* and stores the inspection results in *results*. When this function is called all the enabled regions are inspected according to their inspection mode.

Parameters

image — The image to inspect.

params — A **ccPMInspectRunParams** object containing the inspection parameters.

results — A vector of **ccPMInspectResult** into which the inspection results are placed.

Throws

ccPMInspectDefs::NotTrained
This **ccPMInspectPattern** is not trained.
This **ccPMInspectPattern** was trained without an alignment region.

ccPMInspectDefs::BadImage
The inspection image is unbound.

- ```
  void run(
    const ccPelBuffer_const<c_UInt8>& image,
    const ccPMInspectRunParams& params,
    const cmStd vector<cc2Xform>& poses,
    cmStd vector<ccPMInspectResult>& results);
  ```

  Performs the inspection on *image* using the parameters specified by *params* and stores the inspection results in *results*. The function uses the vector of poses to perform region alignment. When this function is called all the enabled regions are inspected according to their inspection mode.

  Parameters

  image — The image to inspect.

  params — A **ccPMInspectRunParams** object containing the inspection parameters.

  poses — A vector of **cc2Xform**s containing the poses to be used for aligning the inspection regions.

  results — A vector of **ccPMInspectResult**s into which the inspection results are placed.

  Notes

  The length of the *poses* vector argument determines the number of results returned.

  Throws

  ccPMInspectDefs::NotTrained
  This **ccPMInspectPattern** is not trained.

  ccPMInspectDefs::BadImage
  The inspection image is unbound.

boundaryDeformation

```
void boundaryDeformation(double value, c_Int32 index);

double boundaryDeformation(c_Int32 index) const;
```

- ```
  void boundaryDeformation(double value, c_Int32 index);
  ```

  Sets the distance in pixels within which feature boundary points can be matched for the inspection region *index*. This parameter indicates how far away a feature boundary point in the run-time region can be from a feature boundary point in the template region and still be considered for a match. The default value is 0.0. The maximum value is 5.0.

Parameters

value The distance in pixels within which feature boundary points can be matched.

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams

value is less than 0.0 or greater than 5.0.
The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

Notes

Calling this function has no effect in this release.

- `double boundaryDeformation(c_Int32 index) const;`

Returns the distance in pixels within which feature boundary points can be matched for the inspection region *index*.

Parameters

index The index for the inspection region.

Throws

ccPMInspectDefs::BadParams

The index for the inspection region is not valid.
Region *index* does not support feature difference mode.

Notes

Calling this function has no effect in this release.

ccPMInspectRegion

```
#include <ch_cvl/pminspct.h>

class ccPMInspectRegion;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class encodes all the inspection modes and functions assigned to an inspection region and records all the relative statistical training data. This class cannot be directly instantiated.

Constructors/Destructors

This class cannot be directly instantiated.

A **ccPMInspectRegion** object is created when **ccPMInspectPattern::addInspectRegion()** is called. The call to **ccPMInspectPattern::inspectRegion(c_Int32 Index)** returns the reference to the **ccPMInspectRegion** object corresponding to the region *Index*.

Enumerations

InterpolationEx `enum InterpolationEx`

This enumeration defines the interpolation modes supported for blank scene and intensity difference inspection. This interpolation contains the same values as the **ccAffineSamplingParams::Interpolation** with the addtion of the *eBiliearAccurateFast* value.

To specify the *eBilinearAccurateFast* interpolation mode, you must use the **ccPMInspectRegion::interpolationEx()** function instead of **ccPMInspectRegion::interpolation(),** which only accepts the values defined in **ccAffineSamplingParams::Interpolation**.

Note The second enumeration and function are required because while PatInspect supports the *eBilinearAccurateFast* mode, the Affine Sampling tool, with which the **ccAffineSamplingParams::Interpolation** is shared, does not.

Value	Meaning
eNone = 1	Use nearest-neighbor interpolation.
eBilinear = 2 (Also called *eBilinearApprox*)	Use bilinear interpolation of four nearest pixels. This interpolation mode approximates true bilinear interpolation.
eHighPrecision = 3	Use high-precision interpolation to compute the interpolated value.
eBilinearAccurate = 4	Performs an accurate bilinear interpolation of the four nearest pixels. This method is the most accurate.
eBilinearAccurateFast = 5	Performs an accurate bilinear interpolation of the four nearest pixels. This method produces the same result as *eBilinearAccurate*, but is faster.
kDefaultInterpolation	The default mode, *eHighPrecision*

Public Member Functions

inspectRegion

```
ccPelRect inspectRegion() const;
void inspectRegion(ccAffineRectangle& rect);
```

- `ccPelRect inspectRegion() const;`

  Returns this region. This region is the region referenced by **ccPMInspectPattern::inspectRegion(c_Int32 Index)**.

  If this **ccPMInspectRegion** was constructed using an affine rectangle, this function returns the pixel-aligned bounding box that encloses the region.

- `void inspectRegion(ccAffineRectangle& rect);`

  Places this region into the supplied **ccAffineRectangle** this region.

  If this **ccPMInspectRegion** was constructed using a **ccPelRect**, this function returns the equivalent **ccAffineRectangle**.

  Parameters

  rect The **ccAffineRectangle** into which to place the region.

inspectModes

```
c_UInt32 inspectModes() const;
```

Returns the inspection mode of this inspection region. The value returned is the bitwise OR of enumeration entries from *ccPMInspectDefs::InspectMode* and *ccPMInspectDefs::InspectModeModifier* chosen for this region.

enable

```
bool enable()const;

void enable(bool newState);
```

- `bool enable() const;`

  Returns *true* if this region is enabled. Returns *false* if this region is disabled.

- `void enable(bool newState);`

  Sets the enable state of this region to *newState*.

  Parameters

  newState If *true*, this region is enabled, if *false* this region is disabled.

maskImage

```
const ccPelBuffer_const<c_UInt8>& maskImage() const;

void maskImage(const ccPelBuffer_const<c_UInt8>&
  maskImage);
```

- `const ccPelBuffer_const<c_UInt8>& maskImage() const;`

  Returns the mask image for this region.

  Notes

  If no mask is specified, the function returns an unbound pelbuffer.

- `void maskImage(const ccPelBuffer_const<c_UInt8>& maskImage);`

  Sets the mask image for this inspection region.

  Parameters

  maskImage The mask for this inspection region

  Throws

  ccPMInspectDefs::BadImage

  maskImage is unbound or its dimensions and offset do not match those of this region.

  Notes

  The grey-levels of the pixels in the mask encodes 'care' and 'don't care' regions according to the following table (for more information on masking, see *Patmax* in *Vision Tools Guide)*.

Pixel value in mask	Type of region
0 - 127	'don't care' regions
128 - 191	Reserved for future use
192 - 255	'care' regions

hasMaskImage

```
bool hasMaskImage() const;
```

Returns *true* if this region has a valid mask image.

interpolation

```
ccAffineSamplingParams::Interpolation interpolation()
 const;

void interpolation(
 ccAffineSamplingParams::Interpolation value);
```

- `ccAffineSamplingParams::Interpolation interpolation() const;`

  Returns the interpolation method for affine transformation applied to this region.

  Throws

  ccPMInspectDefs::BadParams

  An interpolation mode of *ccPMInspectRegion::eBilinearAccurateFast* was previously set through a call to **ccPMInspectRegion::interpolationEx()**.

- `void interpolation(`
  `ccAffineSamplingParams::Interpolation value);`

  Sets the interpolation method for affine transformation to be applied to this region. The default interpolation method is *ccAffineSamplingParams::eHighPrecision.*

  Parameters

  value The interpolation method to be applied to this region.

  Notes

  To specify the *ccPMInspectRegion::eBilinearAccurateFast* interpolation mode, you must call **ccPMInspectRegion::interpolationEx()** instead of this function.

interpolationEx

```
InterpolationEx interpolationEx() const;

void interpolationEx(InterpolationEx value);
```

- `InterpolationEx interpolationEx() const;`

  Returns the extended interpolation method for affine transformation applied to this region. The returned value is a member of **ccPMInspectRegion::InterpolationEx**.

- `void interpolationEx(InterpolationEx value);`

  Sets the extended interpolation method for affine transformation to be applied to this region. The default extended interpolation method is *ccPMInspectRegion::eHighPrecision.*

  Parameters

  value The interpolation method to be applied to this region.

  Notes

  This second enumeration and function are required because while PatInspect supports the *eBilinearAccurateFast* mode, the Affine Sampling tool, with which the **ccAffineSamplingParams::Interpolation** is shared, does not.

inspectGrainLimit

```
double inspectGrainLimit(void) const;
void inspectGrainLimit(double limit);
```

- `double inspectGrainLimit(void) const;`

  Returns the granularity limit to use for feature difference inspection mode. The granularity limit is the size, in pixels, of the radius of interest for feature detection. Values of less than 1.0 are used to handle under-resolved features (using software zoom).

- `void inspectGrainLimit(double limit);`

  Sets the granularity limit to use for feature difference inspection mode. The granularity limit is the size, in pixels, of the radius of interest for feature detection. Specify a value of less than 1.0 if the image contains under-resolved features.

  Parameters

  limit The granularity limit in pixels. *limit* must be greater than 0.0.

  Throws

  ccPMInspectDefs::BadParams

  limit is less than or equal to 0.0; this region is not configured for feature difference inspection; *limit* is less than 1.0 and software zoom is not enabled (either for training or run time); or *limit* is greater than 1.0 and software zoom is enabled (either for training or run time).

  Notes

  The default granularity limit is 1.0. To specify a non-default value, you must call this function before you call **ccPMInspectPattern::statisticTrain()** for the first time.

name

```
ccCvlString name() const;
void name(const ccCvlString& idStr);
```

- `ccCvlString name() const;`

  Returns the string identifier for this region.

- `void name(const ccCvlString& idStr);`

  Sets the string identifier for this region. The default value is the null string.

Parameters

idStr The string identifier for this region

displayFeatures

```
void displayFeatures(ccGraphicList& displayList,
 const ccColor& c = ccColor::greenColor())
 const;
```

Draws the trained boundary inspection pattern of this region in the graphic list *displayList* using color *c*.

Parameters

displayList The graphic list to be used for drawing

c The color to be used for drawing

Throws

ccPMInspectDefs::NotTrained
The pattern has not been trained for feature difference inspection mode.

ccPMInspectRegion

ccPMInspectResult

```
#include <ch_cvl/pminspct.h>

class ccPMInspectResult : public cc_PMResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single PatInspect result. The member functions of the class return the following set of results:

- Intensity difference mode:
  - Correlation coefficient between template and run-time inspection region
  - Thresholded difference region
  - Inspection region found in the run-time inspection image
- Boundary difference mode:
  - List of matched, missing and extra features between template and run-time inspection region
- Blank scene inspection mode:
  - List of extra defect features

For more information on the set of results returned by PatInspect see *PatInspect* chapter in *Vision Tools Guide*.

The member functions of the class can return the inspection results only if the **ccPMInspectPattern** that was used to generate it has not been deleted, retrained or run on another image.

Note See the **cc_PMResult** class for additional functions common to all PatMax result classes. The class is not archiveable because re-loading a PatInspect result does not guarantee that the **ccPMInspectPattern** associated with it has also been loaded.

Constructors/Destructors

ccPMInspectResult

```
ccPMInspectResult();
```

Constructs an empty **ccPMInspectResult** object.

Public Member Functions

pose

```
const cc2Xform& pose(c_Int32 regionIndex) const;
```

Returns a **cc2Xform** describing the specified inspection region. This function only returns a distinct **cc2Xform** if you specified *ccPMInspectDefs::eFineAlign* when you created the **ccPMInspectPattern** used to produce this result.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::PatternNoLongerValid
The pattern used to produce this result has been changed or deleted.

matchImage

```
ccGrey8PelBuf matchImage(c_Int32 regionIndex)
  const;
```

Returns the part of the inspection region *regionIndex* that matches the corresponding template region, transformed to the training image coordinate system.

Parameters

regionIndex The inspection region.

Throws

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::BadImage
The found matching region is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has been changed, deleted or run on another image.

correlationScore

```
double correlationScore(c_Int32 regionIndex,
  ccPMInspectDefs::NormalizationMethod method =
  ccPMInspectDefs::eIdentity) const;
```

The function computes the correlation coefficient between the normalized inspection region *regionIndex* and the corresponding template region. The region is normalized by using the normalization method specified by *method*. The value returned by the function is in the range 0.0 through 1.0.

Parameters

image The index for the inspection region

method The normalization method applied to the run-time region. *method* must be one of the following values:

ccPMInspectDefs::eIdentity
ccPMInspectDefs::eHistogramEqualize
ccPMInspectDefs::eMeanAndStdDev
ccPMInspectDefs::eMatchTails

Throws

ccPMInspectDefs::NotTrained
The region was not trained for intensity difference.

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::BadImage
The found matching region is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has been changed, deleted or run on another image.

diffImage

```
ccGrey8PelBuf diffImage(c_Int32 regionIndex,
  ccPMInspectDefs::NormalizationMethod method =
                                ccPMInspectDefs::eIdentity,
  ccPMInspectDefs::DiffMode diffMode =
                                        ccPMInspectDefs::eAbs,
  bool returnRawDiffImg = false) const;
```

This function calculates a difference image between the model and the result. The difference image includes information about raw intensity differences. The output of this function can then be processed using vision tools such as blob and others. *diffMode* specifies the method for computing the difference:

If *diffMode* = *ccPMInspectDefs::eAbs*

D(x, y) = max(abs(M(x, y) - Templ(x, y)) - Thresh(x, y), 0)

If *diffMode* = *ccPMInspectDefs::eClampNeg*

D(x, y) = max(M(x, y) - Templ(x, y) - Thresh(x, y), 0)

If *diffMode* = *ccPMInspectDefs::eClampPos*

D(x, y) = max(Templ(x, y) - M(x, y) - Thresh(x, y), 0)

Where *M* is **matchImage()** normalized using *method*, *Templ* is the template image and *Thresh* is the threshold image.

Parameters

regionIndex The index for the inspection region.

method The normalization method to apply to the run-time region. *method* must be one of the following values:

ccPMInspectDefs::eIdentity
ccPMInspectDefs::eHistogramEqualize
ccPMInspectDefs::eMeanAndStdDev
ccPMInspectDefs::eMatchTails

diffMode The pixel sign handling mode used in the difference operation. Must be one of the following values:

ccPMInspectDefs::eAbs
ccPMInspectDefs::eClampNeg
ccPMInspectDefs::eClampPos

returnRawDiffImg
When set true, this function returns an intermediate image that can be useful for debugging.

Throws

ccPMInspectDefs::NotTrained
The region was not trained for intensity difference.

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::BadImage
The found matching region is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has been changed, deleted or run on another image.

getBoundaryDiff

```
void getBoundaryDiff(
  ccPMInspectBoundaryData& data,
  c_Int32 regionIndex, bool coarseEval = false) const;
```

Computes the three lists of boundary feature differences (matched, missing, and extra) detected by PatInspect for the inspection region *index* and stores them in *data*.

Parameters

data A **ccPMInspectBoundaryData** object in which the feature lists are stored.

regionIndex The index for the inspection region.

coarseEval If *true*, some small features may be discarded or incorporated within larger features. If *fals*e, the complete feature lists are generated.

Throws

ccPMInspectDefs::NotTrained
The region was not trained for boundary difference inspection.

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has changed or has been deleted.

getBlankSceneMeasurement

```
getBlankSceneMeasurement(ccPMInspectAbsenceData& data,
  c_Int32 regionIndex)const;
```

Evaluates the blankness of the region *index* and stores the extra boundary features results in *data*.

Parameters

data A **ccPMInspectAbsenceData** object in which the blank scene inspection results are stored.

regionIndex The index for the inspection region.

Throws

ccPMInspectDefs::NotTrained
The region was not trained for blank scene inspection.

ccPMInspectDefs::BadParams
The index for the inspection region is not valid.

ccPMInspectDefs::PatternNoLongerValid
The pattern used to produce the result has changed or has been deleted.

Deprecated Members

The functions listed in this section are deprecated in CVL 5.5.1. They are provided for backward compatibility only and will not cause compilation errors in CVL 5.5.1. It is recommended to update your code to use the newer versions. These functions will be obsoleted after CVL 5.5.1, at which time they will cause compilation errors.

matchImage

```
ccPelBuffer<c_UInt8> matchImage(
  const ccPelBuffer_const<c_UInt8>& image) const;
```

Returns the part of the image that matches the template image, transformed to the training image coordinate system.

Parameters

image The inspection image. This argument is ignored in this release.

Throws

ccPMInspectDefs::BadImage
The found template image is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has changed or has been deleted.

correlationScore

```
double correlationScore(
  const ccPelBuffer_const<c_UInt8>& image,
  ccPMInspectDefs::NormalizationMethod method =
  ccPMInspectDefs::eIdentity) const;
```

The function computes the correlation coefficient between the normalized inspection image and the template image. The image is normalized by using the normalization method specified by *method*. The value returned by the function is in the range 0.0 through 1.0.

Parameters

image The inspection image. This argument is ignored in this release.

method The normalization method applied to the run-time image. *method* must be one of the following values:

ccPMInspectDefs::eIdentity
ccPMInspectDefs::eHistogramEqualize
ccPMInspectDefs::eMeanAndStdDev
ccPMInspectDefs::eMatchTails

Throws

ccPMInspectDefs::NotTrained
The region was not trained for intensity difference.

ccPMInspectDefs::BadImage
The found matching image is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has changed or has been deleted.

diffImage

```
ccPelBuffer<c_UInt8> diffImage(
  const ccPelBuffer_const<c_UInt8>& image,
  ccPMInspectDefs::NormalizationMethod method =
  ccPMInspectDefs::eIdentity) const;
```

This function computes the thresholded difference image between the inspection image and the corresponding template image. Each pixel in the difference image is first set to the absolute difference between the corresponding pixels in the template image and the normalized run-time inspection image. The threshold image is then applied to the result, with all pixels with values less than the value of the corresponding pixel in the thresholded image set to 0.

Parameters

image The inspection image. This argument is ignored in this release.

method The normalization method to apply to the run-time image. *method* must be one of the following values:

ccPMInspectDefs::eIdentity
ccPMInspectDefs::eHistogramEqualize
ccPMInspectDefs::eMeanAndStdDev
ccPMInspectDefs::eMatchTails

Throws

ccPMInspectDefs::NotTrained
Intensity differences were not trained for this run.

ccPMInspectDefs::BadImage
The found matching image is not fully in the field of view.

ccPMInspectDefs::PatternNoLongerValid
The **ccPMInspectPattern** used to produce the result has changed or has been deleted.

getSimpleBoundaryDiff

```
void getSimpleBoundaryDiff(
  ccPMInspectBoundaryData& lists,
  bool coarseEval = false);
```

Computes the three lists of boundary feature differences (matched, missing, and extra) detected by PatInspect and stores them in *lists*.

Parameters

lists A **ccPMInspectBoundaryData** into which the feature lists are stored.

coarseEval If *true*, some small features may be discarded or incorporated within larger features. If *false*, the complete feature lists are generated.

Throws

ccPMInspectDefs::NotTrained
Feature differences were not trained for this run.

ccPMInspectResultSet

```
#include <ch_cvl/pminspct.h>

class ccPMInspectResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that stores all the results of PatInspect for each inspection region.

Constructors/Destructors

ccPMInspectResultSet

```
ccPMInspectResultSet();
```

Constructs an empty **ccPMInspectResultSet** object.

Public Member Functions

results

```
const cmStd vector<ccPMInspectResult>& results() const;
```

Returns a reference to a vector whose elements contain the inspection results for each inspection region.

time

```
double time() const;
```

Returns the execution time required to produce this result set in seconds.

draw

```
void draw(ccGraphicList& graphList, c_UInt32 drawMode,
  const cc2Xform& pose = cc2Xform()) const;
```

Appends result graphics for this **ccPMInspectResultSet** to the supplied **ccGraphicList**.

Parameters

graphList	The graphics list to append the graphics to.
drawMode	The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccPMInspectDefs::eDrawDefectBoundary
ccPMInspectDefs::eDrawMatchingBoundary
ccPMInspectDefs::eDrawExtraBoundary
ccPMInspectDefs::eDrawMissingBoundary

pose The pose, in client coordinates, at which to draw the graphics.

Notes

Missing or defect features are drawn in **ccColor::redColor()**, matching features are drawn in **ccColor::blueColor()**, and extra features are drawn in **ccColor::yellowColor()**.

ccPMInspectRunParams

```
#include <ch_cvl/pminspct.h>

class ccPMInspectRunParams : public cc_PMRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters used to control the location of the alignment region during PatInspect run-time inspection.

Note See the **cc_PMRunParams** class for functions common to all PatMax run-time parameter classes.

Constructors/Destructors

ccPMInspectRunParams

```
ccPMInspectRunParams();
```

Constructs a **ccPMInspectRunParams** object with default values.

ccPMInspectRunParams

ccPMInspectSimpleBoundaryDiffData

```
#include <ch_cvl/pminspct.h>

class ccPMInspectSimpleBoundaryDiffData;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the three lists of features computed by PatInspect.

Note See the **cc_PMRunParams** class for functions common to all PatMax run-time parameter classes.

Constructors/Destructors

ccPMInspectSimpleBoundaryDiffData

```
ccPMInspectSimpleBoundaryDiffData();
```

Constructs an empty instance of this class.

Public Member Functions

match

```
const cmStd vector <ccPMInspectMatchedFeature>& match()
  const;
```

Each element of the returned vector represents a feature from the run-time image that was matched in the template image.

missing

```
const cmStd vector <ccPMInspectUnmatchedFeature>& missing()
  const;
```

Each element of the returned vector represents a feature from the template image that was missing from the run-time image.

extra

```
const cmStd vector <ccPMInspectUnmatchedFeature>& extra()
  const;
```

Each element of the returned vector represents a feature that was present in the run-time image but not in the template image.

ccPMInspectSimpleBoundaryDiffData

minDeformation `double minDeformation();`

Returns the minimum deformation in client coordinate system units across all feature boundary points in all matched features.

maxDeformation `double maxDeformation();`

Returns the maximum deformation in client coordinate system units across all feature boundary points in all matched features.

ccPMInspectStatTrainParams

```
#include <ch_cvl/pminspct.h>

class ccPMInspectStatTrainParams : public cc_PMRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters used to control the location of the alignment region during PatInspect inspection training.

Note See the **cc_PMRunParams** class for functions common to all PatMax run-time parameter classes.

Constructors/Destructors

ccPMInspectStatTrainParams

```
ccPMInspectStatTrainParams();
```

Constructs a **ccPMInspectStatTrainParams** object with default values.

ccPMInspectStatTrainParams

ccPMInspectUnmatchedFeature

```
#include <ch_cvl/bndpnts.h>

template <class P> class ccPMInspectUnmatchedFeature :
  public cc_PMInspectFeature<ccPMInspectBP>;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a feature that is present in the trained PatInspect pattern but not in the run-time image or a feature that is present in the run-time image but not in the trained PatInspect pattern.

Note You should not instantiate this class directly.

Constructors/Destructors

ccPMInspectUnmatchedFeature

```
ccPMInspectUnmatchedFeature();
```

Constructs a **ccPMInspectUnmatchedFeature**.

ccPMInspectUnmatchedFeature

ccPMMatchInfo

```
#include <ch_cvl/pmpbase.h>

class ccPMMatchInfo;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains data about how the pattern features matched the runtime image and/or how the runtime image features matched the pattern.

Do not create an instance of this class.

Constructors/Destructors

ccPMMatchInfo `ccPMMatchInfo();`

Default constructor.

Notes

Do not create an instance of this class.

The default copy constructor, assignment operator, and destructor are used.

Public Member Functions

patternFeatures `const ccFeatureletChainSet& patternFeatures() const;`

Returns the trained features in the pattern, where the feature weights are set to the quality of the match to runtime features.

The pattern features are in the client coordinates of the run-time image.

imageFeatures `const ccFeatureletChainSet& imageFeatures() const;`

Get the features in the runtime image, where the feature weights are set to the quality of the match to a pattern feature.

The image features are in the client coordinates of the run-time image.

displayPattern

```
void displayPattern(ccUITablet& tablet) const;
void displayPattern(ccGraphicList& graphList) const;
```

- `void displayPattern(ccUITablet& tablet) const;`

  Generates a display in the specified **ccUITablet** object showing how the pattern matches the image.

  Parameters

  tablet The tablet where the display is created.

- `void displayPattern(ccGraphicList& graphList) const;`

  Generates a display in the specified **ccGraphicList** object showing how the pattern matches the image.

  Parameters

  graphList The display in graphics list format.

  Notes

  Red features indicate a poor match, yellow ones indicate fair match, and green ones indicate good match, as indicated by the following table.

Feature weight	Quality	Color
[0.00, 0.20)	poor	red
[0.20, 0.67)	fair	yellow
[0.67, 1.00]	good	green

displayImage

```
void displayImage(ccUITablet& tablet) const;
void displayImage(ccGraphicList& graphList) const;
```

- `void displayImage(ccUITablet& tablet) const;`

  Generates a display in the specified **ccUITablet** object showing how the image matches the pattern.

  Parameters

  tablet The tablet where the display is created.

- `void displayImage(ccGraphicList& graphList) const;`

  Generates a display in the specified **ccGraphicList** object showing how the image matches the pattern.

  Parameters

  graphList The display in graphics list format.

  Notes

  Red features indicate a poor match, yellow ones indicate fair match, and green ones indicate good match, as indicated by the following table.

Feature weight	Quality	Color
[0.00, 0.20)	poor	red
[0.20, 0.67)	fair	yellow
[0.67, 1.00]	good	green

ccPMMatchInfo

ccPMMultiModel

```
#include <ch_cvl/pmmm.h>

class ccPMMultiModel;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a PatMax Multi-Model.

Constructors/Destructors

ccPMMultiModel

```
ccPMMultiModel();

~ccPMMultiModel();

ccPMMultiModel(const ccPMMultiModel& rhs);
```

- `ccPMMultiModel();`

  Construct an untrained PatMax Multi-Model with default values.

- `~ccPMMultiModel();`

  Destructs the PatMax Multi-Model.

- `ccPMMultiModel(const ccPMMultiModel& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

Operators

operator=

```
ccPMMultiModel& operator=(const ccPMMultiModel& rhs);
```

Assignment operator.

Parameters

rhs Source of the assignment.

Public Member Functions

addModel

```
c_Int32 addModel(
const ccPMAlignPattern& model,
ccPMMultiModelDefs::GrainLimitPolicy grainLimitPolicy =
ccPMMultiModelDefs::kMustMatch,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

Adds a traditionally-trained PatMax model to the Multi-Model and returns the internally assigned id. This model must not have been trained using Composite Model training. See **addCompositeModel()** for that use case.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kMustMatch*, then the coarse and fine granularity limits of the passed PatMax model and those of the component PatMax models already contained in the **ccPMMultiModel** instance are required to match.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainAtFinest*, then the granularity limits of the passed PatMax model and those already contained in the **ccPMMultiModel** instance will be examined. The finest coarse granularity limit and the finest fine granularitygrain limit will then be used to either retrain a copy of the passed PatMax model or all the existing PatMax models contained in the Multi-Model or both. Any model or models that are already trained for these granularity limits will not be affected.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainExistingWithNew* and the passed model's coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then all these models will be retrained at the passed model's granularity limits.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainNewWithExisting* and the passed model's coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then a copy of the passed PatMax model will be retrained with the granularity limits of the models already contained in the **ccPMMultiModel** instance and before being added to the **ccPMMultiModel** instance.

Parameters

model The PatMax model to add.

grainLimitPolicy The granularity limit policy.

diagobj A diagnostic object.

diagFlags Diagnostic flags.

Notes

This function makes a deep copy of the passed **ccPMAlignPattern** object.

Throws

MissingTrainingImage

The passed model was trained with **ccPMAlignPattern::saveImage()** == false.

BadParams

grainLimitPolicy == ccPMMultiModelDefs::kMustMatch and either the model's **coarseGrainLimit()** and/or its **fineGrainLimit()** does not match that of the models already added to (contained in) the Multi-Model.
OR
The passed model was trained using Composite Model training.

addCompositeModel

```
c_Int32 addCompositeModel(
const ccPMCompositeModelManager& compModelMgr,
const ccPMCompositeModelParams& params,
ccPMMultiModelDefs::GrainLimitPolicy grainLimitPolicy =
ccPMMultiModelDefs::kMustMatch,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

Adds a Composite PatMax Model to the Multi-Model and returns the internally assigned id. The Multi-Model will make a copy of the passed **ccPMCompositeModelManager** and **ccPMCompositeModelParams** and use these to train an internal PatMax model.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kMustMatch*, then the coarse and fine granularity limits of the passed Composite Model Manager and those of the component PatMax models already contained in the **ccPMMultiModel** instance are required to match.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainAtFinest*, then the granularity limits of the passed Composite Model Manager and those already contained in the **ccPMMultiModel** instance will be examined. The finest coarse granularity limit and the finest fine granularity limit will then be used to either retrain a copy of the passed

Composite Model Manager or all the existing PatMax models contained in the Multi-Model or both. Any model or models that are already trained for these granularity limits will not be affected.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainExistingWithNew*, then if the passed Composite Model Manager's coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then all these models will be retrained at the passed model's granularity limits.

If *grainLimitPolicy* equals *ccPMMultiModelDefs::kRetrainNewWithExisting*, then if the passed Composite Model Manager's coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then a copy of the passed Composite Model Manager will be retrained with the granularity limits of the models already contained in the **ccPMMultiModel** instance and before being added to the **ccPMMultiModel** instance.

Parameters

compModelMgr	The Composite Model Manager to be added.
params	The Composite Model parameters.
grainLimitPolicy	The granularity limit policy.
diagobj	A diagnostic object.
diagFlags	Diagnostic flags.

Notes

This function makes deep copies of the passed **ccPMCompositeModelManager** and **ccPMCompositeModelParams** objects.

Throws

BadParams

grainLimitPolicy == *ccPMMultiModelDefs::kMustMatch* and either the Composite Model Manager's coarse or fine granularity does not match that of the models already added to (contained in) the Multi-Model.

MissingTrainingImage

The passed *grainLimitPolicy* != *ccPMMultiModelDefs::kMustMatch* and the passed Composite Model Manager or one of any previously added Composite Model Managers requires retraining and was originally trained with **ccPMCompositeModelManager::saveImages()** == false.

numModels

```
c_Int32 numModels() const;
```

Returns the number of component models in the Multi-Model.

The default is 0.

getModelIds

```
cmStd vector<c_Int32> getModelIds() const;
```

Returns a list of model id's for all models contained in the Multi-Model

The default is an empty vector.

model

```
const ccPMAlignPattern& model(c_Int32 modelId) const;
```

Returns a reference to the model corresponding to the supplied id.

Parameters

modelId The model id you supply.

Throws

BadParams

The passed *modelId* is invalid.

removeModel

```
void removeModel(c_Int32 modelId);
```

Removes a model from the Multi-Model. If the Multi-Model owns the model to be removed, then the model will be deleted from the memory.

Parameters

modelId The model id of the model to be removed.

Throws

BadParams

The passed *modelId* is invalid.

resultStatisticWindowLength

```
c_Int32 resultStatisticWindowLength() const;
void resultStatisticWindowLength(c_Int32 length);
```

- `c_Int32 resultStatisticWindowLength() const;`

Returns the window over which result statistics are collected.

- `void resultStatisticWindowLength(c_Int32 length);`

  Sets the window over which result statistics are collected.

  Result statistics are used to compute the most successful model when the run-time mode is set to *ccPMMultiModelDefs::kSequentialMostSuccessful*.

  The default is 10.

  Parameters
  length The length of the window.

  Notes
  Calling the setter causes any existing result statistics to be flushed.

  Throws
  BadParams
  length <= 0

resetResultStatistics

`void resetResultStatistics();`

Resets the statistics that are used to compute the most successful model when the run-time mode is set to *ccPMMultiModelDefs::kSequentialMostSuccessFul*.

modelIdQueue

`cmStd vector<c_Int32> modelIdQueue() const;`

`void modelIdQueue(cmStd vector<c_Int32> modelIdQueue);`

- `cmStd vector<c_Int32> modelIdQueue() const;`

  Returns the model queue used in all sequential run-time modes.

- `void modelIdQueue(cmStd vector<c_Int32> modelIdQueue);`

  Sets the model queue used in all sequential run-time modes.

  It is intended that you may modify the queuing sequence to create model queuing sequences tailored to their application. The queuing sequence may be modified between calls to **ccPMMultiModel::run()** allowing you to create dynamic queuing schemes.

  The default is an empty vector.

  Parameters
  modelIdQueue The model queue.

Notes

The *modelIdQueue* does not have to contain entries for all the models contained in the Multi-Model.

If runtime parameter **ccPMMultiModelRunParams::mode()** is *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful* or *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the *modelIdQueue* will be updated during a call to run.

If **ccPMMultiModelRunParams::mode()** is *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful*, then the queue will be re-ordered so that the model achieving the highest score moves to the front.

If **ccPMMultiModelRunParams::mode()** is *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the queue will be re-ordered so that the models are ranked in order of success tabulated over the previous **resultStatisticWindowLength()** calls to run.

Throws

BadParams

modelIdQueue is supplied with a model id that does not correspond to a model contained within the Multi-Model, *or modelIdQueue* is supplied with a model id vector that contains duplicate entries for the same model.

---

run

```
void run(
const ccPelBuffer_const<c_UInt8>& inputImage,
const ccPMMultiModelRunParams& params,
ccPMMultiModelResultSet& resultSet,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);

void run(
const ccPelBuffer_const<c_UInt8>& inputImage,
const ccPelBuffer_const<c_UInt8>& mask,
const ccPMMultiModelRunParams& params,
ccPMMultiModelResultSet& resultSet,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);

void run(
const ccPelBuffer_const<c_UInt8>& inputImage,
const ccPMMultiModelRunParams& params,
const cc2XformBasePtrh_const& startPose,
```

```
ccPMMultiModelResultSet& resultSet,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);

void run(
const ccPelBuffer_const<c_UInt8>& inputImage,
const ccPelBuffer_const<c_UInt8>& mask,
const ccPMMultiModelRunParams& params,
const cc2XformBasePtrh_const& startPose,
ccPMMultiModelResultSet& resultSet,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

- ```
  void run(
  const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPMMultiModelRunParams& params,
  ccPMMultiModelResultSet& resultSet,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);
  ```

  Run this Multi-Model on the given image with the given run-time parameters. The supplied *resultSet* will be cleared and then filled with new results, in order of decreasing score.

  If the run-time mode is equal to *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful* or *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the internal queuing sequence of the component models will be updated with the results from this call to run.

  Parameters

inputImage	The input image.
params	The Multi-Model run-time parameters.
resultSet	The result set.
diagobj	A diagnostic object.
diagFlags	Diagnostic flags.

  Notes

  The function is terminated if it runs longer than the timeout specified by the *params* argument. If this occurs, no valid results are produced by the tool.

  Throws

NotTrained	This Multi-Model is empty or any of the component models is not currently trained.
  ```

BadImage
The *inputImage* is unbound.

BadParams
Any of the component models was not trained for the algorithm selected by the *params* argument,
or run-time parameter
ccPMMultiModelRunParams::isModeSequential() == true and run-time parameters
ccPMMultiModelRunParams::confusionThreshold() < **ccPMMultiModelRunParams::acceptThreshold()**

NotImplemented
ccPMMultiModelRunParams::algorithm is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp*.

ccTimeout::Expired
This function executes longer than the timeout you specified.

- ```
  void run(
  const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPMMultiModelRunParams& params,
  ccPMMultiModelResultSet& resultSet,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);
  ```

  Run this Multi-Model on the given image with the given run-time parameters. The supplied *resultSet* will be cleared and then filled with new results, in order of decreasing score.

  If the run-time mode is equal to *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful* or *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the internal queuing sequence of the component models will be updated with the results from this call to run.

  Parameters

inputImage	The input image.
mask	The mask used to specify care pixels in the input image.
params	The Multi-Model run-time parameters.
resultSet	The result set.
diagobj	A diagnostic object.
diagFlags	Diagnostic flags.
  ```

Notes

In the *mask*, pixels less than 128 indicate "don't care" pixels in the search image. Those greater than or equal to 128 denote "care" pixels in the search image. All feature boundary points that fall within "don't care" pixels are discarded.

The function is terminated if it runs longer than the timeout specified by the *params* argument. If this occurs, no valid results are produced by the tool.

Throws

NotTrained

This Multi-Model is empty or any of the component models is not currently trained.

BadImage

The *inputImage* is unbound,
or the *mask* is unbound or the *mask*'s region is not equal to the *inputImage*'s region.

BadParams

Any of the component models was not trained for the algorithm selected by the *params* argument,
or run-time parameter
ccPMMultiModelRunParams::isModeSequential() == true and run-time parameters
ccPMMultiModelRunParams::confusionThreshold() < **ccPMMultiModelRunParams::acceptThreshold()**

NotImplemented

ccPMMultiModelRunParams::algorithm is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp*.

ccTimeout::Expired

This function executes longer than the timeout you specified.

-
```
void run(
const ccPelBuffer_const<c_UInt8>& inputImage,
const ccPMMultiModelRunParams& params,
const cc2XformBasePtrh_const& startPose,
```

```
ccPMMultiModelResultSet& resultSet,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

Using the supplied starting pose as a coarse pose of the pattern in the *inputImage*, this method returns a further refined search results based on the given run-time parameters

The supplied *resultSet* will be cleared and then filled with the single new result.

If the run-time mode is equal to *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful* or *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the internal queuing sequence of the component models will be updated with the results from this call to run.

Parameters

inputImage	The input image.
params	The Multi-Model run-time parameters.
startPose	The start pose.
resultSet	The result set.
diagobj	A diagnostic object.
diagFlags	Diagnostic flags.

Notes

startPose is a client-to-client transform representing a coarse initial pose which is subsequently refined.

The function is terminated if it runs longer than the timeout specified by the *params* argument. If this occurs, no valid results are produced by the tool.

Throws

NotTrained

This Multi-Model is empty or any of the component models is not currently trained.

BadImage

The *inputImage* is unbound.

BadParams

This pattern was not trained for the algorithm selected by the *params* argument,
or the run-time parameter
ccPMMultiModelRunParams::isModeSequential() == true and run-time parameters

ccPMMultiModelRunParams::confusionThreshold() < **ccPMMultiModelRunParams::acceptThreshold()**, *or startPose* == NULL

NotImplemented
ccPMMultiModelRunParams::algorithm is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp*, *or ccPMMultiModelRunParams::algorithm* is *cc_PMDefs::kPatquick* and *startPose* != NULL, *or* ! **startPose.isLinear()**

ccTimeout::Expired
This function executes longer than the timeout you specified.

- ```
  void run(
  const ccPelBuffer_const<c_UInt8>& inputImage,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccPMMultiModelRunParams& params,
  const cc2XformBasePtrh_const& startPose,
  ccPMMultiModelResultSet& resultSet,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);
  ```

  Using the supplied starting pose as a coarse pose of the pattern in the *inputImage*, this method returns a further refined search results based on the given run-time parameters.

  The supplied *resultSet* will be cleared and then filled with the single new result.

  If the run-time mode is equal to *ccPMMultiModelDefs::kSequentialMostRecentlySuccessful* or *ccPMMultiModelDefs::kSequentialMostSuccessful*, then the internal queuing sequence of the component models will be updated with the results from this call to run.

  Parameters

inputImage	The input image.
mask	The mask used to specify care pixels in the input image.
params	The Multi-Model run-time parameters.
startPose	The start pose.
resultSet	The result set.
diagobj	A diagnostic object.
diagFlags	Diagnostic flags.
  ```

Notes

startPose is a client-to-client transform representing a coarse initial pose which is subsequently refined.

In the mask, pixels less than 128 indicate "don't care" pixels in the search image. Those greater than or equal to 128 denote "care" pixels in the search image. All feature boundary points that fall within "don't care" pixels are discarded.

The function is terminated if it runs longer than the timeout specified by the *params* argument. If this occurs, no valid results are produced by the tool.

Throws

NotTrained

This Multi-Model is empty or any of the component models is not currently trained.

BadImage

The *inputImage* is unbound,
or the *mask* is unbound or the *mask*'s region is not equal to the *inputImage*'s region.

BadParams

This pattern was not trained for the algorithm selected by the params argument,
or the run-time parameter
ccPMMultiModelRunParams::isModeSequential() == true and run-time parameters
ccPMMultiModelRunParams::confusionThreshold() < **ccPMMultiModelRunParams::acceptThreshold()**,
or startPose == NULL

NotImplemented

ccPMMultiModelRunParams::algorithm is *cc_PMDefs::kPatflex* or *cc_PMDefs::kPatpersp*,
or ccPMMultiModelRunParams::algorithm is *cc_PMDefs::kPatquick* and *startPose* != NULL,
or ! **startPose.isLinear()**

ccTimeout::Expired

This function executes longer than the timeout you specified.

ccPMMultiModel

ccPMMultiModelDefs

```
#include <ch_cvl/pmmm.h>

class ccPMMultiModelDefs;
```

A name space that holds enumerations used with the Multi-Model PatMax tool.

Enumerations

RuntimeMode `enum RuntimeMode;`

This enumeration defines the run-time mode.

Value	Meaning
kSequential = 1	Models are run in a predefined order (queue) until enough results are found with scores greater than or equal to a user-defined confusion threshold to satisfy the PatMax **ccPMMultiModelRunParams::numToFind()** run-time parameter. You define the confusion threshold with **ccPMMultiModelRunParams::confusionThreshold()**. A separate run-time parameter, **ccPMMultiModelRunParams::useXYOverlapBetweenModels()** determines whether lower scoring overlapping results are discarded and are therefore not counted towards the total applied to the **ccPMMultiModelRunParams::numToFind()** threshold. A further run-time parameter, **ccPMMultiModelRunParams::reportResultsFromOneModelOnly()** can be used to allow results from only one PatMax model (within the PatMax Multi-Model) to be counted towards the **ccPMMultiModelRunParams::numToFind()** threshold. (This is intended to address the use case where the application knows that it wants to find/count multiple parts and the parts may be of various types, for example, type A, type B, type C, and so on. In addition, the application has apriori knowledge that at any one time the field of view will contain parts of only one type. The sequence of the type, however, cannot be predicted with certainty.) The order of model execution (queuing sequence) is settable through the external API and this may be done after each run-time call, if so desired. If no models score greater than or equal to the **ccPMMultiModelRunParams::confusionThreshold()**, then the single model results from the highest scoring model are returned.
kSequentialMostRecentlySuccessful = 2	A variant on sequential mode, where after each call to run the successful model is promoted to first in the queuing sequence.

Value	Meaning
kSequentialMostSuccessful = 3	A variant on sequential mode, where after each call to PatMax Multi-Model run-time, a histogram tabulating the successful model id's of the previous N calls run-time is updated (N is an integer you define that provides the temporal window over which model "success" is evaluated). The queuing sequence is then set to reflect the relative values in this histogram.
kExhaustive = 4	All models in a Multi-Model are executed simultaneously (using as many processor cores as are enabled by the work manager – see *ch_cvl/workmgr.h*). The reported result set includes single model results either from all models (if **ccPMMultiModelRunParams::reportResultsFromOneModelOnly()** is false) or just a single model (if **ccPMMultiModelRunParams::reportResultsFromOneModelOnly()** is true). The results are sorted in order of highest score first. The component model used to generate each individual result is identifiable through the API.

GrainLimitPolicy

```
enum GrainLimitPolicy;
```

This enumeration defines the granularity limit policy.

Value	Meaning
kMustMatch = 0	The coarse and fine granularity limits of the passed PatMax model (or Composite Model Manager) and those of the component PatMax models already contained in the **ccPMMultiModel** instance are required to match.
kRetrainAtFinest = 1	The granularity limits of the passed PatMax model (or Composite Model Manager) and those already contained in the **ccPMMultiModel** instance will be examined. The finest coarse granularity limit and the finest fine granularitygrain limit will then be used to either retrain a copy of the passed PatMax model (or Composite Model Manager) or all the existing PatMax models contained in the Multi-Model or both. Any model or models that are already trained for these granularity limits will not be affected.
kRetrainExistingWithNew = 2	If the passed model's (or Composite Model Manager's) coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then all these models will be retrained at the passed model's granularity limits.
kRetrainNewWithExisting = 3	If the passed model's (or Composite Model Manager's) coarse and/or fine granularity limit is/are different from the granularity limits of the component PatMax models already contained in the **ccPMMultiModel** instance, then a copy of the passed PatMax model (or Composite Model Manager) will be retrained with the granularity limits of the models already contained in the **ccPMMultiModel** instance and before being added to the **ccPMMultiModel** instance.

ccPMMultiModelDefs

ccPMMultiModelResultSet

```
#include <ch_cvl/pmmm.h>

class ccPMMultiModelResultSet : public ccPMAlignResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a PatMax Multi-Model result set.

Constructors/Destructors

ccPMMultiModelResultSet

```
ccPMMultiModelResultSet();
```

Constructs an empty result set.

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

draw

```
void draw(
ccGraphicList& graphList,
c_UInt32 drawMode = ccPMAlignDefs::eDrawStandard,
bool drawOnlyAccepted = false) const;
```

Appends graphics for all results to *graphList*. *drawMode* is used to select which graphics are drawn (see the comment in **ccPMAlignResult::draw()**).

The *drawOnlyAccepted* argument, if true, causes this function to append graphics of only the accepted results. If it is false, graphics of all results are appended.

Parameters

graphList The graphics list.

drawMode The draw mode.

drawOnlyAccepted
Whether to append graphics of only the accepted results.

trainMethod `ccPMAlignDefs::TrainMethod trainMethod(c_Int32 modelId);`

Returns the training method for the supplied model ID.

Parameters

modelId The model ID.

Friends

ccPMMultiModel

```
friend class ccPMMultiModel;
```

ccPMAlignResult

```
friend class ccPMAlignResult;
```

ccPMMultiModelRunParams

```
#include <ch_cvl/pmmm.h>

class ccPMMultiModelRunParams : public ccPMAlignRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains PatMax Multi-Model run-time parameters.

Constructors/Destructors

ccPMMultiModelRunParams

```
ccPMMultiModelRunParams();
```

Constructs a **ccPMMultiModelRunParams** object using the default values.

Notes

The compiler-generated copy constructor, assignment operator, and destructor are used.

Public Member Functions

mode

```
ccPMMultiModelDefs::RuntimeMode mode() const;

void mode(ccPMMultiModelDefs::RuntimeMode mode);
```

- ```
  ccPMMultiModelDefs::RuntimeMode mode() const;
  ```

  Returns the run-time mode.

- ```
  void mode(ccPMMultiModelDefs::RuntimeMode mode);
  ```

  Sets the run-time mode.

  The default is *ccPMMultiModelDefs::kSequential*

  Parameters

mode	The run-time mode to be set.

Throws

BadParams

The setter is given a value that is not a member of **ccPMMultiModelDefs::RuntimeMode**.

isModeSequential

```
bool isModeSequential() const;
```

Gets whether the run-time mode is sequential.

The default is true.

isModeExhaustive

```
bool isModeExhaustive() const;
```

Gets whether the run-time mode is exhaustive.

The default is false.

confusionThreshold

```
double confusionThreshold() const;
void confusionThreshold(double threshold);
```

- `double confusionThreshold() const;`

  Returns the confusion threshold.

- `void confusionThreshold(double threshold);`

  Sets the confusion threshold.

  If **isModeSequential()** is true, then the confusion threshold is used to determine the stopping condition of the sequential search, that is, if the total number of results found scoring greater than or equal to **confusionThreshold()** is greater than or equal to **numToFind()**, then no further PatMax models within a **ccPMMultiModel** instance will be run.

  The default is 0.5 (which is identical to the default **acceptThreshold()**).

  Parameters

  threshold The confusion threshold to be set.

Notes

If **isModeSequential()** equals true and **confusionThreshold()** is less than **acceptThreshold()**, then the **ccPMMultiModel** run functions will throw *BadParams*

The confusion threshold is not used if **isModeSequential()** == false.

Throws

BadParams

The setter is given a value < 0 or > 1

useXYOverlapBetweenModels

```
bool useXYOverlapBetweenModels() const;
void useXYOverlapBetweenModels(bool enabled);
```

- `bool useXYOverlapBetweenModels() const;`

  Returns whether the **xyOverlap()** threshold will be applied to results generated by different models run from a **ccPMMultiModel** instance.

- `void useXYOverlapBetweenModels(bool enabled);`

  Sets whether the **xyOverlap()** threshold will be applied to results generated by different models run from a **ccPMMultiModel** instance.

  If **useXYOverlapBetweenModels()** equals true and two results from different models overlap by greater than **xyOverlap()**, then only the higher scoring of these results will be returned in the result set. Also, if **isModeSequential()** equals true, **useXYOverlapBetweenModels()** equals true, and two results from different models overlap by greater than **xyOverlap()**, then only the higher scoring of these results will count towards reaching the **numToFind()** stopping condition of the sequential search.

  The default is true.

  Parameters

  enabled — Whether the **xyOverlap()** threshold will be applied to results generated by different models run from a **ccPMMultiModel** instance.

reportResultsFromOneModelOnly

```
bool reportResultsFromOneModelOnly() const;

void reportResultsFromOneModelOnly(bool enabled);
```

- `bool reportResultsFromOneModelOnly() const;`

  Returns whether results are to be reported from one component PatMax model contained within a **ccPMMultiModel** instance.

- `void reportResultsFromOneModelOnly(bool enabled);`

  Sets whether results are to be reported from one component PatMax model contained within a **ccPMMultiModel** instance.

  If **reportResultsFromOneModelOnly()** equals true and **isModeSequential()** equals true, then only results from one model will be reported and only results from one model will count towards reaching the **numToFind()** stopping condition of the sequential search.

  If **reportResultsFromOneModelOnly()** equals true and no component PatMax models generate greater than or equal to **numToFind()** results with scores greater than or equal to **acceptThreshold()**, then the results from the single model with the most results scoring greater than or equal to **acceptThreshold()** will be returned. In the event of a tie, results from the model with the highest single score will be returned.

  The default is false.

  Parameters

enabled	Whether results are to be reported from one component PatMax model contained within a **ccPMMultiModel** instance.

ccPMPerspectiveResult

```
#include <ch_cvl/pmpbase.h>

class ccPMPerspectiveResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single PatPersp result. You should not instantiate objects of this class in your programs. **ccPMPerspectiveResult** objects are created for you as needed.

To run PatPersp, prepare PatMax using the *kPatpersp* algorithm. You run PatPersp by calling **ccPMAlignPattern::run()** as you would for other PatMax algorithms.

PatMax runs using the PatPersp algorithm and produces a PatPersp result along with its normal results. You access the PatPersp result with the getter **cc_PMResult::perspectiveResult()**.

The PatPersp result contains the **ccPMPerspectiveResult::perspectiveXformRunImageFromTrainImage()** deformation transform that you can apply to the run-time image to transform it into an image that matches the trained model. Cognex provides the global function **cfSampledImageWarp()** you can use for this transformation.

Constructors/Destructors

The default constructor, destructor, copy constructor, and assignment operator are used. Do not instantiate this class in your programs. Objects are created for you as needed.

Public Member Functions

perspectivePose

```
cc2XformPerspectivePtrh_const perspectivePose() const;
```

Returns a perspective transform that maps the pattern of the run-time image to the client coordinates of the run-time image. This is a pattern-coordinates-to-client-coordinates transform.

Notes

If not the PatPersp algorithm is run or PatPersp fails to find any result, this will be a null pointer-handle.

perspectiveXformRunImageFromTrainImage

```
cc2XformPerspectivePtrh_const
perspectiveXformRunImageFromTrainImage() const;
```

Returns a perspective transform that maps the training image to the image coordinates of the run-time image. This is an image-coordinates-to-image-coordinates transform.

Notes

If not the PatPersp algorithm is run or PatPersp fails to find any result, this will be a null pointer-handle.

ccPNG

```
#include <ch_cvl/png.h>

class ccPNG;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class defines the API for loading and storing various types of images in CVL in Portable Network Graphics (PNG) format, including:

a. 8-bit images

b. 16-bit images

c. 3-channel 8-bit color images (encoded as 24-bit packed)

d. 4-channel 8-bit color images (encoded as 32-bit packed)

e. 3-plane 8-bit images

PNG is a lossless image compression format.

The API provides interface to the PNG image file's Signficant Bits (the number of significant bits encoded in a PNG image file) - via **ccPNG::numSignificantBits()**, a getter function.

Notes

The user can only set the *numSignificantBits* value for 16-bit images (that is, **numSignificantBits()** is automatically set to 8 for 8-bit images, 3-plane 8-bit images, 3-channel 8-bit color images, and 4-chanel 8-bit color images).

Each image's image-coordinate offset is stored into/loaded from the PNG file. In other words, the PNG file contains the image coordinate offset.

Each image's client-coordinate transform is not stored into, nor loaded from, the PNG file. In other words, the PNG file does not contain the client coordinate transform. Consequently, images loaded from PNG data always have identity client coordinates.

The **pelBuffer()** getter functions return deep copies of the pel buffers.

Enumerations

ImageType

```
enum ImageType;
```

These values specify the image types.

Value	Meaning
eImage8Bit	8 bit image type.
eImage16Bit	16 bit image type.
eImageColor	Color image type.

Constructors/Destructors

ccPNG

```
ccPNG();
```

Constructs an uninitialized **ccPNG** object with no image pixel data and *numSignificantBits* == 0.

Notes

Compiler-generated copy constructor and assignment operator are used.

Public Member Functions

init

```
void init(const ccCvlString& filename);

void init(cmStd istream&);

void init(const ccPelBuffer_const<c_UInt8>& pelBuf);

void init(const ccPelBuffer_const<c_UInt16>& pelBuf,
  c_Int32 numSignificantBits = 16);

void init(const ccPelBuffer_const<ccPackedRGB32Pel>&
  pelBuf);

void init(const cc3PlanePelBuffer_const& pelBuf);
```

- `void init(const ccCvlString& filename);`

Reads a PNG from the given filename and initializes this object with pixel data.

Parameters

filename The name of the file.

Notes

Sets the *numSignificantBits* value from the file.

Sets the *imageType* according to the file content.

Throws

ccPNG::ReadError
The given file cannot be opened or read.

ccPNG::BadFormat
The given file is not in the proper PNG format.

- `void init(cmStd istream&);`

Reads a PNG from the given istream and initializes this object with pixel data. This operation moves the stream position to the end of this PNG data.

Parameters

istream The given istream.

Notes

Sets the *numSignificantBits* value from the stream.

Sets the *imageType* according to the PNG content of the stream.

Throws

ccPNG::ReadError
The given istream is not in the proper PNG format.

- `void init(const ccPelBuffer_const<c_UInt8>& pelBuf);`

Given a pelBuffer, initializes this object with image data from the pelBuffer.

Parameters

pelBuf The given pelBuffer.

Notes

Sets the *numSignificantBits* to 8.

Sets the *imageType* to *eImage8Bit*.

The image's image-coordinate offset is stored.

The image's client-coordinate transform is not stored.

Throws

ccPel::UnboundWindow
pelBuf is not bound.

- `void init(const ccPelBuffer_const<c_UInt16>& pelBuf, c_Int32 numSignificantBits = 16);`

  Given a pelBuffer, initializes this object with image data from the pelBuffer, and stores the provided *numSignificantBits* value.

  Parameters

  pelBuf The given pelBuffer.

  numSignificantBits
  The number of significant bits.

  Notes

  Sets the *imageType* to *eImage16Bit.*

  The image's image-coordinate offset is stored.

  The image's client-coordinate transform is not stored.

  Throws

  ccPNG::BadParams
  numSignificantBits < 8 OR *numSignificantBits* > 16

  ccPel::UnboundWindow
  pelBuf is not bound.

  ccPNG::BadParams
  Any pel in pelBuf has greylevel greater than (or equal to) 1 << *numSignificantBits*.

- `void init(const ccPelBuffer_const<ccPackedRGB32Pel>& pelBuf);`

  Given a pelBuffer, initializes this object with image data from the pelBuffer.

  Parameters

  pelBuf The given pelBuffer.

  Notes

  Sets the *numSignificantBits* to 8.

  Sets the *imageType* to *eImageColor*.

  The image's image-coordinate offset is stored.

  The image's client-coordinate transform is not stored.

  Throws

ccPel::UnboundWindow
pelBuf is not bound.

- `void init(const cc3PlanePelBuffer_const& pelBuf);`

Given a pelBuffer, initializes this object with image data from the pelBuffer.

Parameters
pelBuf The given pelBuffer.

Notes
Sets the *numSignificantBits* to 8.

Sets the *imageType* to *eImageColor*.

The image's image-coordinate offset is stored.

The image's client-coordinate transform is not stored.

Throws
ccPel::UnboundWindow
pelBuf is not bound

imageType `ImageType imageType() const;`

Returns the image type associated with this **ccPNG** object.

Throws
ccPNG::NoPngData
This **ccPNG** was default constructed.

---

write `void write(const ccCvlString& filename) const;`

`void write(cmStd ostream&) const;`

- `void write(const ccCvlString& filename) const;`

Writes this **ccPNG** object out to the given file in PNG format.

Parameters
filename The name of the file.

Throws
ccPNG::NoPngData
This **ccPNG** was default constructed.

- `void write(cmStd ostream&) const;`

Writes this **ccPNG** object out to the given stream in PNG format.

Parameters

ostream The given ostream.

Throws

ccPNG::WriteError
The given stream cannot be written.

ccPNG::NoPngData
This **ccPNG** was default constructed.

---

pelBuffer

```
ccPelBuffer<c_UInt8> pelBuffer() const;

void pelBuffer(ccPelBuffer<c_UInt16>& pelBuf) const;

void pelBuffer(ccPelBuffer<ccPackedRGB32Pel>& pelBuf)
 const;

void pelBuffer(cc3PlanePelBuffer& pelBuf) const;
```

- `ccPelBuffer<c_UInt8> pelBuffer() const;`

Returns a pelBuffer representation of this **ccPNG** object.

Notes

A 16-bit pel buffer (or PNG file) is scaled down to 8 bits by rightshifting by **numSignficantBits()**-8 and then clamped to 255.

A color pel buffer (or PNG file) is converted to greyscale. The algorithm used for converting color PNGs to 8-bit images is as follows:
pixel value = (Red + Green + Blue) / 3

The image's image-coordinate offset is read from the data.

The image's client-coordinate transform is identity.

Throws

ccPNG::NoPngData
This **ccPNG** was default constructed.

- `void pelBuffer(ccPelBuffer<c_UInt16>& pelBuf) const;`

Fills in a pelBuffer representation of this **ccPNG** object.

Parameters

pelBuf The pelBuffer.

Notes

An 8-bit pel buffer (or PNG file) is converted into a 16-bit pel buffer.

A color pel buffer (or PNG file) is converted to greyscale. The algorithm used for converting color PNGs to 8 bit values in a 16-bit image is as follows:
pixel value = (Red + Green + Blue) / 3

pelBuf's image-coordinate offset is read from the data.

pelBuf's client-coordinate transform is set to identity.

The function will discard the originally provided *pelBuf* and allocate an appropriately sized image. In other words, the *pelBuf* provided will be ignored and not be reused.

Throws

ccPNG::NoPngData

This **ccPNG** was default constructed.

- `void pelBuffer(ccPelBuffer<ccPackedRGB32Pel>& pelBuf) const;`

Fills in a color pelBuffer representation of this **ccPNG** object.

Parameters

pelBuf The pelBuffer.

Notes

An 8-bit greyscale pel buffer (or PNG file) is converted to color by copying the greyvalues into all three colors and setting all the alpha values to 0.

A 16-bit pel buffer (or PNG file) is converted to color by first rightshifting by **numSignficantBits()**-8 and then being saturated to 255, and then copying the clamped greyvalues into all three colors and setting all the alpha values to 0.

A 3-plane pel buffer (or PNG file) is converted to a packed 32-bit image by setting all the alpha values to 0.

pelBuf's image-coordinate offset is read from the data.

pelBuf's client-coordinate transform is set to identity.

The function will discard the originally provided *pelBuf* and allocate an appropriately sized image. In other words, the *pelBuf* provided will be ignored and not be reused.

Throws

ccPNG::NoPngData
This **ccPNG** was default constructed.

- `void pelBuffer(cc3PlanePelBuffer& pelBuf) const;`

Fills in a color pelBuffer representation of this **ccPNG** object.

Parameters

pelBuf The pelBuffer.

Notes

An 8-bit greyscale pel buffer (or PNG file) is converted to color by copying the greyvalues into all three planes.

A 16-bit greyscale pel buffer (or PNG file) is converted to color by scaling down to 8 bits by rightshifting by **numSignficantBits()**-8 and then clamping to 255 and then copying into all three planes.

A packed 32-bit color pel buffer (or PNG file) is converted to a color three plane pel buffer by preserving the r,g,b content but discarding the alpha channel.

pelBuf's image-coordinate offset is read from the data.

pelBuf's client-coordinate transform is set to identity.

The function will discard the originally provided *pelBuf* and allocate an appropriately sized image. In other words, the *pelBuf* provided will be ignored and not be reused.

Throws

ccPNG::NoPngData
This **ccPNG** was default constructed.

numSignificantBits

`c_Int32 numSignificantBits() const;`

Gets the number of significant bits.

The *numSignificantBits* is read when loading a PNG file.

The default is 0.

ccPoint

```
#include <ch_cvl/simpshap.h>

class ccPoint : public cc2Vect;
```

Note The **ccPoint** class is deprecated. Use **cc2Point** instead.

ccPoint

ccPointMatcher

```
#include <ch_cvl/ptmatch.h>

class ccPointMatcher;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The Point Matcher tool finds a correspondence between a set of 2D model points (trained points) and a set of 2D data points (runtime points). This correspondence matches each model point with at most one data point and each data point with at most one model point. The number of data points may be more or less than the number of model points. You can assign the model points weights that may be positive, negative, or zero.

The tool finds a transformation (**cc2Xform**) that transforms the matched model points to a set of points that constitutes the best fit of model points among the data points.

The Point Matcher tool currently has two modes:

- Point to point mode: This mode attempts to find a match for model points that may be in any arbitrary position.
- Point to grid mode: This mode attempts to find a match for model points that are known to lie on a grid of 2D points, although each point of the grid may not be a model point. A grid is a set of 2D points of the form:

  ```
  { O + m*U + n*V : m,n are integers }
  ```

  where O is the 2D origin of the grid and U and V are 2D pitch vectors that span the grid.

Caution *The behavior of the Point Matcher tool in point to grid mode is preliminary and subject to change. Further, the point to grid mode currently represents beta level functionality and may not yet have been as extensively tested as the point to point mode.*

Constructors/Destructors

ccPointMatcher `ccPointMatcher();`

Construct a **ccPointMatcher** object.

Public Member Functions

train

```
void train(const cmStd vector<cc2Vect>& modelPoints);

void train(const cmStd vector<cc2Vect>& modelPoints,
  const cmStd vector<c_Int32>& weights);

void train(const ccPelBuffer_const<c_UInt8>& pattern);
```

- `void train(const cmStd vector<cc2Vect>& modelPoints);`

  Trains this **ccPointMatcher** for point to point matching. You can retrain an already trained Point Matcher tool for the same mode or a different mode.

  Parameters

  modelPoints A vector of points.

  Note The weight of each model point is one.

  Figure 1. Class Diagram of ccPointMatcher Class

  Throws

  ccPointMatcherDefs::InsufficientModelPoints

  The *modelPoints* vector contains fewer than three points.

- `void train(const cmStd vector<cc2Vect>& modelPoints, const cmStd vector<c_Int32>& weights);`

  Trains this **ccPointMatcher** for point to point matching with each model point carrying a weight specified by the weights vector. Only the ratio of each weight to the sum of all positive weights is used to calculate coverage for a correspondence.

  You can retrain an already trained Point Matcher tool for the same mode or a different mode.

  Parameters

  modelPoints A vector of points.

weights A vector of weights. Each weight in the vector affects the coverage score as follows:

Weight	Effect on Coverage Score
> 0	A match for this point increases coverage.
0	A match for this point does not affect coverage.
< 0	A match for this point decreases coverage.

Notes

The minimum coverage value for the tool must be less than or equal to the ratio of the number of model points with positive weights to the total number of model points.

Throws

ccPointMatcherDefs::InsufficientModelPoints
The *modelPoints* vector contains fewer than three points.

ccPointMatcherDefs::BadParams
The number of model points is not equal to the number of weights, or there is no positive weight.

- `void train(const ccPelBuffer_const<c_UInt8>& pattern);`

Trains this **ccPointMatcher** for point to grid matching. You can retrain an already trained Point Matcher tool for the same mode or a different mode.

Parameters

pattern Contains information on the placement of points on a grid. The pixel values and **clientFromImageXForm** of the pattern specify model points using the following convention:

A pixel (i,j) in the pattern is non-zero if and only if the point **clientFromImageXForm * cc2Vect(i,j)** is a model point.

Throws

ccPointMatcherDefs::InsufficientModelPoints
The *pattern* contains fewer than three points.

Caution *The behavior of the Point Matcher tool in point to grid mode is preliminary and subject to change. Further, the point to grid mode currently represents beta level functionality and may not yet have been as extensively tested as the point to point mode.*

isTrained `bool isTrained() const;`

Returns true if this **ccPointMatcher** has been trained, false otherwise.

trainMode `ccPointMatcherDefs::Mode trainMode() const;`

Returns the mode for which this **ccPointMatcher** was trained. This function returns one of the following values:

ccPointMatcherDefs::ePointToPoint
ccPointMatcherDefs::ePointToGrid

Throws

ccPointMatcherDefs::NotTrained
This **ccPointMatcher** is not trained for either matching mode.

untrain `void untrain();`

Untrains this **ccPointMatcher**.

Notes

Calling this function has no effect if this **ccPointMatcher** is not trained.

run

```
void run(const cmStd vector<cc2Vect>& dataPoints,
  const ccPointMatcherRunParams& rp,
  ccPointMatcherResultSet& results) const;
```

Runs the Point Matcher tool and stores the results to the results object.

Parameters

dataPoints	The run-time points to match.
rp	A **ccPointMatcherRunParams** object containing the parameters to use for this run.
results	A reference to a **ccPointMatcherResultSet** to which the results of this run are stored.

Notes

The **ccPointMatcher::run()** function supports the use of **ccTimeout**-based time-outs (defined in *ch_cvl/attent.h*). This function terminates if it runs longer than the time-out specified by a user-created **ccTimeout** object. If the function times out, no valid results are produced.

Throws

ccPointMatcherDefs::NotTrained

This **ccPointMatcher** object is not trained for either matching mode.

ccTimeout::Expired

The execution time of this function has exceeded the time-out interval specified by a user-created **ccTimeout** object.

modelPoints

```
const cmStd vector<cc2Vect>& modelPoints() const;
```

Returns the trained points.

Throws

ccPointMatcherDefs::NotTrained

This **ccPointMatcher** object is not trained for point to point matching.

weights

```
cmStd vector<c_Int32> weights() const;
```

Returns the weights vector for model points. Returns a vector of ones if the Point Matcher tool was trained with the **ccPointMatcher::train()** overload that does not take a vector of weights.

Throws

ccPointMatcherDefs::Not Trained

This **ccPointMatcher** object is not trained for point to point matching.

pattern

```
const ccPelBuffer_const<c_UInt8>& pattern() const;
```

Returns the model pattern.

Throws

ccPointMatcherDefs::NotTrained

This **ccPointMatcher** object is not trained for point to grid matching.

ccPointMatcherDefs

```
#include <ch_cvl/ptmatch.h>

class ccPointMatcherDefs;
```

A name space that holds enumerations and constants used with the Point Matcher tool.

Enumerations

Mode

```
enum Mode;
```

This enumeration defines types of point matching supported by the Point Matcher tool.

Value	Meaning
ePointToPoint	Point-to-point matching
ePointToGrid	An optimization of point-to-point matching that assumes that the points lie on a grid

ccPointMatcherDefs

ccPointMatcherResult

```
#include <ch_cvl/ptmatch.h>

class ccPointMatcherResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single Point Matcher tool result.

Constructors/Destructors

ccPointMatcherResult

```
ccPointMatcherResult();
```

Construct **ccPointMatcherResult** with no valid data.

Public Member Functions

runMode

```
ccPointMatcherDefs::Mode runMode() const;
```

Returns the mode in which the tool was run to get this result. This function returns one of the following values:

ccPointMatcherDefs::ePointToPoint
ccPointMatcherDefs::ePointToGrid

Notes

Returns *ccPointMatcherDefs::ePointToPoint* if this **ccPointMatcherResult** is default-constructed.

modelToDataXform

```
const cc2Xform& modelToDataXform() const;
```

Returns a **cc2Xform** object that describes the transformation from the trained points to the run-time points.

Notes

Returns **cc2Xform::I** if this **ccPointMatcherResult** is default-constructed.

coverage `double coverage() const;`

Returns the matching coverage score for this result as a number from 0.0 to 1.0, inclusive. Returns 0.0 if this result object was default constructed.

Note Matching coverage is the larger of zero and the ratio of the sum of the weights of the matched model points to the sum of all positive weights. If all model points have weights of one, coverage is equal to the ratio of the number of matched model points to the total number of model points.

modelToDataMap

```
const cmStd vector<c_Int32>& modelToDataMap() const;
```

Returns a vector that gives the correspondence between trained points and matched run-time points. Each element of the returned vector gives the index of the matched run-time point that corresponds to that trained point.

The size of the returned vector is same as the size of vector of model points. Model points that were not matched are assigned a value of -1.

Notes

Returns a zero-length vector if this **ccPointMatcherResult** is default-constructed.

Throws

ccPointMatcherDefs::NotRun

These results were not obtained using point-to-point mode.

fitError `double fitError() const;`

Returns the point fitting error. This is the RMS error between the transformed matched model points and the corresponding data points. Unmatched points are not considered in computing this score.

Notes

Returns 0.0 if this **ccPointMatcherResult** is default-constructed.

ccPointMatcherResultSet

```
#include <ch_cvl/ptmatch.h>

class ccPointMatcherResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a set of Point Matcher tool results.

Constructors/Destructors

ccPointMatcherResultSet

```
ccPointMatcherResultSet();
```

Construct a result set object

Public Member Functions

time

```
double time() const;
```

Returns the time in seconds required to compute this result set.

results

```
const cmStd vector<ccPointMatcherResult>& results() const;
```

Returns a vector containing all of the results for this run of the tool.

ccPointMatcherResultSet

ccPointMatcherRunParams

```
#include <ch_cvl/ptmatch.h>

class ccPointMatcherRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains Point Matcher tool run-time parameters.

Constructors/Destructors

ccPointMatcherRunParams

```
ccPointMatcherRunParams(double minCoverage=0.5,
  const cc2Xform& startPose=cc2Xform(),
  const ccRange& xTranslationUncertainty =
    ccRange::FullRange(),
  const ccRange& yTranslationUncertainty =
    ccRange::FullRange(),
  const ccAngleRange& rotationUncertainty =
    ccAngleRange(ccDegree(-15), ccDegree(15)),
  const ccRange& scaleUncertainty = ccRange(0.0, 0.0),
  bool autoGridSize = true, double gridSize=0.0,
  bool autoCaptureRange = true, double captureRange=0.0,
  c_Int32 maxNumResults=1);
```

Constructs a **ccPointMatcherRunParams** and initializes it to the supplied values.

Parameters

minCoverage	Only matches where the coverage ratio is greater than or equal to *minCoverage* are evaluated and returned. Matching coverage is the larger of zero and the ratio of the sum of the weights of the matched model points to the sum of all positive weights.
startPose	The initial nominal pose for the run-time points. Each trained point is mapped through *startPose* before the initial point correspondences are performed.

xTranslationUncertainty
: The maximum expected displacement in the x-direction with respect to *startPose*. The tool will attempt to match the run-time points at all points along this range.

yTranslationUncertainty
: The maximum expected displacement in the y-direction with respect to *startPose*. The tool will attempt to match the run-time points at all points along this range.

rotationUncertainty
: The maximum expected rotation with respect to *startPose*. The tool will attempt to match the run-time points across the angular range you specify.

scaleUncertainty
: The maximum expected scale change with respect to *startPose*. The tool will attempt to match the run-time points across the range of scale changes you specify.

autoGridSize
: If true, then the user-specified value of *gridSize* is not used and the tool automatically sets the grid size to be 25% of the distance between the closest pair of points in the trained point set. If false, the user-specified value for *gridSize* is used instead.

gridSize
: The grid size is used to quantize point locations before computing the coarse transformation. The *autoGridSize* parameter must be false for the user-specified value of *gridSize* to be used.

autoCaptureRange
: If true, the tool automatically sets the capture range to be 25% of the distance between the closest pair of points in the trained point set. If false, the user-specified value for *captureRange* is used instead.

captureRange
: The capture range is the radius from each model point where a run-time point is considered to be a matching point. The *autoCaptureRange* parameter must be false for the user-specified value of *captureRange* to be used.

maxNumResults
: The maximum number of results to compute. The tool will not return more than *maxNumResults*. The results are returned in descending coverage score order, and within matching coverage scores in increasing fit error order.

Throws

ccPointMatcherDefs::BadParams

minCoverage is less than 0.0 or greater than 1.0; one or more of the uncertainty ranges is empty; *scaleUncertainty* is full; the start of *scaleUncertainty* range is less than -0.9; *autoGridSize* is false and *gridSize* is less than or equal to 0.0; *autoCaptureRange* is false and *captureRange* is less than 0.0; or *maxNumResults* is less than 1.

Operators

operator==

```
bool operator==(const ccPointMatcherRunParams& that) const;
```

Returns true if this **ccPointMatcherRunParams** is equal to the supplied object, otherwise returns false. Two **ccPointMatcherRunParams** objects are equal if and only if all of their corresponding data members are equal.

Parameters

that The **ccPointMatcherRunParams** to compare to this one.

Public Member Functions

minCoverage

```
void minCoverage(double minCoverage);

double minCoverage() const;
```

- `void minCoverage(double minCoverage);`

Sets the coverage threshold. Only those matches where the ratio of matched points to trained points is greater than or equal to the coverage threshold are marked as found results.

Parameters

minCoverage The coverage threshold. Must be from 0.0 through 1.0.

Notes

Matching coverage is defined to be the larger of zero and the ratio of the sum of the weights of matched model points to the sum of all positive weights. If all model points have weights of one, the coverage is equal to the ratio of the number of matched model points to the total number of model points.

If the point matcher tool is trained with weights, *minCoverage* must be less than or equal to the ratio of the number of model points with positive weights to the total number of model points.

Throws

ccPointMatcherDefs::BadParams

minCoverage is less than 0.0 or greater than 1.0.

- `double minCoverage() const;`

  Returns the coverage threshold. Only those matches where the ratio of matched points to trained points is greater than or equal to the coverage threshold are marked as found results.

startPose

```
void startPose(const cc2Xform& startPose);

cc2Xform startPose() const;
```

- `void startPose(const cc2Xform& startPose);`

  Sets the starting pose for this **ccPointMatcherRunParams**. The starting pose is applied to each trained point before the points are matched.

  Parameters

  startPose The starting pose.

- `cc2Xform startPose() const;`

  Returns the starting pose for this **ccPointMatcherRunParams**.

xTranslationUncertainty

```
void xTranslationUncertainty(
  const ccRange& xTranslationUncertainty);

ccRange xTranslationUncertainty() const;
```

- ```
  void xTranslationUncertainty(
    const ccRange& xTranslationUncertainty);
  ```

  Sets the translation uncertainty in the x-direction. The Point Matcher tool searches for and evaluates point matches within the specified translation range, relative to the starting pose.

  Parameters

  xTranslationUncertainty

  A **ccRange** giving the range of translation to evaluate.
  ```

Throws

ccPointMatcherDefs::BadParams
xTranslationUncertainty is empty.

- `ccRange xTranslationUncertainty() const;`

  Returns the translation uncertainty in the x-direction.

yTranslationUncertainty

```
void yTranslationUncertainty(
 const ccRange& yTranslationUncertainty);

ccRange yTranslationUncertainty() const;
```

- `void yTranslationUncertainty(`
  `const ccRange& yTranslationUncertainty);`

  Sets the translation uncertainty in the y-direction. The Point Matcher tool searches for and evaluates point matches within the translation range, relative to the starting pose.

  Parameters

  yTranslationUncertainty
  A **ccRange** giving the range of translation to evaluate.

  Throws

  ccPointMatcherDefs::BadParams
  yTranslationUncertainty is empty.

- `ccRange yTranslationUncertainty() const;`

  Returns the translation uncertainty in the y-direction.

rotationUncertainty

```
void rotationUncertainty(
 const ccAngleRange& rotationUncertainty);

ccAngleRange rotationUncertainty() const;
```

- `void rotationUncertainty(`
  `const ccAngleRange& rotationUncertainty);`

  Sets the rotational uncertainty. The Point Matcher tool searches for and evaluates point matches within the specified angle range, relative to the starting pose.

Parameters

rotationUncertainty

A **ccAngleRange** giving the range of rotation to evaluate.

Throws

ccPointMatcherDefs::BadParams

rotationUncertainty is empty.

- `ccAngleRange rotationUncertainty() const;`

Returns the rotational uncertainty.

scaleUncertainty

```
void scaleUncertainty(const ccRange& scaleUncertainty);

ccRange scaleUncertainty() const;
```

- `void scaleUncertainty(const ccRange& scaleUncertainty);`

Sets the scale uncertainty. The Point Matcher tool searches for and evaluates point matches within the specified scale range.

Parameters

scaleUncertainty

A **ccRange** giving the range of scale to evaluate.

Throws

ccPointMatcherDefs::BadParams

scaleUncertainty is empty or full or the start of *scaleUncertainty* is less than -0.9.

- `ccRange scaleUncertainty() const;`

Returns the scale uncertainty.

Notes

The start and end values of the supplied **ccRange** are interpreted as the fractional scale changes. For example, setting a range of -0.1 to 0.2 means scales between 90% to 120% relative to the starting pose are evaluated.

autoGridSize

```
void autoGridSize(bool autoGridSize);

bool autoGridSize() const;
```

- `void autoGridSize(bool autoGridSize);`

  Sets whether or not this **ccPointMatcherRunParams** is configured to automatically determine the grid size.

  Parameters

  autoGridSize Set to true to have this **ccPointMatcherRunParams** automatically set the grid size to 25% of the distance between the two closest points in the trained point set, false to use the value supplied to **gridSize()**.

- `bool autoGridSize() const;`

  Returns true if this **ccPointMatcherRunParams** is configured to automatically determine the grid size, false if the grid size supplied to **gridSize()** is used.

gridSize

```
void gridSize(double gridSize);

double gridSize() const;
```

- `void gridSize(double gridSize);`

  Sets the grid size for this **ccPointMatcherRunParams**. The grid size specifies the size of the cells in the grid used to quantize both trained and run-time point locations before computing the coarse transformation. If *autoGridSize* is true, then the grid size set using this setter is ignored.

  You should specify a grid size that is small enough that no more than one point is quantized to a given grid cell.

  Parameters

  gridSize The grid size.

  Throws

  ccPointMatcherDefs::BadParams

  gridSize is less than or equal to 0.0 and this **ccPointMatcherRunParams** is not configured for automatic grid size determination.

Notes

If you have specified automatic grid size determination (by either calling **autoGridSize()** with an argument of true or setting *autoGridSize* to true at construction), the tool automatically sets the grid size. Otherwise, you should specify the grid size to be approximately 25% of the distance between the two trained points that are closest to each other and set *autoGridSize* to false.

- `double gridSize() const;`

  Returns the grid size for this **ccPointMatcherRunParams**.

autoCaptureRange

```
void autoCaptureRange(bool autoCaptureRange);

bool autoCaptureRange() const;
```

- `void autoCaptureRange(bool autoCaptureRange);`

  Sets whether or not this **ccPointMatcherRunParams** is configured to automatically determine the capture range.

  Parameters

  autoCaptureRange

  Set to true to have this **ccPointMatcherRunParams** automatically set the capture range to be 25% of the distance between the closest pair of points in the trained point set, false to use the value supplied to **captureRange()**

- `bool autoCaptureRange() const;`

  Returns true if this **ccPointMatcherRunParams** is configured to automatically determine the capture range, false if the capture range to **captureRange()** is used.

captureRange

```
void captureRange(double captureRange);

double captureRange() const;
```

- `void captureRange(double captureRange);`

  Sets the capture range for this **ccPointMatcherRunParams**. Any run-time point lying within the capture range from a trained point is treated as a matching point. If multiple run-time points lie within the capture range of a single trained point, then a separate result is computed for each point. If *autoCaptureRange* is false, then the capture range set using this setter is ignored.

  Parameters

  captureRange The capture range.

  Throws

  ccPointMatcherDefs::BadParams

  captureRange is less than or equal to 0.0 and this **ccPointMatcherRunParams** is not configured for automatic capture range determination.

  Notes

  If you have specified capture range size determination (by calling **autoCaptureRange()** with an argument of true or by setting *autoCaptureRange* to true at construction), the tool automatically sets the capture range. Otherwise, you should set the capture range to be approximately 25% of the distance between the two trained points that are closest to each other and set *autoCaptureRange* to false.

- `double captureRange() const;`

  Returns the capture range for this **ccPointMatcherRunParams**.

maxNumResults

```
void maxNumResults(c_Int32 maxNumResults);

c_Int32 maxNumResults() const;
```

- `void maxNumResults(c_Int32 maxNumResults);`

  Sets the maximum number of results to compute. The Point Matcher tool will only compute the requested number of matches.

  Parameters

  maxNumResults The maximum number of results. *maxNumResults* must be greater than 0.

Throws

ccPointMatcherDefs::BadParams
maxNumResults is less than 1.

- `c_Int32 maxNumResults() const;`

  Returns the maximum number of results.

ccPointSet

```
#include <ch_cvl/simpshap.h>

class ccPointSet;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes a set of points. **ccPointSet** uses a the C++ Standard Library template class vector to create an array of points.

Note **ccPointSet** is one of the few shapes that does not inherit from **ccShape**.

Constructors/Destructors

ccPointSet

```
ccPointSet();

ccPointSet(cmStd vector<cc2Vect> &pts);
```

- `ccPointSet();`

  The default constructor creates an empty point set.

- `ccPointSet(cmStd vector<cc2Vect> &pts);`

  Creates a point set that contains all the points in the *pts* vector.

  Parameters

pts	A vector of points.

Operators

operator[]

```
cc2Vect& operator[] (long i);
cc2Vect const& operator[] (long i) const;
```

- `cc2Vect& operator[] (long i);`

  Provides array-like access to the point set.

  Parameters

  i The index of the point.

- `cc2Vect const& operator[] (long i) const;`

  Provides array-like access to the point set.

  Parameters

  i The index of the point.

operator==

```
bool operator==(const ccPointSet& that) const;
```

Returns true if this point set is equal to *that*, false otherwise. The comparison tests for equality of the points in the set, taking into account a small tolerance.

Parameters

that The other point set.

operator!=

```
bool operator!=(const ccPointSet& that) const;
```

Returns true if this point set is not equal to *that*, false otherwise. The comparison tests for equality of the points in the set, taking into account a small tolerance.

Parameters

other The other point set.

Public Member Functions

map

```
ccPointSet map(const cc2Xform& c) const;
```

Returns a point set that is the result of mapping this point set with the transformation object *c*.

Parameters

c The transformation object.

mapCentered

```
ccPointSet mapCentered(const cc2Xform& c) const;
```

Returns a point set that is the result of mapping this point set with the transformation object *c* using the first point in the set as the origin.

Parameters

c The transformation object.

pos

```
cc2Vect pos() const;
```

Returns the position of the point set (the first point in the set).

angle

```
ccRadian angle() const;
```

Returns the angle of the point set (the angle between the first two points in the set).

boundingBox

```
ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this set of points. See **ccShape::boundingBox()** for more information.

distanceToPoint

```
double distanceToPoint(const cc2Vect& v) const;
```

Returns the minimum distance from this shape to the given point, computed as the distance between the point *v* and **nearestPoint(v)**.

Parameters

v The point.

size

```
int size() const;
```

Returns the number of points in the set.

degen

```
bool degen() const;
```

Returns true if the point set is degenerate, that is the set contains fewer than 2 points.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint `double distToPoint(const cc2Vect& v) const;`

Use **distanceToPoint()** instead of this function.

ccPolarSamplingParams

```
#include <ch_cvl/polar.h>

class ccPolarSamplingParams;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Yes

This class contains the parameters needed to specify a sampling region for polar transformation. The region is an annular section that is divided into a (polar) grid of smaller sampling areas. The function **cfPolarTransformImage()** maps the source pixels within each sampling area to a corresponding pixel of the destination image.

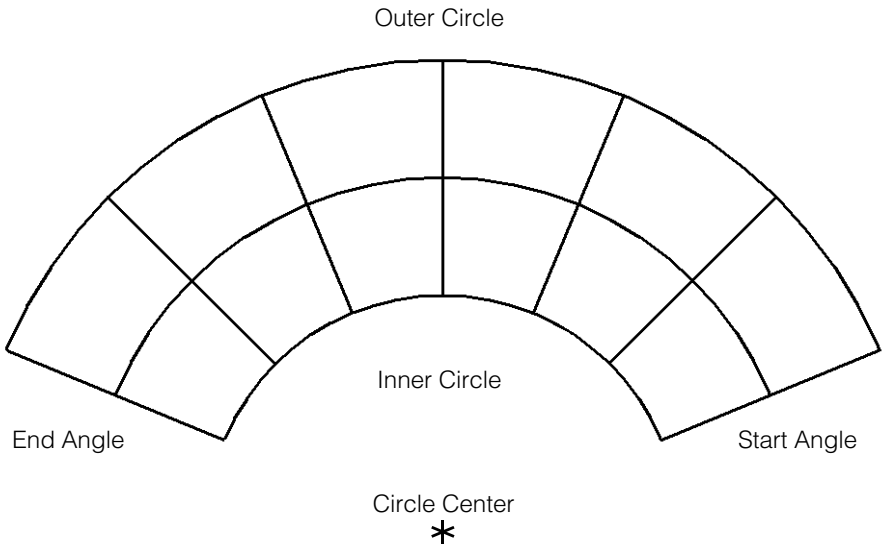
A polar sampling region is specified using the following parameters:

- An ellipse annulus section. This object describes an angular wedge, or section, of the annulus formed between two aligned ellipses with the same major/minor axis ratio.
- The number of X and Y samples. These parameters specify the size of the destination image and (equivalently) the number of divisions in the polar sampling grid. *yNumSamples* nominally specifies the height of the destination image and the number of samples in the radial grid direction. *xNumSamples* nominally specifies the width of the destination and the number of samples in the angular grid direction (see picture below).
- An interpolation method selects how the image pixels are processed to generate the sample value at each sampling point. If you specify no interpolation, the sample value is the value of the single pixel whose center lies nearest to the sampling point. If you specify bilinear interpolation, the sample value is the bilinearly weighted average of the four pixels whose centers are nearest to the sampling point.

The function **cfPolarTransformImage()** maps pixels in the (Cartesian) source image to pixels in the (polar) destination image. Each pixel in the destination image contains some number of whole and/or fractional pieces of the source image pixels. The source pixels are averaged together and normalized to form the corresponding output pixel for the destination image.

See also the Polar Coordinate Transformation Tools section of the Image Transformation Tools chapter in the *CVL Vision Tools Guide*.

The polar transformation tool works in client coordinates.



In the above example, *xNumSamples* = 6 and *yNumSamples* = 2.
There are six angular divisions and two radial divisions.

Constructors/Destructors

ccPolarSamplingParams

```
ccPolarSamplingParams();

ccPolarSamplingParams(
  const ccEllipseAnnulusSection &section,
  c_Int16 xNumSamples, c_Int16 yNumSamples,
  enum ccPolarTransDefs::Interpolation method =
  ccPolarTransDefs::kDefaultInterpolation);

ccPolarSamplingParams(const ccPolarSamplingParams&);
```

- `ccPolarSamplingParams();`

  Default constructor.

- ```
  ccPolarSamplingParams(
    const ccEllipseAnnulusSection &section,
    c_Int16 xNumSamples, c_Int16 yNumSamples,
    enum ccPolarTransDefs::Interpolation method =
    ccPolarTransDefs::kDefaultInterpolation);
  ```

  Convert constructor. Constructs a **ccPolarSamplingParams** object with the given parameters.

  Parameters

section	The **ccEllipseAnnulusSection** that describes the angular wedge, or section, of the annulus formed between two aligned ellipses with the same major/minor axis ratio.
xNumSamples	Number of samples in the horizontal direction.
yNumSamples	Number of samples in the vertical direction.
method	Interpolation method. The default method is **ccPolarTransDefs::kDefaultInterpolation**.

  Throws

  ccPolarTransDefs::BadParams
  The inner ellipse is equal to the outer ellipse.
  The end angle for the section is less than the start angle.
  xNumSamples is less than one.
  yNumSamples is less than one.

- ```
  ccPolarSamplingParams(const ccPolarSamplingParams&);
  ```

  Copy constructor.

Operators

operator=

```
ccPolarSamplingParams& operator=(
  const ccPolarSamplingParams& psp);
```

Assigns the value *psp* to this **ccPolarSamplingParams** object.

Parameters

psp	The **ccPolarSamplingParams** to assign to this one.

operator==

```
bool operator==(const ccPolarSamplingParams& that) const;
```

Returns true if this polar sampling parameters object equals *that*, false otherwise. Two **ccPolarSamplingParams** objects are considered equal if their *section*, *xNumSamples*, *yNumSamples*, and *interpolation method* properties are equal.

Parameters

that The **ccPolarSamplingParams** object to compare to this one.

Public Member Functions

section

```
const ccEllipseAnnulusSection &section() const;

ccEllipseAnnulusSection &section();

void section(const ccEllipseAnnulusSection &section);
```

- `const ccEllipseAnnulusSection &section() const;`

  Retrieves the **ccEllipseAnnulusSection** associated with these polar sampling parameters. The section describes the angular wedge of the annulus formed between two aligned ellipses with the same major/mionor axis ratio.

- `ccEllipseAnnulusSection &section();`

  Retrieves the **ccEllipseAnnulusSection** associated with these polar sampling parameters. The section describes the angular wedge of the annulus formed between two aligned ellipses with the same major/mionor axis ratio. This is the non-const version of the getter.

- `void section(const ccEllipseAnnulusSection &section);`

  Sets the ellipse annulus section associated with these polar sampling parameters. The section describes the angular wedge of the annulus formed between two aligned ellipses with the same major/mionor axis ratio.

  Parameters

  section The **ccEllipseAnnulusSection** to which these polar sampling parameters apply.

  Throws

  ccPolarTransDefs::BadParams
  The inner ellipse of the annulus section is equal to the outer ellipse (**section.innerEllipse() == section.outerEllipse()** evaluates to true).

  ccPolarTransDefs::BadParams
  The end angle for the section is less than the start angle for the section.

xNumSamples

```
c_Int16 xNumSamples() const;
void xNumSamples(c_Int16 xNum);
```

- `c_Int16 xNumSamples() const;`

  Returns the number of samples to be made in the X direction of the destination image. Nominally, this is also the number of divisions of the sampling grid in the angular direction.

- `void xNumSamples(c_Int16 xNum);`

  Sets the number of samples to be made in the X direction of the destination image. Nominally, this is also the number of divisions of the sampling grid in the angular direction.

  Parameters

  xNum The 16-bit integer specifying the number of samples to be made in the X direction of the destination image.

  Throws

  ccPolarTransDefs::BadParams
  xNum is less than one.

yNumSamples

```
c_Int16 yNumSamples() const;
void yNumSamples(c_Int16 yNum);
```

- `c_Int16 yNumSamples() const;`

  Returns the number of samples to be made in the Y direction of the destination image. Nominally, this is also the number of divisions of the sampling grid in the radial direction.

- `void yNumSamples(c_Int16 yNum);`

  Sets the number of samples to be made in the Y direction of the destination image. Nominally, this is also the number of divisions of the sampling grid in the radial direction.

  Parameters

  yNum The 16-bit integer specifying the number of samples to be made in the Y direction of the destination image.

  Throws

  ccPolarTransDefs::BadParams
  yNum is less than one.

interpolation

```
enum ccPolarTransDefs::Interpolation interpolation()
  const;

void interpolation(
  enum ccPolarTransDefs::Interpolation interpolation);
```

- ```
  enum ccPolarTransDefs::Interpolation interpolation()
    const;
  ```

  Returns the interpolation method used during projection. The interpolation method determines how the pixels around the sample point are combined to create the value of the sample.

- ```
  void interpolation(
    enum ccPolarTransDefs::Interpolation interpolation);
  ```

  Sets the interpolation method used during projection. The interpolation method determines how the pixels around the sample point are combined to create the value of the sample.

  Parameters

  interpolation The interpolation method used during projection. Must be one of:

  ccPolarTransDefs::eNone
  ccPolarTransDefs::eBilinear
  ccPolarTransDefs::kDefaultInterpolation

  The default interpolation is bilinear.

willClip

```
bool willClip(const cc_PelBuffer& srcImg) const;
```

Returns true if the polar sampling parameters will access pixels outside of the specified source image.

Parameters

srcImg The source image that the sampling parameters will access.

Throws

ccPel::UnboundWindow
srcImg is an unbound pel buffer.

mapPolarPosition

```
cc2Vect mapPolarPosition(const cc2Vect &polarPosition)
  const;
```

Returns the position in the original source image corresponding to the given position in the (polar transformed) destination image. The source image position is returned in client coordinates. The destination image position is specified in image coordinates.

Parameters

polarPosition Position in the (polar transformed) destination image in image coordinates.

mapImagePosition

```
cc2Vect mapImagePosition(const cc2Vect &imagePosition)
  const;
```

Returns the position in the (polar transformed) destination image corresponding to the given position in the original source image. The destination image position is returned in image coordinates. The source image position is specified in client coordinates.

Parameters

imagePosition Position in the original source image in client coordinates.

Throws

ccPolarTransDefs::BadParams

imagePosition is at the center of the ellipse annulus section associated with these polar sampling parameters. In other words *imagePosition* is equal to **section().center()**.

ccPolarSamplingParams

ccPolarTransDefs

```
#include <ch_cvl/polar.h>

class cmImport_cogip ccPolarTransDefs;
```

A name space class that holds enumerations and errors associated with polar transformations.

Enumerations

Interpolation

```
enum Interpolation;
```

Interpolation methods used for polar transformation.

Value	Meaning
eNone = 1	No interpolation
eBilinear = 2	Bilinear interpolation
kDefaultInterpolation = *eBilinear*	The default interpolation method is bilinear.

See also the Polar Coordinate Transformation Tools section of the Image Transformation Tools chapter in the *CVL Vision Tools Guide*.

ccPolarTransDefs

ccPolygon

```
#include <ch_cvl/oldshape.h>

class ccPolygon;
```

This class is deprecated. Use the **ccPolyline** class instead. See **ccPolyline** on page 2639.

ccPolygon

ccPolyline

```
#include <ch_cvl/shapes.h>

class ccPolyline : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccPolyline** class describes a polyline, a shape made up of two or more vertices connected by line segments. A polyline can be open or closed. Polylines can self-intersect, although some methods in **ccPolyline** and the **ccShape** base class assume non-self-intersecting polylines. These assumptions are documented where applicable.

Constructors/Destructors

ccPolyline

```
explicit ccPolyline(bool closed = false);

ccPolyline(const cmStd vector<cc2Vect> &vertices,
  bool closed = false);
```

- `explicit ccPolyline(bool closed = false);`

  Constructs a **ccPolyline** with the supplied open/closed status. The default constructor constructs an open **ccPolyline** with no vertices. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  closed — True specifies that the polyline is a closed shape, false that it is open.

  Notes

  The open/closed status of a **ccPolyline** is controlled through the **isClosed()** flag, and is independent of the vertex positions. For instance, a **ccPolyline** may be open even though its first and last vertex coincide or it may be closed when they do not, in which case there is an implied line segment connection between the last and first vertex.

- `ccPolyline(const cmStd vector<cc2Vect> &vertices, bool closed = false);`

  Constructs a **ccPolyline** with an initial set of vertices and the supplied open/closed status. A **ccPolyline** may have any number of vertices, including zero.

  Parameters

  closed — True specifies that the polyline is a closed shape, false that it is open.

Operators

operator==

```
bool operator==(const ccPolyline &rhs) const;
```

Returns true if and only if this **ccPolyline** is equal to *rhs*. Two **ccPolyline** objects are equal if their vertex sequences are identical (no tolerance is used in coordinate comparisons), and they have the same open/closed status.

Parameters

rhs — The other polyline.

operator!=

```
bool operator!=(const ccPolyline &rhs) const;
```

Returns true if *rhs* is not equal to this **ccPolyline**.

Parameters

rhs — The other polyline.

operator=

```
ccPolyline& operator=(const ccPolyline &rhs);
```

Assigns *rhs* to this ccPolyline.

Parameters

rhs — The other polyline.

Public Member Functions

numVertices

```
c_Int32 numVertices() const;
```

Returns the number of vertices of this **ccPolyline**.

vertex

```
const cc2Vect &vertex(c_Int32 idx) const;
void vertex(c_Int32 idx, const cc2Vect &vertex);
```

- `const cc2Vect &vertex(c_Int32 idx) const;`

  Gets the indexed vertex of this **ccPolyline**.

  Parameters

  idx The index.

- `void vertex(c_Int32 idx, const cc2Vect &vertex);`

  Sets the indexed vertex of this **ccPolyline**.

  Parameters

  idx The index.

  vertex The value to assign the indexed vertex.

  Throws

  ccShapesError::BadIndex

  idx is less than zero or greater than or equal to **numVertices()**.

vertices

```
const cmStd vector<cc2Vect> &vertices() const;
void vertices(const cmStd vector<cc2Vect> &vertices);
```

- `const cmStd vector<cc2Vect> &vertices() const;`

  Gets the entire set of vertices of this **ccPolyline**.

- `void vertices(const cmStd vector<cc2Vect> &vertices);`

  Sets the entire set of vertices of this **ccPolyline**.

  Parameters

  vertices The set of vertices.

insertVertex

```
void insertVertex(c_Int32 idx, const cc2Vect &vertex);
```

Inserts a vertex into this **ccPolyline**. The vertex is inserted into the vertex sequence so that after the insertion it has index *idx*.

Parameters

idx The index at which to insert the vertex.
A value of 0 inserts the vertex at the front of the vertex sequence. A value of **numVertices()** inserts it at the end of the vertex sequence.

vertex The vertex.

Notes

Inserting a vertex will change the indices of all existing vertices whose indices prior to the insertion were greater than or equal to *idx*.

Throws

ccShapesError::BadIndex
idx is less than zero or greater than **numVertices()** before insertion.

insertVertices

```
void insertVertices(c_Int32 idx,
  const cmStd vector<cc2Vect> &vertices);
```

Inserts multiple vertices into this **ccPolyline**. The vertices are inserted contiguously into the sequence of vertices so that after the insertion, they have indices *idx* through *idx + vertices.size() - 1*.

Parameters

idx The index at which to insert the vertices.
A value of 0 inserts the vertices at the front of the vertex sequence. A value of **numVertices()** inserts them at the end of the vertex sequence.

vertices The vertices.

Notes

Inserting vertices will change the indices of all existing vertices whose indices prior to the insertion were greater than or equal to *idx*.

Throws

ccShapesError::BadIndex
idx is less than zero or greater than **numVertices()** before insertion.

addVertex

```
void addVertex(const cc2Vect &vertex);
```

Inserts a vertex at the end of this **ccPolyline**'s vertex sequence. Functionally equivalent to invoking **insertVertex()** with *idx* equal to **numVertices()**. See **insertVertex()** for details.

Parameters
vertex The vertex.

addVertices

```
void addVertices(const cmStd vector<cc2Vect> &vertices);
```

Inserts multiple vertices at the end of this **ccPolyline**'s vertex sequence. Functionally equivalent to invoking **insertVertices()** with *idx* equal to **numVertices()**. See **insertVertices()** for details.

Parameters
vertices The vertices.

removeVertex

```
void removeVertex(c_Int32 idx);
```

Removes the indexed vertex of this **ccPolyline**.

Parameters
idx The index.

Notes
Removing a vertex will change the indices of all remaining vertices whose indices prior to the removal were greater than *idx*.

Throws
ccShapesError::BadIndex
idx is less than zero or greater than or equal to **numVertices()** before removal.

isClosed

```
bool isClosed() const;
```

```
void isClosed(bool closed);
```

- `bool isClosed() const;`

  Gets the closed status of this **ccPolyline**.

- `void isClosed(bool closed);`

  Sets the closed status of this **ccPolyline**.

  Parameters
  closed True sets this **ccPolyline** to closed, false sets it to open.

Notes

The setter does not change the vertex sequence. Closed **ccPolyline** objects have an assumed connection between the first and last vertices of the sequence, while open ones do not.

map

```
ccPolyline map(const cc2Xform &xform) const;
```

Returns this **ccPolyline** mapped by *xform*.

Parameters

xform The transformation object.

reserve

```
void reserve(c_Int32 n) const;
```

Preallocates enough memory for this **ccPolyline** to store at least the given number of vertices before additional memory allocations are needed. After a successful invocation of this method, **capacity()** will be no less than the given number.

Parameters

n The number of vertices for which memory is to be allocated.

Throws

cmStd bad_alloc

The required amount of memory cannot be allocated. If this throw occurs, this **ccPolyline** and its capacity are not changed.

Notes

Invoking this method with **capacity()** greater than or equal to *n* has no effect.

This method is the analog of the STL vector method **reserve()**.

capacity

```
c_Int32 capacity() const;
```

Returns the number of vertices that can be stored in this **ccPolyline** before more memory must be allocated. The value returned is never less than **numVertices()**.

Notes

This method is the analog of the STL vector method **capacity()**.

perimeter

```
double perimeter() const;
```

Returns the perimeter of this **ccPolyline**.

Notes

Returns zero if this **ccPolyline** has fewer than two vertices.

perimeter `virtual double perimeter() const;`

Returns the perimeter of this polyline.

Notes
This method returns zero if this polyline has fewer than two vertices.

See **ccShape::perimeter()** for more information.

area `double area() const;`

Returns the area enclosed by this closed **ccPolyline**. This is always non-negative, regardless of this **ccPolyline**'s handedness.

Notes
Returns zero if this **ccPolyline** has fewer than three vertices.

Notes
The return value is undefined for self-intersecting **ccPolyline**s.

Throws
ccShapesError::NotRegion
This **ccPolyline** is not closed.

centerArea `cc2Vect centerArea() const;`

Returns the center of area (centroid) of this closed **ccPolyline**.

Throws
ccShapesError::NotRegion
This **ccPolyline** is not a region.

ccShapesError::DegenerateShape
This **ccPolyline** encloses zero area.

Notes
This method requires this polyline to be non-self-intersecting.

The throw conditions listed above are tested in the given order.

centerArcLength `cc2Vect centerArcLength() const;`

Returns the center of arc length of this **ccPolyline**.

Notes
The center of arc length is where the center of mass would be if mass were evenly distributed along the perimeter of the **ccPolyline** but not over any enclosed area. Unlike **centerArea()**, this measure is defined for both open and closed **ccPolyline**s.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

ccShapesError::DegenerateShape
This **ccPolyline** has zero perimeter.

Notes

The throw conditions listed above are tested in the given order.

center

```
cc2Vect center() const;
```

Returns a reasonable center point for this **ccPolyline**.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

Notes

If this **ccPolyline** is a region and encloses non-zero area, this function returns **centerArea()**. Otherwise, if this **ccPolyline** has non-zero perimeter, this function returns **centerArcLength()**. Otherwise, the vertices are all coincident and if there is at least one vertex, its coordinates are returned.

meanVertex

```
cc2Vect meanVertex() const;
```

Returns the average position of the polyline vertices.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

extremalVertexIndex

```
c_Int32 extremalVertexIndex(const ccRadian &direction)
const;
```

Returns the index of the vertex that has the greatest dot product with a unit vector in the given direction.

Parameters

direction The direction expressed in radians.

Notes

If the extremal vertex is not unique, this function returns the index of one of the extremal vertices.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

closestVertexIndex

```
c_Int32 closestVertexIndex(const cc2Vect &point) const;
```

Returns the index of the vertex closest to the given point.

Parameters

point The point.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

Notes

If the closest vertex is not unique, this function returns the index of one of the closest vertices.

nearestPoints

```
void nearestPoints(const ccPolyline &poly,
 cc2Vect &p1, cc2Vect &p2) const;
```

Returns the nearest two points between this polyline and the given polyline.

Parameters

poly The other polyline.

p1 Return parameter for the nearest point on this polyline.

p2 Return parameter for the nearest point on the other polyline.

Throws

ccShapesError::EmptyShape
Either of the two polylines has no vertices.

Notes

If more than one pair of points have the same nearest distance, this function returns an arbitrary pair among them.

principalMomentsArea

```
void principalMomentsArea(cc2Vect &moments,
  cc2Rigid &polyFromPrincipalXform) const;
```

Computes the principal moments of area of this closed, non empty **ccPolyline**. Also computes the transform from the coordinate system in which the principal moments are computed to the system in which this **ccPolyline**'s vertices are defined. The translational component of the returned transform is always **centerArea()**.

Parameters

moments Return parameter principal moments of area.

polyFromPrincipalXform
Return parameter for the transform that maps from the coordinate system in which the moments are computed to the system in which this polyline's vertices are defined.

Throws

ccShapesError::NotRegion
This **ccPolyline** is not a region.

ccShapesError::DegenerateShape
This **ccPolyline** encloses zero area.

Notes

The throw conditions listed above are tested in the given order.

This method requires this **ccPolyline** to be non-self-intersecting.

The principal axis is the axis about which the moment of area is minimzed. Thus, the first component of the returned moments is always less than or equal to the second component.

If the principal moments are exactly equal, the angle of the principal axes is not well-defined. In this case, the angle of the returned **cc2Rigid** object is arbitrarily chosen as zero. If the principal moments are nearly equal, the angle of the returned **cc2Rigid** object is unstable. This occurs for symmetric shapes such as circles or even squares. There is no such instability in the translational component of the returned **cc2Rigid** object nor in the values of the principal moments.

principalMomentsArcLength

```
void principalMomentsArcLength(cc2Vect &moments,
  cc2Rigid &polyFromPrincipalXform) const;
```

Computes the principal moments of arc length of this **ccPolyline**. Also computes the transform from the coordinate system in which the principal moments are computed to the system in which this **ccPolyline**'s vertices are defined. The translational component of the returned transform is always **centerArcLength()**.

Parameters

moments Return parameter for principal moments of arc length.

polyFromPrincipalXform
Return parameter for the transform that maps from the coordinate system in which the moments are computed to the system in which this polyline's vertices are defined.

Throws

ccShapesError::EmptyShape
This **ccPolyline** has no vertices.

ccShapesError::DegenerateShape
This **ccPolyline** has zero perimeter.

Notes

The throw conditions listed above are tested in the given order.

The principal axis is the axis about which the moment of area is minimized. Thus, the first component of the returned moments is always less than or equal to the second component.

If the principal moments are exactly equal, the angle of the principal axes is not well-defined. In this case, the angle of the returned **cc2Rigid** object is arbitrarily chosen as zero. If the principal moments are nearly equal, the angle of the returned **cc2Rigid** object is unstable. This occurs for symmetric shapes such as circles or even squares. There is no such instability in the translational component of the returned **cc2Rigid** object nor in the values of the principal moments.

areaMoment0 `double areaMoment0() const;`

Computes the zeroth moment of area over this closed **ccPolyline**.

Notes

The **areaMoment*()** functions use Greens's Theorem from vector calculus to convert an integral over an area to an integral over its boundary. This has the side effect of flipping the sign of the result if the boundary is left-handed. For example, even though area (that is, the integral of unity over a polygonal region) is always positive, **areaMoment0()** will return a negative value for left-handed boundaries. This sign can be useful, for example in determining handedness or processing polygonal regions with holes.

All computed moments are zero if this **ccPolyline** has fewer than three vertices.

Throws

ccShapesError::NotRegion
This **ccPolyline** is not closed.

areaMoment1

```
void areaMoment1(double &int_1, double &int_x,
  double &int_y) const;
```

Computes moments of area 0 and 1 over this closed **ccPolyline**.

Parameters

int_1	Integral of the function 1 over the area of the closed polyline.
int_x	Integral of the function x over the area of the closed polyline.
int_y	Integral of the function y over the area of the closed polyline.

Throws

ccShapesError::NotRegion
This **ccPolyline** is not closed.

areaMoment2

```
void areaMoment2(double &int_1, double &int_x,
  double &int_y, double &int_x2, double &int_y2,
  double &int_xy) const;
```

Computes the zeroth, first, and second moments and product of area over this closed **ccPolyline**.

Parameters

int_1	Integral of the function 1 over the area of the closed polyline.
int_x	Integral of the function x over the area of the closed polyline.
int_y	Integral of the function y over the area of the closed polyline.
int_x2	Integral of the function x^2 over the area of the closed polyline.
int_y2	Integral of the function y^2 over the area of the closed polyline.
int_xy	Integral of the function xy over the area of the closed polyline.

Throws

ccShapesError::NotRegion
This **ccPolyline** is not closed.

arcLengthMoment0

```
double arcLengthMoment0() const;
```

Computes the zeroth moment of arc length over this **ccPolyline**.

Notes

All computed moments are zero if this **ccPolyline** has fewer than two vertices.

arcLengthMoment1

```
void arcLengthMoment1(double &int_1, double &int_x,
  double &int_y) const;
```

Computes the zeroth and first moments of arc length over this **ccPolyline**.

Parameters

int_1	Integral of the function 1 over the arc length of the polyline.
int_x	Integral of the function x over the arc length of the polyline.
int_y	Integral of the function y over the arc length of the polyline.

arcLengthMoment2

```
void arcLengthMoment2(double &int_1, double &int_x,
  double &int_y, double &int_x2, double &int_y2,
  double &int_xy) const;
```

Computes the zeroth, first, and second moments and product of arc length over this **ccPolyline**.

Parameters

int_1	Integral of the function 1 over the arc length of the polyline.
int_x	Integral of the function x over the arc length of the polyline.
int_y	Integral of the function y over the arc length of the polyline.
int_x2	Integral of the function x^2 over the arc length of the polyline.
int_y2	Integral of the function y^2 over the arc length of the polyline.
int_xy	Integral of the function xy over the arc length of the polyline.

convexHull

```
ccPolyline convexHull() const;
```

Returns the convex hull of this **ccPolyline**. The convex hull is the smallest closed, convex polygon that encloses this **ccPolyline**. The vertices of the convex hull are always a subset of the vertices of this **ccPolyline**.

Notes

This method always computes a right-handed hull.

It returns an empty, closed polyline if this polyline is empty.

generalWindingAngle

```
ccRadian generalWindingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve. This implementation is equivalent to the **windingAngle()** method of the **ccShape** base class, with the exception that this method may be applied to any polyline, including one that is closed or empty.

Parameters

p	The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

Notes

If this polyline is empty, this method returns 0 radians.

The winding angle of a closed polyline is always a multiple of 2π radians.

See **ccShape::windingAngle()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this polyline.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if and only if this polyline is open and has at least one vertex. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if and only if this polyline is closed and has at least one vertex. A polyline is a region even if it encloses zero area. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For polylines, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if this polyline has no vertices, otherwise false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

This function returns true if the perimeter of this polyline is positive. It returns false if the perimeter is zero. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For polylines, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For polylines, this function always returns true. See **ccShape::reverse()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this polyline.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this polyline to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p The point.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

See **ccShape::nearestPoint()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this polyline to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this polyline.

point The point.

See **ccShape::nearestPerimPos()** for more information.

startPoint

```
virtual cc2Vect startPoint() const;
```

Returns the starting point of this polyline if it is an open contour.

Throws

ccShapesError::NotOpenContour
This polyline is not an open contour.

See **ccShape::startPoint()** for more information.

endPoint

```
virtual cc2Vect endPoint() const;
```

Returns the ending point of this polyline if it is an open contour.

Throws

ccShapesError::NotOpenContour
This polyline is not an open contour.

See **ccShape::endPoint()** for more information.

startAngle

```
virtual ccRadian startAngle() const;
```

Returns the starting tangent direction of this polyline if it is an open contour.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this polyline.

ccShapesError::NoTangent
hasTangent() is false for this polyline.

See **ccShape::startAngle()** for more information.

endAngle

```
virtual ccRadian endAngle() const;
```

Returns the ending tangent direction of this polyline if it is an open contour. Note that polylines can be either open or closed.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this polyline.

ccShapesError::NoTangent
hasTangent() is false for this polyline.

See **ccShape::endAngle()** for more information.

tangentRotation

```
virtual ccRadian tangentRotation() const;
```

Returns the net signed angle through which the tangent vector rotates from the start point to the end point.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this polyline.

ccShapesError::NoTangent
hasTangent() is false for this polyline.

See **ccShape::tangentRotation()** for more information.

windingAngle

```
virtual ccRadian windingAngle(const cc2Vect &p) const;
```

Returns the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

Parameters

p	The start point of the vector *p->t* whose angle is measured as the end point *t* traces this polyline.

Notes

This method is used for determining whether *p* is inside or outside of a region whose boundary includes this polyline.

Throws

ccShapesError::NotOpenContour
isOpenContour() is false for this polyline.

See **ccShape::windingAngle()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Implements the **within()** method of the **ccShape** base class for polylines.

Parameters

p	The point.

Throws

ccShapesError::NotRegion
This polyline is not a region.

See **ccShape::within()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if and only if this polyline is right-handed.

Throws

ccShapesError::NotRegion
This polyline is not a region.

Notes

The value returned by this function is undefined for self-intersecting polylines.

See **ccShape::isRightHanded()** for more information.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this polyline. See **ccShape::reverse()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
 ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.
result	Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores polylines for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this polyline mapped by *X*.

Parameters

X The transformation object.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccContourTree** consisting of connected **ccLineSeg**s.

See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this polyline over the given perimeter range.

Parameters

info Shape information for this polyline.

range The perimeter range.

See **ccShape::subShape()** for more information.

ccPolyline

ccPtrHandle

```
#include <ch_cvl/handle.h>

template <class T,
          class B = ccPtrHandleBase<T>,
          class C = ccPtrHandleBase_const<T> >
  class ccPtrHandle : public B,
                      public virtual ccPtrHandle_const<T,C> ;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

ccPtrHandle is a template class used to create a pointer handle to another class.

T	The class for which a handle pointer is being created.
B	The class that serves as a pointer handle to the base class.
C	The class that serves as a **const** pointer handle to the base class.

For more information on pointer handles, see the section *CVL Programming Conventions* in the chapter *CVL Programming Overview* in the *CVL User's Guide*.

To define a pointer handle **ccAlphaPtrh** to objects of class **ccAlpha**, you would use the following declaration:

```
typedef ccPtrHandle<ccAlpha> ccAlphaPtrh;
```

Note that **ccAlpha** must be derived from **ccRepBase** as shown on page 2727.

To define pointer handles to a class, **ccBeta**, that is derived from a class that is already derived from **ccRepBase**, use the **cmDerivedPtrHdlDcl** macro like this:

1. Define **const** and non-**const** pointer handle types for the ancestor class **ccAlpha**.

   ```
   typedef ccPtrHandle<ccAlpha> ccAlphaPtrh;
   typedef ccPtrHandle_const<ccAlpha> ccAlphaPtrh_const;
   ```

2. Use the **cmDerivedPtrHdlDcl** macro to declare the pointer handle types for **ccBeta**.

   ```
   cmDerivedPtrHdlDcl(ccBetaPtrh, ccBeta,
                      ccAlphaPtrh, ccAlphaPtrh_const);
   ```

The macro defines the pointer handle types **ccBetaPtrh** and **ccBetaPtrh_const** that point the rep class **ccBeta**.

Constructors/Destructors

ccPtrHandle

```
ccPtrHandle(T* rep = 0);
```

Creates a pointer handle to object *rep*. The reference count of *rep* is incremented.

Parameters

rep A pointer to the handled object.

operator=

```
ccPtrHandle& operator=(T*rep);
ccPtrHandle& operator=(const ccPtrHandle& rhs);
```

- `ccPtrHandle& operator=(T*rep);`

Assignment operator. This pointer handle will point to a handled object *rep*. If this pointer handle pointed to an object before assignment, its reference count is decremented. The reference count of *rep* is incremented.

Parameters

rep A pointer to an object of the handled class.

- `ccPtrHandle& operator=(const ccPtrHandle& rhs);`

Assignment operator. This pointer handle will point to the same object that the pointer handle *rhs* points to. If this pointer handle pointed to an object before assignment, its reference count is decremented. The reference count of *rep* is incremented.

Parameters

rhs A pointer handle.

operator*

```
T& operator*() const;
```

Returns a reference to the object that this pointer handle points to.

Throws

ccBadPointer The pointer handle is null.

operator->

```
T* operator->() const;
```

Returns a pointer to the handled object that can be used to refer to data members. This function allows you to use the **->** operator as if the pointer handle were a regular pointer.

Throws

ccBadPointer The pointer handle is null.

operator const void*

```
operator const void* () const;
```

Allows for testing for null pointers. If this pointer handle is null, this function returns a null pointer. Otherwise, it returns a non-null pointer.

Use this cast operator only for testing whether a pointer handle is null. To get the object that the pointer handle points to, use **rep()** instead.

operator!

```
bool operator!() const;
```

Allows testing for null pointers. Returns true if the pointer handle is null.

Public Member Functions

rep

```
T* rep() const;
```

Returns the handled object. Returns null if this pointer handle is null.

disconnectRep

```
T* disconnectRep();
```

Returns the handled object and disconnects it from this handle. The handled object's reference count is decremented, and the pointer handle is set to null.

Macros

cmDerivedPtrHdlDcl

```
cmDerivedPtrHdlDcl(derivedHdl, derivedRep,
  baseHdl, baseHdl_const);
```

Defines pointer handle types for classes that are derived from classes that are derived from **ccRepBase**. This macro defines two types named ***derivedHdl*** and ***derivedHdl*_const**.

For an example of how to use this macro see the beginning of this chapter.

Parameters

derivedHdl The non-**const** type name of the new pointer handle type. Usually ***derivedRep*PtrH**

derivedRep	The name of the class for which to create pointer handle types. This is a class that is derived from a class derived from **ccRepBase**.
baseHdl	The name of the non-**const** pointer handle type to the class from which *derivedRep* is derived.
baseHdl_const	The name of the **const** pointer handle type to the class from which *derivedRep* is derived.

ccPtrHandle_const

```
#include <ch_cvl/handle.h>

template <class T,
          class B = ccPtrHandleBase_const<T> >
  class ccPtrHandle_const : public virtual B ;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

ccPtrHandle_const is a template class that creates a const pointer handle to another class.

T	The class for which a handle pointer is being created.
B	The class that serves as a **const** pointer handle to the base class.

A **const** pointer handle has similar semantics to a C++ **const** pointer. For more information on pointer handles, see the section *CVL Programming Conventions* in the chapter *CVL Programming Overview* in the *CVL User's Guide*.

To define a **const** pointer handle **ccAlphaPtrh_const** to objects of class **ccAlpha**, you would use the following declaration:

```
typedef ccPtrHandle_const<ccAlpha> ccAlphaPtrh_const;
```

Note that **ccAlpha** must be derived from **ccRepBase** as shown on page 2727.

To define pointer handles to a class, **ccBeta**, that is derived from a class that is already derived from **ccRepBase**, use the **cmDerivedPtrHdlDcl** macro like this:

1. Define **const** and non-**const** pointer handle types for the ancestor class **ccAlpha**.

   ```
   typedef ccPtrHandle<ccAlpha> ccAlphaPtrh;
   typedef ccPtrHandle_const<ccAlpha> ccAlphaPtrh_const;
   ```

2. Use the **cmDerivedPtrHdlDcl** macro to declare the pointer handle types for **ccBeta**.

   ```
   cmDerivedPtrHdlDcl(ccBetaPtrh, ccBeta,
                      ccAlphaPtrh, ccAlphaPtrh_const);
   ```

   The macro defines the pointer handle types **ccBetaPtrh** and **ccBetaPtrh_const** that point the rep class **ccBeta**.

Constructors/Destructors

ccPtrHandle_const

```
ccPtrHandle_const(T* rep = 0);
```

Creates a pointer handle to object *rep*. The reference count of *rep* is incremented.

Parameters

rep	A pointer to the handled object.

Operators

operator=

```
ccPtrHandle_const& operator=(T*rep);

ccPtrHandle_const& operator=(const ccPtrHandle_const&
rhs);
```

- ```
  ccPtrHandle_const& operator=(T* rep);
  ```

  Assignment operator. This pointer handle will point to a handled object *rep*. If this pointer handle pointed to an object before assignment, its reference count is decremented. The reference count of *rep* is incremented.

  Parameters

rep	A pointer to an object of the handled class.

- ```
  ccPtrHandle_const& operator=(
    const ccPtrHandle_const& rhs);
  ```

  Assignment operator. This pointer handle will point to the same object that the pointer handle *rhs* points to. If this pointer handle pointed to an object before assignment, its reference count is decremented. The reference count of *rep* is incremented.

  Parameters

rhs	A pointer handle.

operator*

```
const T& operator*() const;
```

Returns a reference to the object that this pointer handle points to.

Throws

ccBadPointer	The pointer handle is null.

operator->

```
const T* operator->() const;
```

Returns a pointer to the handled object that can be used to refer to data members. This function allows you to use the **->** operator as if the pointer handle were a regular pointer.

Throws

ccBadPointer The pointer handle is null.

operator const void*

```
operator const void* () const;
```

Allows for testing for null pointers. If this pointer handle is null, this function returns a null pointer. Otherwise, it returns a non-null pointer.

Use this cast operator only for testing whether a pointer handle is null. To get the object that the pointer handle points to, use **rep()** instead.

operator!

```
bool operator!() const;
```

Allows testing for null pointers. Returns true if the pointer handle is null.

Public Member Functions

rep

```
const T* rep() const;
```

Returns the handled object. Returns null if this pointer handle is null.

disconnectRep

```
const T* disconnectRep();
```

Returns the handled object and disconnects it from this handle. The handled object's reference count is decremented, and the pointer handle is set to null.

ccPtrHandle_const

ccPVEReceiver

```
#include <ch_cvl/pve_xfer.h>

class ccPVEReceiver;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

Programmable Vision Engines (PVE) is a legacy technology from Cognex. This class provides functions to read files written by the following PVE functions, written by PVE versions 5.2 through 8.1:

- **ctr_transmit_model()**
- **cip_transmit_image()**
- **cnls_transmit_model()**

Constructors/Destructors

ccPVEReceiver

```
ccPVEReceiver();

ccPVEReceiver(const ccCvlString& pathname);

ccPVEReceiver(cmStd istream& i,
  const ccCvlString& name = cmT("[unknown]"));
```

- `ccPVEReceiver();`

  Creates an unbound **ccPVEReceiver**.

- `ccPVEReceiver(const ccCvlString& pathname);`

  Creates a **ccPVEReceiver** from a file on disk. If successful, the receiver is bound to the file. This function expects that only one object is stored in a file.

  This constructor is intended for use with temporary instantiations of **ccPVEReceiver**. For example:

```
ccPelBuffer<c_UInt8> pelbuf; // some pel buffer

try {
   // extract an image
  pelbuf = ccPVEReceiver(filename).image();
  ...
}
catch(ccPVEReceiver::Warning& w) { ... }
catch(ccException& e) { ... }
```

  Parameters

  pathname The name of the file.

  Throws

  ccPVEReceiver::FileNotFound
  pathname cannot be opened.

  ccPVEReceiver::BadFormat
  The PVE transfer file is improperly formatted and cannot be read.

  ccPVEReceiver::NotImplemented
  The PVE transfer file contains a valid object type but one that **ccPVEReceiver** cannot parse.

  The PVE transfer file contains an image deeper than 8 bits.

  ccPVEReceiver::Warning
  Initialization encountered a recoverable error. See **warnings()** on page 2674.

- `ccPVEReceiver(cmStd istream& i,`
  `const ccCvlString& name = cmT("[unknown]"));`

  Creates a **ccPVEReceiver** using a stream. If successful, the receiver is bound to the stream.

  Parameters

  i The input stream.

name The name of the stream. This name is used only when generating error messages. It should be the name of the file or input source of the input stream.

Throws

ccPVEReceiver::BadFormat
The PVE transfer stream is improperly formatted and cannot be read.

ccPVEReceiver::NotImplemented
The PVE transfer stream contains a valid object type but one that **ccPVEReceiver** cannot parse.

The PVE transfer file contains an image deeper than 8 bits.

ccPVEReceiver::Warning
Initialization encountered a recoverable error. See **warnings()** on page 2674.

Enumerations

ObjectType

```
enum ObjectType;
```

This enumeration is used by **objectType()** to return the type of object that a **ccPVEReceiver** is bound to.

Value	Meaning
eModel	The object is a PVE model.
eImage	The object is a PVE image or CNLSearch model. (See **isCnls()** on page 2672.)

Public Member Functions

init

```
void init();

void init(const ccCvlString& pathname);

void init(cmStd istream& i,
  const ccCvlString& name = cmT("[unknown]"));
```

- `void init();`

  Unbinds this **ccPVEReceiver** if it was bound.

- `void init(const ccCvlString& pathname);`

  Initializes an existing **ccPVEReceiver** to use a file on disk. If successful, the **ccPVEReceiver** is bound to the file.

  Parameters

  pathname The name of the file.

  Throws

  ccPVEReceiver::FileNotFound
  pathname cannot be opened.

  ccPVEReceiver::BadFormat
  The PVE transfer file is improperly formatted and cannot be read.

  ccPVEReceiver::NotImplemented
  The PVE transfer file contains a valid object type but one that **ccPVEReceiver** cannot parse.

  The PVE transfer file contains an image deeper than 8 bits.

  ccPVEReceiver::Warning
  Initialization encountered a recoverable error. **warnings()** on page 2674.

- ```
  void init(cmStd istream& i,
    const ccCvlString& name = cmT("[unknown]"));
  ```

  Initializes a **ccPVEReceiver** from a stream. If successful, the receiver is bound to the stream, and leaves the stream at the end of the first persisted object. Successive calls to this version of **init()** provide access to other persisted objects in the stream.

  Parameters

  i The input stream.

  name The name of the stream. This name is used only when generating error messages. It should be the name of the file or input source of the input stream.

  Throws

  ccPVEReceiver::BadFormat
  The PVE transfer stream is improperly formatted and cannot be read.

  ccPVEReceiver::NotImplemented
  The PVE transfer stream contains a valid object type but one that **ccPVEReceiver** cannot parse.

  The PVE transfer stream contains an image deeper than 8 bits.
  ```

ccPVEReceiver::Warning
Initialization encountered a recoverable error. **warnings()** on page 2674

image

```
ccPelBuffer_const<c_UInt8> image() const;
```

Returns the image stored in the PVE transfer file or stream bound to this **ccPVEReceiver**.

Throws

ccPVEReceiver::Unbound
This **ccPVEReceiver** has not been successfully initialized.

maskImage

```
ccPelBuffer_const<c_UInt8> maskImage() const;
```

Returns the mask image of the search model stored in the PVE transfer file or stream bound to this **ccPVEReceiver**. If the persisted object was a model that was trained without a mask image, **maskImage()** returns an unbound **ccPelBuffer**.

In mask images, the pixel values have the following meanings:

Pixel value	PVE Type	Description
0	*cse_normal*	An ordinary “care” pixel
1	*cse_border*	A “care” pixel that borders an EdgeType
2	*cse_edge*	An “edge don‘t care” pixel
3	*cse_mask*	A “mask don’t care” pixel

Pixel values 0 and 1 are generally “care” pixels, and pixel values 2 and 3 are “don’t care” pixels. For more information, see the PVE search documentation on the subject of mask images for training and the header file *cse_mdl.h*.

Throws

ccPVEReceiver::Unbound
The **ccPVEReceiver** has not been successfully initialized.

ccPVEReceiver::WrongType
This type of transmitted PVE object has no mask image associated with it (for example, a **cip_buffer** or CNLSearch model).

origin `cc2Vect origin() const;`

Returns the origin of the search model.

Throws

ccPVEReceiver::Unbound
This **ccPVEReceiver** has not been successfully initialized.

ccPVEReceiver::WrongType
objectType() returned *ccPVEReceiver::eImage* and **isCnls()** returned false.

hasID `bool hasID() const;`

Returns whether an ID was part of the PVE object.

id `c_Int32 id() const;`

Returns the ID of the CNLPAS model.

Throws

ccPVEReceiver::WrongType
If **hasID()** is false, that is, if this type of transmitted PVE object has no ID.

isBound `bool isBound() const;`

Returns true if this **ccPVEReceiver** is bound to a file or stream, false otherwise.

objectType `ObjectType objectType() const;`

Returns the object type that this **ccPVEReceiver** contains:

- *ccPVEReceiver::eModel*
- *ccPVEReceiver::eImage*

Notes

The **objectType()** of a CNLSearch model is *ccPVEReceiver::eImage*. To determine if this object contains a CNLSearch model, use **isCnls()**.

isCnls `bool isCnls() const;`

Returns true if the image is a PVE CNLSearch model, false if it is a **cip_buffer**.

imageDepth

```
int imageDepth() const;
```

Returns the depth of the image, **cip_buffer.depth**.

version

```
int version() const;
```

Returns the version number of the PVE object.

filename

```
ccCvlString filename() const;
```

Returns the name of the file that this object is stored in.

Throws

ccPVEReceiver::Unbound
This **ccPVEReceiver** has not been successfully initialized.

modelResolution

```
ccIPair modelResolution() const;
```

Returns the amount by which the original image was subsampled before a model was trained as a pair of integers: **ccIPair(cse_model.prx, cse_model.pry)**.

If these two values are not both equal to 1, then **image()** will return an image that is of reduced resolution (subsampled) compared to the original image upon which the model was trained. See the Search PVE documentation for more information on *prx* and *pry*.

Throws

ccPVEReceiver::Unbound
This **ccPVEReceiver** has not been successfully initialized.

ccPVEReceiver::WrongType
The **ccPVEReceiver** does not contain a model object.

warnings `const ccCvlString& warnings() const;`

Returns any recoverable errors, such as corrupted data, internal inconsistencies, or known PVE bugs, encountered while initializing this **ccPVEReceiver**. If there are no warnings, this function returns a zero-length string.

In general, when any of the **ccPVEReceiver** functions throw an exception during initialization, an unrecoverable error has occurred, and the **ccPVEReceiver** is not bound to a file or stream. However, if a function throws the exception *ccPVEReceiver::Warning* during initialization, a recoverable error has occurred and the persisted object data may still be partially or completely intact.

In the case of an initialization warning, all functions will return correct values and the image will be the correct size, but some or all of its pixels may be corrupted or lost. Such pixels are set to zero. This corruption can happen in the following cases:

- The input serialized object is incomplete.
- Some of the pixels are corrupted because of one of the known bugs in PVE persistence
- One of the error-detection mechanisms (blocking and checksumming) detects data corruption

Use this function or **ccPVEReceiver::Warning.message()** to get an explanation of the warning.

Throws

ccPVEReceiver::Unbound
This **ccPVEReceiver** has not been successfully initialized.

ccRadian

```
#include <ch_cvl/units.h>

class ccRadian;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class describes an angle in radians using a floating point representation.

Note that you can use the constructors to convert from one angle representation to another. For example, to specify 36° in radians, you could write:

```
ccRadian rad(ccDegree(36.0));
```

Constructors/Destructors

ccRadian

```
ccRadian();
ccRadian(ccDegree a);
ccRadian(ccAngle8 a);
ccRadian(ccAngle16 a);
explicit ccRadian(double a);
```

- `ccRadian();`

  Creates an uninitialized **ccRadian** object.

- `ccRadian(ccDegree a);`

  Creates a **ccRadian** object from the given **ccDegree** object.

  Parameters

  a The **ccDegree** object to convert to radians.

- `ccRadian(ccAngle8 a);`

  Creates a **ccRadian** object from the given **ccAngle8** object.

  Parameters

  a The **ccAngle8** object to convert to radians.

- `ccRadian(ccAngle16 a);`

  Creates a **ccRadian** object from the given **ccAngle16** object.

  Parameters

  a The **ccAngle16** object to convert to radians.

- `explicit ccRadian(double a);`

  Creates a **ccRadian** object with the specified value.

  Parameters

  a The angle in radians.

Operators

operator+

```
ccRadian operator+(ccRadian a) const;
```

Returns the result of adding the angle *a* in radians to this angle.

Parameters

a The angle to add to this angle.

operator-

```
ccRadian operator-(ccRadian a) const;
ccRadian operator-() const;
```

- `ccRadian operator-(ccRadian a) const;`

  Returns the result of subtracting the angle *a* in radians from this angle.

  Parameters

  a The angle to subtract from this angle.

- `ccRadian operator-() const;`

  Returns the negative of this angle. The unary minus operator.

operator*

```
ccRadian operator*(double a) const;
double operator*(ccRadian a) const;
friend ccRadian operator*(double a, ccRadian b);
```

- `ccRadian operator*(double a) const;`

  Returns the result of multiplying this angle by *a*.

  Parameters

  a The amount to multiply by.

- `double operator*(ccRadian a) const;`

  Returns the result of multiplying this angle by the angle *a* in radians.

  Parameters

  a The angle to multiply by.

- `friend ccRadian operator*(double a, ccRadian b);`

  Returns the result of multiplying the angle *b* by *a*.

  Parameters

  a The amount to multiply by.

  b The angle to multiply.

operator/

```
ccRadian operator/(double a) const;
double operator/(ccRadian a) const;
```

- `ccRadian operator/(double a) const;`

  Returns the result of dividing this angle by *a*.

  Parameters

  a The amount to divide by.

- `double operator/(ccRadian a) const;`

  Returns the result of dividing this angle by the angle *a* in radians.

  Parameters

  a The angle to divide by.

operator=

```
ccRadian& operator=(double a);
```

Assigns the value *a* to this angle.

Parameters

a The value to assign.

---

operator*=

```
ccRadian& operator*=(double a);
ccRadian& operator*=(ccRadian a);
```

- ```
  ccRadian& operator*=(double a);
  ```

  Multiplies this angle by *a* and returns the result.

  Parameters

  a The value to multiply by.

- ```
  ccRadian& operator*=(ccRadian a);
  ```

  Multiplies this angle by the angle *a* and returns the result.

  Parameters

  a The angle to multiply by.

---

operator/=

```
ccRadian& operator/=(double a);
ccRadian& operator/=(ccRadian a);
```

- ```
  ccRadian& operator/=(double a);
  ```

  Divides this angle by the value *a* and returns the result.

  Parameters

  a The value to divide by.

- ```
  ccRadian& operator/=(ccRadian a);
  ```

  Divides this angle by the angle *a* and returns the result.

  Parameters

  a The angle to divide by.

operator+= `ccRadian& operator+=(ccRadian a);`

Adds the angle *a* to this angle and returns the result.

Parameters

a The angle to add.

operator-= `ccRadian& operator-=(ccRadian a);`

Subtracts the angle *a* from this angle and returns the result.

Parameters

a The angle to subtract.

operator== `bool operator==(ccRadian a) const;`

Returns true if this angle is exactly equal to the angle *a*. See **cfRealEq()** on page 3827 for an equality function that lets you specify a tolerance.

Parameters

a The other angle.

operator!= `bool operator!=(ccRadian a) const;`

Returns true if this angle is not equal to the angle *a*.

Parameters

a The other angle.

operator< `bool operator<(ccRadian a) const;`

Returns true if this angle is less than angle *a*.

Parameters

a The other angle.

operator<= `bool operator<=(ccRadian a) const;`

Returns true if this angle is less than or equal to angle *a*.

Parameters

a The other angle.

operator> `bool operator>(ccRadian a) const;`

Returns true if this angle is greater than angle *a*.

Parameters

a The other angle.

operator>= `bool operator>=(ccRadian a) const;`

Returns true if this angle is greater than or equal to angle *a*.

Parameters

a The other angle.

Public Member Functions

toDouble `double toDouble() const;`

Returns this angle as a **double** value.

plain `double plain() const;`

Returns this angle as a **double**.

norm `ccRadian norm() const;`

Returns this angle normalized to the range from 0 up to (but not including) 2π.

signedNorm `ccRadian signedNorm() const;`

Returns this angle normalized to the range from $-\pi$ up to (but not including) π.

ccRange

```
#include <ch_cvl/range.h>

class ccRange;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class characterizes ranges of values and provides methods for performing the following operations:

- Check whether a value is within a range.
- Create a new range by intersecting one range with another.
- Dilate ranges (Minkowski sum operation).
- Erode ranges (Minkowski difference operation).

For example, the class **ccRange** can specify a range such as the range from 2 through 3, which includes the values 2 and 3 and every value in between (2 <= x <= 3).

Constructors/Destructors

ccRange

```
ccRange ();

ccRange (double start, double end);
```

- `ccRange ();`

  Returns the default constructed empty range.

- `ccRange (double start, double end);`

  Returns a **ccRange** object characterized by the given start and end values.

  Parameters

start	The start position of the range.
end	The end position of the range.

Throws

ccRangeDefs::BadParams
The start is greater than the end.

Public Member Functions

dilate

```
ccRange dilate(const ccRange &r) const;
```

Returns a new **ccRange** object that is created by dilating this range with another range specified by *r*. Dilation is accomplished by using the Minkowski sum of two sets A and B. The resulting range is the set of all points which can be generated by adding an element of A to an element of B.

Parameters

r The range used to dilate this range.

EmptyRange

```
static ccRange EmptyRange();
```

Returns the default constructed empty range.

end

```
double end() const;
```

Returns the end position of a partial range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial range.

erode

```
ccRange erode(const ccRange &r) const;
```

Returns a new **ccRange** object that is created by eroding this range by another range specified by *r*. Erosion is accomplished by using the Minkowski difference between two sets A and B. The resulting range is the set of all values generated by subtracting an element of B from an element of A.

Parameters

r The range used to erode this range.

FullRange

```
static ccRange FullRange();
```

Returns the default constructed full range.

intersect

```
ccRange intersect(const ccRange &r) const;
```

Returns a new **ccRange** object that specifies the intersection of this range and another range specified by *r*.

Parameters

r The range that intersects this range.

isWithin

```
bool isWithin(double x) const;
```

Returns a bool that indicates whether or not the value *x* is inside this range.

Parameters

x The value that may or may not be inside this range.

length

```
double length() const;
```

Returns the length of the range which is defined as one of the following:

DBL_MAX if the range is full (range_ == *eFull*)

0 if the range is empty (range_ == *eEmpty*)

*end_-start_* if the range contains some members (range_ == ePartial).

middle

```
double middle() const;
```

Returns the middle of the given range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial range.

scale

```
ccRange scale(double x) const;
```

Returns a new **ccRange** object constructed by scaling this range by *x*.

Parameters

x The scaling factor that is used to scale this range.

Throws

ccRangeDefs::BadParams
x is less than or equal to 0.

someOverlap

```
bool someOverlap(const ccRange &r,
  double threshold=0) const;
```

Returns a bool that indicates whether two ranges have some overlap.

Parameters

r The range that is compared to this range.

threshold The length of the range that is compared to this range. The length should be greater than 0.

start

```
double start() const;
```

Returns the start position of a partial range.

Throws

ccRangeDefs::NotPartialRange
This is not a partial range.

translate

```
ccRange translate(double x) const;
```

Returns a new **ccRange** object constructed by translating this range by *x*.

Parameters

x The amount by which this range is translated.

Operators

operator==

```
bool operator== (const ccRange& that) const;
```

True if this range equals the other range; false otherwise.

Parameters

that The other range.

Notes

Two **ccRange** objects are considered equal if their range types, start values, and end values are equal or if they are both empty or both full.

operator!=

```
bool operator!= (const ccRange& that) const;
```

True if this range does not equal that range; false if this range equals that range.

Parameters

that The other range.

Notes

Two **ccRange** objects are considered equal if their ranges, start values and end values are equal or if they are both empty or both full.

ccRange

ccRangeDefs

```
#include <ch_cvl/range.h>

class ccRangeDefs;
```

A name space that holds enumerations and exceptions used with range classes.

Enumerations

Range

```
enum Range;
```

Values for the *Range* parameter.

Value	Meaning
ePartial = 0	Range spans a finite segment that begins with the start number and ends with the end number.
eEmpty = 1	Range is completely empty.
eFull = 2	Range is completely full.

ccRangeDefs

ccRasterizationDefs

```
#include <ch_cvl/raster.h>

class ccRasterizationDefs;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	Simple

This class serves as a namespace for the sampling parameters passed to **ccShape::sample()** operations called by the **cfRasterize()** and **cfRasterizeContour()** global functions. These functions are used to rasterize regions and contours defined by **ccShape** objects.

Note The default constructor is never called. This class has no instances.

Enumerations

BoundaryFillMode

```
enum BoundaryFillMode {
  eUseInterpolatedPelValue,
  eUseLargestPortionPelValue,
  eUseForegroundPelValue,
  eUseBackgroundPelValue,
  kDefaultBoundaryFillMode = eUseInterpolatedPelValue
};
```

This enumeration specifies the value assigned to pixels that are on the boundary between solid and hole regions in a region tree. This is one of the parameters passed to the **cfRasterize()** function.

Value	Meaning
eUseInterpolatedPelValue	Use a grey level that interpolates the existing grey level and the foreground grey level using the fraction of the pixel area covered by region. This is the anti-aliasing mode.
eUseLargestPortionPelValue	Use the foreground grey level if the region covers at least half of the boundary pixel. Otherwise, do not change the pel value.

Value	Meaning
eUseForegroundPelValue	Use the foreground grey level for boundary pixels.
eUseBackgroundPelValue	Do not change boundary pixel values. The existing pixel values remain.
kDefaultBoundaryFillMode	The default boundary fill mode is *eUseInterpolatedPelValue.*

Static Functions

RasterizeSampParams

```
static const
  ccShape::ccSampleParams &RasterizeSampParams();
```

Specifies the sampling parameters used to sample region trees that will be rasterized to a pel buffer using the **cfRasterize()** global function. Returns a reference to a **ccShape::ccSampleParams** object with the following parameter values.

Parameter	Value
Tolerance	0.1
Spacing	0.0
Maximum number of points	*ckMaxInt32*
Compute tangents	False
Duplicate corners	False

ccRect

```
#include <ch_cvl/shapes.h>

class ccRect : public ccShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a rectangle oriented to the client coordinate system's x- and y-axes. You specify the location of the upper left corner of the rectangle and its size. For a general rectangle whose sides are not parallel to the axes, see **ccGenRect**.

Constructors/Destructors

ccRect

```
ccRect();

ccRect(const cc2Vect& ul, const cc2Vect& sz);

ccRect(const ccPelRect &rect);
```

- `ccRect();`

  Default constructor. Constructs a degenerate rectangle whose upper left corner is at (0,0) and whose size is (0,0).

- `ccRect(const cc2Vect& ul, const cc2Vect& sz);`

  Constructs a rectangle at the specified location and of the specified size.

  Parameters

ul	The location of the upper left corner of the rectangle.
sz	The size of the rectangle as a 2-element vector specifying the rectangle's width and height.

  Notes

  Both components of *sz* must be non-negative.

- `ccRect(const ccPelRect &rect);`

  Constructs a rectangle from the supplied **ccPelRect**.

  Parameters

  rect The **ccPelRect** from which to construct this object.

  Notes

  The origin and size are set to those of *rect*.

Operators

operator== `bool operator==(const ccRect& other) const;`

Returns true if this rectangle is equal to another rectangle.

Parameters

other The other rectangle.

operator!= `bool operator!=(const ccRect& other) const;`

Returns true if this rectangle is not equal to another rectangle.

Parameters

other The other rectangle.

operator& `ccRect operator&(const ccRect& r) const;`

Returns the intersection of this rectangle and the rectangle *r*.

Parameters

r The other rectangle.

Public Member Functions

ul `const ccPoint& ul() const;`

Returns the coordinates of the corner with the minimum x- and y- values in client coordinates. This is the upper-left corner of a rectangle in left-handed, non-rotated client coordinates.

ur

```
ccPoint ur() const;
```

Returns the coordinates of the corner with the maximum x- and minimum y- values in client coordinates. This is the upper-right corner of a rectangle in left-handed, non-rotated client coordinates.

lr

```
ccPoint lr() const;
```

Returns the coordinates of the corner with the maximum x- and y- values in client coordinates. This is the lower-right corner of a rectangle in left-handed, non-rotated client coordinates.

ll

```
ccPoint ll() const;
```

Returns the coordinates of the corner with the minimum x- and maximum y- values in client coordinates. This is the lower-left corner of a rectangle in left-handed, non-rotated client coordinates.

sz

```
const cc2Vect& sz () const;
```

Returns the size of the rectangle as a 2-element vector (width, height).

lSeg

```
ccLineSeg lSeg() const;
```

Returns the left line segment of the rectangle.

rSeg

```
ccLineSeg rSeg() const;
```

Returns the right line segment of the rectangle.

tSeg

```
ccLineSeg tSeg() const;
```

Returns the top line segment of the rectangle.

bSeg

```
ccLineSeg bSeg() const;
```

Returns the bottom line segment of the rectangle.

map

```
ccGenRect map(const cc2Xform& c) const;
```

Returns a generalized rectangle that is the result of mapping this rectangle with the transformation object *c*.

Parameters

c The transformation object.

Notes

Both dimensions of this rectangle must be strictly positive, and the transform must be non-singular. If this is not the case, use **mapshape()** instead of this function.

enclose

```
ccRect enclose(const ccRect& r) const;
```

Returns the smallest rectangle that encloses this rectangle and the rectangle *r*.

Parameters

r The rectangle.

degen

```
bool degen() const;
```

Returns true if this rectangle is *degenerate*. A rectangle is degenerate if both of its dimensions are non-positive (less than or equal to zero).

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this rectangle.

isOpenContour

```
virtual bool isOpenContour() const;
```

Returns true if this shape is an open contour. For rectangles, this function always returns false. See **ccShape::isOpenContour()** for more information.

isRegion

```
virtual bool isRegion() const;
```

Returns true if this shape is a region. For rectangles, this function always returns true, even for rectangles that are degenerate. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For rectangles, this function always returns true. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

Returns true if the set of points that lie on the boundary of this shape is empty. For rectangles, this function always returns false. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

This function returns true for most rectangles. It returns false if all four vertices of the rectangle are coincident, in which case the rectangle collapses to a single point and there is no tangent. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For rectangles, this function always returns false. See **ccShape::isDecomposed()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For rectangles, this function always returns false. See **ccShape::reverse()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

For rectangles, this function always returns true. Rectangles are always right-handed. See **ccShape::isRightHanded()** for more information.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this rectangle. See **ccShape::boundingBox()** for more information.

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point on the boundary of this rectangle to the given point. If the nearest point is not unique, one of the nearest points will be returned.

Parameters

p	The point.

See **ccShape::nearestPoint()** for more information.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
  ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this shape.

Parameters

params	Specifies details of how the sampling should be done.

result Result object to which position and tangent chains are appended.

Notes

If **params.computeTangents()** is true, this function ignores rectangles for which **hasTangent()** is false.

See **ccShape::sample()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this rectangle mapped by *X*.

Parameters

X The transformation object.

Notes

If *X* is the identity transform or this rectangle is degenerate, this function returns a **ccRect**. If both of these conditions are false, this function returns a **ccGenRect** if *X* is nonsingular, and a **ccPolyline** if *X* is singular.

See **ccShape::mapShape()** for more information.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a right-handed **ccContourTree** consisting of four connected **ccLineSeg**s. See **ccShape::decompose()** for more information.

within

```
virtual bool within(const cc2Vect& p) const;
```

Returns true if the given point is within this rectangle.

Parameters

p The point.

See **ccShape::within()** for more information.

enclosePelRect

```
ccPelRect enclosePelRect() const;
```

Returns the minimum **ccPelRect** that encloses this **ccRect**.

Deprecated Members

These functions are deprecated and are provided for backwards compatibility only. Use the appropriate functions provided by **ccShape** instead.

encloseRect

```
ccRect encloseRect() const;
```

Use **boundingBox()** instead of this function.

distToPoint

```
double distToPoint(const cc2Vect& v) const;
```

Use **distanceToPoint()** instead of this function.

ccRectangle

```
#include <ch_cvl/rect.h>

template <class T> class ccRectangle;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

The **ccRectangle** class is a template class for describing rectangular regions. Rectangles have an origin, also known as the upper left component, and a height and a width.

T — Template parameter specifying the type of the component values. CVL provides instantiations of **ccRectangle** for the types **c_Int32** and **double**.

Constructors/Destructors

ccRectangle

```
ccRectangle();

ccRectangle(T w, T h);

ccRectangle(T x, T y, T w, T h);

ccRectangle(const ccPair<T>& v1, const ccPair<T>& v2);
```

- `ccRectangle();`

  Makes this rectangle have origin (0,0), with width and height both equal to zero.

- `ccRectangle(T w, T h);`

  Makes this rectangle have width *w* and height *h*. If *w* and *h* are both non-negative, the origin is (0,0).

  Parameters

  w — The width of the rectangle.

  h — The height of the rectangle.

Notes

If *w* is negative, the rectangle's origin x-component is *w* (negative), and its width is *-w* (positive). Similarly, if *h* is negative, the rectangle's origin y-component is *h* (negative), and its height is *-h* (positive).

- `ccRectangle(T x, T y, T w, T h);`

Makes this rectangle have the indicated origin, width, and height.

Parameters

x	The origin's x-component.
y	The origin's y-component.
w	The width of the rectangle.
h	The height of the rectangle.

Notes

If *w* is negative, the rectangle's origin x-component is *x+w*, and its width is *-w* (positive). Similarly, if *h* is negative, the rectangle's origin y-component is *y+h,* and its height is *-h* (positive).

- `ccRectangle(const ccPair<T>& v1, const ccPair<T>& v2);`

Makes this rectangle the minimum enclosing rectangle of the indicated two points.

Parameters

v1	The origin (upper left component)
v2	The lower right component

Operators

operator== `bool operator== (const ccRectangle<T>& other) const;`

Returns true if this rectangle and *other* have the same origin, width, and height.

Parameters

other	The other rectangle to test.

operator!= `bool operator!= (const ccRectangle<T>& other) const;`

Returns true if this rectangle and *other* do not have the same origin, width, and height.

Parameters

other	The other rectangle to test.

operator&

```
ccRectangle<T> operator& (const ccRectangle<T>& other)
  const;
```

Return the rectangle that is the intersection of this rectangle and *other*. This operator has the same effect as calling:

```
ccRectangle<T>::intersect(other, false);
```

Parameters

other The other rectangle to test against this one

Notes

To compute the Greatest Common Rectangle (GCR) of several rectangles, use the following:

```
gcr = (rect1 & rect2 & rect3 & rect4 & ...);
if (!gcr.isNull())
  ...
```

operator&=

```
ccRectangle<T>& operator&= (const ccRectangle<T>& other);
```

Modifies this rectangle to be the intersection of this rectangle and *other*. Returns a reference to this modified object.

Parameters

other The other rectangle to test against this one.

operator|

```
ccRectangle<T> operator| (const ccRectangle<T>& other)
  const;
```

Returns the smallest rectangle that completely encloses this rectangle and *other*. If this rectangle is a null rectangle or if *other* is a null rectangle, this function returns the non-null rectangle. If both this rectangle and other are null rectangles, this function returns a null rectangle whose origin is undefined.

This operator has the same effect as calling:

```
ccRectangle<T>::enclose(other);
```

Parameters

other The other rectangle to consider when constructing the smallest enclosing rectangle.

Notes

To compute the minimum enclosing rectangle of several rectangles, use the following:

```
minRect = (rect1 | rect2 | rect3 | rect4 | ...);
```

operator|=

```
ccRectangle<T>& operator|= (const ccRectangle<T>& other);
```

Modifies this rectangle to be the minimum enclosing rectangle of this rectangle and *other*.

Parameters

other	The other rectangle to consider when constructing the smallest enclosing rectangle.

Public Member Functions

origin

```
const ccPair<T>& origin() const;
void origin(const ccPair<T>&) const;
```

- `const ccPair<T>& origin() const;`

  Returns the origin, or upper left corner, of this rectangle.

- `void origin(const ccPair<T>& orig) const;`

  Sets the origin of this rectangle without modifying its width or height.

  Parameters

orig	The new origin of the rectangle.

translate

```
void translate(const ccPair<T>& trans);
```

Moves the origin of this rectangle without modifying its width or height, by adding *trans* to the rectangle's origin.

Parameters

trans	The point to add to the rectangle's origin

ul

```
const ccPair<T>& ul() const;
```

Returns the coordinates of the corner with the minimum x- and y- values in client coordinates. Same as **origin()**. This is the upper-left corner of a rectangle in left-handed, non-rotated client coordinates.

ur

```
ccPair<T> ur() const;
```

Returns the coordinates of the corner with the maximum x- and minimum y- values in client coordinates. This is the upper-right corner of a rectangle in left-handed, non-rotated client coordinates.

ll

```
ccPair<T> ll() const;
```

Returns the coordinates of the corner with the minimum x- and maximum y- values in client coordinates. This is the lower-left corner of a rectangle in left-handed, non-rotated client coordinates.

lr

```
const ccPair<T>& lr() const;
```

Returns the coordinates of the corner with the maximum x- and y- values in client coordinates. This is the lower-right corner of a rectangle in left-handed, non-rotated client coordinates.

width

```
T width() const;
void width(T w);
```

- `T width() const;`

  Returns the width of this rectangle.

- `void width(T w);`

  Sets the width of this rectangle without changing its origin.

  Parameters

  w The new width of the rectangle.

  Notes

  If *w* is negative, its value is added to the x component of the rectangle's origin, and the rectangle's width is set to *-w* (positive).

height

```
T height() const;
void height(T h);
```

- `T height() const;`

  Returns the height of this rectangle.

- `void height(T h);`

Sets the height of this rectangle without changing its origin.

Parameters

h The new height of the rectangle.

Notes

If *h* is negative, its value is added to the y component of the rectangle's origin, and the rectangle's height is set to *-h* (positive).

---

size

```
ccPair<T> size() const;
void size(const ccPair<T>&);
```

- `ccPair<T> size() const;`

Returns the size of this rectangle. The width is the x component of the returned pair; the height is the y component.

- `void size(const ccPair<T>& siz);`

Sets the width from the x component of *siz*, and sets the height from the y component of *siz*.

Parameters

siz The new size of the rectangle.

Notes

See **width()** and **height()** on page 2703 for a description of how this function handles negative size values.

isNull

```
bool isNull(void) const;
```

Returns true if this rectangle is a null rectangle, that is, its height is zero or its width is zero.

overlaps

```
bool overlaps(const ccRectangle<T>& other,
  bool touching=false) const;
```

Returns true if the *other* overlaps this rectangle.

Parameters

other The rectangle to compare to this rectangle.

touching If true, rectangles that touch at their borders are considered overlapping. If not true, rectangles are considered to overlap only if a portion of one rectangle's border is within the other rectangle

Notes

A rectangle, *rectA*, overlaps a null rectangle, *rectNull*, only if *touching* is true and the following expression is true:

```
rectA.contains(rectNull)
```

contains

```
bool contains(const ccRectangle<T>& rect) const;

bool contains(const ccPair<T>& pt) const;
```

- `bool contains(const ccRectangle<T>& rect) const;`

Returns true if the indicated rectangle is contained within this rectangle.

Parameters

rect The rectangle to test for inclusion in this rectangle.

- `bool contains(const ccPair<T>& pt) const;`

Returns true if the indicated point is contained within this rectangle.

Parameters

pt The point to test for inclusion in this rectangle.

Notes

A point that barely touches the bottom or right borders of a rectangle is not contained in the rectangle.

intersect

```
ccRectangle<T> intersect(const ccRectangle<T>& other,
  bool throwIfNoOverlap=false) const;
```

Returns a rectangle that is the intersection of *other* and this rectangle. If *throwIfNoOverlap* is true, this function throws an error if the rectangles do not overlap. Otherwise, the function returns a null rectangle. It is your responsibility not to use this null rectangle for further rectangle operations.

Parameters

other The other rectangle to test against this one

throwIfNoOverlap
If true, throw an error if the rectangles don't overlap.

Throws

ccRect::NoOverlap
The two rectangles do not overlap and *throwIfNoOverlap* is set.

Notes
Rectangles that just barely touch produce a null ccRectangle whose origin is valid.

enclose

```
ccRectangle<T> enclose(const ccRectangle<T>& other) const;
```

Returns the smallest rectangle that completely encloses this rectangle and *other*. If this rectangle is a null rectangle or if *other* is a null rectangle, this function returns the non-null rectangle. If both this rectangle and other are null rectangles, this function returns a null rectangle whose origin is undefined.

Parameters

other — The other rectangle to consider when constructing the smallest enclosing rectangle.

trim

```
ccRectangle<T> trim(T left, T right, T top, T bottom,
  bool throwIfNegativeSize=false) const;
```

Returns a copy of this rectangle whose edges are trimmed by the amounts specified in *left*, *right*, *top*, and *bottom*. Positive values trim, or shrink, the rectangle. Negative values grow the rectangle.

If *left + right* > **width()** or if *top + bottom* > **height()** and *throwIfNegativeSize* is false, the resulting values are treated as negative values passed to **width()** and **height()**.

Parameters

left — The amount by which to shrink (positive values) or grow (negative values) the left edge of the rectangle

right — The amount by which to shrink (positive values) or grow (negative values) the right edge of the rectangle

top — The amount by which to shrink (positive values) or grow (negative values) the top edge of the rectangle

bottom — The amount by which to shrink (positive values) or grow (negative values) the bottom edge of the rectangle

throwIfNegativeSize
If true, throw an error if *left + right* > **width()** or if *top + bottom* > **height()**.

Throws

ccRect::NegativeSize
: The trimming requested results in negative size values for rectangle and *throwIfNegativeSize* is set.

transpose

```
ccRectangle<T> transpose () const;
```

Returns the transposition of this object. The transposition operation for two rectangles A and B such that

```
A = B.transpose();
```

is defined as follows:

```
A.origin().x() = B.origin.y();
A.origin().y() = B.origin.x();
A.height()     = B.width();
A.width()      = B.height();
```

ccRectangle

ccRegionTree

```
#include <ch_cvl/shaptree.h>

class ccRegionTree : public ccShapeTree;
```

Class Properties

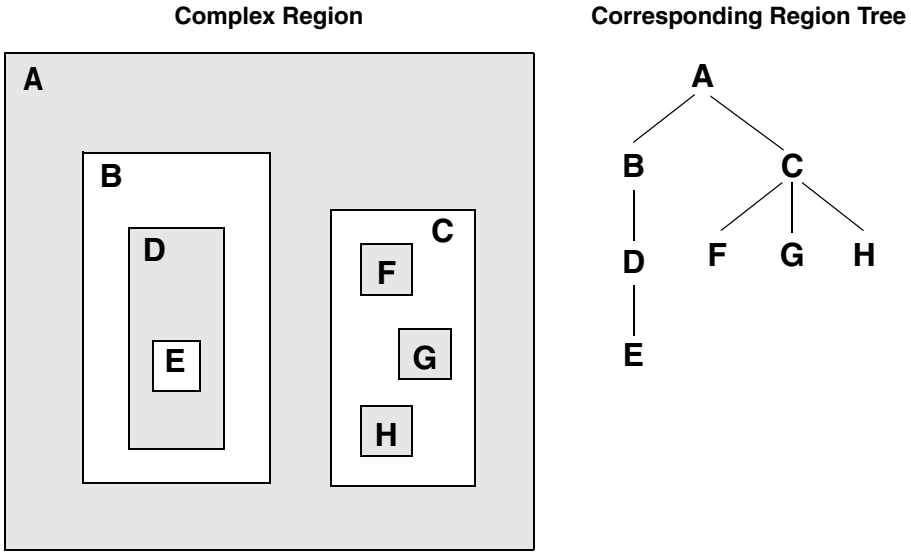
Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class is a concrete class for maintaining hierarchies that define regions of the plane. The regions may or may not be connected and may have holes. Holes may contain solid regions, which may in turn contain more holes, ad infinitum.

The only allowable children for a **ccRegionTree** are other **ccRegionTree**s. In addition to children, all **ccRegionTree**s have a boundary. The boundary must be any shape, other than a **ccRegionTree**, for which **isRegion()** is true. Possibilities include primitive shapes, such as **ccEllipse**, or closed **ccContourTree**s. Note that **ccRegionTree**s have a different structure than other hierarchical shapes. Primitive shapes are stored at the internal nodes of the hierarchy as boundaries, not as leaf nodes in the hierarchy.

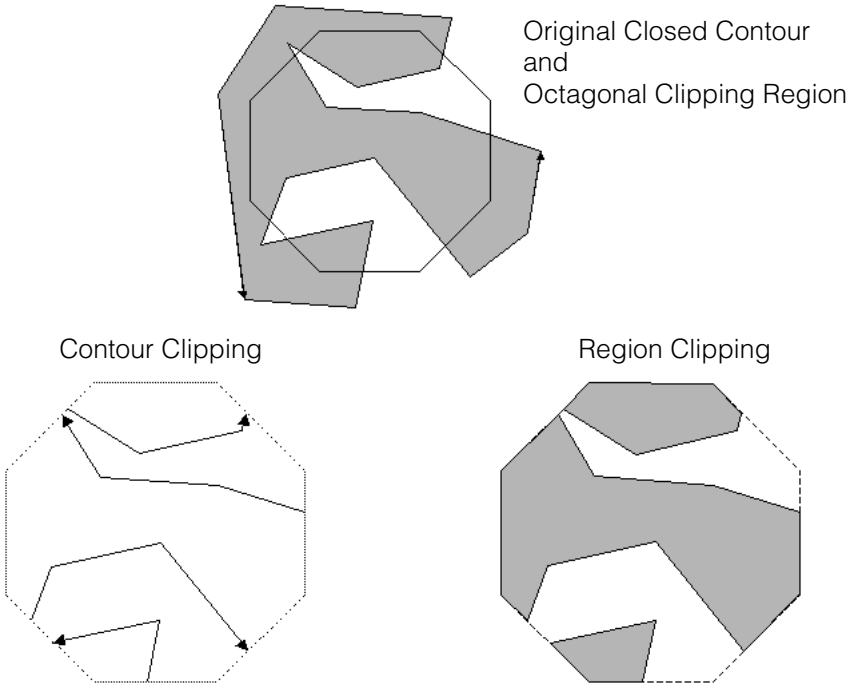
If node A is a parent of node B in a **ccRegionTree**, then B is a hole within solid region A, or B is a solid region within hole A. Thus, the boundary of the root of a **ccRegionTree** encloses the boundaries of all of its descendants. The following figure shows a complex

region and the corresponding region tree. Solid regions are grey and holes are white. In this example the boundaries are all rectangles, but in general they can be any region shapes other than a **ccRegionTree**s.



Multiple disjoint solid regions can be represented in a single **ccRegionTree** by enclosing all of them with a hole region forming the root of the hierarchy. Such *phantom holes* are not rasterized. They are also excluded from certain geometric calculations, such as **area()** and **perimeter()**.

ccRegionTrees are clipped as regions rather than contours. The following figure illustrates the difference between region clipping and contour clipping.



Contour clipping produces a set of contours inside the clipping region. Information regarding whether the contours came from the same continuous boundary and their ordering along such a boundary is lost. Contour clipping is appropriate for applications such as PatMax training where the contours, not the area enclosed by them, is significant.

Region clipping produces a set of regions, bounded by closed contours, inside the clipping region. It does this by appropriately joining the contours produced by contour clipping and adding portions of the clipping region boundary when necessary. Region clipping is appropriate for applications like such as rasterization where the area enclosed by the contours is significant.

Constructors/Destructors

ccRegionTree

```
ccRegionTree();

explicit ccRegionTree(const ccShape &boundary,
  bool hole = false);

explicit ccRegionTree(const ccShapePtrh_const &boundary,
  bool hole = false);

ccRegionTree(const ccRegionTree &orig);
```

- `ccRegionTree();`

  Default constructor. Constructs a solid (non-hole) **ccRegionTree** with a boundary that is a degenerate circle (zero radius, centered at the origin) and no children.

  Notes

  A default constructed **ccRegionTree** is generally not useful. This method is provided to support STL vectors and the complex persistence framework, which both require a default constructor.

- `explicit ccRegionTree(const ccShape &boundary, bool hole = false);`

  Constructs a **ccRegionTree** with the given boundary and no children. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  boundary — The boundary of the region tree, specified as a reference to a **ccShape**.

  hole — If true, the region enclosed by the boundary is set to a hole region; if false (the default), it is set to a solid region.

  Notes

  This version of the constructor copies the boundary, specified as a reference to a **ccShape**, into this region tree using **clone()**. This version is somewhat slower than the pointer handle version (see the next overload). However, Cognex recommends using this version unless there is a compelling reason not to.

  Throws

  ccShapesError::NotRegion
  boundary is not a region shape.

  ccShapesError::BadGeom
  boundary is neither a primitive shape nor a **ccContourTree**.

- ```
  explicit ccRegionTree(const ccShapePtrh_const &boundary,
    bool hole = false);
  ```

  Constructs a **ccRegionTree** with the given boundary and no children. This constructor is used for explicit construction only and not for implicit conversions.

  Parameters

  boundary The boundary of the region tree, specified as a pointer handle to a **ccShape**.

  hole If true, the region enclosed by the boundary is set to a hole region; if false (the default), it is set to a solid region.

  Notes

  This version of the constructor inserts the boundary directly into the region tree and is, therefore, faster than the reference version (see the previous overload). In this version, this region tree takes ownership of the object to which *boundary* points, and you should not modify the object after this constructor has been invoked. This version of the constructor is provided as an optimization. Cognex recommends using the reference version unless there is a compelling reason not to.

  Throws

  ccShapesError::NotRegion
  boundary is not a region shape.

  ccShapesError::BadGeom
  boundary is neither a primitive shape nor a **ccContourTree**.

- ```
  ccRegionTree(const ccRegionTree &orig);
  ```

  Copy constructor. Constructs a **ccRegionTree** that is a copy of the supplied **ccRegionTree**.

  Parameters

  orig The original region tree.

  Notes

  The newly constructed **ccRegionTree** is identical to *orig* in all respects, except that it is always the root of a hierarchy. Hence, **isRoot()** always returns true for the newly constructed **ccRegionTree**, regardless of the value of **orig.isRoot()**.

  Copies and assignments are shallow, that is, they are achieved by copying pointer handles. Hence, both copy construction and assignment lead to sharing of children between different **ccShapeTree**s.

Operators

operator==

```
bool operator==(const ccRegionTree &rhs) const;
```

Returns true if and only if this **ccRegionTree** is equal to *rhs*. Two **ccRegionTree**s are equal if all of the following conditions are true:

- They are equal as **ccShapeTree**s.
- Their corresponding boundaries are all equal and have the same solid/hole status.
- They are either both roots of a hierarchy, or both not roots.

Parameters

rhs The other **ccRegionTree**.

operator!=

```
bool operator!=(const ccRegionTree &rhs) const;
```

Returns true if and only if this **ccRegionTree** is not equal to *rhs*.

Parameters

rhs The other **ccRegionTree**.

Public Member Functions

isHole

```
bool isHole() const;
```

Returns true if the root boundary of this **ccRegionTree** encloses a hole region, false if it encloses a solid region.

isRoot

```
bool isRoot() const;
```

Returns true if and only if this **ccRegionTree** is the root of a hierarchy (that is, has no parent).

Notes

This method is primarily useful for detecting phantom holes, which are holes at the root of a hierarchy used to group disjoint solid regions into a single **ccRegionTree**. Phantom holes are not rasterized. They should also be excluded from certain geometric calculations, such as **area()** and **perimeter()**.

boundary

```
void boundary(const ccShape &shape);
void boundary(const ccShapePtrh_const &shape);
const ccShape &boundary() const;
```

- `void boundary(const ccShape &shape);`

Sets the boundary of this **ccRegionTree**. The hole status of the boundary remains unchanged.

Parameters

shape The shape that defines the boundary of this region tree.

Notes

This version of **boundary()** copies the new boundary into this **ccRegionTree** indirectly using **clone()**. It is somewhat slower than the pointer handle version (see next overload), which inserts the boundary directly. However, Cognex recommends using this version rather than the pointer handle version unless there is a compelling reason not to.

Throws

ccShapesError::NotRegion
boundary is not a region shape.

ccShapesError::BadGeom
boundary is a **ccRegionTree**.

- `void boundary(const ccShapePtrh_const &shape);`

Sets the boundary of this **ccRegionTree**. The hole status of the boundary remains unchanged.

Parameters

shape The shape that defines the boundary of this region tree.

Notes

A valid boundary shape is any shape for which **isRegion()** is true other than another **ccRegionTree**, such as a closed primitive shape (for example, **ccCircle**) or a closed **ccContourTree**.

This version of **boundary()** inserts the new boundary directly into this **ccRegionTree**. It is faster than the reference version (see previous overload), which copies the boundary indirectly using **clone()**. In this version, this **ccRegionTree** takes ownership of the object to which *boundary* points, and you should not modify the object after this constructor has been invoked. For this reason, Cognex recommends using the reference version unless there is a compelling reason not to.

Throws

ccShapesError::NotRegion
boundary is not a region shape.

ccShapesError::BadGeom
boundary is a **ccRegionTree**.

- `const ccShape &boundary() const;`

Returns the root boundary of this **ccRegionTree**. The boundary is a shape for which **isRegion()** is true. It may be either a primitive shape or a **ccContourTree**.

flip

```
ccRegionTreePtrh flip() const;
```

Returns a new **ccRegionTree** that is identical to this one, except that it has the opposite solid/hole status. Each of the descendants of returned tree also has the opposite solid/hole status from the corresponding descendant in this **ccRegionTree**.

insertChild

```
virtual void insertChild(c_Int32 idx,
 const ccShape &child);

virtual void insertChild(c_Int32 idx,
 const ccShapePtrh_const &child, bool direct = false);
```

- `virtual void insertChild(c_Int32 idx,`
  `const ccShape &child);`

Inserts the given child into this **ccRegionTree** at the given index.

Parameters

idx The index.

child The child to insert.

Throws

ccShapesError::BadGeom
An attempt was made to insert a child that is not itself a **ccRegionTree**.

An attempt was made to insert a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a

child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

ccShapesError::BadIndex
idx is less than zero or greater than **numChildren()** before the insertion.

See **ccShapeTree::insertChild()** for more information.

- ```
  virtual void insertChild(c_Int32 idx,
    const ccShapePtrh_const &child, bool direct = false);
  ```

Inserts the given child into this **ccRegionTree** at the given index. The child is inserted by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

idx The index.

child The child to insert.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to insert a child that is not itself a **ccRegionTree**.

An attempt was made to insert a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

ccShapesError::BadIndex
idx is less than zero or greater than **numChildren()** before the insertion.

See **ccShapeTree::insertChild()** for more information.
  ```

insertChildren

```
virtual void insertChildren(c_Int32 idx,
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Inserts the given children into this **ccRegionTree** at the given index. The children are inserted by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

idx The index.

children The vector of children to insert.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom

An attempt was made to insert a child that is not itself a **ccRegionTree**.

An attempt was made to insert children that have the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of the children, if necessary, prior to invoking this method.

ccShapesError::BadIndex

idx is less than zero or greater than **numChildren()** before the insertion.

See **ccShapeTree::insertChildren()** for more information.

---

addChild

```
virtual void addChild(const ccShape &child);

virtual void addChild(const ccShapePtrh_const &child,
  bool direct = false);
```

- ```
  virtual void addChild(const ccShape &child);
  ```

Appends the given child to the end of this **ccRegionTree**.

Parameters

child The child to add.
  ```

Throws

ccShapesError::BadGeom

An attempt was made to add a child that is not itself a **ccRegionTree**.

An attempt was made to add a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

See **ccShapeTree::addChild()** for more information.

- ```
  virtual void addChild(const ccShapePtrh_const &child,
    bool direct = false);
  ```

Appends the given child to the end of this **ccRegionTree**. The child is added by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

child To child to add.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom

An attempt was made to add a child that is not itself a **ccRegionTree**.

An attempt was made to add a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

See **ccShapeTree::addChild()** for more information.

addChildren

```
virtual void addChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Adds the given children to this **ccRegionTree**. The children are added by copy insertion or direct insertion, depending on the status of the *direct* flag.
```

Parameters

children The vector of children to add.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom

An attempt was made to add children that are not themselves **ccRegionTree**s.

An attempt was made to insert children that have the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of the children, if necessary, prior to invoking this method.

See **ccShapeTree::addChildren()** for more information.

---

replaceChild

```
virtual void replaceChild(c_Int32 idx,
 const ccShape &child);

virtual void replaceChild(c_Int32 idx,
 const ccShapePtrh_const &child, bool direct = false);
```

- ```
  virtual void replaceChild(c_Int32 idx,
   const ccShape &child);
  ```

Replaces the child at the given index with the given child.

Parameters

idx The index.

child The child replacing the indexed child.

Throws

ccShapesError::BadGeom

An attempt was made to replace with a child that is not itself a **ccRegionTree**.

An attempt was made to replace with a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a
  ```

child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

ccShapesError::BadIndex
idx is less than zero or greater than or equal to **numChildren()** before the replacement.

See **ccShapeTree::replaceChild()** for more information.

- ```
  virtual void replaceChild(c_Int32 idx,
    const ccShapePtrh_const &child, bool direct = false);
  ```

Replaces the child of this **ccRegionTree** at the given index with the given child. The child is replaced by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

idx The index.

child The child replacing the indexed child.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom
An attempt was made to replace with a child that is not itself a **ccRegionTree**.

An attempt was made to replace with a child that has the same solid/hole status as this **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse the solid/hole status of a child, if necessary, prior to invoking this method.

ccShapesError::BadIndex
idx is less than zero or greater than or equal to **numChildren()** before the replacement.

See **ccShapeTree::replaceChild()** for more information.
  ```

replaceChildren

```
virtual void replaceChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Replaces all of the children of this **ccRegionTree** with the given children. The children are replaced by copy insertion or direct insertion, depending on the status of the *direct* flag.

Parameters

children The vector of children replacing the current children.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it.

Throws

ccShapesError::BadGeom

An attempt was made to replace the current children with children that are not themselves **ccRegionTree**s.

An attempt was made to replace with children that have the same solid/hole status as their parent **ccRegionTree**. The solid/hole status of a child must be the opposite of its parent. You can use **flip()** to reverse a child's solid/hole status, if necessary, prior to invoking this method.

See **ccShapeTree::replaceChildren()** for more information.

clone

```
virtual ccShapePtrh clone() const;
```

Returns a pointer to a copy of this region tree.

isRegion

```
virtual bool isRegion() const;
```

For **ccRegionTree**s, this method always returns true. See **ccShape::isRegion()** for more information.

isFinite

```
virtual bool isFinite() const;
```

For **ccRegionTree**s, this method always returns true. Region shapes are necessarily finite. See **ccShape::isFinite()** for more information.

isEmpty

```
virtual bool isEmpty() const;
```

For **ccRegionTree**s, this method always returns false. All boundaries in a region tree hierarchy must be region shapes, which are always non-empty. See **ccShape::isEmpty()** for more information.

hasTangent

```
virtual bool hasTangent() const;
```

Returns true if any of the boundaries in the hierarchy has a tangent. See **ccShape::hasTangent()** for more information.

isDecomposed

```
virtual bool isDecomposed() const;
```

For **ccRegionTree**s, this method always returns false. See **ccShape::isDecomposed()** for more information.

isOpenContour

```
virtual bool isOpenContour() const;
```

For **ccRegionTree**s, this method always returns false. See **ccShape::isOpenContour()** for more information.

isRightHanded

```
virtual bool isRightHanded() const;
```

Returns true if this region tree is right handed.

Notes

A **ccRegionTree** is right handed if and only if its root boundary encloses a solid region. Thus, **isRightHanded()** is equivalent to **!isHole()** for **ccRegionTree**s. Sampling a **ccRegionTree** produces right-handed boundaries for solid regions and left-handed boundaries for hole regions.

See **ccShape::isRightHanded()** for more information.

isReversible

```
virtual bool isReversible() const;
```

For **ccRegionTree**s, this function always returns false. See **ccShape::isReversible()** for more information.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if the boundary of the hierarchy that most tightly encloses the given point corresponds to a solid region. Returns false if the boundary of the root node of the hierarchy does not enclose the given point.

Parameters

p The point.

See **ccShape::within()** for more information./

nearestPoint

```
virtual cc2Vect nearestPoint(const cc2Vect &p) const;
```

Returns the nearest point along the boundary of this shape to the given point.

Parameters

p The point.

Notes

The nearest point to *p* is taken among all boundaries in the hierarchy, excluding phantom holes.

sample

```
virtual void sample(const ccShape::ccSampleParams &params,
 ccShape::ccSampleResult &result) const;
```

Returns sample positions, and possibly tangents, along this region tree.

Parameters

params Parameters object specifying details of how the sampling should be done.

result Result object to which position and tangent chains are stored.

Notes

A separate chain is generated for each boundary in the hierarchy. Each chain is an approximating polygon to a boundary. The polygon is right-handed for boundaries of solid regions and left-handed for boundaries of hole regions. This is true even if, for example, a right-handed polygonal hole is added to a **ccRegionTree**. The **sample()** method reverses the sample points when necessary. The reason for this is that making solid boundaries and hole boundaries have opposite handedness is the best approach for algorithms for which handedness matters. For example, algorithms that rasterize or compute areas of polygonal solid regions can easily be extended to handle regions with holes if the holes are guaranteed to have the opposite handedness to the solid regions.

boundingBox

```
virtual ccRect boundingBox() const;
```

Returns the smallest rectangle that encloses this region tree.

Notes

The enclosing rectangle of this **ccRegionTree** is the smallest rectangle that encloses all the component primitives of the boundaries. This class must override the **boundingBox()** method of **ccShapeTree** because the primitives are stored at internal nodes of the hierarchy instead of at the leaf nodes.

See **ccShape::boundingBox()** for more information.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this region tree.

Notes

Phantom boundaries are not included in the perimeter.

See **ccShape::perimeter()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this region tree to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this region tree.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this region tree mapped by the transformation object *X*.

Parameters

X	The transformation object.

Notes

This method generates a new **ccRegionTree** obtained by mapping each of its boundaries by *X*. The new boundaries are hierarchical refinements of the original boundaries.

Mapping by an affine transform does not change the topology of the region tree; enclosure relationships are maintained. Therefore, the structure of the hierarchy is preserved.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a **ccGeneralShapeTree** that is the decomposed version of the equivalent **ccGeneralShapeTree**. See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this region tree over the given perimeter range.

Parameters

info	Shape information for this region tree.
range	The perimeter range.

See **ccShape::subShape()** for more information.

ccRepBase

```
#include <ch_cvl/handle.h>

class ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

ccRepBase allows any class to be accessed through a pointer handle. For more information on pointer handles, see the section *CVL Programming Conventions* in the chapter *CVL Programming Overview* in the *CVL User's Guide*.

To make a class **ccFoo** accessible through a pointer handle, define **ccFoo** so that it is derived from **ccRepBase**:

```
class ccFoo : public virtual ccRepBase {
  ...
};
```

Use **ccPtrHandle** on page 2659 and **ccPtrHandle_const** on page 2663 to define pointer handles.

Constructors/Destructors

This class is never used on its own. It is always used as a base class.

Public Member Functions

refc

```
c_Int32 refc() const;
```

Returns the number of pointer handles that refer to this object.

ccRepBase

ccRGB

```
#include <ch_cvl/color.h>

class ccRGB;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class represents an RGB color, a color composed of red, green, and blue components. Most CVL functions that operate on colors use **ccColor** on page 1021, a class related to this class. **ccColor** provides stock colors defined as constants and as functions.

Constructors/Destructors

ccRGB

```
ccRGB(c_UInt8 r = 0, c_UInt8 g = 0, c_UInt8 b = 0);
```

Creates a new RGB color.

Parameters

r	The red component. Must be a value from 0 to 255.
g	The green component. Must be a value from 0 to 255.
b	The blue component. Must be a value from 0 to 255.

Operators

operator!=

```
bool operator!= (const ccRGB& c);
```

Returns true if this color is not equal to another color.

Parameters

c	The color to compare to this color.

operator==

```
bool operator== (const ccRGB& c) const;
```

Returns true if this color is equal to another color.

Parameters

c The color to compare to this color.

operator<

```
bool operator< (const ccRGB& c) const;
```

Returns true if the intensity of this color is less than the intensity of another color. The intensity of a color is the average of all three components.

Parameters

c The color compare to this color.

operator>

```
bool operator> (const ccRGB& c) const;
```

Returns true if the intensity of this color is greater than the intensity of another color. The intensity of a color is the average of all three components.

Parameters

c The color compare to this color.

Public Member Functions

r

```
c_UInt8 r() const;
void r(c_UInt8 c);
```

- `c_UInt8 r() const;`

  Returns this color's red component.

- `void r(c_UInt8 c);`

  Sets this color's red component.

  Parameters

  c The red component. Must be a value from 0 to 255.

g

```
c_UInt8 g() const;
void g(c_UInt8 c);
```

- `c_UInt8 g() const;`

  Returns this color's green component.

- `void g(c_UInt8 c);`

  Sets this color's green component.

  Parameters

c	The green component. Must be a value from 0 to 255.

b

```
c_UInt8 b() const;
void b(c_UInt8 c);
```

- `c_UInt8 b() const;`

  Returns this color's blue component.

- `void b(c_UInt8 c);`

  Sets this color's blue component.

  Parameters

c	The blue component. Must be a value from 0 to 255.

rgb

```
void rgb(c_UInt8 r, c_UInt8 g, c_UInt8 b);
c_UInt32 rgb() const;
```

- `void rgb(c_UInt8 r, c_UInt8 g, c_UInt8 b);`

  Sets this color's RGB values.

  Parameters

r	The red component. Must be a value from 0 to 255.
g	The green component. Must be a value from 0 to 255.
b	The blue component. Must be a value from 0 to 255.

- `c_UInt32 rgb() const;`

  Returns this color's RGB value as a single 32-bit value in the format `0x00rrggbb`.

bgr

`c_UInt32 bgr() const;`

Returns this color's RGB value as a single 32-bit value in the format `0x00bbggrr`.

rgb15 `c_UInt16 rgb15() const;`

Returns this color's RGB value as a single "5-5-5" 16-bit value, using 5 bits for each component. The low-order 3 bits of each original component are ignored.

rgb16 `c_UInt16 rgb16() const;`

Returns this color's RGB values as a single "5-6-5" 16-bit value, using 5 bits for the red component, 6 bits for this green component, and 5 bits for the blue component. The low-order bits of each original component are ignored.

ccRGB16AcqFifo

```
#include <ch_cvl/acq.h>

class ccRGB16AcqFifo : public ccAcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This class describes acquisition FIFO queues that return 16-bit RGB images.

Notes

There is no need for you to create objects of this type in your program. When you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()** it returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccRGB16AcqFifo

```
ccRGB16AcqFifo(const ccVideoFormat& vf,
  ccFrameGrabber& fg);
```

Creates an idle acquisition FIFO suitable for capturing packed 16-bit color images of the format *vf* from the frame grabber *fg*.

Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.

Public Member Functions

baseComplete

```
PelBuffer* baseComplete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns a pointer to the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed or if the *maxWait* period elapsed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus — If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow

You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

complete

```
PelBuffer complete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow

You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

Typedefs

PelBuffer `typedef ccPelBuffer<ccPackedRGB16Pel> PelBuffer;`

ccRGB32AcqFifo

```
#include <ch_cvl/acq.h>

class ccRGB32AcqFifo : public ccAcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This class describes acquisition FIFO queues that return 32-bit RGB images.

Notes

There is no need for you to create objects of this type in your program. When you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()** it returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccRGB32AcqFifo

```
ccRGB32AcqFifo(const ccVideoFormat& vf,
  ccFrameGrabber& fg);
```

Creates an idle acquisition FIFO suitable for capturing packed 32-bit color images of the format *vf* from the frame grabber *fg*.

Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.

Public Member Functions

baseComplete

```
PelBuffer* baseComplete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns a pointer to the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed or if the *maxWait* period elapsed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus — If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow

You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

complete

```
PelBuffer complete (ccAcqFailure* result = 0,
  c_UInt32* appTag = 0, bool makeLocal = true,
  double maxWait = HUGE_VAL, bool autoStart = false,
  ceStartReqStatus* startReqStatus = 0);
```

Returns the image of the oldest outstanding acquisition and removes it from the FIFO. If there are no completed acquisitions in the FIFO, this function waits for one. Returns null if the acquisition failed.

Parameters

result — If not null, **result* is set to a description of why the acquisition failed. See **ccAcqFailure** on page 209.

appTag — If not null, **appTag* is set to the value that was passed to **start()**. If the acquisition failed because of too many outstanding acquisitions, or because acquisition was incomplete below then the returned **appTag* value is undefined. For trigger models that do not use **start()** to initiate the acquisition, this value is undefined.

makeLocal — If true, **baseComplete()** forces the image to be local (see **ccPelRoot::move()**). Otherwise, the image remains where it was acquired. For example, if your frame grabber (**ccFrameGrabber**) is also an accelerator (**ccAccelerator**), you might want to set *makeLocal* to false to leave the image on the accelerator to be processed there.

maxWait — The maximum number of seconds to wait for a complete acquisition to become available. The special value *HUGE_VAL* means to wait indefinitely. If the *maxWait* period elapses, **result->isIncomplete()** returns true.

autoStart — If *autoStart* is true and the selected trigger model associated with this FIFO allows **start()** to be invoked, then **start()** is invoked automatically when an acquisition completes. In this case, **start()** is invoked with an *appTag* of zero. If the acquisition is incomplete (**result->isIncomplete()** returns true) or if this function throws, **start()** is not invoked automatically.

startReqStatus If not NULL, returns whether the acquisition request was processed completely or not. See **ceStartReqStatus** on page 218.

Throws

ccPel::BadWindow

You specified a region of interest, but the intersection of the ROI and the entire window was a null rectangle. See **ccRoiProp** on page 2763.

Typedefs

PelBuffer

```
typedef ccPelBuffer<ccPackedRGB32Pel> PelBuffer;
```

ccRLEBuffer

```
#include <ch_cvl/rlebuf.h>

class ccRLEBuffer : public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains a run-length encoded (RLE) image. Unlike an ordinary image, which is composed of a two-dimensional array of pixels, an RLE image is composed of a collection of *runs*. Each run has a pixel value and a length. RLE images are a compact method for storing images with regions of identical pixel values.

Unlike **ccPelBuffer**, the **ccRLEBuffer** class is not templated. Only images of **c_UInt8** pixels are supported.

To increase the efficiency of this class, a helper class, **cc_TmpRLEBuffer**, is provided. You should not create or manipulate **cc_TmpRLEBuffer** objects yourself.

Constructors/Destructors

ccRLEBuffer

```
ccRLEBuffer();

ccRLEBuffer(c_Int32 width, c_Int32 height,
  c_UInt8 background);

ccRLEBuffer(const ccRLEBuffer& rhs);

ccRLEBuffer(const cc_TmpRLEBuffer& rhs);
```

- `ccRLEBuffer();`

  Constructs a **ccRLEBuffer** with no pixels. This is also called a *degenerate* **ccRLEBuffer**.

- ```
  ccRLEBuffer(c_Int32 width, c_Int32 height,
    c_UInt8 background);
  ```

  Constructs a **ccRLEBuffer** with the specified dimensions and with every pixel set to the specified background value.
  ```

Parameters

width	The width of the image in pixels.
height	The height of the image in pixels.
background	The value to assign to all pixels in the image.

Notes

Both *width* and *height* must be greater than zero.

- `ccRLEBuffer(const ccRLEBuffer& rhs);`

  Copy constructor.

- `ccRLEBuffer(const cc_TmpRLEBuffer& rhs);`

  Copy constructor that takes a **cc_TmpRLEBuffer** as input.

Operators

operator= `ccRLEBuffer& operator= (const ccRLEBuffer&);`

Assignment operator.

operator= `ccRLEBuffer& operator= (const cc_TmpRLEBuffer& rhs);`

Assignment operator for assigning a **cc_TmpRLEBuffer** to a **ccRLEBuffer**.

operator== `bool operator== (const ccRLEBuffer&) const;`

Equality operator. Two **ccRLEBuffer**s are equal if their dimensions and the values of all their pixels are the same.

operator!= `bool operator!= (const ccRLEBuffer& rhs) const;`

See the description of the **operator==** member for the definition of inequality.

Enumerations

Shape

```
enum Shape
```

This enumeration defines the structuring element shapes for the grey-scale morphology operations supported by **ccRLEBuffer**.

Value	Meaning
eHoriz	Use a 1x3 horizontal structuring element.
eVert	Use a 1x3 vertical structuring element.
eSquare	Use a 1x3 square structuring element

Structures

ccRLEBufferRun

```
struct ccRLEBufferRun
  {
  c_UInt8 value;
  c_UInt8 length;
  friend ccArchive& operator|| (ccArchive&,
    const ccRLEBufferRun&);
  bool operator< (const ccRLEBufferRun&) const;
  bool operator== (const ccRLEBufferRun&) const;
  }
```

This structure defines a single run of pixels within a **ccRLEBuffer**.

Members

value The pixel value of this run.

length The length of this run, in pixels.

Public Member Functions

transfer

```
void transfer(ccRLEBuffer& rhs);
```

Assigns the contents of the supplied **ccRLEBuffer** to this **ccRLEBuffer**. This member is identical to **operator=**.

Parameters

rhs The the **ccRLEBuffer** to assign.

isDegenerate `bool isDegenerate() const;`

Returns *true* if this **ccRLEBuffer** has no pixels.

setUnbound `void setUnbound();`

Frees all the pixel storage associated with this **ccRLEBuffer**. Calling **isDegenerate()** after calling **setUnbound()** returns true.

hintNumRuns `void hintNumRuns(int hint);`

You can improve the efficiency with which an image is encoded by the **encode()** and **encodePercent()** functions by calling this function and providing the number of runs required to encode the image. The **encode()** and **encodePercent()** functions will pre-allocate the number of runs you specify and will guarantee that all the runs will be contiguous in memory.

The value you supply to this function is used for all subsequent calls to **encode()** and **encodePercent()**.

Parameters

hint — The number of runs to pre-allocate.

If you specify 0 for *hint*, then subsequent calls to **encode()** and **encodePercent()** are not guaranteed to produce runs contiguous in memory.

encode

```
void encode(const ccPelBuffer_const<c_UInt8>& image);

void encode(const ccPelBuffer_const<c_UInt8>& image,
 const cmStd vector<c_UInt8>& pmap);

void encode(const ccPelBuffer_const<c_UInt8>& image,
 c_UInt8 thresh, bool invert=false);

void encode(const ccPelBuffer_const<c_UInt8>& image,
 c_UInt8 loThresh, c_UInt8 hiThresh, int softness,
 bool invert=false);

void encode(const ccPelBuffer_const<c_UInt8>& image,
 const cmStd vector<c_UInt8>& preMap,
 const ccPelBuffer_const<c_UInt8>& thresh,
 const cmStd vector<c_UInt8>& postMap);
```

- `void encode(const ccPelBuffer_const<c_UInt8>& image);`

  Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

  Parameters

  image The image to run-length encode.

  Notes

  Any client coordinate system associated with *image* is preserved in this **ccRLEBuffer**.

- `void encode(const ccPelBuffer_const<c_UInt8>& image, const cmStd vector<c_UInt8>& pmap);`

  Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

  As the image is encoded, the supplied pixel map is applied to each pixel in the input image.

  Parameters

  image The image to run-length encode.

  pmap The pixel map to apply to the input image. Each pixel in the input image is used as an index into *pmap*; the input pixel value is replaced with the value from *pmap*.

  pmap must be at least as large as the largest pixel value in *image*.

Notes

Any client coordinate system associated with *image* is preserved in this **ccRLEBuffer**.

- ```
  void encode(const ccPelBuffer_const<c_UInt8>& image,
    c_UInt8 thresh, bool invert=false);
  ```

  Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

  As the image is encoded, the supplied hard threshold is used to segment the image.

  Parameters

image	The image to run-length encode
thresh	The threshold value. All pixels in *image* with values greater than or equal to *thresh* are set to 1; pixels with values less than *thresh* are set to 0.
invert	If *invert* is *true*, then all pixels in *image* with values greater than or equal to *thresh* are set to 0 and pixels with values less than *thresh* are set to 1. If *invert* is *false*, then all pixels in *image* with values greater than or equal to *thresh* are set to 1 and pixels with values less than *thresh* are set to 0.

- ```
  void encode(const ccPelBuffer_const<c_UInt8>& image,
    c_UInt8 loThresh, c_UInt8 hiThresh, int softness,
    bool invert=false);
  ```

  Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

  As the image is encoded, the supplied thresholds are used to segment the image.

  Parameters

image	The image to run-length encode
loThresh	The low threshold value. All pixels in *image* with values less than *loThresh* are set to 0.
hiThresh	The high threshold value. All pixels in *image* with values greater than or equal to *hiThresh* are set to *softness+1*.
softness	The number of intermediate pixel weight ranges into which the image will be segmented. *softness* evenly spaced ranges of pixel values are defined. Each range of pixel values is assigned a pixel weight between 0 and *softness*, with the pixel weights distributed

in a linear fashion. Each pixel in the input image with a value between *loThresh* and *hiThresh* is assigned the pixel weight associated with the range into which the pixel's value falls.

invert — *invert* defines the polarity of the image. If *invert* is *false*, *loThresh* and *hiThresh* are interpreted as described above. If *invert* is *true*, pixels with values less than *loThresh* are assigned a weight of *softness*+1 while pixels with values greater than *hiThresh* are assigned a weight of 0. For images of dark objects on a light background, *invert* should be *false*.

Notes

Any client coordinate system associated with *image* is preserved in this **ccRLEBuffer**.

- ```
  void encode(const ccPelBuffer_const<c_UInt8>& image,
    const cmStd vector<c_UInt8>& preMap,
    const ccPelBuffer_const<c_UInt8>& thresh,
    const cmStd vector<c_UInt8>& postMap);
  ```

Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

As the image is encoded, the supplied threshold image, threshold value, and pixel maps are used to segment the image.

Parameters

image — The image to encode.

preMap — The pixel map to apply to the input image. Each pixel in the input image is used as an index into *preMap*; the input pixel value is replaced with the value from *preMap*.

preMap must be at least as large as the largest pixel value in *image*.

thresh — The threshold image. *thresh* must have the same dimensions as *image*. The value of each pixel in *thresh* is subtracted from the corresponding pixel in *image*, after *image* is mapped by *preMap*. The value that results from this operation is mapped using *postMap*.

postMap — The pixel map to apply to the result of the image subtraction. Each pixel value that results from the subtraction of the *thresh* from *image* is used as an index into *postMap*; the pixel value in the encoded image set to the value from *postMap*.
  ```

postMap must be at least as large as the largest difference in pixel values between *image* and *thresh*.

Notes

Any client coordinate system associated with *image* is preserved in this **ccRLEBuffer**.

encodePercent

```
void encodePercent(
 const ccPelBuffer_const<c_UInt8> &image,
 int lowTailPercent, int highTailPercent,
 int threshPercent, bool invert = false);

void encodePercent(
 const ccPelBuffer_const<c_UInt8> &image,
 int lowTailPercent, int highTailPercent,
 int threshLowPercent, int threshHighPercent,
 int softness, bool invert = false);
```

-
```
void encodePercent(
 const ccPelBuffer_const<c_UInt8> &image,
 int lowTailPercent, int highTailPercent,
 int threshPercent, bool invert = false);
```

Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

As the image is encoded, the supplied histogram tail percentages and relative threshold value are used to segment the image. The segmentation is performed by discarding the specified percentages of low and high tail pixels, then setting the threshold value at the specified percentage of the remaining pixels.

Parameters

image — The image to encode.

lowTailPercent — The lower *lowTailPercent* of all pixels in *image* are discarded before computing the threshold value. This value must be greater than or equal to 0 and less than *highTailPercent*.

highTailPercent — The upper 100-*highTailPercent* of all pixels in *image* are discarded before computing the threshold value. This value must be less than or equal to 100 and greater than *lowTailPercent*.

threshPercent — After discarding the pixels specified by *lowTailPercent* and *highTailPercent*, the threshold value is computed to be the value of the pixel below which *threshPercent* of all remaining pixels in *image* lie.

invert If *invert* is *false* (the default), all pixels in *image* with values greater than or equal to the computed threshold value are set to 1 and all pixels in *image* with values less than the computed threshold value are set to 0. If *invert* is *true*, all pixels in *image* with values greater than or equal to the computed threshold value are set to 0 and all pixels in *image* with values less than the computed threshold value are set to 1.

- ```
  void encodePercent(
    const ccPelBuffer_const<c_UInt8> &image,
    int lowTailPercent, int highTailPercent,
    int threshLowPercent, int threshHighPercent,
    int softness, bool invert = false);
  ```

  Sets the contents of this **ccRLEBuffer** to be the run-length encoded equivalent of the supplied **ccPelBuffer_const<c_UInt8>**.

  As the image is encoded, the supplied histogram tail percentages and relative threshold value are used to segment the image. The segmentation is performed by discarding the specified percentages of low and high tail pixels, then setting the low and high threshold values at the specified percentages of the remaining pixels.

  Parameters

  image The image to encode.

  lowTailPercent The lower *lowTailPercent* of all pixels in *image* are discarded before computing the threshold values. This value must be greater than or equal to 0 and less than *highTailPercent*.

  highTailPercent The upper 100-*highTailPercent* of all pixels in *image* are discarded before computing the threshold values. This value must be less than or equal to 100 and greater than *lowTailPercent*.

  threshLowPercent

  After discarding the pixels specified by *lowTailPercent* and *highTailPercent*, the low threshold value is computed to be the value of the pixel below which *threshLowPercent* of all remaining pixels in *image* lie. This value must be greater than or equal to 0 and less than *threshHighPercent*.

  threshHighPercent
  ```

After discarding the pixels specified by *lowTailPercent* and *highTailPercent*, the high threshold value is computed to be the value of the pixel above which *threshHighPercent* of all remaining pixels in *image* lie. This value must be less than or equal to 100 and greater than *threshLowPercent*

softness — The number of intermediate pixel weight ranges into which the image will be segmented. *softness* evenly spaced ranges of pixel values between the computed low and high thresholds are defined. Each range of pixel values is assigned a pixel weight between 0 and *softness*, with the pixel weights distributed in a linear fashion. Each pixel in the input image with a value between the computed low threshold and the computed high threshold is assigned the pixel weight associated with the range into which the pixel's value falls.

invert — *invert* defines the polarity of the image. If *invert* is *false*, the computed low and high thresholds are interpreted as described above. If *invert* is *true*, pixels with values less than the computed low threshold are assigned a weight of *softness*+1 while pixels with values greater than or equal to the computed high threshold are assigned a weight of 0. For images of dark objects on a light background, *invert* should be *false*.

isBinary

```
bool isBinary() const;
```

Returns *true* if this **ccRLEBuffer** was encoded using a hard binary threshold.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

createTime

```
double createTime() const;
```

Returns the amount of time in milliseconds that were required to create or modify this **ccRLEBuffer**.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

Notes

This function might return a value of 0 if the current platform cannot provide accurate and inexpensive timing information.

isContiguous

```
bool isContiguous() const;
```

Returns *true* if all of the runs that make up this **ccRLEBuffer** are stored in a single contiguous block of memory.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

makeContiguous

```
void makeContiguous();
```

This function reallocates memory as needed, then stores all of the runs that make up this **ccRLEBuffer** in a single contiguous block of memory. If all of the runs that make up this **ccRLEBuffer** are already stored in a single contiguous block of memory, this function has no effect.

Notes

createTime() will return the amount of time that was required by this function.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

offset

```
ccIPair offset() const;
void offset(c_Int32 left, c_Int32 top);
void offset(const ccIPair&);
```

- `ccIPair offset() const;`

  Returns a **ccIPair** which gives the image coordinates of this **ccRLEBuffer**'s upper left corner.

  Throws

  ccRLEBuffer::Degenerate
  This **ccRLEBuffer** has no pixels.

- `void offset(c_Int32 left, c_Int32 top);`

  Sets this **ccRLEBuffer**'s image coordinate offset. Calling this function has no effect on the contents of this **ccRLEBuffer**, nor on any client coordinate system associated with it.

  Parameters

  left The x-coordinate of the offset

top The y-coordinate of the offset

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

- `void offset(const ccIPair& offset);`

Sets this **ccRLEBuffer**'s image coordinate offset. Calling this function has no effect on the contents of this **ccRLEBuffer**, nor on any client coordinate system associated with it.

Parameters

offset The offset

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

clientFromImageXform

```
cc2Xform clientFromImageXform() const;

void clientFromImageXform(const cc2Xform& xform);
```

- `cc2Xform clientFromImageXform() const;`

Returns the **cc2Xform** that transforms points in this **ccRLEBuffer**'s image coordinate system to the client coordinate system.

- `void clientFromImageXform(const cc2Xform& xform);`

Sets the **cc2Xform** that transforms points in this **ccRLEBuffer**'s image coordinate system to the client coordinate system.

Parameters

xform The **cc2Xform**

Notes

Setting either the image to client **cc2Xform** or the client to image **cc2Xform** also sets the other **cc2Xform**.

imageFromClientXform

```
cc2Xform imageFromClientXform() const;
void imageFromClientXform(const cc2Xform& xform);
```

```
cc2Xform imageFromClientXform() const;
```

Returns the **cc2Xform** that transforms points in this **ccRLEBuffer**'s client coordinate system to the image coordinate system.

- `void imageFromClientXform(const cc2Xform& xform);`

  Sets the **cc2Xform** that transforms points in this **ccRLEBuffer**'s client coordinate system to the image coordinate system.

  Parameters

  xform The **cc2Xform**

  Notes

  Setting either the image to client **cc2Xform** or the client to image **cc2Xform** also sets the other **cc2Xform**.

copyXforms

```
void copyXforms(const ccRLEBuffer& rlebuf);
void copyXforms(const cc_PelBuffer& pelbuf);
```

- `void copyXforms(const ccRLEBuffer& rlebuf);`

  Sets the **cc2Xform**s associated with this **ccRLEBuffer** to be those associated with the supplied **ccRLEBuffer**. Both the **cc2Xform** that transforms points in this **ccRLEBuffer**'s image coordinate system to the client coordinate system and the **cc2Xform** that transforms points in the client coordinate system to this **ccRLEBuffer**'s image coordinate system are copied from the supplied **ccRLEBuffer**.

  Cognex recommends that you use this function rather than **imageFromClientXform()** and **clientFromImageXform()**.

  Parameters

  rlebuf The **ccRLEBuffer** from which to copy the two **cc2XForm**s.

- `void copyXforms(const cc_PelBuffer& pelbuf);`

  Sets the **cc2Xform**s associated with this **ccRLEBuffer** to be those associated with the supplied **cc_PelBuffer**. Both the **cc2Xform** that transforms points in this **ccRLEBuffer**'s image coordinate system to the client coordinate system and the **cc2Xform** that transforms points in the client coordinate system to this **ccRLEBuffer**'s image coordinate system are copied from the supplied **ccPelBuffer**.

  Cognex recommends that you use this function rather than **imageFromClientXform()** and **clientFromImageXform()**.

  Parameters

  pelbuf The **cc_PelBuffer** from which to copy the two **cc2XForm**s

---

image

```
ccPelBuffer<c_UInt8> image() const;

void image(ccPelBuffer<c_UInt8>& answer) const;
```

- `ccPelBuffer<c_UInt8> image() const;`

  Returns a **ccPelBuffer<c_UInt8>** that is identical in size and in the value of every pixel to this **ccRLEBuffer**.

  Notes

  If this **ccRLEBuffer** contains no pixels, then the returned **ccPelBuffer<c_UInt8>** is constructed by the default **ccPelBuffer<c_UInt8>** constructor.

- `void image(ccPelBuffer<c_UInt8>& answer) const;`

  Copies a **ccPelBuffer<c_UInt8>** that is identical in size and in the value of every pixel to this **ccRLEBuffer** to the supplied **ccPelBuffer<c_UInt8>** reference.

  Parameters

  answer A reference to a **ccPelBuffer<c_UInt8>** into which the image is placed.

  Notes

  If this **ccRLEBuffer** contains no pixels, then the returned **ccPelBuffer<c_UInt8>** is as constructed by the default **ccPelBuffer<c_UInt8>** constructor.

width

```
c_Int32 width() const;
```

Returns the width in pixels of this **ccRLEBuffer**.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

height `c_Int32 height() const;`

Returns the height in pixels of this **ccRLEBuffer**.

Throws
ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

size `ccIPair size() const;`

Returns the height and width in pixels of this **ccRLEBuffer**. The height is returned as **size().y()**; the width is returned as **size().x()**.

Throws
ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

pointToRow `const ccRLEBufferRun* pointToRow(c_Int32 rowNum) const;`

Returns a pointer to the first **ccRLEBufferRun** of the specified row of this **ccRLEBuffer**. All of the **ccRLEBufferRun**s that make up a single row of a **ccRLEBuffer** are guaranteed to be contiguous in memory.

The end of every row in a **ccRLEBuffer** is marked by a **ccRLEBufferRun** with a length of zero.

ccRLEBufferRuns in different rows of a **ccRLEBuffer** are guaranteed to be contiguous only if **isContiguous()** returns *true*.

Parameters
rowNum The row number

Notes
The pointer returned by this function is only valid until the next non-**const** member of this **ccRLEBuffer** is called.

Row numbers are specified in image coordinates; the first row of runs should be accessed as shown below:

```
this->pointToRow(this->offset().y())
```

Throws
ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

ccPel::BadCoord
Invalid row number.

pointToRat

```
const ccRLEBufferRun* const * pointToRat() const;
```

Returns a pointer to the row address table (RAT). The returned pointer points to the beginning of a contiguous array of pointers to **ccRLEBufferRun**. Each element in the array points to the first run of the corresponding row of this **ccRLEBuffer**.

All rows have at least two **ccRLEBufferRun** objects (each row is terminated with a zero-length **ccRLEBufferRun**).

Notes

The returned pointers are only valid until the next call to a non-**const** function in this **ccRLEBuffer**.

getPel

```
c_UInt8 getPel(const ccIPair& location) const;
c_UInt8 getPel(c_Int32 x, c_Int32 y) const;
```

- `c_UInt8 getPel(const ccIPair& location) const;`

Returns the value of the pixel at the specified location within this **ccRLEBuffer**.

Parameters

location A **ccIPair** containing the location of the pixel to get

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

- `c_UInt8 getPel(c_Int32 x, c_Int32 y) const;`

Returns the value of the pixel at the specified location within this **ccRLEBuffer**.

Parameters

x The x-coordinate of the pixel to get

y The y-coordinate of the pixel to get

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

subWindow

```
cc_TmpRLEBuffer subWindow(const ccPelRect& theRect) const;
```

Returns a **cc_TmpRLEBuffer** representing a subwindow, specified by the supplied **ccPelRect**, of this **ccRLEBuffer**.

The offset of the subwindow will be equal to the offset of this **ccRLEBuffer** plus the values specified for the origin of the supplied **ccPelRect**.

The client coordinate system transformation of the returned **cc_TmpRLEBuffer** is the same as that of this **ccRLEBuffer**.

Parameters

theRect A rectangle defining the region of this **ccRLEBuffer** to return.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

ccPel::BadWindow
theRect is not contained entirely within this **ccRLEBuffer** or *theRect* has either a width or height of zero.

Notes

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

mask

```
cc_TmpRLEBuffer mask(const ccRLEBuffer& mask,
  c_UInt8 match, c_UInt8 replace, bool invert=false) const;
```

Returns a **cc_TmpRLEBuffer** that is a masked version of this **ccRLEBuffer**. The masked image is constructed as follows: Each pixel in this **ccRLEBuffer** that corresponds to a pixel in *mask* which has the same value as *match* is replaced with a pixel of with the value *replace*. If *invert* is *true*, then each pixel in this **ccRLEBuffer** that does not correspond to a pixel in *mask* which has the same value as *match* is replaced with a pixel of the value *replace*.

Parameters

mask A **ccRLEBuffer** containing the mask image.

match The match value. Pixels in this **ccRLEBuffer** which correspond to pixels in *mask* with a value of *match* are replaced with a value of *replace.*

replace The replacement value.

invert If *invert* is true, then pixels this **ccRLEBuffer** which do not correspond to pixels in *mask* with a value of *match* are replaced with a value of *replace*.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels, or *mask* has no pixels.

Notes

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

The mask image must have the same offset and dimensions as this **ccRLEBuffer**.

combine

```
cc_TmpRLEBuffer combine(ccIPair offset,
  const ccRLEBuffer& subImage,
  const cmStd vector<c_UInt8>& pmap, c_UInt8 passVal=0)
  const;
```

Returns a **cc_TmpRLEBuffer** produced by combining the supplied **ccRLEBuffer** with this one. The **ccRLEBuffer**s are combined by overwriting part or all of this **ccRLEBuffer** with the contents of the supplied **ccRLEBuffer**. *offset* specifies where in this **ccRLEBuffer**'s image coordinate system the origin of *subImage* is placed. If *subImage* has an offset, it is respected as well.

You can specify a pixel map to apply to *subImage*, and you can specify that pixels in this **ccRLEBuffer** that correspond to pixels in the mapped *subImage* with a specified value not be replaced.

Parameters

offset — The location in this **ccRLEBuffer** at which to place the contents of the supplied **ccRLEBuffer**.

subImage — The **ccRLEBuffer** to copy into this **ccRLEBuffer**.

pmap — The pixel map to apply to *subImage*. Each pixel in *subImage* is replaced with the value at the corresponding offset in *pmap*.

passVal — Only pixels in this **ccRLEBuffer** which correspond to pixels in *subImage* that do not have a value of *passVal* (after the mapping operation) are replaced with pixels from *subImage*.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels, or *subImage* has no pixels.

Notes

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

map

```
cc_TmpRLEBuffer map(const cmStd vector<c_UInt8>& map)
  const;
```

Returns a mapped version of this **ccRLEBuffer**. Every pixel in this **ccRLEBuffer** is replaced with the pixel value found at the pixel's offset within the supplied pixel map

Parameters

map A vector of **c_UInt8** that contains the pixel map. *map* must contain at least as many elements as the largest pixel value in this **ccRLEBuffer**.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

Notes

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

---

histo

```
void histo(cmStd vector<c_UInt32>& histo) const;

void histo(cmStd vector<c_UInt32>& histoPels,
  cmStd vector<c_UInt32>& histoRuns) const;
```

- ```
  void histo(cmStd vector<c_UInt32>& histo) const;
  ```

  Calculates a histogram of the distribution of pixel values in this **ccRLEBuffer**.

  Parameters

  histo A reference to a vector of **c_UInt32** in which the histogram is placed. This vector must contain at least as many elements as the largest pixel value in this **ccRLEBuffer**.

  Notes

  The supplied vector of **c_UInt32** is *not* initialized by this function.

- ```
  void histo(cmStd vector<c_UInt32>& histoPels,
    cmStd vector<c_UInt32>& histoRuns) const;
  ```

  Computes two histograms of the distribution of pixel values in this **ccRLEBuffer**. The first histogram is a simple histogram of the pixel values in this **ccRLEBuffer**. The second histogram is of the distribution of runs of pixels of each pixel value.

  For example, if this **ccRLEBuffer** contained five runs with a pixel value of 27, and each of these runs had a length of 50, the value of the 27th element of the first histogram would be 250 while the value of the 27th element of the second histogram would be 5.

Parameters

histoPels A reference to a vector of **c_UInt32** in which the histogram of pixel values is placed. This vector must contain at least as many elements as the largest pixel value in this **ccRLEBuffer**.

histoRuns A reference to a vector of **c_UInt32** in which the histogram of runs is placed. This vector must contain at least as many elements as the largest pixel value in this **ccRLEBuffer**.

Notes

The supplied vectors of **c_UInt32** are *not* initialized by this function.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

gmorphMin

```
cc_TmpRLEBuffer gmorphMin(Shape=eSquare) const;
```

Performs a grey-scale morphological minimize operation using the specified structuring element.

Parameters

Shape The shape of the structuring element to apply. *shape* must be one of the following values:

ccRLEBuffer::eHoriz
ccRLEBuffer::eVert
ccRLEBuffer::eSquare

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

Notes

At image borders, where full neighborhoods cannot be formed, partial neighborhoods are used. The returned **cc_TmpRLEBuffer** has the same dimensions as the source.

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

gmorphMax

```
cc_TmpRLEBuffer gmorphMax(Shape=eSquare) const;
```

Performs a grey-scale morphological maximize operation using the specified structuring element.

Parameters

Shape The shape of the structuring element to apply. *shape* must be one of the following values:

ccRLEBuffer::eHoriz
ccRLEBuffer::eVert
ccRLEBuffer::eSquare

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

Notes

At image borders, where full neighborhoods cannot be formed, partial neighborhoods are used. The returned **cc_TmpRLEBuffer** has the same dimensions as the source.

The **cc_TmpRLEBuffer** type can be efficiently copied or assigned to a **ccRLEBuffer**.

numRuns

```
int numRuns() const;
int numRuns(c_UInt8 val) const;
```

- `int numRuns() const;`

Return the number of runs in this **ccRLEBuffer**.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

- `int numRuns(c_UInt8 val) const;`

Return the number of runs in this **ccRLEBuffer** that have the supplied pixel value.

Parameters

val The pixel value.

Throws

ccRLEBuffer::Degenerate
This **ccRLEBuffer** has no pixels.

avgRunLength

```
double avgRunLength() const;
double avgRunLength(c_UInt8 val) const;
```

- `double avgRunLength() const;`

  Return the average run length of the runs in this **ccRLEBuffer**.

  Throws

  ccRLEBuffer::Degenerate
  This **ccRLEBuffer** has no pixels.

- `double avgRunLength(c_UInt8 val) const;`

  Return the average run length of the runs in this **ccRLEBuffer** that have the supplied pixel value.

  Parameters

  val The pixel value.

  Throws

  ccRLEBuffer::Degenerate
  This **ccRLEBuffer** has no pixels.

ccRoiProp

```
#include <ch_cvl/prop.h>

class ccRoiProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The region of interest (ROI) property lets you specify which part of the acquired image you wish to process. The acquisition FIFO uses the ROI property to optimize acquisition time. For line scan cameras, you use the ROI property to refine the height and width of the acquired image.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Depending on the capabilities of the video hardware, the ROI setting may affect which pixels are actually written in the pixel root image, allowing the acquisition FIFO to acquire a smaller number of pixels, thereby reducing acquisition time.

For example, the following code fragments are equivalent, but the second fragment may be optimized:

```
   // Never optimized
fifo->start();
pb = fifo->complete();
pb.subWindow(x,y,w,h);

   // May be optimized
fifo->properties().roi(ccPelRect(x,y,w,h));
fifo->start();
pb = fifo->complete();
```

Pixels outside the ROI have unspecified values. The ROI setting does not affect the root image size. The resulting pel buffer window size is the intersection of the ROI and the whole image; in other words, an ROI larger than the image is clipped to the root image size. A null rectangle (see **ccPelRect::isNull()**) specifies the entire image.

For line scan cameras, the ROI property specifies the height and width of the acquired image. The height and width must satisfy the following three conditions. Assume that **videoFormat.width()** is the width of the video format (see **width()** on page 3400), *width* and *height* are the desired width and height of the image, and *xOffset* is the x-offset.

- 1 <= width <= **videoFormat.width()** - xOffset
- 1 <= height <= 8192
- width x height <= 4194304 (4 x 1024 x 1024)

Enumerations

Mode

```
enum Mode;
```

This enumeration defines the automatic ROI behavior.

Value	Meaning
eAutomatic = 0	The acquisition software will adjust the ROI to the capabilities of the hardware. If the actual ROI is larger than the requested ROI, a window of the requested size is applied to each acquired image.
eManual = 1	The ROI setting is written to the hardware as given and no adjustment is made to the acquired image. *eManual* should only be used in specific circumstances where *eAutomatic* does not work correctly. For example, a line scan camera that acquires lines while a trigger signal is active, such that the height of the image is determined by the trigger signal and not the ROI setting.

Constructors/Destructors

ccRoiProp

```
ccRoiProp();
explicit ccRoiProp(const ccPelRect& roi);
```

- `ccRoiProp();`

  Creates a new ROI property not associated with any FIFO. The region of interest is the entire image.

- `explicit ccRoiProp(const ccPelRect& roi);`

  Creates a new ROI property not associated with any FIFO. The region of interest is specified by the rectangle *roi*.

  Parameters

  roi The region of interest. A null ROI means the entire image.

Public Member Functions

roi

```
const ccPelRect& roi() const;
void roi(const ccPelRect& r);
```

- `const ccPelRect& roi();`

  Returns the current region of interest.

  Notes

  If the region of interest was never set in the constructor or with the setter, this function returns a null ROI. Once you set an ROI, this function and **actualRoi()** return the same value.

- `void roi(const ccPelRect& roi);`

  Sets the region of interest to the rectangle specified by *roi*.

  Parameters

  roi The region of interest. A null ROI means the entire image.

Notes

If you specify a region of interest, the **window()** of the pel buffer returned by **complete()** or **baseComplete()** is the intersection of the ROI and the entire image. If this intersection is null, **complete()** or **baseComplete()** will throw *ccPel::BadWindow*.

Throws

ccRoiProp::BadParams
roi.ul().x(), **roi.ul().y()**, **roi.height()**, or **roi.width()** were negative.

actualRoi

```
ccPelRect actualRoi() const;
```

Returns the actual region of interest for the FIFO associated with this property even if the setter **roi()** has never been called. If the region of interest is the entire image, the returned rectangle is the size of the image, not the null rectangle.

Once the setter has been called, **roi()** and **actualRoi()** return the same value.

Throws

ccRoiProp::NoFrameGrabber
This property is not associated with an acquisition FIFO.

roiMode

```
ccRoiProp::Mode roiMode() const;

void roiMode(ccRoiProp::Mode mode);
```

- `ccRoiProp::Mode roiMode() const;`

Gets the ROI mode for this FIFO. The returned value is one of

ccRoiProp::eAutomatic
ccRoiProp::eManual

Throws

ccRoiProp::NoFrameGrabber
This property is not associated with an acquisition FIFO.

- `void roiMode(ccRoiProp::Mode mode);`

Sets the ROI mode for this FIFO.

Parameters

mode The mode to set. *mode* must be one of

ccRoiProp::eAutomatic
ccRoiProp::eManual

Throws

ccRoiProp::BadParams

mode is not supported on the hardware associated with this FIFO.

isModeSupported

```
bool isModeSupported(ccRoiProp::Mode mode);
```

Returns true if the specified mode can be set on this FIFO, false if it cannot.

Parameters

mode The mode to test. *mode* must be one of

ccRoiProp::eAutomatic
ccRoiProp::eManual

ccRSIDefs

```
#include <ch_cvl/rsi.h>

class ccRSIDefs
```

A name space that holds enumerations and constants used with the RSI Search tool. See **ccRSIModel**.

Enumerations

DOF

`enum DOF`

This enumeration defines constants that specify degrees of freedom at train time or at search time.

Value	Meaning
eAngle = 0x1	Consider rotation.
eUniformScale = 0x2	Consider uniform scaling along both the x- and y-axis.
eXScale = 0x4	Consider scaling along the x-axis.
eYScale = 0x8	Consider scaling along the y-axis.
eShear = 0x10	Consider shear.

Method

`enum Method`

This enumeration defines constants that specify the method used to compute the sub-pixel model pose.

Value	Meaning
eStandard = 1	A basic mathematical model is used to estimate the sub-pixel position with the highest score. This model may not accuractly model changes in the correlation score at small image offsets.
eHighAccuracy = 2	A mathematical model that better characterizes how the normalized correlation coefficient changes at small sub-pixel image offsets is used.
kDefaultMode	The default mode (*eStandard)*.

Mode

`enum Mode`

This enumeration defines constants that specify when the template images are generated.

Value	Meaning
eGenerateTemplates = 0x1	Templates are generated at training time, based on the specified DOF range or nominal values.
eUnrestrictedDOFs = 0x2	Templates are generated at run time.
kDefaultMode	The default mode (*eGenerateTemplates)*.

GranularityGenerator

`enum GranularityGenerator`

This enumeration defines constants that specify how to generate the coarse granularity model.

Value	Meaning
eGranularityGeneratorRobust = 0x1	Recommended for most applications. Generates a coarse model that will find all model instances.
eGranularityGeneratorFast = 0x2	Generates a coarse model that provides faster execution at run time. For some model images, particularly those with all fine features, using this generator may cause the tool to fail to find some model instances.
kDefaultGranularityGenerator	The default mode (*eGranularityGeneratorRobust)*.

Compression

`enum Compression`

This enumeration defines constants that specify what type of compression to apply to the trained model.

Value	Meaning
eCompressionNone = 0x1	Do not compress the trained model.
eCompressionLossy = 0x2	Compress the trained model using a lossy compression method. This method produces the fastest search, but may miss some model instances.
eCompressionLossless = 0x4	Compress the trained model using a lossless compression method. This method may result in a faster search than using *eCompressionNone*, but without the risk of failing to find some instances.
kDefaultCompression	The default mode (*eCompressionNone)*.

CombineDOF

`enum CombineDOF`

This enumeration defines constants that specify whether a non-identity generalized model origin (**ccRSIModel::trainClientFromModel()**) is considered to have been combined with training-time DOF nominal or range values. This enumeration only applies when training-time template generation is specified *(***ccRSITrainParams::mode()** *is eGenerateTemplates).*

Value	Meaning
eCombineDOFTrainClientFromModel = 0x1	The DOFs are considered to have been combined with the generalized origin.
eCombineDOFIdentity = 0x2	The DOFs are not considered to have been combined.
kDefaultCombineDOF	The default combination mode (*eCombineDOFTrainClientFromModel)*.

DrawMode `enum DrawMode`

This enumeration defines types of result graphics you can draw for RSI results

Value	Meaning
eDrawOrigin = 0x1	Draws a cross at the location of the result. The cross is aligned to the angle at which the pattern is found.
eDrawLabel = 0x2	Draws a text label at the result location.
eDrawBoundingBox = 0x4	Draws a box around the region of the image that corresponds to the matched model.
eDrawStandard = 0x7	Draws a labeled, pattern-aligned cross at the pattern location along with a box that corresponds to the matched model.

ccRSIModel

```
#include <ch_cvl/rsi.h>

class ccRSIModel
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains the trained representation of an RSI model as well as the functions to do the training and to search an image for the model.

Constructors/Destructors

ccRSIModel

```
ccRSIModel();

~ccRSIModel();
```

- `ccRSIModel();`

  Construct an untrained RSI alignment model with default values.

- `~ccRSIModel();`

  Destructor.

Public Member Functions

origin

```
cc2Vect origin() const;

void origin(const cc2Vect &origin);
```

- `cc2Vect origin() const;`

  Returns the origin of the model in the client coordinate system. You can get the origin whether the model is trained or untrained.

- `void origin(const cc2Vect &origin);`

  Sets the origin of the model in the client coordinate system. You can set the origin whether the model is trained or untrained.

  The origin is associated with the model, but may reside outside of the model. When an instance of the model is found in the search image, the result location is defined by the position of the origin in the search image.

  Parameters

  origin The origin of the model. Default **cc2Vect(**0,0**)**.

  Note Setting **trainClientFromModel()** changes the origin. Setting the origin changes the translation component of **trainClientFromModel()** but not the matrix portion of the transform.

  Setting the origin affects both the **location()** and the **pose()**.

trainClientFromModel

```
cc2Xform trainClientFromModel() const;

virtual void trainClientFromModel(const cc2Xform& xform);
```

- `cc2Xform trainClientFromModel() const;`

  Get the transform that maps from model coordinates to the training image client coordinates.

- `virtual void trainClientFromModel(const cc2Xform&);`

  Set the transform that maps from model coordinates to the training image client coordinates.

  Model coordinates are a client-controlled coordinate system that specifies how RSI search is to match the model to an image and report a result pose. A result pose maps from model coordinates to runtime client coordinates. The specified degrees of freedom define the search range as a mapping from model coordinates to runtime coordinates.

  Model coordinates include the model's origin as its translation component, and setting the model coordinates with this function always sets the origin.

  Training never modifies model coordinates. They are relative to the client coordinates established by the most recent training.

  Note You can set the **trainClientFromModel()** transform only before training, To change the **trainClientFromModel()** transform on a trained model, you must first call **untrain()** and then train again.

Parameters

xform The transform used to perform the mapping. Default is the identity transform.that model coordinates includes the

Throws

ccRSIDefs::AlreadyTrained
The model is already trained.

---

train

```
void train(const ccPelBuffer_const<c_UInt8>& image,
                  const ccRSITrainParams &trainParams,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0);

void train(const cc3PlanePelBuffer_const& image,
                  const ccRSITrainParams& trainParams,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0);

void train(const ccPelBuffer_const<c_UInt8>& image,
                  const ccPelBuffer_const<c_UInt8>& mask,
                  const ccRSITrainParams &trainParams,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0);

void train(const cc3PlanePelBuffer_const& image,
                  const ccPelBuffer_const<c_UInt8>& mask,
                  const ccRSITrainParams& trainParams,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0);
```

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
                    const ccRSITrainParams &trainParams,
                    ccDiagObject* diagobj=0,
                    c_UInt32 diagFlags=0);
  ```

Trains this model from the given 8-bit image using the specified training parameters. If the model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

Parameters

image The 8-bit training image.

trainParams The training parameters

diagobj A diagnostic object

diagFlags Diagnostic flags
  ```

Throws

ccRSIDefs::BadImageContent
The Image is featureless.

ccRSIDefs::BadImage
image is unbound or has a null window

ccRSIDefs::NotImplemented
The image client coordinate system is nonlinear

ccRSIDefs::BadImageSize
The image is too small.

ccTimeout::Expired
The operation timed out.

- ```
  void train(const cc3PlanePelBuffer_const& image,
                  const ccRSITrainParams& trainParams,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0);
  ```

Trains this model from the given three-plane (R,G,B) image using the specified training parameters. If the model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

Parameters

image The three-plane training image.

trainParams The training parameters

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::BadImageContent
The Image is featureless.

ccRSIDefs::BadImage
image is unbound or has a null window

ccRSIDefs::NotImplemented
The image client coordinate system is nonlinear

ccRSIDefs::BadImageSize
The image is too small.
  ```

ccTimeout::Expired
The operation timed out.

- ```
  void train(const ccPelBuffer_const<c_UInt8>& image,
                   const ccPelBuffer_const<c_UInt8>& mask,
                   const ccRSITrainParams &trainParams,
                   ccDiagObject* diagobj=0,
                   c_UInt32 diagFlags=0);
  ```

Trains this model from the given 8-bit image and mask using the specified training parameters. If the model is already trained, it is automatically untrained and retrained.

This function respects CVL timeouts. If a timeout occurs, the model is not trained.

Parameters

image The 8-bit training image.

mask The image mask. Pixels whose value is 0 indicate “don’t care” pixels in the training image; pixels whose value is 255 indicate “care” pixels in the training image.

trainParams The training parameters

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::BadImageContent
The Image is featureless.

ccRSIDefs::BadImage
image is unbound or has a null window
mask is unbound
mask does not have the same window as image
mask pels have values other than 0 or 255

ccRSIDefs::NotImplemented
The image client coordinate system is nonlinear

ccRSIDefs::BadImageSize
The image is too small.

ccTimeout::Expired
The operation timed out.
  ```

- ```
  void train(const cc3PlanePelBuffer_const& image,
                   const ccPelBuffer_const<c_UInt8>& mask,
                   const ccRSITrainParams& trainParams,
                   ccDiagObject* diagobj=0,
                   c_UInt32 diagFlags=0);
  ```

  Trains this model from the given three-plane (R,G,B) image and mask using the specified training parameters. If the model is already trained, it is automatically untrained and retrained.

  This function respects CVL timeouts. If a timeout occurs, the model is not trained.

  Parameters

  image The three-plane training image.

  mask The image mask. Pixels whose value is 0 indicate “don’t care” pixels in the training image; pixels whose value is 255 indicate “care” pixels in the training image.

  trainParams The training parameters

  diagobj A diagnostic object

  diagFlags Diagnostic flags

  Throws

  ccRSIDefs::BadImageContent
  The Image is featureless.

  ccRSIDefs::BadImage
  image is unbound or has a null window
  mask is unbound
  mask does not have the same window as image
  mask pels have values other than 0 or 255

  ccRSIDefs::NotImplemented
  The image client coordinate system is nonlinear

  ccRSIDefs::BadImageSize
  The image is too small.

  ccTimeout::Expired
  The operation timed out.

untrain

```
void untrain();
```

Untrains this model and releases any saved training data. No effect if the model is not trained.
```

trainParams `ccRSITrainParams trainParams() const;`

Returns **ccRSITrainParams** used to train this model

Throws
ccRSIDefs::NotTrained
The model is not trained.

trainImage `ccPelBuffer_const<c_UInt8> trainImage() const;`

Returns 8-bit image pixels used to train this model

Throws
ccRSIDefs::NotTrained
The model is not trained.
The model was trained using a three-plane image.

trainColorImage
`cc3PlanePelBuffer_const trainColorImage() const;`

Returns three-plane image pixels used to train this model

Throws
ccRSIDefs::NotTrained
The model is not trained.
The model was trained using an 8-bit image.

trainMask `ccPelBuffer_const<c_UInt8> trainMask() const;`

Returns mask image pixels used when this model was trained. If the model was trained without a mask, returns an unbound pel bugger.

Throws
ccRSIDefs::NotTrained
The model is not trained.

isTrained `bool isTrained() const;`

Returns True if model is currently trained, False otherwise

isTrainedMonochrome
`bool isTrainedMonochrome() const;`

Returns True if model is currently trained with a monochrome (8-bit) image, False otherwise

isTrainedColor

```
bool isTrainedColor() const;
```

Returns True if model is currently trained with a color image (three-plane), False otherwise

---

run

```
void run(const ccPelBuffer_const<c_UInt8>& image,
                 const ccRSIRunParams &runParams,
                 ccRSIResultSet &resultSet,
                 ccDiagObject* diagobj=0,
                 c_UInt32 diagFlags=0) const;

void run(const ccPelBuffer_const<c_UInt8>& image,
                 const ccPelBuffer_const<c_UInt8>& mask,
                 const ccRSIRunParams &runParams,
                 ccRSIResultSet &resultSet,
                 ccDiagObject* diagobj=0,
                 c_UInt32 diagFlags=0) const;

void run(const cc3PlanePelBuffer_const& image,
                 const ccRSIRunParams& runParams,
                 ccRSIResultSet& resultSet,
                 ccDiagObject* diagobj=0,
                 c_UInt32 diagFlags=0) const;

void run(const cc3PlanePelBuffer_const& image,
                 const ccPelBuffer_const<c_UInt8>& mask,
                 const ccRSIRunParams& runParams,
                 ccRSIResultSet& resultSet,
                 ccDiagObject* diagobj=0,
                 c_UInt32 diagFlags=0) const;
```

-
```
void run(const ccPelBuffer_const<c_UInt8>& image,
                 const ccRSIRunParams &runParams,
                 ccRSIResultSet &resultSet,
                 ccDiagObject* diagobj=0,
                 c_UInt32 diagFlags=0) const;
```

Searches *image* for this model using the given *runParams*. The *resultSet* is cleared and filled with new results in order of decreasing score.

You can use this function for models that were trained using a mask as well as models that were trained without a mask.

Parameters

image	The 8-bit input image.
runParameters	The search parameters

resultSet The results of the search

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::NotTrained
The model is not trained.
The model was trained for a three-plane color image.

ccRSIDefs::BadImage
image is unbound.

ccRSIDefs::BadParams
One of the DOF ranges specified in *runParams* (composed by the **startPose()**) exceeds the corresponding DOF in the training parameters of this model.

ccRSIDefs::NotImplemented
The *image* client coordinate system is nonlinear.

ccTimeout::Expired
The function executed longer than the timeout specified. No valid results are produced.

- ```
  void run(const ccPelBuffer_const<c_UInt8>& image,
           const ccPelBuffer_const<c_UInt8>& mask,
           const ccRSIRunParams &runParams,
           ccRSIResultSet &resultSet,
           ccDiagObject* diagobj=0,
           c_UInt32 diagFlags=0) const;
  ```

Searches *image* for this model using *mask* and the given *runParams*. The *resultSet* is cleared and filled with new results in order of decreasing score.

You can use this function for models that were trained using a mask as well as models that were trained without a mask.

Masking is not supported for models trained with compression.

Parameters

image The 8-bit input image.

mask The image mask. Pixels whose value is 0 indicate “don’t care” pixels in the input image; pixels whose value is 255 indicate “care” pixels in the input image.

runParameters The search parameters
  ```

resultSet The results of the search

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::NotTrained
The model is not trained.
The model was trained for a three-plane color image.

ccRSIDefs::BadImage
image is unbound
mask is unbound
mask does not have the same window as image
mask pels have values other than 0 or 255

ccRSIDefs::BadParams
One of the DOF ranges specified in *runParams* (composed by the **startPose()**) exceeds the corresponding DOF in the training parameters of this model.

ccRSIDefs::NotImplemented
The *image* client coordinate system is nonlinear, or this model was trained with **ccRSITrainParams::compression()** not set to *ccRSIDefs::eCompressionNone*.

ccTimeout::Expired
The function executed longer than the timeout specified. No valid results are produced.

- ```
  void run(const cc3PlanePelBuffer_const& image,
                  const ccRSIRunParams& runParams,
                  ccRSIResultSet& resultSet,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0) const;
  ```

Searches the three-plane *image* for this model using the given *runParams*. The *resultSet* is cleared and filled with new results in order of decreasing score.

You can use this function for models that were trained using a mask as well as models that were trained without a mask.

Parameters

image The three-plane input image.

runParameters The search parameters

resultSet The results of the search
  ```

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::NotTrained
The model is not trained.
The model was trained for an 8-bit greyscale image.

ccRSIDefs::BadImage
image is unbound

ccRSIDefs::BadParams
One of the DOF ranges specified in *runParams* (composed by the **startPose()**) exceeds the corresponding DOF in the training parameters of this model.

ccRSIDefs::NotImplemented
The *image* client coordinate system is nonlinear.

ccTimeout::Expired
The function executed longer than the timeout specified. No valid results are produced.

- ```
  void run(const cc3PlanePelBuffer_const& image,
                  const ccPelBuffer_const<c_UInt8>& mask,
                  const ccRSIRunParams& runParams,
                  ccRSIResultSet& resultSet,
                  ccDiagObject* diagobj=0,
                  c_UInt32 diagFlags=0) const;
  ```

Searches the three-plane *image* for this model using *mask* and the given *runParams*. The *resultSet* is cleared and filled with new results in order of decreasing score.

You can use this function for models that were trained using a mask as well as models that were trained without a mask.

Masking is not supported for models trained with compression.

Parameters

image The three-plane input image.

mask The image mask. Pixels whose value is 0 indicate “don’t care” pixels in the input image; pixels whose value is 255 indicate “care” pixels in the input image.

runParameters The search parameters

resultSet The results of the search
  ```

diagobj A diagnostic object

diagFlags Diagnostic flags

Throws

ccRSIDefs::NotTrained
The model is not trained.
The model was trained for an 8-bit greyscale image.

ccRSIDefs::BadImage
image is unbound
mask is unbound
mask does not have the same window as image
mask pels have values other than 0 or 255

ccRSIDefs::BadParams
One of the DOF ranges specified in *runParams* (composed by the **startPose()**) exceeds the corresponding DOF in the training parameters of this model.

ccRSIDefs::NotImplemented
The *image* client coordinate system is nonlinear, or this model was trained with **ccRSITrainParams::compression()** not set to *ccRSIDefs::eCompressionNone*.

ccTimeout::Expired
The function executed longer than the timeout specified. No valid results are produced.

ccRSIResult

```
#include <ch_cvl/rsi.h>

class ccRSIResult
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single RSI search result. You should not create a **ccRSIResult** directly.

Constructors/Destructors

ccRSIResult

```
ccRSIResult();
```

Constructs a result object containing no useful data.

Public Member Functions

location

```
cc2Vect location() const;
```

Returns the location of the model origin in the client coordinate system of the runtime image.

The default is (0,0).

pose

```
const cc2Xform& pose() const;
```

Returns a transform from the training time client coordinates (translated to the model origin) to run-time client coordinates. Map **cc2Vect(**0,0**)** through this transform to get the location of the model origin in runtime client coordinates.

The default is **cc2Xform::I**

ccRSIResult

angle

```
ccDegree angle() const;
```

Returns the angle of the located model in the client coordinate system of the runtime image.

The default is 0.

shear

```
ccDegree shear() const;
```

Returns the shear angle of the located model in the client coordinate system of the runtime image.

The default is 0.

xScale

```
double xScale() const;
```

Returns the x-scale of the located model. The default is 1.

yScale

```
double yScale() const;
```

Returns the y-scale of the located model. The default is 1.

scale

```
double scale() const;
```

Returns the scale of the located model. The default is 1.

score

```
double score() const;
```

Returns the score, a number between 0.0 and 1.0. The default is 0.

relativeContrast

```
double relativeContrast() const;
```

Returns the relative contrast of this result. Relative contrast is defined as the scale factor of the standard deviation of the runtime grey levels as compared to the standard deviation of the training time grey levels.

The default is 0.

relativeBrightness

```
double relativeBrightness() const;
```

Returns the relative brightness of this result. Relative brightness is defined as the scale factor of the mean of the runtime grey levels as compared to the mean of the training time grey levels.

The default is 0.

accepted

```
bool accepted() const;
```

Returns True if **score()** is greater than or equal to **ccRSIRunParams::acceptThreshold()**. Otherwise it returns false.

The default is False.

matchRegion

```
ccAffineRectangle matchRegion() const;
```

Returns an affine rectangle that describes the location of the matched model in the runtime image's client coordinates.

The default is **ccAffineRectangle()**.

imageRegion

```
ccPelRect imageRegion() const;
```

Returns the smallest rectangle in runtime image's image coordinates that completely contains the matched model.

default **ccPelRect()**.

draw

```
void draw(ccGraphicList& graphList,
  c_UInt32 drawMode=ccRSIDefs::eDrawStandard,
  const ccCvlString& label=ccCvlString()) const;
```

Appends result graphics for this **ccRSIResult** to the supplied **ccGraphicList**.

Parameters

graphList The graphics list to append the graphics to.

drawMode The drawing mode to use. *drawMode* must be composed by ORing together one or more of the following values:

ccRSIDefs::eDrawOrigin
ccRSIDefs::eDrawLabel
ccRSIDefs::eDrawBoundingBox
ccRSIDefs::eDrawStandard

label	If you include *ccRSIDefs::eDrawLabel* in *drawMode*, then the contents of *label* are used to label the origin of this result.

Notes

Graphics are drawn in **ccColor::greenColor()** if **accepted()** is True for this result, **ccColor::redColor()** if it is not.

ccRSIResultSet

```
#include <ch_cvl/rsi.h>

class ccRSIResultSet
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains all of the **ccRSIResult** objects returned by an RSI search.

Constructors/Destructors

ccRSIResultSet

```
ccRSIResultSet();

~ccRSIResultSet();

ccRSIResultSet(const ccRSIResultSet&);
```

- `ccRSIResultSet();`

  Creates a **ccRSIResultSet** with no results. **numFound()** and **time()** both return 0 when called on a default-constructed **ccRSIResultSet**.

Public Member Functions

numFound

```
c_Int32 numFound() const;
```

Returns the number of **ccRSIResult**s in this **ccRSIResultSet**.

results

```
const cmStd vector<ccRSIResult>& results() const;
```

Returns a vector of **ccRSIResult**s that contains all the results from this search.

ccRSIResultSet

ccRSIRunParams

```
#include <ch_cvl/rsi.h>

class ccRSIRunParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters used to control an RSI search.

This class lets you specify the runtime parameters used to control an RSI search. These parameters include degrees of freedom (DOF) for four *zones*: angle, uniform scale, x-scale and y-scale. You specify which zones are enabled and the range in each zone the tool can use. For zones not enabled, the tool uses a nominal value instead of a range of values.

If the **ccRSIModel** was trained with **ccRSITrainParams::mode()** set to *ccRSIDefs::eGenerateTemplates*, then to use a zone during a search, the tool must have been trained to use that zone. You don't have to enable a zone that you trained for, but you cannot enable a zone that was not trained.

The runtime zones are relative to the start pose. For example, if the start pose is rotated by 30 degrees, then enabling the rotation DOF by -10 degrees to +10 degrees would mean that the tool would search from +20 degrees to +40 degrees. If the start pose has a uniform scale of 1.05, enabling the uniform scale DOF from 0.9 to 1.1 means that the tool would search from 0.945 (0.9 * 1.05) to 1.155 (0.9 *

The following table summarizes these four DOF zones, their defaults, and their ranges. All scale values must be greater than 0.

DOF	Units	Nom.	Default		Range	Zone Enable	Restrictions
			Low	High			
ccRSIDefs::eAngle	degrees	0	-45	+45	any	False	none
ccRSIDefs::eShear	degrees	0	0	0	any	False	none
ccRSIDefs::eUniformScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh

Table 1. Zone defaults and ranges

DOF	Units	Nom.	Default Low	Default High	Range	Zone Enable	Restrictions
ccRSIDefs::eXScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh
ccRSIDefs::eYScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh

Table 1. Zone defaults and ranges

The *angle* zone is always searched from zoneLow to zoneHigh, so setting zoneLow to 0 and zoneHigh to 180 searches one half of the 360 degree angle range. Setting zoneHigh to 0 and zoneLow to 180 searches the other half.

x-scale and *y-scale* only scale in the given dimension. *Uniform scale* performs equal scale in both the x- and y-dimensions. Choose either uniform scale or a combination of x-scale and y-scale. Do not use both uniform scale and x- and y-scale.

Uniform scale is specified as a multiplier of the trained model size. For example, a uniform scale of 1.25 implies that the run-time (client coordinate) size of the model will be 25% larger in both dimensions than the trained model.

Constructors/Destructors

ccRSIRunParams

```
ccRSIRunParams();
~ccRSIRunParams();
ccRSIRunParams(const ccRSIRunParams&);
```

Constructs a **ccRSIRunParams** object using the default values.

Public Member Functions

acceptThreshold

```
double acceptThreshold() const;
void acceptThreshold(double a);
```

- `double acceptThreshold() const;`

  Returns the acceptance threshold.

- `void acceptThreshold(double a);`

  Sets a new acceptance threshold. A result is considered accepted if its score is greater than or equal to this value.

  Parameters

  a The threshold. Must be in the range 0.0 through 1.0. The default value is 0.5.

  Throws

  ccRSIDefs::BadParams

  a < 0 or > 1.0

confusionThreshold

```
double confusionThreshold() const;
void confusionThreshold(double c);
```

- `double confusionThreshold() const;`

  Returns the current confusion threshold.

- `void confusionThreshold(double c);`

  Sets a new confusion threshold.

  Parameters

  c The new confusion threshold.

  Throws

  ccRSIDefs::BadParams

  c < 0 or > 1.0

  Notes

  If the confusion threshold is < **acceptThreshold(), ccRSIModel::run()** will throw *ccRSIDefs::BadParams.*

relativeContrastRange

```
ccRange relativeContrastRange() const;

void relativeContrastRange(
                    const ccRange &relativeContrastRange);
```

- `ccRange relativeContrastRange() const;`

  Returns the current relative contrast range.

- `void relativeContrastRange(`
  `const ccRange &relativeContrastRange);`

  Sets a new relative contrast range, where contrast is defined as the relative scale factor of the standard deviation of the runtime grey levels as compared to the standard deviation of the training time grey levels. Candidate results with lower contrast are removed and never reported as found.

  Parameters

  relativeContrastRange
  The new relative contrast range. The default is **ccRange(**0,HUGE_VAL**)**.

  Throws

  ccRSIDefs::BadParams
  If *relativeContrastRange* has a negative start value, or if *relativeContrastRange* is empty.

  Notes

  Setting *relativeContrastRange* to **ccRange(**0,HUGE_VAL**)** effectively disables the constraint.

relativeBrightnessRange

```
ccRange relativeBrightnessRange() const;

void relativeBrightnessRange(
                 const ccRange &relativeBrightnessRange);
```

- `ccRange relativeBrightnessRange() const;`

  Returns the current relative brightness range.

- `void relativeBrightnessRange(const ccRange &relativeBrightnessRange);`

Sets a new relative brightness range, where brightness is defined as the relative scale factor of the mean of the runtime grey levels as compared to the mean of the training time grey levels. Candidate results with lower or higher brightness are removed and never reported as found.

Parameters

relativeBrightnessRange
The new relative brightness range. The default is **ccRange(**0,HUGE_VAL**)**.

Throws

ccRSIDefs::BadParams
If *relativeBrightnessRange* has a negative start value, or if *relativeBrightnessRange* is empty.

Notes

Setting *relativeBrightnessRange* to **ccRange(**0,HUGE_VAL**)** effectively disables the constraint.

ignorePolarity

```
bool ignorePolarity() const;
void ignorePolarity(bool t);
```

- `bool ignorePolarity() const;`

Returns the current ignore polarity parameter.

- `void ignorePolarity(bool t);`

Sets the ignore polarity parameter. When the ignore polarity parameter is True, the exact grey level inverse of the model can be found.

Parameters

t The new setting. The default is False.

numToFind

```
c_Int32 numToFind() const;
void numToFind(c_Int32 n);
```

- `c_Int32 numToFind() const;`

Returns the number of results to look for.

- `void numToFind(c_Int32 n);`

  Sets the number of results to look for. The **ccRSIModel::run()** function may return fewer results, but it will never return more results than you specify here.

  Parameters

  n The number of results to look for. The default is 1.

  Throws

  ccRSIDefs::BadParams
  If *n* <= 0

startPose

```
cc2XformLinear startPose() const;

void startPose(const cc2XformLinear &startPose);
```

- `cc2XformLinear startPose() const;`

  Returns the current start pose.

- `void startPose(const cc2XformLinear &startPose);`

  Sets the start pose. This start pose maps the model from train-time coordinates into runtime coordinates. If the start pose is exactly correct, then the found result will have exactly the same pose.

  Parameters

  startPose The new start pose. The default is **cc2XformLinear()**.

  Throws

  ccRSIDefs::BadParams
  If *startPose* is singular.

translationUncertainty

```
ccRect translationUncertainty() const;

void translationUncertainty(
                  const ccRect& translationUncertainty);
```

- `ccRect translationUncertainty() const;`

  Returns a rectangle that defines the translation uncertainty bounds.

- `void translationUncertainty(`
  `const ccRect& translationUncertainty);`

  Sets a rectangle that defines the translation uncertainty bounds. The translation uncertainty is specified in client coordinate units and is aligned to the client coordinate axes. The rectangle may be (0, 0, 0, 0) to indicate a point search. Otherwise, the rectangle must contain the point (0, 0).

  Parameters

  translationUncertainty

  The new translation uncertainty. The default is **ccRect(**-HUGE_VAL,-HUGE_VAL,HUGE_VAL,HUGE_VAL**)**;

  Throws

  ccRSIDefs::BadParams

  If *translationUncertainty* does not contain the point (0, 0) and is not the rect (0, 0, 0, 0),
  or if *translationUncertainty* has HUGE_VAL or -HUGE_VAL for any corner or size except for the fully infinite rect (-HUGE_VAL,-HUGE_VAL,HUGE_VAL,HUGE_VAL).

---

xyOverlap

`double xyOverlap() const;`

`void xyOverlap(double overlapThresh);`

- `double xyOverlap() const;`

  Returns the current x/y overlap threshold.

- `void xyOverlap(double overlapThresh);`

  Sets a new x/y overlap threshold required to consider two instances to be the same result. Two results are considered overlapping if the overlap value (approximately the ratio of overlap area to the total area of the model) is greater than *overlapThresh*.

  Meaningful values range from 0.0 to 1.0. When *overlapThresh* is 1.0, no results overlap (overlapping is disabled). When *overlapThresh* is 0.0, results with non-null intersections overlap.

  Parameters

  overlapThresh The new x/y overlap threshold. The default value is 0.8.

  Throws

  ccRSIDefs::BadParams

  If *overlapThresh* is outside the range 0.0 through 1.0.

zoneEnable

```
c_UInt32 zoneEnable() const;
void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

  Returns the current zone settings.

- `void zoneEnable(c_UInt32 enable);`

  Sets which degrees-of-freedom (DOF) zones to consider when searching. The non-zero bits in enable correspond to the values of the **ccRSIDefs::DOF** constants.

  If a zone is enabled for a particular DOF, **ccRSIModel::run()** searches between **zoneLow()** and **zoneHigh()** for that DOF. Otherwise it uses the **nominal()** value for that DOF.

  If a DOF zone is enabled, **run()** results may fall slightly outside **zoneLow()** and **zoneHigh()**. If no DOF zone enabled, the result that **run()** produces will always be **nominal()** for that DOF.

  Parameters

  enable — The enabled zones.
  The default is zero: no DOF zones enabled.

  Throws

  ccRSIDefs::BadParams

  enable is not zero or a combination created by a bitwise-OR of the values from **ccRSIDefs::DOF**.

nominal

```
double nominal(ccRSIDefs::DOF dof) const;
void nominal(ccRSIDefs::DOF dof, double val);
```

- `double nominal(ccRSIDefs::DOF dof) const;`

  Returns the nominal value for the specified DOF.

  Parameters

  dof — The specified degree of freedom.

- `void nominal(ccRSIDefs::DOF dof, double val);`

  Sets a nominal value for the specified DOF.

  The nominal value for a given degree of freedom (DOF) is used only if it is not enabled by **zoneEnable()** The **zoneLow()** and **zoneHigh()** values are ignored when the nominal value is used.:

DOF	Default Nominal Value
ccRSIDefs::eAngle	0.0
ccRSIDefs::eShear	0.0
ccRSIDefs::eUniformScale	1.0
ccRSIDefs::eXScale	1.0
ccRSIDefs::eYScale	1.0

  Parameters

  dof The specified degree of freedom.

  val The value to set.

  Throws

  ccRSIDefs::BadParams

  dof is not in ccRSIDefs::DOF
  val <= 0 and *dof* is **ccRSIDefs::eUniformScale, ccRSIDefs::eXScale,** or **ccRSIDefs::eYScale**

zoneLow `double zoneLow (ccRSIDefs::DOF dof) const;`

Returns the low value for the specified degree of freedom (DOF). **ccRSIModel::run()** searches between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**.

dof The specified degree of freedom.

zoneHigh `double zoneHigh(ccRSIDefs::DOF dof) const;`

Returns the high value for the specified degree of freedom (DOF). **ccRSIModel::run()** searches between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**

Parameters

dof The specified degree of freedom.

zone

```
void zone(ccRSIDefs::DOF dof, double low, double high);
```

Sets the low and high values for the specified degree of freedom (DOF). **ccRSIModel::run()** searches between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**

Notes

The span of each degree of freedom's runtime zone must be smaller than or equal to the span of the corresponding training zone or a runtime exception will be thrown.

Parameters

dof The specified degree of freedom.

low The low value.

high The high value.

Throws

ccRSIDefs::BadParams

dof is not in **ccRSIDefs::DOF**
low and *high* do not meet the restrictions listed in Table 1.

zoneOverlap

```
double zoneOverlap(ccRSIDefs::DOF dof) const;
void zoneOverlap(ccRSIDefs::DOF dof, double overlapThresh);
```

- `double zoneOverlap(ccRSIDefs::DOF dof) const;`

Return the overlap threshold for the specified degree of freedom.

Parameters

dof The specified degree of freedom.

- `void zoneOverlap(ccRSIDefs::DOF dof, double overlapThresh);`

  Sets the zone overlap threshold for the specified degree of freedom. The meaning of overlap is different for angles and for scales.

  For **ccRSIDefs::eAngle**, two results are considered overlapping if the absolute difference between their angles is less than or equal to *overlapThresh*. This means that for **ccRSIDefs::eAngle**, *overlapThresh* must be greater than or equal to zero.

  For the other degrees of freedom overlap is specified as a ratio of the result with the greater scale to the result with the smaller scale. If the ratio of the two results is less than or equal to *overlapThresh*, the results are considered overlapping. This means that overlapThresh must be greater than 1.0.

  overlapThresh must be >= 1.0. For example, if *dof* is one of the scale degrees of freedom, and *overlapThresh* = 1.2, then two results, one with a scale of 1.25 and one with a scale of 2.5, would not overlap in scale since 2.5/1.25 is greater than 1.2.

  Parameters

dof	The specified degree of freedom.
overlapThresh	The overlap threshold. For angles, the default is 360.0. FOr scales, the default is 1.4.

  Throws

  ccRSIDefs::BadParams
  overlapThresh is not valid for the specified *dof*.

method

```
ccRSIDefs::Method method() const;

void method(ccRSIDefs::Method method);
```

- `ccRSIDefs::Method method() const;`

  Returns the method used to determine the sub-pixel position. The returned value is one of the following:

  ccRSIDefs::eStandard
  ccRSIDefs::eHighAccuracy

- `void method(ccRSIDefs::Method method);`

  Sets the method used to determine the sub-pixel position. The default value is *ccRSIDefs::eStandard*.

Parameters

method The method to use. *method* must be one of the following values:

ccRSIDefs::eStandard
ccRSIDefs::eHighAccuracy

Throws

BadParams

method is neither *eStandard* nor *eHighAccuracy*.

forceUncompressedForScore

```
bool forceUncompressedForScore() const;

void forceUncompressedForScore(bool f);
```

- `bool forceUncompressedForScore() const;`

  Returns true if RSI search uses an uncompressed version of the model to compute the score, false otherwise.

- `void forceUncompressedForScore(bool f);`

  Sets whether or not to use an uncompressed verison of the trained model to compute the score.

  Parameters

  f The new setting. The default is True.

  Notes

  This setting has no effect if the model was trained with **ccRSIRunParams::compression()** set to *ccRSIDefs::eCompressionNone*.

ccRSITrainParams

```
#include <ch_cvl/rsi.h>

class ccRSITrainParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

When you train the RSI Search tool you specify parameters the tool uses during searches. These parameters include degrees of freedom (DOF) for four *zones*: angle, uniform scale, x-scale and y-scale. You specify which zones are enabled and the range in each zone the tool can use. For zones not enabled, the tool uses a nominal value instead of a range of values.

The following table summarizes these four DOF zones, their defaults, and their ranges. All scale values must be greater than 0.

DOF	Units	Nom.	Default Low	Default High	Range	Zone Enable	Restrictions
ccRSIDefs::eAngle	degrees	0	-45	+45	any	False	none
ccRSIDefs::eUniformScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh
ccRSIDefs::eXScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh
ccRSIDefs::eYScale	multiplier	1	0.8	1.2	> 0	False	zoneLow <= zoneHigh
ccRSIDefs::eShear	degrees	0	0	0	any	False	zoneLow <= zoneHigh

Table 1. Zone defaults and ranges

The *angle* zone is always searched from zoneLow to zoneHigh, so setting zoneLow to 0 and zoneHigh to 180 searches one half of the 360 degree angle range. Setting zoneHigh to 0 and zoneLow to 180 searches the other half.

x-scale and *y-scale* only scale in the given dimension. *Uniform scale* performs equal scale in both the x- and y-dimensions.

Uniform scale is specified as a multiplier of the trained model size. For example, a uniform scale of 1.25 implies that the run-time (client coordinate) size of the model will be 25% larger in both dimensions than the trained model.

Constructors/Destructors

ccRSITrainParams

```
ccRSITrainParams();
```

Constructs an RSI Search tool training parameters object using the default values.

Public Member Functions

mode

```
ccRSIDefs::Mode mode() const;

void mode(ccRSIDefs::Mode mode);
```

mode() controls whether RSI Search creates template images at training time or at run time.

When **mode()** is set to *ccRSIDefs::eGenerateTemplates*, RSI Search creates, at training time, all of the template images required to cover the search space that is specified by the **zone()**, **nominal(), zoneEnable(), zoneLow()**, and **zoneHigh()** members of this class.

When **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs*, RSI Search does not create any template images at training time. Instead, the tool automatically generates template images at run time, based on the search space specified for the particular search.

In general, *ccRSIDefs::eGenerateTemplates* provides for faster operation at run time, but specifying this mode creates the requirement that the search space specified for training must enclose the search space for each run-time search.

- `ccRSIDefs::Mode mode() const;`

  Returns the current mode. The returned value is one of the following values:

  ccRSIDefs::eGenerateTemplates
  ccRSIDefs::eUnrestrictedDOFs

- `void mode(ccRSIDefs::Mode mode);`

  Sets the mode. The default value is *ccRSIDefs::eGenerateTemplates*.

mode	The mode to set. *mode* must be one of the following values: *ccRSIDefs::eGenerateTemplates* *ccRSIDefs::eUnrestrictedDOFs*

Throws

ccRSIDefs::BadParams

mode is neither *ccRSIDefs::eGenerateTemplates nor ccRSIDefs::eUnrestrictedDOFs*.

combineDOF

```
ccRSIDefs::CombineDOF combineDOF() const;

void combineDOF(ccRSIDefs::CombineDOF c);
```

This value of **combineDOF()** is used by RSI Search to interpret the meaning of **ccRSIModel::trainClientFromModel()**.

When **combineDOF()** is set to *ccRSIDefs::eCombineDOFTrainClientFromModel*, RSI Search interprets the values specified for the **zone()**, **nominal(), zoneLow()**, and **zoneHigh()** members as having been combined with the values for the corresponding degrees of freedom found in **ccRSIModel::trainClientFromModel()**.

When **combineDOF()** is set to *ccRSIDefs::eCombineDOFIdentity*, RSI Search interprets the values specified for the **zone()**, **nominal(), zoneLow()**, and **zoneHigh()** members without regard to the values for the corresponding degrees of freedom found in **ccRSIModel::trainClientFromModel()**.

The value specified for this member is only used when **mode()** is set to *ccRSIDefs::eGenerateTemplates* and **ccRSIModel::trainClientFromModel()** is set to a non-identity transform.

- `ccRSIDefs::CombineDOF combineDOF() const;`

  Returns the current DOF combination mode. The returned value is one of the following:

  ccRSIDefs::eCombineDOFTrainClientFromModel
  ccRSIDefs::eCombineDOFIdentity

- `void combineDOF(ccRSIDefs::CombineDOF c);`

  Sets the current DOF combination mode.

  Parameters

  c — The combination mode to set. *c* must be one of the following values:

  ccRSIDefs::eCombineDOFTrainClientFromModel
  ccRSIDefs::eCombineDOFIdentity

Throws

ccRSIDefs::BadParams

c is neither *ccRSIDefs::eCombineDOFTrainClientFromModel nor ccRSIDefs::eCombineDOFIdentity*.

zoneEnable

```
c_UInt32 zoneEnable() const;

void zoneEnable(c_UInt32 enable);
```

The value of this member is ignored if **mode()** is set to *ccRSIDefs::eGenerateTemplates*

- `c_UInt32 zoneEnable() const;`

  Returns the current zone settings.

- `void zoneEnable(c_UInt32 enable);`

  Sets which degrees-of-freedom (DOF) zones to consider when training. The non-zero bits in enable correspond to the values of the **ccRSIDefs**::**DOF** constants.

  If a zone is enabled for a particular DOF, **ccRSIModel::train()** trains between **zoneLow()** and **zoneHigh()** for that DOF. Otherwise it trains the **nominal()** value for that DOF.

  Parameters

  enable — The enabled zones. The default is zero: no DOF zones enabled.

  Throws

  ccRSIDefs::BadParams

  enable is not zero or a combination created by a bitwise-OR of the values from **ccRSIDefs::DOF**.

  Notes

  The value of this member is ignored if **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs.*

nominal

```
double nominal(ccRSIDefs::DOF dof) const;

void nominal(ccRSIDefs::DOF dof, double val);
```

- `double nominal(ccRSIDefs::DOF dof) const;`

  Returns the nominal value for the specified DOF.

Parameters

dof The degree of freedom.

- `void nominal(ccRSIDefs::DOF dof, double val);`

The nominal value for a given degree of freedom (DOF) is used only if it is not enabled by **zoneEnable()** The **zoneLow()** and **zoneHigh()** values are ignored when the nominal value is used.:

DOF	Default Nominal Value
ccRSIDefs::eAngle	0.0
ccRSIDefs::eUniformScale	1.0
ccRSIDefs::eXScale	1.0
ccRSIDefs::eYScale	1.0
ccRSIDefs::eShear	0.0

Parameters

dof The specified degree of freedom.

val The value to set.

Throws

ccRSIDefs::BadParams

dof is not in ccRSIDefs::DOF
val <= 0 and *dof* is *ccRSIDefs::eUniformScale*, *ccRSIDefs::eXScale*, *ccRSIDefs::eYScale* or *ccRSIDefs::eShear*.

Notes

The value of this member is ignored if **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs*.

zoneLow `double zoneLow (ccRSIDefs::DOF dof) const;`

Returns the low value for the specified degree of freedom (DOF). **ccRSIModel::train()** trains between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**.

dof The specified degree of freedom.

Notes

The value of this member is ignored if **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs*.

zoneHigh

```
double zoneHigh(ccRSIDefs::DOF dof) const;
```

Returns the high value for the specified degree of freedom (DOF). **ccRSIModel::train()** trains between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**.

dof The specified degree of freedom.

Notes

The value of this member is ignored if **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs*.

zone

```
void zone(ccRSIDefs::DOF dof, double low, double high);
```

Sets the low and high values for the specified degree of freedom (DOF). **ccRSIModel::train()** trains between **zoneLow()** and **zoneHigh()** for a specified DOF only when it is enabled with **zoneEnable()**

Notes

The span of each degree of freedom's runtime zone must be smaller than or equal to the span of the corresponding training zone or a runtime exception will be thrown.

Parameters

dof The specified degree of freedom.

low The low value.

high The high value.

Throws

ccRSIDefs::BadParams

dof is not in **ccRSIDefs::DOF**

low and *high* do not meet the restrictions listed in Table 1.

Notes

The value of this member is ignored if **mode()** is set to *ccRSIDefs::eUnrestrictedDOFs*.

autoSelectGrainLimits

```
bool autoSelectGrainLimits() const;

void autoSelectGrainLimits(bool b);
```

Returns whether granularity limits are set automatically.

Notes

Enabling automatic selection generally doubles training time.

- `bool autoSelectGrainLimits() const;`

  Returns the current automatic selection setting.

- `void autoSelectGrainLimits(bool b);`

  Allows the automatic selection of granularity limits at training time. The default is True.

  Parameters

  b The new automatic selection flag.

coarseGrainLimit

`float coarseGrainLimit () const;`

Returns the current coarse granularity limit setting. Ignored if **autoSelectGrainLimits()** is True.

fineGrainLimit

`float fineGrainLimit () const;`

Returns the current fine granularity limit setting. Ignored if **autoSelectGrainLimits()** is True.

grainLimits

`void grainLimits(float coarse, float fine);`

Sets the coarse and fine granularity limits.

Notes

If **autoSelectGrainLimits()** is true, these limit values are ignored.

Parameters

coarse The new coarse granularity limit. Default is 4.0.

fine The new fine granularity limit. Default is 1.0.

Throws

ccRSIDefs::BadParams

If *coarse* < *fine,*
or if coarse < 1,
or if fine < 1

granularityGenerator

```
ccRSIDefs::GranularityGenerator
   granularityGenerator() const;

void granularityGenerator(
   ccRSIDefs::GranularityGenerator g);
```

Sets or gets the method used to generate the coarse granularity model. The default value, *ccRSIDefs::eGranularityGeneratorRobust*, provides the best results in most cases, and is guaranteed to find all valid model instances. If you specify *eGranularityGeneratorFast*, it can improve run-time speed but when used with models containing primarily fine features, it can fail to find some model instances.

The default value is *ccRSIDefs::eGranularityGeneratorRobust*.

- ```
  ccRSIDefs::GranularityGenerator
     granularityGenerator() const;
  ```

  Returns the current coarse granularity generator. The returned value is one of the following:

  ccRSIDefs::eGranularityGeneratorRobust
  ccRSIDefs::eGranularityGeneratorFast

- ```
  void granularityGenerator(
     ccRSIDefs::GranularityGenerator g);
  ```

  Sets the coarse granularity generator.

  Parameters

  g — The generator to use. *g* must be one of the following values:

  cRSIDefs::eGranularityGeneratorRobust
  ccRSIDefs::eGranularityGeneratorFast

compression

```
ccRSIDefs::Compression compression() const;
void compression(ccRSIDefs::Compression c);
```

Sets or gets the compression mode for this model. Using compression reduces the amount of data required to represent the trained model and can improve run-time execution speed. The use of *ccRSIDefs::eCompressionLossless* is not recommended. You can specify the degree of lossy compression, when using *ccRSIDefs::eCompressionLossy*, using **lossyCompressionQuality()**.

The default value is *ccRSIDefs::eCompressionNone*.

- `ccRSIDefs::Compression compression() const;`

  Returns the current compression mode. The returned value is one of the following:

  ccRSIDefs::eCompressionNone
  ccRSIDefs::eCompressionLossy
  ccRSIDefs::eCompressionLossless

- `void compression(ccRSIDefs::Compression c);`

  Sets the compression mode.

  Parameters

  c — The compression mode to set. *c* must be one of the following values:

  ccRSIDefs::eCompressionNone
  ccRSIDefs::eCompressionLossy
  ccRSIDefs::eCompressionLossless

lossyCompressionQuality

```
double lossyCompressionQuality() const;

void lossyCompressionQuality(double q);
```

Sets or gets the degree of compression that is applied. This only applies when **compression()** is *ccRSIDefs::eCompressionLoss.* The compression quality must be greater than zero and less than or equal to 1.0. Larger values indicate higher quality and lower compression.

In general, higher values produce slower, more robust searches, while lower values produce faster, less robust searches.

The default value is 0.95.

- `double lossyCompressionQuality() const;`

  Returns the current compression quality. The returned value is greater than 0 and less than or equal to 1.0.

- `void lossyCompressionQuality(double q);`

  Sets the compression quality.

  Parameters

q	The compression quality. The supplied value must be greater than 0 and less than or equal to 1.0.

ccSampleConvolveParams

```
#include <ch_cvl/smplconv.h>

class ccSampleConvolveParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class defines parameter objects used by the **cfSampleConvolve()** global function.

Constructors/Destructors

ccSampleConvolveParams

```
ccSampleConvolveParams();
```

Constructs object using the default values. The default values are the following:

sample_ = (1.0, 1.0)

(The internally stored sample value.)

kernelX_ = (empty)

(The internally stored calculated or provided 1D kernel in x.)

kernelY_ = (empty)

(The internally stored calculated or provided 1D kernel in y.)

canUsePelRoot_ = true

(The internally stored flag to indicate whether it is okay to use pels outside the src **ccPelBuffer**'s rect in its pelroot.)

Notes

The default copy constructor, assignment operator, and destructor are used.

Public Member Functions

sample

```
ccDPair sample() const;
void sample(const ccDPair &samp);
void sample(double samp);
```

- `ccDPair sample() const;`

  Gets the sampling rates in x and y.

- `void sample(const ccDPair &samp);`

  Sets the sampling rates in x and y.

  Parameters

  samp The sampling rates to be set in x and y.

  The default is (1.0, 1.0).

  Throws

  ccSampleConvolveDefs::BadParams

  samp.x() <= 0 or **samp.y()** <= 0

- `void sample(double samp);`

  Sets the sampling rates in x and y. This overload sets sampling rates in both directions to the same value.

  For example, to specify sampling every third pixel, set sample to (3,3).

  Parameters

  samp The sampling rates to be set in x and y.

  The default is (1.0, 1.0).

  Notes

  Non-integer sampling is fully supported.

  Non-integer sampling is typically slightly slower than sampling of FLOOR (sample) and significantly slower than sampling of CEIL(sample).

kernelX

```
const cmStd vector<c_Int16> &kernelX() const;
void kernelX(const cmStd vector<c_Int16> &kX);
```

- `const cmStd vector<c_Int16> &kernelX() const;`

  Gets the kernel used for separable X convolution.

- `void kernelX(const cmStd vector<c_Int16> &kX);`

  Sets the kernel used for separable X convolution.

  The setter makes a copy of the provided vector, while the getter returns a const reference to the stored vector.

  Parameters

  kX The kernel to be set for separable X convolution.

  Throws

  ccSampleConvolveDefs::NotImplemented
  The kernel is larger than 128 elements or the kernel size is an even number,
  or the sum of all positive elements of the kernel is greater than 128, or the sum of all negative elements of the kernel is less than -128.

  Notes

  Default parameters cannot be used for convolve/sampling. A valid kernel must be set, either directly or by using **setGaussSample()** or **setGaussSmoothing()**.

kernelY

```
const cmStd vector<c_Int16> &kernelY() const;
void kernelY(const cmStd vector<c_Int16> &kY);
```

- `const cmStd vector<c_Int16> &kernelY() const;`

  Gets the kernel used for separable Y convolution.

- `void kernelY(const cmStd vector<c_Int16> &kY);`

  Sets the kernel used for separable Y convolution.

  The setter makes a copy of the provided vector, while the getter returns a const reference to the stored vector.

Parameters

kY The kernel to be set for separable Y convolution.

Throws

ccSampleConvolveDefs::NotImplemented
The kernel is larger than 128 elements or the kernel size is an even number,
or the sum of all positive elements of the kernel is greater than 128, or the sum of all negative elements of the kernel is less than -128.

Notes

Default parameters cannot be used for convolve/sampling. A valid kernel must be set, either directly or by using **setGaussSample()** or **setGaussSmoothing()**.

setGaussSample

```
void setGaussSample(const ccDPair &samp);

void setGaussSample(double samp);
```

- `void setGaussSample(const ccDPair &samp);`

Quickly sets up sample and kernel values for Gaussian smoothing in a single function call. The sample value is set to the provided value (*samp*) as in the **sample()** setters, and 2D Gaussian kernel is defined with sigma = 0.5 * **floor(***samp***)**

Parameters

samp The sample value to be set for Gaussian smoothing.

Notes

These parameters emphasize speed of operation and ease of use. Other kinds of convolution can be defined explicitly using the **sample()**, **kernelX()**, and **kernelY()** setters.

Throws

ccSampleConvolveDefs::NotImplemented
Any *samp* value is greater than 64.

ccSampleConvolveDefs::BadParams
Any *samp* value is less than or equal to 0.

- `void setGaussSample(double samp);`

Quickly sets up sample and kernel values for Gaussian smoothing in a single function call. The sample value is set to the provided value (*samp*) as in the **sample()** setters, and 2D Gaussian kernel is defined with sigma = 0.5 * **floor(***samp***)**

Parameters

samp The sample value to be set for Gaussian smoothing.

Notes

This parameter emphasizes speed of operation and ease of use. Other kinds of convolution can be defined explicitly using the **sample()**, **kernelX()**, and **kernelY()** setters.

Throws

ccSampleConvolveDefs::NotImplemented
Any *samp* value is greater than 64.

ccSampleConvolveDefs::BadParams
Any *samp* value is less than or equal to 0.

setGaussSmoothing

```
void setGaussSmoothing(const ccDPair &sigma);

void setGaussSmoothing(double sigma);
```

- `void setGaussSmoothing(const ccDPair &sigma);`

Quickly sets up kernel values for Gaussian smoothing in a single function call. A 2D Gaussian kernel is defined with the given sigma value(s). The sample rate is left unchanged.

Parameters

sigma The kernel values to be set for Gaussian smoothing.

Notes

These parameters emphasize speed of operation and ease of use. Other kinds of convolution can be defined explicitly using the **kernelX()** and **kernelY()** setters.

Throws

ccSampleConvolveDefs::NotImplemented
Any sigma value is greater than 32.

ccSampleConvolveDefs::BadParams
Any sigma value is less than 0.

- `void setGaussSmoothing(double sigma);`

Quickly sets up kernel values for Gaussian smoothing in a single function call. A 2D Gaussian kernel is defined with the given sigma value. The sample rate is left unchanged.

Parameters

sigma The kernel value to be set for Gaussian smoothing.

Notes

This parameter emphasizes speed of operation and ease of use. Other kinds of convolution can be defined explicitly using the **kernelX()** and **kernelY()** setters.

Throws

ccSampleConvolveDefs::NotImplemented
The *sigma* value is greater than 32.

ccSampleConvolveDefs::BadParams
The *sigma* value is less than 0.

canUsePelRoot

```
bool canUsePelRoot () const;

void canUsePelRoot (bool canUseRoot);
```

- `bool canUsePelRoot () const;`

  Gets whether or not it is okay to use pels outside the src **ccPelBuffer**'s rect in its pelroot.

- `void canUsePelRoot (bool canUseRoot);`

  Sets whether or not it is okay to use pels outside the src **ccPelBuffer**'s rect in its pelroot.

  Parameters

  canUseRoot Whether or not it is okay to use pels outside the src **ccPelBuffer**'s rect in its pelroot.

  The default is true.

computeDestRect

```
void computeDestRect(
  const ccRect &srcRect,
  ccRect &destRect) const;
```

Computes the maximum destination region that could result from the given source region and parameters.

Parameters

srcRect The source region.

destRect The destination region.

Notes

If **cfSampleConvolve()** is called with an unbound destination, the result rect is exactly the return result of this function. Otherwise, the result of the tool will be to fill in the GCR of the input destination window and the window that results from this function.

The relationship of *srcRect* and *destRect* depends both on the sampling factor and (in general) the sub-pixel offset.

computeMaxSrcRect

```
void computeMaxSrcRect(
  const ccRect &srcRect,
  const ccRect &destRect,
  ccRect &maxSrcRect) const;
```

Computes the maximum source region that would be referenced by this operation.

Parameters

srcRect The source region.

destRect The destination region.

maxSrcRect The maximum source region.

Notes

The rectangle returned by this function contains exactly the src input pels that are "referenced" if the same parameters are sent to **cfSampleConvolve()**. In particular, if **cfSampleConvolve()** is called with a src image that contains *maxSrcRect*, or (if **canUsePelRoot()** is true) with a src image root that contains *maxSrcRect*, then no input pels are artificially produced by reflection.

ccSampleConvolveParams

ccSampleParams

```
#include <ch_cvl/shapbase.h>

class ccShape::ccSampleParams;
```

This class specifies shape sampling parameters. An instance of this class is passed to **ccShape::sample()** to describe how the sampling should be done. This is a nested class defined inside of **ccShape**.

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

Constructors/Destructors

ccSampleParams

```
ccSampleParams(const double &tolerance = 0.0,
  const double &spacing = 0.0,
  c_Int32 maxPoints = 2,
  bool computeTangents = false,
  bool duplicateCorners = true);
```

Constructs a **ccSampleParams** with the given parameters. The default parameter values construct a **ccSampleParams** set for the coarsest possible sampling, with position sampling enabled and tangent direction sampling disabled.

Parameters

tolerance Maximum bound on the distance between the approximating polygon, formed by connecting the sample positions, and the true curve.

spacing Maximum bound on the arc length between successive sample points along a shape.

maxPoints Maximum number of sample points that may be taken along a single curved element of a primitive shape.

computeTangents Specifies whether or not to compute and return a tangent vector at each sample point (default = false).

duplicateCorners

Specifies how to handle points where either 1) two distinct contours meet (as in a contour tree), or 2) the tangent direction is discontinuous within a single contour (as at the corner of a rectangle). See *duplicateCorners* on page 2825 for more information.

Throws

ccShapesError::BadParams

tolerance is less than 0.0,
spacing is less than 0.0, or
maxPoints is less than 2.0.

Operators

operator==

```
bool operator==(const ccSampleParams &rhs) const;
```

Returns true if *rhs* is equal to this **ccSampleParams** object.

Parameters

rhs The other **ccSampleParams** object.

operator!=

```
bool operator!=(const ccSampleParams &rhs) const;
```

Returns true if *rhs* is not equal to this **ccSampleParams** object.

Parameters

rhs The other **ccSampleParams** object.

Public Member Functions

tolerance

```
double tolerance() const;
```

```
void tolerance(const double val);
```

- `double tolerance() const;`

Gets the tolerance bound. This is a maximum bound on the distance between the approximating polygon, formed by connecting the sample positions, and the true curve. If meeting the tolerance bound would cause more than **maxPoints()** to be generated along a curved element of a primitive shape, the **sample()** method throws *ccShapesError::SampleOverflow*. A tolerance value of 0.0 (the default) is special, indicating that there is no maximum tolerance bound; use this value to generate the coarsest possible sampling. The tolerance bound is only significant for contours that contain curves.

- `void tolerance(const double val);`

  Sets the tolerance bound.

  Parameters

  val The tolerance value. Must be greater than or equal to 0.0.

  Throws

  ccShapesError::BadParams

  val is less than 0.0.

spacing

```
double spacing() const;

void spacing(double val);
```

- `double spacing() const;`

  Gets the spacing bound. This is a maximum bound on the arc length between successive sample points along a shape. If meeting the spacing bound would cause more than **maxPoints()** to be generated along a curved element of a primitive shape, the **sample()** method throws *ccShapesError::SampleOverflow*. A spacing value of 0.0 (the default) is a special flag indicating that there is no maximum spacing bound; use this value to generate the coarsest possible sampling.

- `void spacing(double val);`

  Sets the spacing bound.

  Parameters

  val The spacing bound. Must be greater than or equal to 0.0.

  Throws

  ccShapesError::BadParams

  val is less than 0.0.

maxPoints

```
c_Int32 maxPoints() const;

void maxPoints(c_Int32 val);
```

- `c_Int32 maxPoints() const;`

  Gets the maximum points value. This value is the maximum number of sample points that may be taken along a single element of a primitive shape. If the spacing or tolerance bounds are set in a manner that requires more than **maxPoints()** samples, the **sample()** method will throw *ccShapesError::SampleOverflow*.

- `void maxPoints(c_Int32 val);`

  Sets the max points value.

  val The maximum points value. Must be greater than or equal to 2.

  Throws

  ccShapesError::BadParams

  val is less than 2.

computeTangents

```
bool computeTangents() const;

void computeTangents(bool flag);
```

- `bool computeTangents() const;`

  Gets the compute tangents flag. This flag determines whether or not tangent direction sampling should be done along with the standard position sampling.

  Notes

  If **computeTangents()** is true, the **sample()** method ignores shapes for which **hasTangent()** is false.

- `void computeTangents(bool flag);`

  Sets the compute tangents flag. This flag determines whether or not tangent direction sampling should be done along with the standard position sampling.

  Parameters

  flag If true, the **sample()** method will compute tangents in addition to sample points, ignoring shapes for which **hasTangent()** is false.

  Notes

  Do not change this value between invocations of **sample()** if results are collected in a single **ccSampleResult** object.

  See **ccShape::sample()** for more information.

duplicateCorners

```
bool duplicateCorners() const;

void duplicateCorners(bool flag);
```

- `bool duplicateCorners() const;`

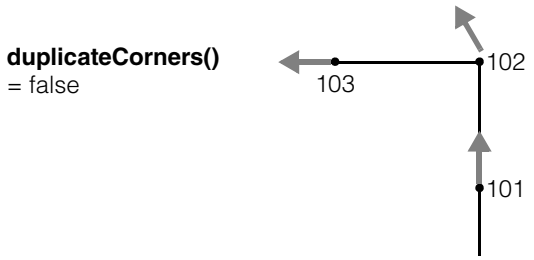
  Gets the *duplicateCorners* flag. This flag determines how to handle points where two distinct contours meet (as in a **ccContourTree**) or the tangent direction is discontinuous within a single contour (as at the corner of a rectangle).

  - If **duplicateCorners()** is true, two samples are generated at each junction. The two samples share the same position, but the first sample takes its tangent direction from the first curve, and the second sample takes its tangent direction from the second curve. For example, in the following figure in which **duplicateCorners()** is true, there are two sample points (102 and 103) at the corner and each takes its tangent direction from one of the two line segments that join at the corner.

    duplicateCorners()
    = true

    
    If **duplicateCorners()** is true, point samples are duplicated at the corners even if **computeTangents()** is false.

- If **duplicateCorners()** is false, only one sample is generated at the junction, and the tangent direction is the average of the tangent directions from the two curves. For example, in the following figure in which **duplicateCorners()** is false, there is only one sample point (102) at the corner and its tangent direction is the average of the tangent directions of the two line segments that join at the corner.



- `void duplicateCorners(bool flag);`

  Sets the duplicate corners flag.

  flag The duplicate corners flag. Must be a boolean value.

uniformMode

```
bool uniformMode() const;
void uniformMode(bool flag);
```

- `bool uniformMode() const;`

  For Cognex internal use only.

- `void uniformMode(bool flag);`

  For Cognex internal use only.

ccSampleProp

```
#include <ch_cvl/prop.h>

class ccSampleProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class encapsulates subsampling properties applied to acquired images. Image x and y subsampling are performed independently. Subsampling can be used to reduce the image size and may also result in faster acquires. Subsample values specify the ratio of full frame pixels to sampled pixels. For example, an x subsample of 8 specifies an 8:1 reduction in the number of pixels along the x (horizontal) axis. The y subsample specifies a reduction of pixels along the y (vertical) axis.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccSampleProp

```
ccSampleProp();

ccSampleProp(
  c_Int32 subSampleX,
  c_Int32 subSampleY);

virtual ~ccSampleProp() {};
```

- `ccSampleProp();`

  Default constructor.

- ```
  ccSampleProp(
    c_Int32 subSampleX,
    c_Int32 subSampleY);
  ```

  Constructor with specified subsampling.

  Parameters

  subSampleX The x subsample value.

  subSampleY The y subsample value.

  Notes

  An invalid *subSampleX defaults to* 1, no x subsampling. Also, an invalid `subSampleY` defaults to 1, no y subsampling.

- ```
  virtual ~ccSampleProp() {};
  ```

  Destructor.

Operators

operator== `bool operator==(const ccSampleProp& that) const;`

Comparison operator. Returns true if *that* = this object. Returns false otherwise.

Parameters

that A **ccSampleProp** object to compare with this one.

operator!= `bool operator!=(const ccSampleProp& that) const;`

Comparison operator. Returns false if *that* = this object. Returns true otherwise.

Parameters

that A **ccSampleProp** object to compare with this one.

Public Member Functions

sampleX

```
void sampleX(c_Int32 v);
c_Int32 sampleX() const;
```

- `void sampleX(c_Int32 v);`

  Sets a new subsample x-value.

  Notes

  An invalid subsample x-value sets *v* = 1, no x subsampling.

  Parameters

v	The new subsample value.

- `c_Int32 sampleX() const;`

  Returns the current subsample x-value.

sampleY

```
void sampleY(c_Int32 v);
c_Int32 sampleY() const;
```

- `void sampleY(c_Int32 v);`

  Sets a new subsample y-value.

  Parameters

v	The new subsample value.

  Notes

  An invalid subsample y-value sets *v* = 1, no y subsampling.

- `c_Int32 sampleY() const;`

  Returns the current subsample y-value.

Constants

defaultSampleX `static const c_Int32 defaultSampleX;`

Default = 1, no subsampling.

defaultSampleY `static const c_Int32 defaultSampleY;`

Default = 1, no subsampling.

ccSampleResult

```
#include <ch_cvl/shapbase.h>

class ccShape::ccSampleResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

The **ccSampleResult** class describes the result of a **ccShape::sample()** operation. This is a nested class defined inside of **ccShape**.

When sampling a shape with multiple contours, such as an annulus or hierarchical shape, there are multiple *chains* of sampled positions and tangents. You can retrieve these positions and tangents as flat (one-dimensional) vectors from a **ccSampleResult** object using the **positions()** and **tangents()** methods, respectively.

The **breaks()** method returns a vector that describes how these composite vectors are partitioned into individual chains: each element of the *breaks* vector indexes the starting element of a distinct chain in the *positions* and *tangents* vectors. Thus, the size of the *breaks* vector equals the number of distinct chains. This scheme facilitates effective pre-allocation of storage for position and tangent samples.

The *closedFlags* vector always has the same number of elements as the *breaks* vector. The *i*th element of *closedFlags* indicates whether the chain indexed by the *i*th element of *breaks* is an open or closed chain.

Constructors/Destructors

ccSampleResult

```
ccSampleResult();
```

Default constructor. Constructs an empty **ccSampleResult** object.

Operators

operator==

```
bool operator==(const ccSampleResult &rhs) const;
```

Returns true if *rhs* is equal to this **ccSampleResult** object.

Parameters

rhs	The other **ccSampleResult** object.

operator!=

```
bool operator!=(const ccSampleResult &rhs) const;
```

Returns true if *rhs* is not equal to this **ccSampleResult** object.

Parameters

rhs The other **ccSampleResult** object.

Public Member Functions

reset

```
void reset();
```

Removes all position samples, tangent direction samples, and break indices stored within this **ccSampleResult**.

numChains

```
c_Int32 numChains() const;
```

Returns the number of distinct chains within this **ccSampleResult**.

positions

```
const cmStd vector<cc2Vect> &positions() const;
cmStd vector<cc2Vect> &positions();
```

- ```
  const cmStd vector<cc2Vect> &positions() const;
  ```

  Returns the positions computed from one or more sample operations.

  Notes

  If this **ccSampleResult** object has not been used in any sampling operations, the returned vector will be empty. If this **ccSampleResult** has been used in multiple sampling operations, the returned vector will contain the concatenation of sampled positions from all of the operations.

- ```
  cmStd vector<cc2Vect> &positions();
  ```

  This overload is for Cognex internal use only.

tangents

```
const cmStd vector<ccRadian> &tangents() const;
cmStd vector<ccRadian> &tangents();
```

- ```
  const cmStd vector<ccRadian> &tangents() const;
  ```

  Returns the tangent directions computed from one or more sample operations.
  ```

Notes

If this **ccSampleResult** object has not been used in any sampling operations, the returned vector will be empty. If this **ccSampleResult** has been used in multiple sampling operations, this vector will contain the concatenation of sampled tangent directions from all of the operations.

- `cmStd vector<ccRadian> &tangents();`

  This overload is for Cognex internal use only.

breaks

```
const cmStd vector<c_Int32> &breaks() const;
cmStd vector<c_Int32> &breaks();
```

- `const cmStd vector<c_Int32> &breaks() const;`

  Returns the break indices computed from one or more sample operations. The break indices impose a structure on the flat vectors returned by **positions()** and **tangents()**. See comments at the beginning of this class for details.

  Notes

  If this **ccSampleResult** object has not been used in any sampling operations, the returned vector will be empty. If this **ccSampleResult** has been used in multiple sampling operations, this vector will contain the concatenation of breakpoints from all of the operations.

- `cmStd vector<c_Int32> &breaks();`

  This overload is for Cognex internal use only.

closedFlags

```
const cmStd vector<bool> &closedFlags() const;
cmStd vector<bool> &closedFlags();
```

- `const cmStd vector<bool> &closedFlags() const;`

  Returns the closed flags computed from one or more sample operations. There is one closed flag for each sample chain indicating whether or not that chain was obtained from a closed contour. See comments at the top of this class for details on chains.

Notes

If this **ccSampleResult** object has not been used in any sampling operations, this vector will be empty. If this **ccSampleResult** has been used in multiple sampling operations, this vector will contain the concatenation of closed flags from all of the operations.

- `cmStd vector<bool> &closedFlags();`

  This overload is for Cognex internal use only.

getPolylines

```
void getPolylines(cmStd vector<ccPolyline> &polylines)
  const;
```

Computes a vector of polylines corresponding to the position samples of this **ccSampleResult**. Each polyline corresponds to one chain of samples.

Parameters

polylines The vector of polylines returned.

positionsReserve

```
void positionsReserve(c_Int32 n);
```

Pre-allocates enough memory to store *n* position samples within this **ccSampleResult** object.

Parameters

n The number of position samples to allocate memory for.

Notes

This class dynamically re-allocates memory as needed. It is never necessary for you to use this method. It is provided strictly as an optimization.

If *n* is less than the current size of the *positions* vector, this method has no effect.

positionsTangentsReserve

```
void positionsTangentsReserve(c_Int32 n);
```

Pre-allocates enough memory to store *n* position samples and *n* tangent direction samples within this **ccSampleResult** object.

Parameters

n The number of position samples and tangent direction samples to allocate memory for.

Notes

This class dynamically re-allocates memory as needed. It is never necessary for you to use this method. It is provided strictly as an optimization.

If *n* is less than the current size of the *positions* vector, this method has no effect.

chainsReserve `void chainsReserve(c_Int32 n);`

Pre-allocates enough memory to store *n* break indices and *n* closed flags within this **ccSampleResult** object.

Parameters

n	The number of break indices and closed flags to allocate memory for.

Notes

This class dynamically re-allocates memory as needed. It is never necessary for you to use this method. It is provided strictly as an optimization.

If *n* is less than the current size of the *positions* vector, this method has no effect.

ccSampleResult

ccSceneAngleFinderIIResult

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderIIResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single Scene Angle Finder-II tool result.

Note You should not instantiate this class directly.

Constructors/Destructors

ccSceneAngleFinderIIResult

```
ccSceneAngleFinderIIResult(double signalToNoise = 0,
  double rawScore = 0, const ccDegree& angle = ccDegree(0));
```

Constructs a **ccSceneAngleFinderIIResult**.

Parameters

signalToNoise	The signal-to-noise value (in dB) of this result.
rawScore	The raw score of this result
angle	The angle of the predominant feature boundary in client coordinates.

Operators

operator==

```
bool operator==(const ccSceneAngleFinderIIResult& rhs)
  const;
```

Two **ccSceneAngleFinderIIResult**s are equal if all their members are equal.

Parameters

rhs	The **ccSceneAngleFinderIIResult** to compare to this one.

Public Member Functions

angle

```
ccDegree angle() const;
```

Returns the detected scene angle in the client coordinate system of the runtime image.

Notes

In unidirectional mode, the angle returned ranges from -90 to 90 degrees. In bidirectional mode, the angle returned ranges from -45 to 45 degrees.

rawScore

```
double rawScore() const;
```

Returns the raw score of this result.

signalToNoise

```
double signalToNoise() const;
```

Returns the signal to noise ratio of this result in dB.

ccSceneAngleFinderIIResultSet

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderIIResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a set of **ccSceneAngleFinderResultII** objects.

Constructors/Destructors

ccSceneAngleFinderIIResultSet

```
ccSceneAngleFinderIIResultSet();
```

Creates a **ccSceneAngleFinderIIResultSet** with no results and with its execution time set to 0.0.

Operators

operator==

```
bool operator== (const ccSceneAngleFinderIIResultSet& rhs)
  const;
```

Two **ccSceneAngleFinderIIResultSet**s are equal if all their members are equal.

Parameters

rhs The **ccSceneAngleFinderIIResultSet** to compare to this one.

Public Member Functions

time

```
double time() const;
```

Returns the time required to produce this result set in seconds.

numFound

```
c_Int32 numFound() const;
```

Returns the number of results in this **ccSceneAngleFinderIIResultSet**.

results

```
const cmStd vector<ccSceneAngleFinderIIResult>&
  results() const;
```

Returns a vector containing all of the individual results. The number of elements in the returned vector is returned by **numFound()**.

Notes

The results are sorted by raw score.

ccSceneAngleFinderIIRunParams

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderIIRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters for the Scene Angle Finder-II tool.

Enumerations

Interpolation `enum Interpolation`

This enumeration defines supported interpolation accuracy levels for the Scene Angle Finder-II tool.

Value	Meaning
eNormal	Performs image interpolation using standard bilinear interpolation.
eHighPrecision	Performs image interpolation using an advanced interpolation method.
kDefaultInterpolation	The default interpolation method, defined in *scnangle.h*.

Constructors/Destructors

ccSceneAngleFinderIIRunParams

```
ccSceneAngleFinderIIRunParams(c_Int32 maxNumResults = 1,
  const ccDegree& startAngle = ccDegree(-90),
  const ccDegree& endAngle = ccDegree(90),
  c_Int32 initialSampling = 4, c_Int32 finalSampling = 1,
  double acceptThreshold = 0.5,
  double lowResThreshold = 50.0,
```

```
bool bidirectional = false,
ccSceneAngleFinderIIRunParams::Interpolation precision =
ccSceneAngleFinderIIRunParams::kDefaultInterpolation);
```

Constructs a **ccSceneAngleFinderIIRunParams** using the supplied parameters.

Parameters

maxNumResults The maximum number of results to compute.

startAngle The start of the angle range to consider.

endAngle The end of the angle range to consider

initialSampling The subsampling value for the preliminary evaluation.

finalSampling The subsampling value for the final measurement.

acceptThreshold
The minimum score for a valid result, expressed as the signal to noise ratio in dB.

lowResThreshold
The minimum raw score threshold. Only preliminary results with raw scores above this value are evaluated further. Raw scores can be in the range 0.0 through the square of the maximum pixel value. In most cases, the default value of 50 is appropriate.

bidirectional If true, all features are assumed to lie at 90° angles to each other and the returned angle is in the range -45° through 45°. If false, then features are assumed to lie at 180° angles to each other and the returned angle is in the range -90° through 90°.

precision The interpolation precision to use. Using the *eHighPrecision* interpolation method produces more accurate results but takes slightly longer. The default is *eNormal*.

precision must be one of the following values:

ccSceneAngleFinderIIRunParams::eNormal
ccSceneAngleFinderIIRunParams::eHighPrecision
ccSceneAngleFinderIIRunParams::kDefault

Operators

operator==

```
bool operator== (const ccSceneAngleFinderIIRunParams& rhs)
 const;
```

Two **ccSceneAngleFinderIIRunParams**s are equal if all their members are equal.

Parameters

rhs The **ccSceneAngleFinderIIRunParams** to compare to this one.

Public Member Functions

maxNumResults

```
c_Int32 maxNumResults() const;
void maxNumResults(c_Int32 maxNum);
```

- `c_Int32 maxNumResults() const;`

  Returns the maximum number of results the tool will compute.

- `void maxNumResults(c_Int32 maxNum);`

  Sets the maximum number of results specified for this **ccSceneAngleFinderIIRunParams**. No more than the specified number of results are computed when the tool is run.

  Parameters

  maxNum The maximum number of results.

  Throws

  ccSceneAngleFinderDefs::BadParams
  maxNum is less than or equal to 0.

bidirectional

```
bool bidirectional() const;
```

Returns true if this **ccSceneAngleFinderIIRunParams** specifies bidirectional mode, false if it specifies unidirectional mode.

In bidirectional mode, angles at θ and θ+ 90° are evaluated together. The maximum angle span is 90°. In unidirectional mode, the maximum angle span is 180°.

startAngle

```
ccDegree startAngle() const;
```

Returns the start of the angle range specified for this **ccSceneAngleFinderIIRunParams**.

endAngle

```
ccDegree endAngle() const;
```

Returns the end of the angle range specified for this **ccSceneAngleFinderIIRunParams**.

ccSceneAngleFinderIIRunParams

angleSpan

```
void angleSpan(const ccDegree& degreeStartAngle,
  const ccDegree& degreeEndAngle, bool bidirectional);
```

Sets the angle span over which to search for the dominant scene angle or angles. The search will be conducted from the start angle to the end angle. Either or both angles can be negative.

Parameters

degreeStartAngle
The start angle in client coordinates.

degreeEndAngle
The end angle in client coordinates

bidirectional If true, this **ccSceneAngleFinderIIRunParams** is set to bidirectional mode. If false, it is set to unidirectional mode.

Notes

In unidirectional mode, all angles are mapped to the range -90° through 90°. In bidirectional mode, all angles are mapped to the range -45 through 45°.

The angles are specified in client coordinates.

Throws

ccSceneAngleFinderDefs::BadParams
startAngle is greater than or equal to *endAngle*; the specified angle range is greater than 90° in bidirectional mode; or the angle range is greater than 180° in unidirectional mode.

initialSampling

```
c_Int32 initialSampling() const;
```

Returns the subsampling rate for the initial phase of the analysis.

finalSampling

```
c_Int32 finalSampling() const;
```

Returns the subsampling rate for the final phase of the analysis.

setSampling

```
void setSampling(c_Int32 initialSampling,
  c_Int32 finalSampling);
```

Sets the subsampling rate for both phases of the analysis.

Parameters

initialSampling The subsampling rate for the initial phase of the analysis.

finalSampling The subsampling rate for the final phase of the analysis.

Throws

ccSceneAngleFinderDefs::BadParams

initialSampling or *finalSampling* is less than or equal to 0 or *initialSampling* is less than *finalSampling*

Notes

If *initialSampling* is equal to *finalSampling*, only the preliminary phase of analysis is performed.

---

acceptThreshold

```
double acceptThreshold() const;
void acceptThreshold(double accept);
```

- `double acceptThreshold() const;`

  Returns the accept threshold for this **ccSceneAngleFinderIIRunParams**.

- `void acceptThreshold(double accept);`

  Sets the accept threshold for this **ccSceneAngleFinderIIRunParams**. Only results with a signal to noise ratio that is greater than the accept threshold are returned by the tool.

  Parameters

  accept The accept threshold.

  Notes

  If you specify an accept threshold less than or equal to 0.0, then the tool returns all the results it finds, up to the maximum number you specify.

lowResThreshold

```
double lowResThreshold() const;
void lowResThreshold(double threshold);
```

- `double lowResThreshold() const;`

  Returns the low-resolution accept threshold.

- `void lowResThreshold(double threshold);`

  Sets the low-resolution accept threshold. Only results with raw scores greater than this threshold will be evaluated during the final phase of analysis.

Parameters

threshold The threshold.

Notes

If the low resolution threshold is less than or equal to 0, it will use any relative maximum raw score as starting points for the search in the final pass.

---

accuracyMode

```
ccSceneAngleFinderIIRunParams::Interpolation
  accuracyMode() const;

void accuracyMode(
  ccSceneAngleFinderIIRunParams::Interpolation precision);
```

- ```
  ccSceneAngleFinderIIRunParams::Interpolation
    accuracyMode() const;
  ```

  Returns the interpolation mode used by this **ccSceneAngleFinderIIRunParams**. The returned value is one of the following:

  ccSceneAngleFinderIIRunParams::eNormal
  ccSceneAngleFinderIIRunParams::eHighPrecision

- ```
  void accuracyMode(
    ccSceneAngleFinderIIRunParams::Interpolation precision);
  ```

  Sets the interpolation mode used by this **ccSceneAngleFinderIIRunParams**.

  Parameters

  precision The interpolation precision to use. Using the *eHighPrecision* interpolation method produces more accurate results but takes slightly longer. The default is *eNormal*.

  precision must be one of the following values:

  ccSceneAngleFinderIIRunParams::eNormal
  ccSceneAngleFinderIIRunParams::eHighPrecision
  ccSceneAngleFinderIIRunParams::kDefault

ccSceneAngleFinderResult

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class contains a single Scene Angle Finder tool result.

Note You should not instantiate this class directly.

Constructors/Destructors

ccSceneAngleFinderResult

```
ccSceneAngleFinderResult(
  double dfilteredPeakMagnitude = 0,
  ccDegree degreeAngle = ccDegree(0));
```

Constructs a **ccSceneAngleFinderResult**.

Parameters

dfilteredPeakMagnitude
The peak magnitude.

degreeAngle The scene angle.

Public Member Functions

angle

```
ccDegree angle() const;
```

Returns the scene angle in the client coordinate system of the run-time image.

filteredPeakMagnitude

```
double filteredPeakMagnitude() const;
```

Returns the magnitude of the peak in the filtered histogram.

ccSceneAngleFinderResult

ccSceneAngleFinderResultSet

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderResultSet;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a set of **ccSceneAngleFinderResult** objects.

Constructors/Destructors

ccSceneAngleFinderResultSet

```
ccSceneAngleFinderResultSet();
```

Creates a **ccSceneAngleFinderResultSet** with no results.

Public Member Functions

time

```
double time() const;
```

Returns the amount time required to produce this result set in seconds.

numFound

```
c_Int32 numFound() const;
```

Returns the number of **ccSceneAngleFinderResult**s in this **ccSceneAngleFinderResultSet**.

histogram

```
const cmStd vector<c_UInt32>& histogram() const;
```

Returns the unfiltered edge angle histogram.

results

```
const cmStd vector<ccSceneAngleFinderResult>& results()
  const;
```

Return all of the results from the Scene Angle Finder tool.

ccSceneAngleFinderResultSet

ccSceneAngleFinderRunParams

```
#include <ch_cvl/scnangle.h>

class ccSceneAngleFinderRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters for the Scene Angle Finder tool.

Constructors/Destructors

ccSceneAngleFinderRunParams

```
ccSceneAngleFinderRunParams(c_Int32 nToFind = 1,
  ccDegree degreeStartAngle = ccDegree(-90),
  ccDegree degreeEndAngle = ccDegree(90),
  c_Int32 numberOfFolds = 2, c_Int32 binFilterWidth = 5,
  c_Int32 nContrastThreshold = -1, c_Int32 nSubsampling = 2,
  c_Int32 nSmoothingOffset = -1);
```

Constructs a **ccSceneAngleFinderRunParams** with the specified parameters.

For more information on the individual parameters, see the individual member functions in this class.

Parameters

nToFind The number of scene angle peaks to find.

degreeStartAngle The start of the angle span in which to search for peaks.

degreeEndAngle The end of the angle span in which to search for peaks.

numberOfFolds The number of folds to apply to the edge angle histogram.

binFilterWidth The width of the kernel used to filter the edge angle histogram.

nContrastThreshold The minimum edge magnitude required for including an edge in the edge angle histogram.

nSubsampling The subsampling value applied to the image before computing the edge angle image.

nSmoothingOffset
The smoothing value to apply to the image before computing the edge angle is equal to *nSubsampling*+*nSmoothingOffset*.

Public Member Functions

maxNumResults

```
c_Int32 maxNumResults() const;
void maxNumResults(c_Int32 nToFind);
```

- `c_Int32 maxNumResults() const;`

  Returns the maximum number of scene angle peaks this **ccSceneAngleFinderRunParams** is configured to find.

- `void maxNumResults(c_Int32 nToFind);`

  Sets the maximum number of scene angle peaks this **ccSceneAngleFinderRunParams** is configured to find.

  Parameters
  nToFind The number of peaks to find.

  Throws
  ccSceneAngleFinderDefs::BadParams
  nToFind is less than 1.

startAngle `ccDegree startAngle() const;`

Returns the start angle of the angle span.

endAngle `ccDegree endAngle() const;`

Returns the end angle of the angle span.

angleSpan

```
void angleSpan(const ccDegree& degreeStartAngle,
  const ccDegree& degreeEndAngle);
```

Sets the angle span over which to search for the dominant scene angles. The search will be conducted from the start angle to the end angle. Either or both angle can be negative, however a positive angle increment will be used with wrapping from 360 to zero.

The size of the angle span must be less than or equal to the number of degrees per fold. You can call **angleSpanAndNumberOfFolds()** to change the degrees per fold at the same time as the angle span.

Parameters

degreeStartAngle
The start angle of the angle span, expressed as the angle from the client coordinate x-axis to the positive gradient direction of the feature.

degreeEndAngle The end angle of the angle span, expressed as the angle from the client coordinate x-axis to the positive gradient direction of the feature.

Notes

The default start angle is -90; end angle is 90

If either *degreeStartAngle* or *degreeEndAngle* is greater than 180°, then the returned scene angle is mapped to the range 0° to 360°. If both *degreeStartAngle* and *degreeEndAngle* are less than or equal to 180°, then the returned scene angle is mapped to the range -180° to +180°.

Throws

ccSceneAngleFinderDefs::BadParams
The angle span is greater than the number of degrees per fold, or the difference between *degreeStartAngle* and *degreeEndAngle* is greater than 360°.

numberOfFolds

```
c_Int32 numberOfFolds() const;
```

Returns the number of folds configured for this **ccSceneAngleFinderRunParams**.

angleSpanAndNumberOfFolds

```
void angleSpanAndNumberOfFolds(
  const ccDegree& degreeStartAngle,
  const ccDegree& degreeEndAngle,
  c_Int32 numberOfFolds);
```

Sets the number of folds and the angle span. The number of folds controls how many times the raw edge angle histogram is folded upon itself to produce the edge angle histogram used to score scene angles.

You should set the fold value to match the number of reinforcing edges in a scene. For example, if the image contains rectilinear features then you should set the fold value to 4.

The angle span must be less than or equal to the number of degrees per fold. The number of degrees per fold is computed by dividing 360° by the fold value.

Parameters

degreeStartAngle
The start of the angle span in which to search for peaks.

degreeEndAngle The end of the angle span in which to search for peaks.

numberOfFolds The number of folds to apply to the edge angle histogram.

Notes

If the polarity of the edges in the image can vary, set the fold value to be greater than or equal to 2. This ensures that edge polarity is not considered.

Throws

ccSceneAngleFinderDefs::BadParams
The angle span is greater than the number of degrees per fold, or *numberOfFolds* is not 2, 4, 8, 16, or 32.

filterWidth

```
c_Int32 filterWidth() const;

void filterWidth(c_Int32 binFilterWidth);
```

- `c_Int32 filterWidth() const;`

  Returns the width of the one-dimensional filter applied to the folded edge angle histogram.

- `void filterWidth(c_Int32 binFilterWidth);`

  Sets the width of the one-dimensional filter applied to the folded edge angle histogram. The specified width must be odd. If an even width is supplied, it is incremented by 1.

  Increasing the filter width increases the smoothing of the peaks in the edge angle histogram. This can improve accuracy when many closely grouped angle peaks are present. Increasing the filter width too much can blur distinct peaks into one peak. The default filter width is 5.

  Parameters

  binFilterWidth The filter width, in histogram pixels.

  Throws

  ccSceneAngleFinderDefs::BadParams
  binFilterWidth is less than 1.

contrastThreshold

```
c_Int32 contrastThreshold() const;

void contrastThreshold(c_Int32 nContrastThreshold);
```

- `c_Int32 contrastThreshold() const;`

  Returns the minimum contrast required before an edge is added to the edge angle histogram.

- `void contrastThreshold(c_Int32 nContrastThreshold);`

  Sets the minimum contrast required before an edge is added to the edge angle histogram. Set the threshold to be 1 or 2 more than number of grey levels of contrast in the direction of the gradient in the edges of interest.

  For horizontal and vertical edges the magnitude will be the grey level difference. For edges which are not horizontal or vertical the magnitude is slightly greater than the number of grey level difference.

  Specify -1 for the contrast threshold to use the Edge tool's default threshold.

  Parameters

  nContrastThreshold
  The contrast threshold.

  Throws

  ccSceneAngleFinderDefs::BadParams
  nContrastThreshold is less than -1.

subsampling

```
c_Int32 subsampling() const;
```

Returns the subsampling value applied to the input image before the edge angle image is computed.

smoothingOffset

```
c_Int32 smoothingOffset() const;
```

Returns the smoothing offset applied to the input image before the edge angle image is computed. The input image is smoothed using a smoothing value equal to the subsampling value plus the smoothing offset before the edge angle image is computed.

subsamplingAndSmoothing

```
void subsamplingAndSmoothing(c_Int32 nSubsampling,
  c_Int32 nSmoothingOffset = -1);
```

Sets the subsampling and smoothing values applied to the input image before the edge angle image is computed. The image is subsampled by the subsampling value, then smoothed using a smoothing value equal to the subsampling value plus the smoothing offset before the edge angle image is computed.

Parameters

nSubsampling The subsampling value applied to the image before computing the edge angle image.

nSmoothingOffset
The smoothing value to apply to the image before computing the edge angle is equal to *nSubsampling*+*nSmoothingOffset*.

Notes

The default subsampling value is 2; the default smoothing offset is -1.

Throws

ccSceneAngleFinderDefs::BadParams
nSubsampling is less than 1 or greater than 25, or *nSubsampling*+*nSmoothingOffset* is less than 0 or greater than 24.

ccScoreContrast

```
#include <ch_cvl/clpscore.h>

class ccScoreContrast: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the contrast of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the difference in normalized pixel values across the edge.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreOneSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Constructors/Destructors

ccScoreContrast

```
ccScoreContrast (double x0 = 255.0, double x1 = 0.0,
  double xc = 0.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScoreContrast** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreContrast** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreContrast**.
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScoreContrast** and for the supplied **ccScoreContrast**.

Parameters

that The **ccScoreContrast** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScoreOneSided

```
#include <ch_cvl/clpscore.h>

class ccScoreOneSided : public ccCaliperScore;
```

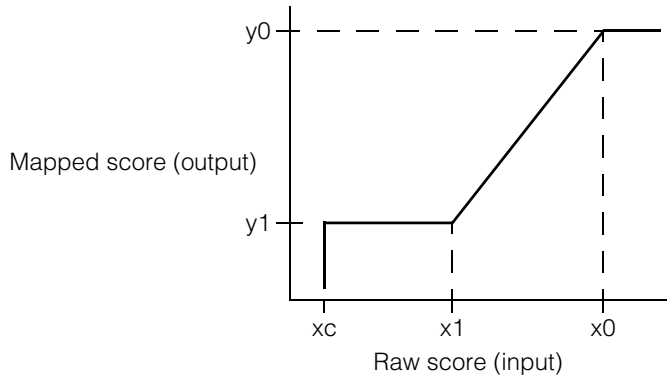
Class Properties

Copyable	Yes
Derivable	By Cognex-supplied classes only
Archiveable	Complex

A class from which concrete classes such as **ccScoreContrast** and **ccScorePosition** are derived.

You use the public member functions in this class to change the points that define a scoring function used by one of the concrete classes.

A one-sided scoring function maps a raw input score to a mapped output score using a function defined by the points shown in the following figure:



Constructors/Destructors

ccScoreOneSided

```
ccScoreOneSided (double x0 = 0.0, double x1 = 1.0,
  double xc = 1.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScoreOneSided** using the supplied values to construct the scoring function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
 const;
```

Tests this **ccScoreOneSided** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreOneSided**
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScoreOneSided** and for the supplied **ccScoreOneSided**

Parameters

that	The **ccScoreOneSided** to compare to this one.

Public Member Functions

x0

```
double x0 () const;

void x0 (double x0);
```

- `double x0 () const;`

  Returns the *x0* value.

- `void x0 (double x0);`

  Sets the *x0* value.

  Parameters

x0	The value to set.

x1

```
double x1 () const;
void x1 (double x1);
```

- `double x1 () const;`

  Returns the *x1* value.

- `void x1 (double x1);`

  Sets the *x1* value.

  Parameters

x1	The value to set *x1* must be between *x0* and *xc*.

xc

```
double xc () const;
void xc (double xc);
```

- `double xc () const;`

  Returns the *xc* value.

- `void xc (double xc);`

  Sets the *xc* value.

  Parameters

xc	The value to set.

y0

```
double y0 () const;
void y0 (double y0);
```

- `double y0 () const;`

  Returns the *y0* value.

- `void y0 (double y0);`

  Sets the *y0* value.

Parameters

y0 The value to set. *y0* must be greater than or equal to *y1* and must be between 0.0 and 1.0.

Throws

ccCaliperDefs::BadParams
y0 is outside the range 0.0 to 1.0.

---

y1

```
double y1 () const;
void y1 (double y1);
```

- `double y1 () const;`

  Returns the *y1* value.

- `void y1 (double y1);`

  Sets the *y1* value.

  Parameters

  y1 The value to set. *y1* must be less than or equal to *y0* and must be between 0.0 and 1.0.

  Throws

  ccCaliperDefs::BadParams
  y1 is outside the range 0.0 to 1.0.

ccScorePosition

```
#include <ch_cvl/clpscore.h>

class ccScorePosition: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the position of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the absolute value of the position at which this edge was found.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreOneSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Constructors/Destructors

ccScorePosition

```
ccScorePosition (double x0 = 0.0, double x1 = 100.0,
  double xc = 10000.0, double y0 = 1.0, double y1 = 0.1);
```

Constructs a **ccScorePosition** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScorePosition** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScorePosition**.
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScorePosition** and for the supplied **ccScorePosition**.

Parameters

that	The **ccScorePosition** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges	The number of edges.

ccScorePositionNeg

```
#include <ch_cvl/clpscore.h>

class ccScorePositionNeg: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the position of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the position at which this edge was found.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreOneSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Constructors/Destructors

ccScorePositionNeg

```
ccScorePositionNeg (double x0 = -100.0, double x1 = 100.0,
  double xc = 10000.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScorePositionNeg** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScorePositionNeg** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScorePositionNeg**.
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScorePositionNeg** and for the supplied **ccScorePositionNeg**.

Parameters

that The **ccScorePositionNeg** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScorePositionNorm

```
#include <ch_cvl/clpscore.h>

class ccScorePositionNorm: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the normalized position of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the absolute value of the position at which this edge pair was found, divided by the nominal size of the edge pair.

Unlike **ccScorePosition**, this class normalizes the edge position by dividing it by the width of the edge model.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score models with two edges.

Constructors/Destructors

ccScorePositionNorm

```
ccScorePositionNorm (double x0 = 0.0, double x1 = 5.0,
  double xc = 5.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScorePositionNorm** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.

y1 The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScorePositionNorm** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScorePositionNorm**.
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScorePositionNorm** and for the supplied **ccScorePositionNorm**.

Parameters

that The **ccScorePositionNorm** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScorePositionNormNeg

```
#include <ch_cvl/clpscore.h>

class ccScorePositionNormNeg: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the normalized position of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the position at which this edge pair was found, divided by the nominal size of the edge pair.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score models with two edges.

Constructors/Destructors

ccScorePositionNormNeg

```
ccScorePositionNormNeg (double x0 = -5.0, double x1 = 5.0,
  double xc = 5.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScorePositionNormNeg** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScorePositionNormNeg** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScorePositionNormNeg**.
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScorePositionNormNeg** and for the supplied **ccScorePositionNormNeg**.

Parameters

that The **ccScorePositionNormNeg** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScoreSizeDiffNorm

```
#include <ch_cvl/clpscore.h>

class ccScoreSizeDiffNorm: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the normalized difference between the size of an edge candidate and the size of the edge model to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the absolute difference between the nominal size of the edge pair and the found size of the edge pair, divided by the nominal size of the edge pair.

Unlike **ccScoreSizeDiff**, the difference between the expected size and the actual size is normalized by dividing it by the expected size.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreOneSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score edge models with two edges.

Constructors/Destructors

ccScoreSizeDiffNorm

```
ccScoreSizeDiffNorm (double x0 = 0.0, double x1 = 1.0,
  double xc = 1.0, double y0 = 1.0, double y1 = 0.0);
```

Constructs a **ccScoreSizeDiffNorm** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.

xc	The value for the *xc* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreSizeDiffNorm** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreSizeDiffNorm**
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScoreSizeDiffNorm** and for the supplied **ccScoreSizeDiffNorm**

Parameters

that	The **ccScoreSizeDiffNorm** to compare to this one.

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges	The number of edges.

ccScoreSizeDiffNorm

ccScoreSizeDiffNormAsym

```
#include <ch_cvl/clpscore.h>

class ccScoreSizeDiffNormAsym: public ccScoreTwoSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreTwoSided** that lets you define a single scoring method that maps the normalized difference between the size of an edge candidate and the size of the edge model to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the difference between the nominal size of the edge pair and the found size of the edge pair, divided by the nominal size of the edge pair.

Like **ccScoreSizeDiffNorm**, the difference between the expected size and the actual size is normalized by dividing it by the expected size. The raw score produced by this class can be negative.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreTwoSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score edge models with two edges.

Constructors/Destructors

ccScoreSizeDiffNormAsym

```
ccScoreSizeDiffNormAsym (double x0 = 0.0, double x1 =-1.0,
  double xc =-1.0, double x0h = 0.0, double x1h = 2.0,
  double xch = 2.0, double y0 = 1.0, double y1 = 0.0,
  double y0h = 1.0, double y1h = 0.0);
```

Constructs a **ccScoreSizeDiffNormAsym** using the supplied points to define the mapping function.

Parameters

x0 The value for the *x0* point.

x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point
x0h	The value for the *x0h* point
x1h	The value for the *x1h* point. *x1h* must be between *x0h* and *xch*.
xch	The value for the *xch* point
y0	The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.
y1	The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.
y0h	The value for the *y0h* point. *y0h* must be greater than or equal to *y1h* and between 0.0 and 1.0.
y1h	The value for the *y1h* point. *y1h* must be less than or equal to *y0h* and between 0.0 and 1.0.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreSizeDiffNormAsym** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreSizeDiffNormAsym**.
- The values of *x0*, *x1*, *xc*, *x0h*, *x1h*, *xch*, *y0*, *y1*, *y0h*, and *y1h* are the same for this **ccScoreSizeDiffNormAsym** and for the supplied **ccScoreSizeDiffNormAsym**.

Parameters

that	The **ccScoreSizeDiffNormAsym** to compare to this one

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScoreSizeDiffNormAsym

ccScoreSizeNorm

```
#include <ch_cvl/clpscore.h>

class ccScoreSizeNorm: public ccScoreOneSided;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived from **ccScoreOneSided** that lets you define a single scoring method that maps the normalized size of an edge candidate to a mapped score according to a scoring function that you define.

The raw input score for this scoring method is the found size of the edge pair divided by the nominal size of the edge pair.

Like **ccScoreSizeDiffNorm**, the expected size is normalized by dividing it by the expected size.

To define the break points for the function, specify values in the constructor. To modify the set points, use the member functions in **ccScoreOneSided**.

To use this class, create an instance of it, then pass a pointer to it in a vector of pointers to concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score edge models with two edges.

Constructors/Destructors

ccScoreSizeNorm

```
ccScoreSizeNorm (double x0 = 5.0, double x1 = 0.0,
  double xc = 0.0, double y0 = 1.0, double y1 = 0.0) ();
```

Constructs a **ccScoreSizeNorm** using the supplied points to define the mapping function.

Parameters

x0	The value for the *x0* point.
x1	The value for the *x1* point. *x1* must be between *x0* and *xc*.
xc	The value for the *xc* point

y0 — The value for the *y0* point. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.

y1 — The value for the *y1* point. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

Notes

To *change* the value of any point in the scoring function, use the public member functions of the **ccScoreOneSided** class from which this class is derived.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreSizeNorm** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreSizeNorm**
- The values of *x0*, *x1*, *xc*, *y0*, and *y1* are the same for this **ccScoreSizeNorm** and for the supplied **ccScoreSizeNorm**

Parameters

that — The **ccScoreSizeNorm** to compare to this one.

Public Member Functions

score

For Cognex internal use only. Do not call this function.

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges	The number of edges.

ccScoreSizeNorm

ccScoreStraddle

```
#include <ch_cvl/clpscore.h>

class ccScoreStraddle: public ccCaliperScore;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A concrete class derived directly from **ccCaliperScore** that lets you score an edge pair candidate based on whether or not the two edges straddle the center point of the caliper window (or another, user-supplied origin). If the edges straddle the center point, the score is 1.0. If they do not, the score is 0.0.

To use this class, create an instance of it, then pass it in a vector of instances of concrete classes to **ccCaliperRunParams::scoringMethods()**.

Note This class can only be used to score edge models with two edges.

Constructors/Destructors

ccScoreStraddle

```
ccScoreStraddle();
```

Constructs a **ccScoreStraddle**.

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreStraddle** for equality with the supplied object. The function returns true if the supplied object is of type **ccScoreStraddle**.

Parameters

that The **ccScoreStraddle** to compare to this one

Public Member Functions

score For Cognex internal use only. Do not call this function.

ccScoreStraddle

clone

```
virtual ccCaliperScore* clone () const;
```

Allocates and returns a pointer to a duplicate of this object. This supports polymorphic copying.

willScore

```
virtual bool willScore (c_Int16 numEdges) const;
```

Return true if this scoring function can score candidates which contain the given number of edges.

Parameters

numEdges The number of edges.

ccScoreTwoSided

```
#include <ch_cvl/clpscore.h>

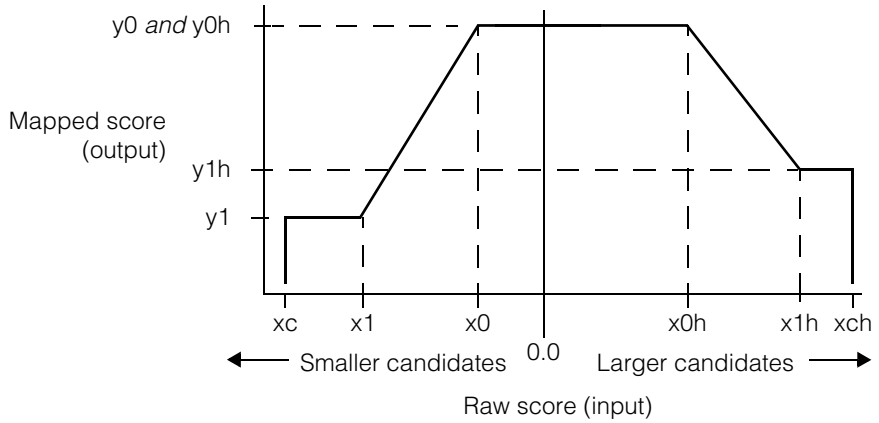
class ccScoreTwoSided: public ccCaliperScore;
```

Class Properties

Copyable	Yes
Derivable	By Cognex-supplied classes only
Archiveable	Complex

A base class that provides common implementations for all scoring methods using two-sided scoring functions.

A two-sided scoring function maps a raw input score to a mapped output score using a function defined by the points shown in the following figure:



Constructors/Destructors

ccScoreTwoSided

```
ccScoreTwoSided (double x0 = 0.0, double x1 = -1.0,
  double xc = -1.0, double x0h = 0.0, double x1h = 1.0,
  double xch = 1.0, double y0 = 1.0, double y1 = 0.0,
  double y0h = 1.0, double y1h = 0.0);
```

Constructs a **ccScoreTwoSided** using the supplied values to construct the scoring function.

Parameters

x0	The value for the *x0* point
x1	The value for the *x1* point
xc	The value for the *xc* point
x0h	The value for the *x0h* point
x1h	The value for the *x1h* point
xch	The value for the *xch* point
y0	The value for the *y0* point
y1	The value for the *y1* point
y0h	The value for the *y0h* point
y1h	The value for the *y1h* point

Operators

operator==

```
virtual bool operator== (const ccCaliperScore &that)
  const;
```

Tests this **ccScoreTwoSided** for equality with the supplied object. The function returns true if both of the following are true:

- The supplied object is of type **ccScoreTwoSided**.
- The values of *x0*, *x1*, *xc*, *x0h*, *x1h*, *xch*, *y0*, *y1*, *y0h*, and *y1h* are the same for this **ccScoreTwoSided** and for the supplied **ccScoreTwoSided**.

Parameters

that	The **ccScoreTwoSided** to compare to this one

Public Member Functions

x0

```
double x0 () const;
void x0 (double x0);
```

- `double x0 () const;`

  Returns the *x0* value.

- `void x0 (double x0);`

  Sets the *x0* value.

  Parameters

x0	The value to set. *x0* should be less than *x0h*, *x1h*, and *xch*.

x1

```
double x1 () const;
void x1 (double x1);
```

- `double x1 () const;`

  Returns the *x1* value.

- `void x1 (double x1);`

  Sets the *x1* value.

  Parameters

x1	The value to set. *x1* should be between *xc* and *x0* and less than *x0h*, *x1h*, and *xch*.

xc

```
double xc () const;
void xc (double xc);
```

- `double xc () const;`

  Returns the *xc* value.

- `void xc (double xc);`

  Sets the *xc* value.

Parameters

xc The value to set. *xc* should be less than *x0h*, *x1h*, and *xch*.

x0h

```
double x0h () const;
void x0h (double x0h);
```

- `double x0h () const;`

  Returns the *x0h* value.

- `void x0h (double x0h);`

  Sets the *x0h* value.

  Parameters

  x0h The value to set. *x0h* should be greater than *xc*, *x1*, and *x0*.

x1h

```
double x1h () const;
void x1h (double x1h);
```

- `double x1h () const;`

  Returns the *x1h* value.

- `void x1h (double x1h);`

  Sets the *x1h* value.

  Parameters

  x1h The value to set. *x1h* should be between *x0h* and *xch* and be greater than *xc*, *x1*, and *x0*.

xch

```
double xch () const;
void xch (double xch);
```

- `double xch () const;`

  Returns the *xch* value.

- `void xch (double xch);`

  Sets the *xch* value.

  Parameters

  xch The value to set. *xch* should be greater than *xc*, *x1*, and *x0*.

y0

```
double y0 () const;
void y0 (double y0);
```

- `double y0 () const;`

  Returns the *y0* value.

- `void y0 (double y0);`

  Sets the *y0* value.

  Parameters

  y0 The value to set. *y0* must be greater than or equal to *y1* and between 0.0 and 1.0.

  Throws

  ccCaliperDefs::BadParams
  y0 is outside the range 0.0 to 1.0.

y1

```
double y1 () const;
void y1 (double y1);
```

- `double y1 () const;`

  Returns the *y1* value.

- `void y1 (double y1);`

  Sets the *y1* value.

  Parameters

  y1 — The value to set. *y1* must be less than or equal to *y0* and between 0.0 and 1.0.

  Throws

  ccCaliperDefs::BadParams — *y1* is outside the range 0.0 to 1.0.

y0h

```
double y0h () const;
void y0h (double y0h);
```

- `double y0h () const;`

  Returns the *y0h* value.

- `void y0h (double y0h);`

  Sets the *y0h* value.

  Parameters

  y0h — The value to set. *y0h* must be greater than or equal to *y1h* and between 0.0 and 1.0.

  Throws

  ccCaliperDefs::BadParams — *y0h* is outside the range 0.0 to 1.0.

y1h

```
double y1h () const;
void y1h (double y1h);
```

- `double y1h () const;`

  Returns the *y1h* value.

- `void y1h (double y1h);`

  Parameters

  y1h — The value to set. *y1h* must be less than or equal to *y0h* and between 0.0 and 1.0.

  Throws

  ccCaliperDefs::BadParams — *y1h* is outside the range 0.0 to 1.0.

ccScoreTwoSided

ccSecurityInfo

```
#include <ch_cvl/secinfo.h>

class ccSecurityInfo;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

This class allows you to retrieve security information for a user-specified source within a Cognex vision system.

Constructors/Destructors

ccSecurityInfo

```
ccSecurityInfo(eInfoSource src = kSystem);

ccSecurityInfo(const ccBoard& board);

ccSecurityInfo(const ccSecurityInfo&);
```

- `ccSecurityInfo(eInfoSource src = kSystem);`

  Constructs a security information object that reports information on the selected source.

  Parameters

  src — The source for security information. The default value, *kSystem*, reports the complete set of licenses available to the application.

- `ccSecurityInfo(const ccBoard& board);`

  Constructs a security information object that reports information about the given board.

  Parameters

  board — The specific board for which licensing information is being reported.

- `ccSecurityInfo(const ccSecurityInfo& secInfo);`

  Copy constructor. Creates a security information object that is a copy of the given **ccSecurityInfo** object.

Parameters

secInfo The security information object to be copied.

~ccSecurityInfo

```
~ccSecurityInfo();
```

Destructor. Destroys this security information object.

Enumerations

eInfoSource

```
enum eInfoSource;
```

Values indicating the source for security information.

Value	Meaning
kSystem	Reports the set of licenses comprising the union of all licenses available on all detected Cognex hardware.
kReserved1	For Cognex internal use only.

Operators

operator=

```
ccSecurityInfo& operator=(const ccSecurityInfo& secInfo);
```

Assignment operator. Assigns the given security information object to this one.

Parameters

secInfo The security information object to assign to this one.

Public Member Functions

licenses

```
cmStd vector<ccCvlString> licenses(
  const ccCvlString& database = cmT("cogtool.dat")) const;
```

Returns a vector of the licenses available on either a specific board or all boards, depending on how this security information object was constructed.

Parameters

database The name of the file in which the set of available licenses is returned. This must be a *cogtool.dat* database file. It can be specified as either a fully qualified file name (such as "*C:\myrelease\cogtool.dat*"), or simply a file name located on the system path.

Throws

ccSecurityInfo::DatabaseError

The given database file cannot be found or read.

isTimeLimited `bool isTimeLimited() const;`

Returns true if the board used to construct this object is a time-limited security device, false otherwise.

Notes

Always returns false if this security information object is constructed with an argument of *kSystem*, or is default constructed.

isSoftwareLicense

`bool isSoftwareLicense() const;`

Returns true if the board used to construct this object represents a software license. Otherwise, returns false.

Notes

Always returns false if this object was constructed with *kSystem*

isActive `bool isActive() const;`

Returns true if the time-limited security device is currently active.

Throws

ccSecurityInfo::NotTimeLimited

The board used to construct this object is not a time-limited security device (**isTimeLimited()** is false).

Notes

This method applies only to security information objects constructed with a time-limited security device (those for which **isTimeLimited()** is true).

isExpired `bool isExpired() const;`

Returns true if the time-limited security device is expired.

Throws

ccSecurityInfo::NotTimeLimited

The board used to construct this object is not a time-limited security device (**isTimeLimited()** is false).

Notes

This method applies only to security information objects constructed with a time-limited security device (those for which **isTimeLimited()** is true).

daysRemaining `double daysRemaining() const;`

Returns the number of days remaining, full and fractional, before the time-limited security device expires.

Throws

ccSecurityInfo::NotTimeLimited

The board used to construct this object is not a time-limited security device (**isTimeLimited()** is false).

Notes

This method applies only to security information objects constructed with a time-limited security device (those for which **isTimeLimited()** is true).

ccSemaphore

```
#include <ch_cvl/threads.h>

class ccSemaphore: public cc_Resource;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A semaphore is a resource with a non-negative count. A thread can lock a semaphore as long as its count remains greater than 0. Each lock of a semaphore decrements the semaphore's count.

Constructors/Destructors

ccSemaphore

```
ccSemaphore(c_Int32 initialCount = 0,
  c_Int32 maximumCount = 1);
```

Constructs a **ccSemaphore** with specified initial and maximum counts

Parameters

initialCount The initial count for this **ccSemaphore**. An *initialCount* of 0 corresponds to a fully locked state; **unlock()** must be called before this **ccSemaphore** can be locked.

maximumCount The maximum number of times that this **ccSemaphore** can be locked.

Notes

initialCount must be greater than or equal to 0 and less than or equal to *maximumCount*. *maximumCount* must be greater than or equal to 1.

Public Member Functions

lock

```
bool lock(double timeout=HUGE_VAL);
```

Decrements the count of this **ccSemaphore**. If this function was able to decrement the count, it returns true. If the count is already at 0 and remained so for the duration of the specified timeout, this function returns false.

Parameters

timeout The number of seconds to block. If you specify *HUGE_VAL* for *timeout*, the thread will wait forever or until the semaphore becomes availab.e.

Throws

cc_Resource::BrokenLock
The **cc_Resource::breakLocks()** static function was invoked on this thread.

unlock `void unlock();`

Increments the count of this **ccSemaphore**. If the count is already at its maximum value, this function has no effect.

ccSensor

```
#include <ch_cvl/sensor.h>

class ccSensor;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This abstract class is used by other classes to provide functions that get information from temperature sensors.

Constructors/Destructors

This is an abstract class. Only derived classes can creates instances of this class.

Public Member Functions

temperatureSensorCpu

```
virtual ccTemperatureSensor temperatureSensorCpu() = 0;
```

In derived classes, returns a temperature sensor object that corresponds to the temperature sensor under the CPU.

temperatureSensorCvm

```
virtual ccTemperatureSensor temperatureSensorCvm() = 0;
```

In derived classes, returns a temperature sensor object that corresponds to the temperature sensor under the Cognex Video Module (CVM).

ccSensor

ccShape

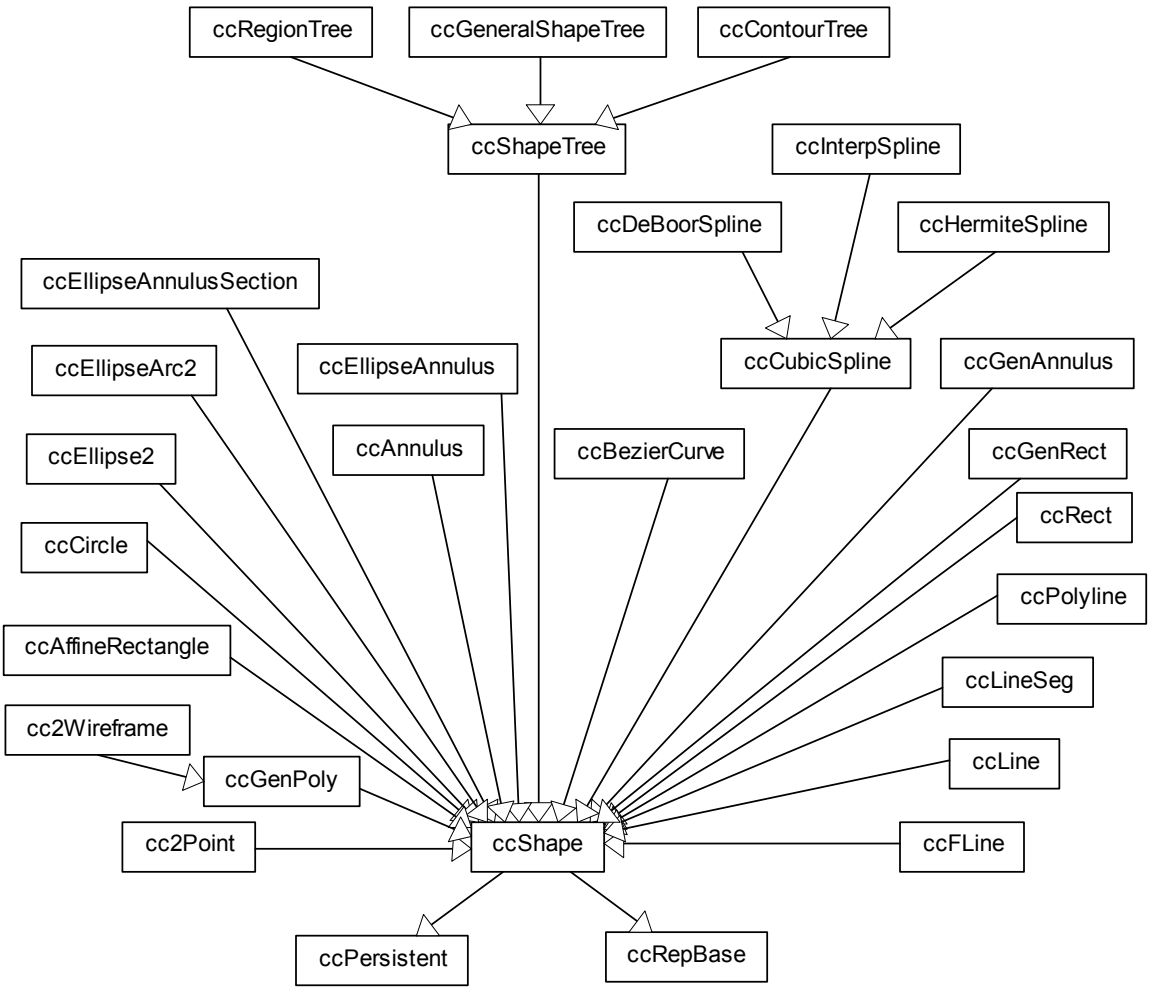
```
#include <ch_cvl/shapbase.h>

class ccShape : public virtual ccPersistent,
  public virtual ccRepBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccShape** class is the abstract base class from which most CVL shapes are derived. Exceptions are some simple shapes (such as **ccPoint, ccPointSet, ccCross**, and **ccCoordAxes**) and some deprecated shapes (such as **ccPolygon**).



The above figure shows the **ccShape** class inheritance hierarchy.

Constructors/Destructors

Notes

As **ccShape** is an abstract base class, your application will not instantiate it directly.

~ccShape `virtual ~ccShape();`

Destructor. Deletes this shape.

Enumerations

ClipResult `enum ClipResult;`

This enumeration is used to classify a clipping operation into one of four categories: inside, outside, enclose, or partial.

Value	Meaning
eInside	The shape to clip lies completely inside the clipping region.
eOutside	The shape to clip lies completely outside the clipping region.
eEnclose	The shape to clip lies outside the clipping region and encloses (surrounds) it. An enclose status can only occur when the shape is a closed curve. For example, a circle may completely enclose a rectangular clipping region. In this case, the result of the clipping operation is an empty shape, just as it would be if the shape were completely outside the clipping region but not surrounding it.
ePartial	The shape to clip lies partially inside and partially outside the clipping region.

Public Member Functions

clone `virtual ccShapePtrh clone() const = 0;`

Returns a pointer to a copy of this shape.

isOpenContour `virtual bool isOpenContour() const = 0;`

Returns true if and only if this shape is an open contour. A shape is an open contour if and only if it is a continuous curve with distinguishable start and end points, which may coincide, through which it can be connected to other open contours.

Notes

Most shapes are either always open (for example, **ccLineSegment**) or always closed (for example, **ccCircle** and **ccRect**). For shapes that can be open or closed, the open/closed status is usually independent of the actual geometry. For example, see the comments under the **ccPolyline** constructor.

isRegion

```
virtual bool isRegion() const = 0;
```

Returns true if and only if this shape is a region. A shape is a region if and only if it divides the plane into well-defined inside and outside regions. The inside must be finite. Empty shapes are not regions. A region shape may contain multiple contours (for example, **ccAnnulus**).

isFinite

```
virtual bool isFinite() const = 0;
```

Returns true if and only if this shape has finite extent. Empty shapes are considered to have finite extent. A **ccShape** has finite extent if it lies within a bounding box.

isEmpty

```
virtual bool isEmpty() const = 0;
```

Returns true if and only if the set of points that lie on the boundary of this shape is empty. For example, a **ccPolyline** with zero vertices is empty.

hasTangent

```
virtual bool hasTangent() const = 0;
```

Returns true if and only if the set of points that lie on the boundary of this shape is infinite, and there is a well-defined tangent at all but a finite number of these points, including the start point and end point, if any.

Notes

This function returns true for most shapes. Examples of exceptions are **cc2Points**, **ccLineSeg** objects of zero length, and empty shapes.

isDecomposed

```
virtual bool isDecomposed() const = 0;
```

Returns true if this shape is already decomposed. That is, if invoking **decompose()** on this shape would produce one that is identical in structure to the original. See **decompose()** for details.

isReversible

```
virtual bool isReversible() const = 0;
```

Returns true if and only if this shape can be reversed. See **reverse()** for details.

boundingBox `virtual ccRect boundingBox() const = 0;`

Returns the smallest rectangle that encloses this shape.

Throws

ccShapesError::InfiniteExtent
isFinite() returns false.

ccShapesError::EmptyShape
isEmpty() returns true.

Notes

This function succeeds the deprecated **encloseRect()**, defined for most shapes. The main differences are the throws and the fact that it is virtual.

nearestPoint `virtual cc2Vect nearestPoint(const cc2Vect &p) const = 0;`

Returns the nearest point on the boundary of this shape to the given point. If the nearest point is not unique, one of the nearest points is returned.

Parameters

p The point.

Notes

The returned result is exact unless otherwise noted.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

distanceToPoint `inline double distanceToPoint(const cc2Vect& p) const;`

Returns the minimum distance from this shape to the given point, computed as the distance between the point *p* and **nearestPoint(p)**.

Parameters

p The point.

Notes

The returned result is exact unless otherwise noted.

This function succeeds the deprecated **distToPoint()**, defined for most shapes. The main differences are the throws and the fact that this function is defined in terms of the virtual function **nearestPoint()**.

Throws

ccShapesError::EmptyShape
isEmpty() returns true.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this shape. This value is exact unless otherwise noted.

The perimeter is returned in the same units as those used for the shape itself. If the shape is defined in image coordinates, the units are pixels. If the shape is defined in client coordinates, the units are those used for the client coordinates.

Notes

If **hasTangent()** is false, this method returns zero, even if this shape is empty.

The base class implementation of this method may not be the most efficient for derived shapes.

Throws

ccShapesError::InfiniteExtent
isFinite() is false for this shape.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this shape to the given point, as determined by **nearestPoint()**.

Parameters

info Shape information for this shape. Must be valid for this particular shape. See **ccShapeInfo** for details.

point The point.

Throws

ccShapesError::EmptyShape
isEmpty() is true for this shape.

ccShapesError::BadParams
info is detectably invalid for this shape.

perimPoint

```
cc2Vect perimPoint(const ccShapeInfo& info,
  const ccPerimPos& pos) const;
```

Returns the point along the perimeter of this shape that the given perimeter position describes.

Parameters

info Shape information for this shape. Must be valid for this particular shape. See **ccShapeInfo** for details.

pos The perimeter position. Must represent a valid perimeter position for this shape.

Throws

ccShapesError::BadParams
Either *info* or *pos* is detectably invalid for this shape. This includes the case where this shape is empty, as an empty shape cannot have any valid perimeter positions.

perimPointAndTangent

```
void perimPointAndTangent(const ccShapeInfo& info,
  const ccPerimPos& pos, cc2Vect& point, ccRadian& angle)
  const;
```

Returns the point along the perimeter of this shape defined by the given perimeter position, and computes the tangent angle at that point.

Parameters

info Shape information for this shape. Must be valid for this particular shape. See **ccShapeInfo** for details.

pos The perimeter position.

point Return parameter for the point described by the perimeter position *pos*.

angle Return parameter for the tangent angle at *point*.

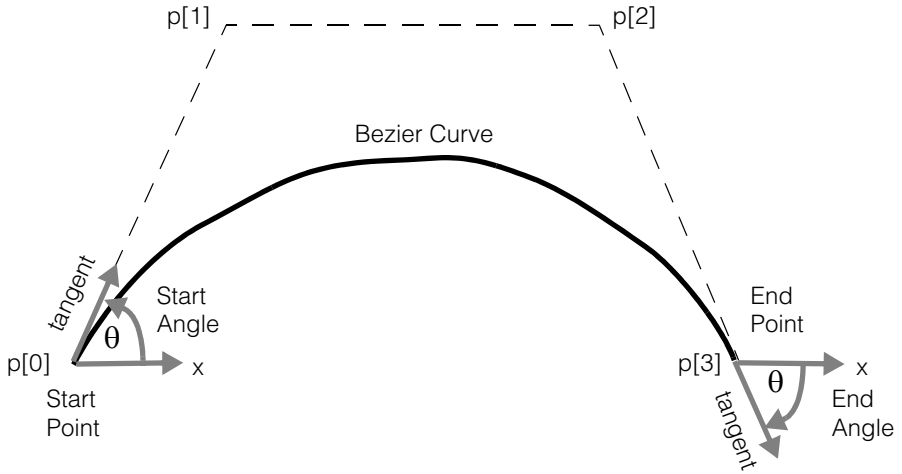
Throws

ccShapesError::BadParams
Either *info* or *pos* is detectably invalid for this shape. This includes the case where this shape is empty, as an empty shape cannot have any valid perimeter positions.

ccShapesError:NoTangent
There is no tangent at the calculated point along the perimeter of this shape.

startPoint `virtual cc2Vect startPoint() const;`

Returns the starting point of this open contour shape. For example, let p[0], p[1], p[2], and p[3] be the four control points of a Bezier curve. The starting point of the Bezier curve in the following figure is the point p[0].



Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

Notes

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

endPoint `virtual cc2Vect endPoint() const;`

Returns the ending point of this open contour shape. The ending point of the Bezier curve in the figure above is the point p[3].

Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

Notes

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

startAngle `virtual ccRadian startAngle() const;`

Returns the starting tangent direction of this open contour shape. The figure on the previous page shows an example of the starting angle for a Bezier curve.

Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this shape.

Notes

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

endAngle `virtual ccRadian endAngle() const;`

Returns the ending tangent direction of this open contour shape. The figure on the previous page shows an example of the ending angle for a Bezier curve.

Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this shape.

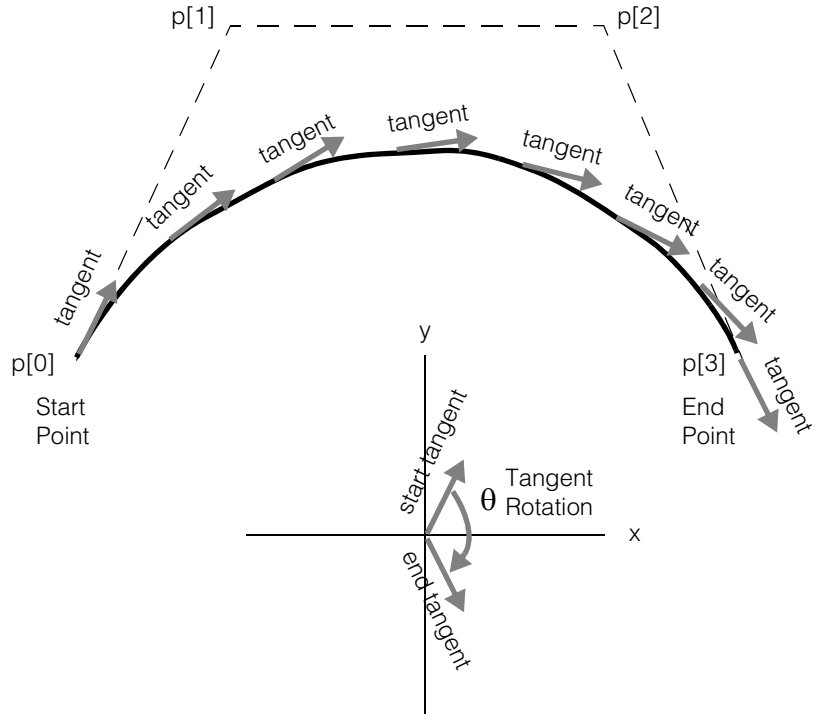
Notes

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

tangentRotation `virtual ccRadian tangentRotation() const;`

Returns the net signed angle through which the tangent vector rotates along the contour of this shape from the start point to the end point. This method is specific to open contour shapes.

The following figure shows an example of tangent rotation for a Bezier curve. In this example, the tangent rotation is approximately 120°.



Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

ccShapesError::NoTangent
hasTangent() is false for this shape.

Notes

The tangent rotation is an integrated angle along the curve, theoretically equal to *endAngle() - startAngle() + 2k*π radians for some integer *k*.

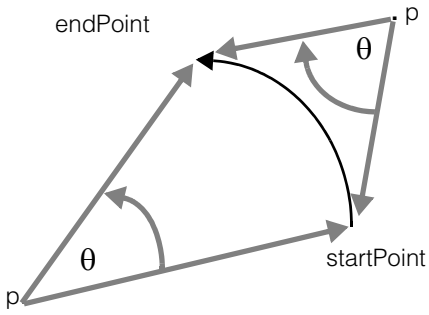
Tangent rotation is used to determine the handedness of a composite contour that includes this shape.

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

windingAngle `virtual ccRadian windingAngle(const cc2Vect &p) const;`

For an open contour shape, let *t* be a point that moves continuously along the curve from the start point to the end point. The winding angle is the net signed angle through which the vector *p->t* rotates as *t* traces the curve.

For example, in the following figure, when *p* is to the right of the ellipse arc, the winding angle θ is roughly $-\pi/4$ (or -45°). When p is to the left of the ellipse arc, the winding angle is roughly $+\pi/6$ (or $+30^\circ$).



Parameters

p The start point of the vector *p->t* whose angle is measured as the end point *t* traces the curve.

Throws

ccShapesError::NotOpenContour
This shape is not an open contour.

Notes

This method is used for determining whether *p* is inside or outside of a region whose boundary includes this shape.

This method is specific to open contour shapes. The default implementation, which throws *ccShapesError::NotOpenContour*, is overriddden only for derived shapes that are open contours.

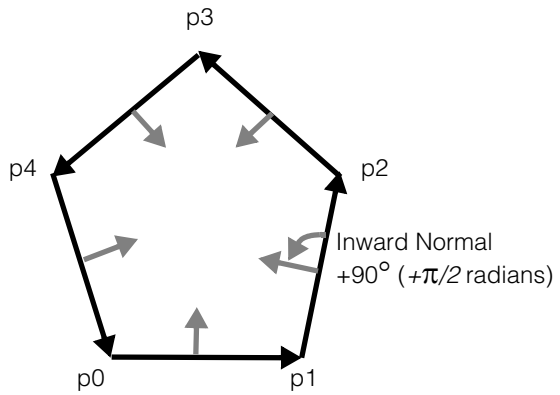
isRightHanded `virtual bool isRightHanded() const;`

Returns true if and only if this region shape is right-handed.

Handedness is an intrinsic property of a shape, and is independent of the coordinate system in which the shape is displayed. For non-intersecting, closed contours, the following criteria are all equivalent ways of characterizing right-handedness:

- The tangent vector rotates through $+2\pi$ radians along the curve.
- The inward normal is rotated $+\pi/2$ radians from the tangent vector.
- In an approximating polygon with vertices $p_1,\ldots, p_N$, the sum of $p_i \times p_{(i+1)}$ over all i is positive, where the x denotes vector cross product.

Right-Handed Shape



The criteria for left-handedness are obvious negations of the above criteria. The positive angle direction is the direction in which x rotates into y. The handedness criteria presume a direction of travel along the contour (a tangent vector). This is defined as the direction in which points are sampled by the method **sample()**, below. Handedness is not equivalent to clockwise/counterclockwise designations, as the latter are dependent on the coordinate system in which the shape is displayed. For a particular display coordinate system, however, there is a correspondence. For example, if the display coordinate system's x-axis points right and its y-axis points down, then a closed curve is right-handed if and only if it traces the enclosed area in a clockwise direction.

Throws

ccShapesError::NotRegion
This shape is not a region.

Notes

This method is specific to region shapes. Boundaries of region shapes are assumed not to self-intersect.

within

```
virtual bool within(const cc2Vect &p) const;
```

Returns true if and only if the given point is inside of the region defined by this shape.

Parameters

p The point.

Throws

ccShapesError::NotRegion
This shape is not a region.

Notes

This method is specific to region shapes. Boundaries of region shapes are assumed not to self-intersect.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const = 0;
```

Returns this shape mapped by X.

Parameters

X The transformation object.

Notes

The returned shape is of the same type as the original shape unless otherwise noted in a derived class.

reverse

```
virtual ccShapePtrh reverse() const;
```

Returns the reversed version of this shape. A reversed shape describes the same locus of points as the original, but parameterizes this locus of points in the opposite direction. Not all shapes are reversible. The **isReversible()** method indicates whether a shape can be reversed. All open contour shapes are reversible; for these shapes, **startPoint()** in the reversed shape corresponds to **endPoint()** in the original shape, and vice versa. Most other shapes (such as **ccCircle**, **ccRect**, and **ccGenRect**) are not reversible. Notable exceptions are closed polygon-like shapes (such as **ccGenPoly**, **ccPolyline**, and **ccCubicSpline**). These shapes can be reversed even when they are closed.

Notes

Sampling a reversed shape always generates sample points that traverse the shape in the opposite direction from that traversed by sampled points from the original shape.

Throws

ccShapesError::NotReversible
This shape is not reversible.

decompose

```
virtual ccShapePtrh decompose() const = 0;
```

Returns a new shape describing the same geometry as this shape, but using only a subset of shape primitives. Decomposed shapes contain only line segments, ellipse arcs, and Bezier curves as primitives, possibly arranged into shape hierarchies. A decomposed shape describes the same locus of points as the original shape, and contains the same connectivity and tangent direction information. For example, a **ccRect** is decomposed into four line segments grouped into a right-handed **ccContourTree**.

A **ccShape** can be decomposed into only the following shapes:

- Decomposed **ccGeneralShapeTree**s
- Decomposed **ccContourTree**s
- **ccLineSeg**s
- **ccEllipseArc**s
- **ccBezierCurve**s

ccGeneralShapeTree::decompose() returns a **ccGeneralShapeTree** that contains decomposed versions of any children that are not **ccGeneralShapeTree**s or **ccRegionTree**s, in addition to the decomposed children of any **ccGeneralShapeTree** or **ccRegionTree** children. A decomposed **ccGeneralShapeTree** can contain only the following types of children:

- Decomposed **ccContourTree**s
- **ccLineSeg**s
- **ccEllipseArc**s
- **ccBezierCurve**s

ccContourTree::decompose() returns a decomposed **ccContourTree** that is a merged version of its decomposed children. A decomposed **ccContourTree** can contain only the following types of children:

- **ccLineSeg**s
- **ccEllipseArc**s
- **ccBezierCurve**s

Notes

Decomposition is a many-to-one transformation. It is not possible to infer from the decomposition alone the structure of the original shape.

Shapes for which **isEmpty()** is true or **isFinite()** is false decompose into **ccGeneralShapeTree**s or **ccContourTree**s without any children. Points decompose into zero-length line segments with both endpoints coincident with the original point.

---

clip

```
ccShapePtrh clip(const ccPolyline &clipRegion,
  bool checkHandedness = true) const;

ccShapePtrh clip(const ccPolyline &clipRegion,
  ClipResult &clipResult, bool checkHandedness = true)
const;
```

- ```
  ccShapePtrh clip(const ccPolyline &clipRegion,
    bool checkHandedness = true) const;
  ```

  Returns the portion of this shape lying within the clipping region. The returned shape may not have the same types of component primitive shapes as this shape.

  Parameters

  clipRegion The clipping region. *clipRegion* must be a closed, convex, polyline. It must be a right-handed polyline if *checkHandedness* is false.

  checkHandedness
  If true, the handedness of the clip region is determined prior to clipping. If false, handedness is not determined prior to clipping. *clipRegion* must be a right-handed polyline if *checkHandedness* is false. The default is true.

- ```
  ccShapePtrh clip(const ccPolyline &clipRegion,
    ClipResult &clipResult, bool checkHandedness = true)
  const;
  ```

  Returns the portion of this shape lying within the clipping region, and a result object containing information on the type of clipping performed. The returned shape may not have the same types of component primitive shapes as this shape.

  Parameters

  clipRegion The clipping region. *clipRegion* must be a closed, convex, polyline. It must be a right-handed polyline if *checkHandedness* is false.

clipResult Result object produced by the clipping operation; contains information on the type of clipping performed. If this shape is empty, the returned *clipResult* is *eInside* (see enum **ClipResult**).

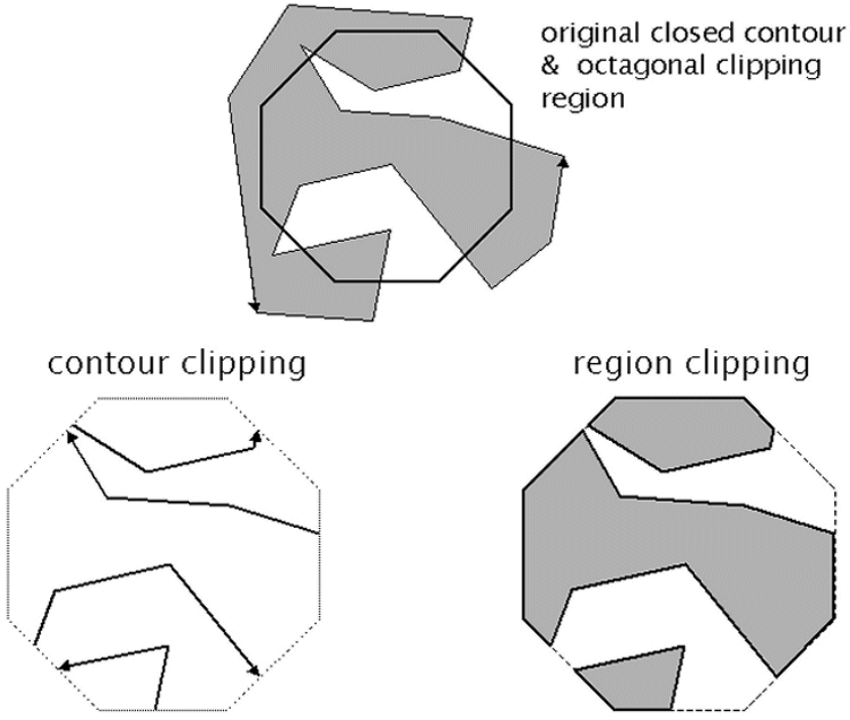
checkHandedness

If true, the handedness of the clip region is determined prior to clipping. If false, handedness is not determined prior to clipping. *clipRegion* must be a right-handed polyline if *checkHandedness* is false. The default is true.

Notes

If *checkHandedness* is true, the handedness of the clip region is determined prior to clipping. The clipping algorithms need this information. To avoid the overhead of automatically determining handedness, pass in a right-handed clip region, and a value of false for *checkHandedness*.

Closed shapes are generally clipped as boundaries, not as regions. The area they enclose is not considered part of the shape. Thus, a partially clipped region shape is not a region, but rather a collection of individual boundary segments. The class **ccRegionTree** is the notable exception to this rule.



subShape

```
virtual ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this shape over the given perimeter range. The perimeter of the final returned shape is equal to the absolute value of the distance component of *range*, assuming the distance is not clipped (see notes).

Parameters

info Shape information for this shape. Must be valid for this particular shape.

range The perimeter range. The perimeter position component of this value must be valid for this particular shape.

Notes

The returned shape does not extend beyond the contour containing the reference position. This method never jumps gaps between contours.

If the contour containing the reference position of *range* is a finite open contour, the distance is clipped internally, if necessary to generate a position on the same contour. If clipping occurs, the returned subshape extends to the start point or the end point of the contour.

If the contour containing the reference position of *range* is a finite closed contour of perimeter *p*, the distance *d* is clipped internally to the range *-p* through *+p*, inclusive. This generates a subshape with a maximum perimeter of *p*. If clipping occurs, the returned subsape is closed, otherwise it is open. Distances wrap around the branch cut of a closed contour appropriately.

When *d* is negative, the tangent direction along the returned shape is opposite to that of the original. As with **reverse()**, this can cause a reversal in the effective model properites. See the *Shape Model Properties* section of the *Shape Models* chapter of the *CVL Vision Tools Guide* for more information on the effects of shape manipulation on shape model properties.

Throws

ccShapesError::BadParams

Either *info* or the perimeter position component of *range* is detectably invalid for this shape. This includes the case where this shape is empty, as an empty shape cannot have any valid perimeter positions.

sample

```
virtual void sample(const ccSampleParams &params,
  ccSampleResult &result) const = 0;
```

Returns sample positions, and possibly tangents, along this shape. A single contour, open or closed, can be modeled by a chain (or sequence) of positions along the contour. Polygonal contours are modeled exactly in this way. Curved contours are only

approximated as the position chain contains a finite number of elements. Optionally, a chain of tangent directions, one corresponding to each sampled position, can also be computed. The **ccSampleParams** object passed in specifies details of how the sampling should be done. The **ccSampleResult** object returned contains the results of the sampling operation.

This method appends position and tangent chains corresponding to this shape to the supplied **ccSampleResult** object. Each chain corresponds to one contiguous portion of the shape. For example, most primitive shapes add one position and tangent chain. Primitive annulus shapes add two position and tangent chains. Hierarchical shapes may add an arbitrary number of chains.

Tangent direction samples may or may not be computed along with position samples, as specified by the **computeTangents()** flag of the supplied **ccSampleParams** object. Once samples have been stored into a **ccSampleResult** object, it is an error to change this flag on subsequent sampling operations. Attempting to do so will result in a throw. This is necessary to maintain a one-to-one correspondence between positions and tangents if tangents are computed.

Parameters

params Parameters object specifying details of how the sampling should be done.

result Result object to which position and tangent chains are stored.

Throws

ccShapesError::SampleOverflow
The supplied spacing and tolerance bounds require more than **ccSampleParams::maxPoints()** samples to be generated along a single element of a primitive shape (see **ccSampleParams**).

ccShapesError::InfiniteExtent
This shape does not have finite extent.

ccShapesError::BadParams
Position samples without tangent directions have already been stored into *result*, but *params* specifies that tangents should be computed. Conversely, tangent direction samples have already been stored into *result*, but *params* specifies that tangents should not be computed.

Notes

The **sample()** method does not repeat vertices for closed primitive contours, such as **ccCircles**. See **ccSampleParams::duplicateCorners()** for more information.

Overrides of this function must return positions that are on the shape. For example, **ccCircle::sample()** should return vertices of an inscribed polygon, not a circumscribed one. Certain algorithms that call **sample()** assume this behavior.

Primitive annulus shapes and region trees generate position chains that bound the inside of the shape in a consistent manner. The chain around the outside, therefore, is in the opposite direction to the chain around the inside hole.

If *params* specifies that tangents should be computed, then this function ignores shapes for which **hasTangent()** is false, such as **cc2Point**. Such shapes do not contribute any samples to the position or tangent chains stored in *result*. If *params* specifies that tangents should not be computed, then shapes such as **cc2Point** will still generate position samples.

Typedefs

ccShapePtrh

```
typedef ccPtrHandle<ccShape> ccShapePtrh;
```

Pointer handle to a **ccShape**.

ccShapePtrh_const

```
typedef ccPtrhHandle_const<ccShape> ccShapePtrh_const;
```

Pointer handle to a `const` **ccShape**.

ccShapeInfo

```
#include <ch_cvl/shapbase.h>

class ccShapeInfo;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class encapsulates detailed information about a shape. The perimeter and parameterization functions of **ccShape** require that this information be explicitly precalculated. This ensures that repeated calls to those functions on an unchanging shape are maximally efficient.

A **ccShapeInfo** object can be constructed for any primitive shape, finite or infinite, but not for a non-primitive shape. For example, a **ccShapeInfo** object can be constructed for a line, but not for a general shape tree containing a line. You can convert an infinite shape into a finite one by clipping it.

Similarly, shape operations that require information stored in a **ccShapeInfo** object can be performed on infinite primitive shapes, but not on infinite non-primitive shapes.

A **ccShapeInfo** object contains information for a particular shape. It is not valid for any other shape, whether obtained from the original through mapping, reversing, clipping, decomposing, or any other type of modification.

Constructors/Destructors

ccShapeInfo

```
ccShapeInfo(const ccShape& shape);
```

Constructs a **ccShapeInfo** object for the given shape.

Parameters

shape The shape.

Throws

ccShapesError::InfiniteShape
The shape this **ccShapeInfo** object describes is infinite and is not a primitive. If the described shape is infinite but primitive, no exception is thrown.

Public Member Functions

perimeter

```
double perimeter() const;
```

Returns the perimeter of the shape that this **ccShapeInfo** object describes.

Throws

ccShapesError::InfiniteExtent
The shape that this **ccShapeInfo** describes is not finite.

Notes

This function is never slower than **ccShape::perimeter()** and may be much faster.

See **ccShape::perimeter()** for more information.

---

perimPos

```
ccPerimPos perimPos(double distanceAlong) const;

ccPerimPos perimPos(const ccPerimPos &referencePos,
  double distance) const;
```

- `ccPerimPos perimPos(double distanceAlong) const;`

Returns the position at the given distance along the perimeter of the shape that this **ccShapeInfo** object describes.

Parameters

distanceAlong The distance from the starting point along the perimeter of the shape.

Throws

ccShapesError::EmptyShape
This shape is empty.

Notes

If the shape that this **ccShapeInfo** object describes is finite, **distanceAlong()** is automatically clipped to the range 0 through **perimeter()**, inclusive. For infinite primitive shapes, **distanceAlong()** is meaningful over all real values, signed and unsigned, and is not clipped.

- `ccPerimPos perimPos(const ccPerimPos &referencePos, double distance) const;`

Returns the position at the given signed distance along the perimeter of the shape that this **ccShapeInfo** object describes, relative to the given reference position. This overload always returns a perimeter position on the same contour as the supplied reference position.

Parameters

referencePos The reference position. Must be a valid perimeter position for the exact shape that this **ccShapeInfo** object describes.

distance The distance from the reference position.

Notes

If the contour containing the reference position is a finite open contour, the distance is clipped internally, if necessary, to generate a position on the same contour. If clipping occurs, the returned position corresponds to either the start point or the end point of the contour.

If the contour containing the reference position is a finite closed contour of perimeter *p*, the distance is clipped internally to the range *-p* through *+p*, inclusive. This generates a new position on the same contour.

Distances wrap around the branch cut of a closed contour appropriately. Hence, it is possible, for example, for the returned position to have a smaller **distanceAlong()** value than the reference position, even when *distance* is positive.

Contours are not synonymous with primitives. Some contours (for example, contour trees) comprise multiple primitives, and some primitives (for example, annulus shapes) comprise multiple contours. Within contour trees, the returned position may lie on a different primitive than the reference position. Within annulus primitives, positions on the contour not containing the reference position are inaccessible from this function.

Throws

ccShapesError::BadParams

referencePos is detectably invalid for this **ccShapeInfo** object.

distanceAlong `double distanceAlong(const ccPerimPos& pos) const;`

Returns the distance from the given point along the perimeter of the shape that this **ccShapeInfo** describes.

Parameters

pos The point. Must be a valid perimeter position for the exact shape that this **ccShapeInfo** object describes.

Notes

If the shape that this **ccShapeInfo** describes is finite, the returned value lies in the range 0 through **perimeter()**, inclusive. If this **ccShapeInfo** object describes an infinite primitive shape, the returned value is unconstrained, and may be negative.

Throws

ccShapesError::BadParams

pos is detectably invalid for this **ccShapeInfo** object.

ccShapeMaskValue

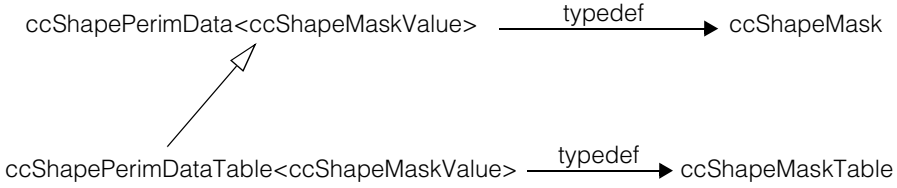
```
#include <ch_cvl/shapemsk.h>

class ccShapeMaskValue
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This class holds mask values suitable for representing masking information for CVL shape descriptions (**ccShape** objects). **ccShapeMaskValue** is used to instantiate the templated class **ccShapePerimData** to create **ccShapeMask** and **ccShapeMaskTable** which are used by the **ccBoundaryInspector** tool to mask out unwanted parts of a **ccShape** model. See the following diagram:



Constructors/Destructors

ccShapeMaskValue

```
ccShapeMaskValue(
  ShapeMaskValue maskValue =
                        ShapeMaskValue::kDefaultMaskValue);
```

Constructs a **ccShapeMaskValue** object with the given mask value.

Parameters

maskValue The shape mask value.

Operators

operator==

```
bool operator== (const ccShapeMaskValue &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

operator!=

```
bool operator!= (const ccShapeMaskValue &that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that	The object to compare with this object.

Enumerations

ShapeMaskValue

```
enum ShapeMaskValue
```

Defines the allowed shape mask values.

Value	Meaning
eNotMasked = 0	Not masked (will be processed by the tool)
eMasked = 1	Masked (masked areas are ignored)
kDefaultMaskValue = *eNotMasked*	The default

Public Member Functions

maskValue

```
ccShapeMaskValue::ShapeMaskValue maskValue() const;
void maskValue(ccShapeMaskValue::ShapeMaskValue maskVal);
```

The shape mask value. Must be one of the **ShapeMaskValue** enums.

- `ccShapeMaskValue::ShapeMaskValue maskValue() const;`

  Returns the current mask value.

- `void maskValue(ccShapeMaskValue::ShapeMaskValue maskVal);`

  Sets a new mask value.

  Parameters

  maskVal The new mask value.

ccShapeMaskValue

ccShapeModel

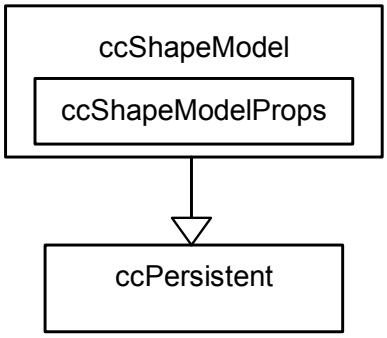
```
#include <ch_cvl/shapemod.h>

class ccShapeModel : public virtual ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccShapeModel** class is a *mixin* class that provides shape model properties for a shape. It also provides several static functions that help to set polarity for shapes.



The above figure shows the **ccShapeModel** class inheritance hierarchy.

ccShapeModel inherits from **ccPersistent**. It contains an instance of **ccShapeModelProps**, which specifies weight and polarity properties for a shape.

See the *Shape Models* chapter of the *CVL Vision Tools Guide* for more information on shape models.

Constructors/Destructors

ccShapeModel

```
ccShapeModel();
ccShapeModel(const ccShapeModelProps& props);
virtual ~ccShapeModel();
```

- `ccShapeModel();`

  Default constructor. Constructs a **ccShapeModel** object with default properties (see **ccShapeModelProps** on page 2937 for details).

- `ccShapeModel(const ccShapeModelProps& props);`

  Constructs a **ccShapeModel** object using the supplied shape model properties.

  Parameters

  props The shape model properties.

- `virtual ~ccShapeModel();`

  Destructor. Destroys this **ccShapeModel** object.

Operators

operator==

```
bool operator==(const ccShapeModel& other) const;
```

Returns true if this **ccShapeModel** is exactly equal to *other*, and false otherwise.

Parameters

other The other **ccShapeModel** object.

operator!=

```
bool operator!=(const ccShapeModel& other) const;
```

Returns true if this **ccShapeModel** is not exactly equal to *other*, and false otherwise.

Parameters

other The other **ccShapeModel** object.

Public Member Functions

modelProps

```
const ccShapeModelProps& modelProps() const;
void modelProps(const ccShapeModelProps& props);
```

- `const ccShapeModelProps& modelProps() const;`

  Gets the shape model properties.

- `void modelProps(const ccShapeModelProps& props);`

  Sets the shape model properties.

  Parameters

  props The shape model properties.

Static Functions

shapeModelProps

```
static ccShapeModelProps shapeModelProps(
  const ccShape& shape);
```

Returns the model properties (explicit or implicit) for the specified shape.

Parameters

shape The shape.

Notes

These properties are not necessarily the effective model properties, as they do not account for the model properties for any existing ancestors of the specified shape.

setInsidePolarity

```
static ccShapePtrh setInsidePolarity(const ccShape& shape,
  bool isPositive = true);
```

Returns a new shape that is identical to the supplied shape except that the polarity of all regions is such that the insides are all positive if *isPositive* is true, and negative if it is false.

Parameters

shape The supplied shape.

isPositive If true (the default), the inside polarity of all regions of the returned shape is positive; otherwise, it is negative.

Notes

The polarities of non-region shapes are left unchanged.

The returned shape is gauranteed to be of type **ccShapeModel**.

Ignore polarity flags do not affect the behavior of this function.

This function requires that no regions of the supplied shape self-intersect.

isInsidePolarity

```
static bool isInsidePolarity(const ccShape& shape,
  bool isPositive);
```

Returns true in the following cases, and false otherwise:

- *isPositive* is true and the inside polarity of all regions of the supplied shape is positive.
- *isPositive* is false and the inside polarity of all regions of the supplied shape is negative.

Parameters

shape	The shape.
isPositive	See above.

Notes

This function always returns true if *shape* is a primitive shape that is not a region.

Ignore polarity flags do not affect the behavior of this function.

This function requires that no regions of this shape self-intersect.

areAnyPolaritiesIgnored

```
static bool areAnyPolaritiesIgnored(const ccShape& shape);
```

Returns true if the ignore polarity flag is true for any portion of the supplied shape, otherwise false.

Parameters

shape	The shape.

features

```
static ccFeatureletChainSetPtrh features(
  const ccShape& shape,
  const ccShapeModel::ccFeatureParams &params);
```

Returns featurelet chains approximating the boundaries of the supplied shape. This method internally calls **ccShape::sample()** on the supplied shape with the supplied sampling parameters, and then converts the sample result into a featurelet chain set according to the following algorithm:

1. Create a *featurelet chain set* for each chain in the sample result (between breaks). The featurelet chain is closed if and only if the corresponding sample chain is closed.
2. Set the *position* of each featurelet to the corresponding sample position.
3. If the sampling parameter **computeTangents()** is true, define the *angle* for each featurelet as the normal to the tangent angle of the corresponding sample point on the positive side of the shape. The positive side is determined by the effective polarity of that portion of the shape from which the feature was sampled. An exception to this rule applies if **duplicateCorners()** is false (see note below for more information). If **computeTangents()** is false, the featurelet angles are undefined.
4. Set the *isMod180* flag for each featurelet to true if and only if the effective ignore polarity flag for that portion of the shape from which the feature was sampled is true.
5. Determine the *weight* of each featurelet. The weight of a featurelet is the product of the effective weight along that portion of the shape from which the feature was sampled and the weight scale supplied by *params*.
6. Determine the *magnitude* of each featurelet. The magnitude of a featurelet is the product of the effective magnitude along that portion of the shape from which the feature was sampled and the magnitude scale supplied by *params*.

Parameters

shape	The shape.
params	The parameters used to extract features from *shape*. These include both shape model specific parameters and shape sampling parameters.

Throws

See **ccShape::sample()** for possible exceptions that can be thrown from a sampling operation.

Notes

If **params.sampleParams().duplicateCorners()** is false, each feature located at a corner between contour tree children with inconsistent effective shape model properties represents the average of the two features that would have been generated at that corner had **duplicateCorners()** been true. In other words, the featurelet angle is the average angle computed after the polarity reversals,

magnitudes, and weights of the two children have been taken into account. The magnitude of the resulting feature is thus the average of the magnitudes of the two contour trees at that corner. The same is true for the weight. The *isMod180* flag of the resulting feaure is the logical OR of the *isMod180* flags of the two contour trees.

draw

```
static void draw(ccGraphicList& gList,
  const ccShape& shape,
  const ccGraphicProps& posGraphicProps,
  const ccGraphicProps& negGraphicProps,
  const ccGraphicProps& zeroGraphicProps = ccGraphicProps()
);
```

Draws the supplied shape in the supplied graphics list. Draws shapes with positive, negative, and zero effective weights using *posGraphicProps*, *negGraphicProps*, and *zeroGraphicProps*, respectively. Contours for which **ccGraphicProps::penColor()** is *passColor* are not drawn at all.

Polarity arrow heads are drawn for a contour if and only if the contour is drawn and **ccGraphicProps::arrowHead()** is true in the associated graphics properties for that contour. If arrowheads are drawn, '+' and '-' signs are placed on each side to indicate the effective polarity. If the effective ignore polarity flag is true, slashes are drawn through these signs.

Parameters

gList The graphics list.

shape The shape.

posGraphicProps
Graphic properties for shapes with positive effective weight.

negGraphicProps
Graphic properties for shapes with negative effective weight.

zeroGraphicProps
Graphic properties for shapes with zero effective weight. If no properties are supplied, the default **ccGraphicProps** drawing properties are used.

Notes

Phantom holes at the roots of region tree shapes are not drawn.

Shapes contained within the supplied shape for which no associated shape model type exists are not drawn.

record

```
static void record(ccDiagObject& obj,
  const ccPelBuffer_const<c_UInt8>& pelBuf,
  const ccShape& shape,
  const ccGraphicProps& posGraphicProps,
  const ccGraphicProps& negGraphicProps,
  const ccGraphicProps& zeroGraphicProps,
  const ccCvlString& annotation);
```

Records the supplied image and shape into the supplied diagnostic record. The shape is recorded in the client coordinate system of the image. Portions of the shape with positive, negative, and zero effective weights are recorded using *posGraphicProps*, *negGraphicProps*, and *zeroGraphicProps*, respectively. Contours for which **ccGraphicProps::penColor()** is *passColor* are not drawn at all.

Polarity arrow heads are recorded for a contour if and only if the contour is drawn and **ccGraphicProps::arrowHead()** is true in the associated graphics properties for that contour. If arrow heads are drawn, '+' and '-' signs are placed on either side to indicate the effective polarity. If the effective ignore polarity flag is true, slashes are drawn through these signs.

Tree structures within the shape are explicitly recorded as distinct levels within the record. All shape properties are recorded as text.

Parameters

obj The diagnostic record.

pelBuf The image.

shape The shape.

posGraphicProps
Graphic properties for shapes with positive effective weight.

negGraphicProps
Graphic properties for shapes with negative effective weight.

zeroGraphicProps
Graphic properties for shapes with zero effective weight. If no properties are supplied, the default **ccGraphicProps** drawing properties are used.

annotation A string that you can add to the diagnostic record.

Notes

Polarity graphics are not drawn for *phantom* holes at the roots of any region tree shapes within the supplied shape.

Shapes contained within the supplied shape for which no associated model shape type exists are not drawn.

rawShape

```
static ccShapePtrh rawShape(const ccShape &shape);
```

Returns a copy of the **ccShape** portion of the supplied shape stripped of any model properties.

Notes

The shape returned by this method is not the same as a reference to the shape portion of a shape model, which can be dynamically cast to a shape model. The shape returned by this method can neither be cast to a shape model, nor does it include the extra storage required for model properties.

Typedefs

ccShapeModelPtrh

```
typedef ccPtrHandle<ccShapeModel> ccShapeModelPtrh;
```

ccShapeModelPtrh_const

```
typedef ccPtrHandle_const<ccShapeModel>
ccShapeModelPtrh_const;
```

Deprecated Members

sampleWithPolarity

```
static void sampleWithPolarity(const ccShape& shape,
  const ccShape::ccSampleParams &params,
  ccShape::ccSampleResult &result);
```

This method is deprecated. Use **features()** instead.

ccShapeModelProps

```
#include <ch_cvl/shapemod.h>

class ccShapeModelProps;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccShapeModelProps** class encapsulates non-geometric information that is often required to describe the appearance of an object in an image. This information includes the following:

- *Polarity reversal flag*: if true, the default polarity of the shape is reversed (default = false).
- *Ignore polarity flag*: if true, polarity information should be ignored (default = false).
- *Weight*: relative importance of the shape as compared to other shapes (default = 1.0).
- *Magnitude*: strength of the boundary modeled by the shape. Magnitude can be any non-negative value (default = 1.0).

If these properties are not explicitly specified for a particular shape, the shape automatically inherits its properties from its parent if it is part of a tree. Otherwise it assumes the default values listed above.

Polarity

Polarity refers to the gradient direction for the boundary modelled by the shape. That is, the polarity of a shape specifies which side of its boundary is relatively dark with respect to the other. To encode this information, each shape has an unique *effective polarity*. The side of the shape boundary that is in the +90 degree direction from the tangent direction has one polarity (either *positive* or *negative*), and the side in the -90 degree direction from the tangent direction has the opposite polarity. The *polarity reversal flag* specifies whether the polarity for a shape is reversed from its normal polarity.

Ignore Polarity Flag

The *ignore polarity flag* specifies whether polarity information should be ignored for a shape. You can use this flag, for example, to effectively invalidate polarity information if it is unknown, or simply to ignore polarity information in cases where it is known. The ignore polarity flag is false by default, which means that the polarities of all shapes are valid and that vision tools can use them.

Weight

The *weight* property determines the relative importance of a shape. In the context of a shape tree, the weight for a child determines the importance of the feature that the child is modelling relative to the overall object that the shape tree is modelling. This assignment of relative importance is often dependent on the application. For example, when using a shape model to perform an alignment (for example, using PatMax), the weight determines how much this shape will contribute to the alignment score. The effective weight for a shape is assumed to be 1.0 by default, if not explicitly specified for that shape or by any of its ancestors.

Magnitude

The *magnitude* property specifies the non-negative strength of the boundary represented by a shape. Magnitude may be used, for example, to denote the edge contrast of an object. Magnitude is 1.0 by default.

Note See the *Shape Models* chapter of the *CVL Vision Tools Guide* for a more detailed discussion of shape model properties.

Constructors/Destructors

ccShapeModelProps

```
explicit
ccShapeModelProps(bool isReversedPolarity = false,
  double weight = 1.0,
  bool isIgnoredPolarity = false,
  double magnitude = 1.0);
```

Constructs a shape model properties object using the specified parameters. This constructor is used for explicit construction only and not for implicit conversions.

Parameters

isReversedPolarity
: If true, the polarity of the shape is reversed (default = false).

weight
: Relative importance of the shape (default = 1.0).

isIgnoredPolarity
: If true, polarity information for a shape should be ignored (default = false).

magnitude Strength of the boundary described by the shape (default = 1.0).

Throws

ccShapeModelDefs::BadParams
magnitude is less than 0.0.

Operators

operator==

```
bool operator==(const ccShapeModelProps& other) const;
```

Returns true if this object is exactly equal to *other*, and false otherwise.

Parameters

other The other **ccShapeModelProps** object.

operator!=

```
bool operator!=(const ccShapeModelProps& other) const;
```

Returns true if this object is not exactly equal to *other*, and false otherwise.

Parameters

other The other **ccShapeModelProps** object.

Public Member Functions

isReversedPolarity

```
void isReversedPolarity(bool b);
bool isReversedPolarity() const;
```

- `void isReversedPolarity(bool b);`

  Sets the *reversePolarity* flag.

  Parameters

  b True sets the polarity of the shape to reversed.

- `bool isReversedPolarity() const;`

  Gets the *reversePolarity* flag.

isIgnoredPolarity

```
void isIgnoredPolarity(bool b);
bool isIgnoredPolarity() const;
```

- `void isIgnoredPolarity(bool b);`

  Sets the ignore polarity flag.

  Parameters

  b — If true, polarity information for the shape is invalid and vision tools should ignore it.

- `bool isIgnoredPolarity() const;`

  Retrieves the ignore polarity flag.

magnitude

```
void magnitude(double m);
double magnitude() const;
```

- `void magnitude(double m);`

  Sets the magnitude property.

  Parameters

  m — The magnitude.

  Throws

  ccShapeModelDefs::BadParams
  m is less than 0.0.

- `double magnitude() const;`

  Gets the magnitude property.

weight

```
void weight(double w);
double weight() const;
```

- `void weight(double w);`

  Sets the weight property.

Parameters

w The weight.

- `double weight() const;`

  Gets the weight.

assign `ccShapePtrh assign(const ccShape& shape) const;`

Returns a new shape that is a shape model version of the supplied shape, containing these shape model properties. The returned shape is also of type **ccShapeModel**.

Parameters

shape The shape.

Notes

The safest way to convert any shape to an equivalent shape model is using **ccShapeModel::shapeModelProps(shape).assign(shape)**. This assigns the original model properties of shape, rather than default model properties, to the shape model. A case in point is **cc2Wireframe**s, which contain polarity information, and therefore possibly non-default model properties, even when they are not shape models.

combine

```
ccShapeModelProps combine(const ccShapeModelProps& other)
  const;
```

Returns a new shape model properties object that is the effective combination of these properties and the properties supplied by another properties object. Properties are combined such that:

- The resulting *weight* is the product of the two weights of this and the supplied properties object. If both values are negative, the resulting weight is zero.
- The resulting *polarity reversal flag* is the logical exclusive OR of the reversal flags of this and the supplied properties object.
- The resulting *ignore polarity flag* is the logical OR of the ignore flags of this and the supplied properties object.
- The resulting *magnitude* is the product of the magnitudes of this and the supplied properties object.

Parameters

other The other **ccShapeModelProps** object.

ccShapeModelProps

ccShapeModelTemplate<>

```
#include <ch_cvl/shapemod.h>

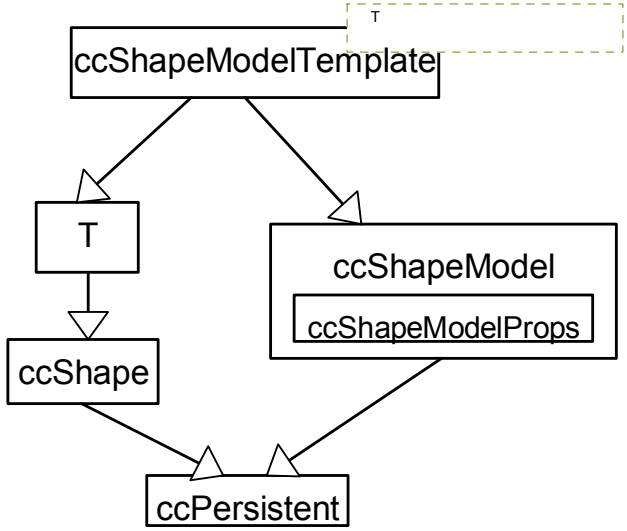
template <class P>
class ccShapeModelTemplate : public T,
  virtual public ccShapeModel;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccShapeModelTemplate<>** class endows a shape with shape model properties. It inherits the shape interface from the specified shape type, and the shape model properties from the **ccShapeModel** mixin class.

Note The shape type, **T**, must derive from **ccShape**.



The above figure shows the **ccShapeModelTemplate<>** class inheritance hierarchy.

See the *Shape Models* chapter of the *CVL Vision Tools Guide* for more information on the use of the **ccShapeModelTemplate<>** class.

Constructors/Destructors

ccShapeModelTemplate

```
ccShapeModelTemplate();

ccShapeModelTemplate(const ccShapeModelProps& props);

ccShapeModelTemplate(const T& shape,
  const ccShapeModelProps& props) : T(shape),
  ccShapeModel(props);
```

- `ccShapeModelTemplate();`

  Default constructor.

- `ccShapeModelTemplate(const ccShapeModelProps& props);`

  Constructs a shape model using the supplied shape model properties.

  Parameters

  props The shape model properties.

- ```
  ccShapeModelTemplate(const T& shape,
    const ccShapeModelProps& props) : T(shape),
    ccShapeModel(props);
  ```

  Constructs a shape model using the supplied shape and shape model properties.

  Parameters

  shape The shape.

  props The shape model properties.

Operators

operator==

```
bool operator==(const ccShapeModelTemplate<T>& other)
  const;
```

Returns true if this object is exactly equal to *other*, and false otherwise.

Parameters

other The other shape model object.
```

operator!=

```
bool operator!=(const ccShapeModelTemplate<T>& other)
  const;
```

Returns true if this object is not exactly equal to *other*, and false otherwise.

Parameters

other The other shape model object.

Public Member Functions

clone

```
ccShapePtrh clone() const;
```

Returns a pointer to a copy of this shape model.

reverse

```
ccShapePtrh reverse() const;
```

Returns the reversed version of this shape model object. See **ccShape::reverse()** for more information.

mapShape

```
ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this shape model object mapped by *X*.

Parameters

X The transformation object.

Throws

ccShapeModelDefs::NotSupported
This tree contains any shapes that do not have an associated model shape type.

See **ccShape::mapShape()** for more information.

decompose

```
ccShapePtrh decompose() const;
```

Returns a **ccContourTree** that describes the same geometry as this shape model, but using only a subset of primitive shapes. See **ccShape::decompose()** for more information.

subShape

```
ccShapePtrh subShape(const ccShapeInfo &info,
  const ccPerimRange &range) const;
```

Returns a pointer handle to the shape describing the portion of this shape model over the given perimeter range. The perimeter of the final returned shape is equal to the absolute value of the distance component of *range*, assuming the distance is not clipped.

Parameters

info	Shape information for this shape model.
range	The perimeter range.

Typedefs

There are several type definitions for **ccShapeModelTemplate<>** instantiations for specific shapes. For example, **ccCircleModel** is a type definition for a **ccShapeModelTemplate<>** that is instantiated with a **ccCircle** argument. A **ccCircleModel**, therefore, is a **ccCircle** shape with explicitly defined polarity and weight values. A **ccCircleModel** can use the polarity and weight values inherited from the **ccShapeModelProps** attribute of its **ccShapeModel** base class, or it can override them.

The following are the type definitions for **ccShapeModelTemplate<>** instantiations that CVL provides for all shapes.

ccGeneralShapeTreeModel

```
typedef ccShapeModelTemplate<ccGeneralShapeTree>
  ccGeneralShapeTreeModel;
```

ccContourTreeModel

```
typedef ccShapeModelTemplate<ccContourTree>
  ccContourTreeModel;
```

ccRegionTreeModel

```
typedef ccShapeModelTemplate<ccRegionTree>
  ccRegionTreeModel;
```

cc2PointModel

```
typedef ccShapeModelTemplate<cc2Point> cc2PointModel;
```

ccFLineModel

```
typedef ccShapeModelTemplate<ccFLine> ccFLineModel;
```

ccLineModel

```
typedef ccShapeModelTemplate<ccLine> ccLineModel;
```

ccLineSegModel

```
typedef ccShapeModelTemplate<ccLineSeg> ccLineSegModel;
```

ccRectModel

```
typedef ccShapeModelTemplate<ccRect> ccRectModel;
```

ccCircleModel

```
typedef ccShapeModelTemplate<ccCircle> ccCircleModel;
```

ccAnnulusModel

```
typedef ccShapeModelTemplate<ccAnnulus> ccAnnulusModel;
```

ccEllipse2Model
```
typedef ccShapeModelTemplate<ccEllipse2> ccEllipse2Model;
```

ccEllipseAnnulusModel
```
typedef ccShapeModelTemplate<ccEllipseAnnulus>
  ccEllipseAnnulusModel;
```

ccEllipseAnnulusSectionModel
```
typedef ccShapeModelTemplate<ccEllipseAnnulusSection>
  ccEllipseAnnulusSectionModel;
```

ccEllipseArc2Model
```
typedef ccShapeModelTemplate<ccEllipseArc2>
  ccEllipseArc2Model;
```

ccGenRectModel
```
typedef ccShapeModelTemplate<ccGenRect> ccGenRectModel;
```

ccGenAnnulusModel
```
typedef ccShapeModelTemplate<ccGenAnnulus>
  ccGenAnnulusModel;
```

ccPolylineModel
```
typedef ccShapeModelTemplate<ccPolyline> ccPolylineModel;
```

ccAffineRectangleModel
```
typedef ccShapeModelTemplate<ccAffineRectangle>
  ccAffineRectangleModel;
```

ccGenPolyModel
```
typedef ccShapeModelTemplate<ccGenPoly> ccGenPolyModel;
```

cc2WireframeModel
```
typedef ccShapeModelTemplate<cc2Wireframe>
  cc2WireframeModel;
```

ccBezierCurveModel
```
typedef ccShapeModelTemplate<ccBezierCurve>
  ccBezierCurveModel;
```

ccDeBoorSplineModel
```
typedef ccShapeModelTemplate<ccDeBoorSpline>
  ccDeBoorSplineModel;
```

ccShapeModelTemplate<>

ccInterpSplineModel

```
typedef ccShapeModelTemplate<ccInterpSpline>
 ccInterpSplineModel;
```

ccHermiteSplineModel

```
typedef ccShapeModelTemplate<ccHermiteSpline>
 ccHermiteSplineModel;
```

ccShapePerimData

```
#include <ch_cvl/shapedat.h>

template <class D> class ccShapePerimData:
                                        public virtual ccPersistent,
                                        public virtual ccRepBase
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This is the templated abstract base class for associating data with CVL shape descriptions. Association of data can be done for whole shape descriptions or for ranges of shape perimeters. This class is templated by the data type so that any kind of data can be associated with CVL shape descriptions. Classes derived from this base class should override the virtual member function **get()**.

The **ccShapePerimData** class can be instantiated by a class D that should have the following defined as public: default constructor, copy constructor, assignment operator, destructor, operator== for comparison, and operatorll for persistence.

Constructors/Destructors

ccShapePerimData

```
explicit ccShapePerimData(const D &defaultData = D());

virtual ~ccShapePerimData();
```

- `explicit ccShapePerimData(const D &defaultData = D());`

  Constructs a **ccShapePerimData** object with the given parameter.

- `virtual ~ccShapePerimData();`

  Destructor.

Operators

operator==

```
virtual bool operator== (const ccShapePerimData<D> &that)
                                                    const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator!=

```
virtual bool operator!= (const ccShapePerimData<D> &that)
                                                    const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

defaultData

```
void defaultData(const D & data);

D defaultData() const;
```

- `void defaultData(const D & data);`

  Sets the default data.

  Parameters

  data The new default data.

- `D defaultData() const;`

  Returns the default data. The default is **D()**.

get

```
virtual bool get(
  const ccPerimPos& perimPos, D &data) const;
```

Finds the associated shape data at the specified perimeter position. If found, the function assigns the found data to *data*, and returns true. If not found, it assigns the default data to *data* and returns false.

Parameters

perimPos The perimeter position. *perimPos* must be valid for this shape description.

data The location where the function places the data.

Throws

ccShapePerimDataDefs::BadParams
If *perimPos* is detectably invalid for the shape description.

Note: Derived classes that implement this function might throw.

clone

```
virtual ccPtrHandle<ccShapePerimData<D> > clone()
                                                    const = 0;
```

Returns a pointer to a new copy of this **ccShapePerimData** object.

Typedefs

ccShapeMask

```
typedef ccShapePerimData<ccShapeMaskValue> ccShapeMask;
```

ccShapeMaskPtrh

```
typedef ccPtrHandle<ccShapeMask> ccShapeMaskPtrh;
```

ccShapeMaskPtrh_const

```
typedef ccPtrHandle_const<ccShapeMask>
                                          ccShapeMaskPtrh_const;
```

ccShapeTol

```
typedef ccShapePerimData<ccBoundaryTol> ccShapeTol;
```

ccShapeTolPtrh

```
typedef ccPtrHandle<ccShapeTol> ccShapeTolPtrh;
```

ccShapeTolPtrh_const

```
typedef ccPtrHandle_const<ccShapeTol>
                                          ccShapeTolPtrh_const;
```

ccShapePerimData

ccShapePerimDataTable

```
#include <ch_cvl/shapedat.h>

template <class D> class ccShapePerimDataTable :
                                        public ccShapePerimData<D>
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

This is a templated concrete class that associates the given shape perimeter ranges with the given data on the shape using a lookup table mechanism. The lookup table uses shape perimeter range vectors and data vectors to find the data value corresponding to a given shape perimeter position.

The shape perimeter ranges are represented by a start perimeter position and a signed range length. The shape perimeter range will not extend beyond the contour containing the start position. For example, perimeter ranges never jump gaps between contours. The perimeter length will be clipped if necessary to achieve this constraint. If clipping occurs, one endpoint of the perimeter range will correspond to the first or last point of the original contour that contains the perimeter range.

You provide a vector of data values. The data value and the perimeter range at index i of their respective vectors correspond to each other.

Note If you wish to associate a global data value with all perimeter ranges, leave the *perimRanges* and *rangeData* vectors empty and all perimeter ranges will use the *defaultData* value.

The **ccShapePerimDataTable** class can be instantiated by a class D that should have the following defined as public: default constructor, copy constructor, assignment operator, destructor, operator== for comparison, and operatorll for persistence.

Note that **ccShapePerimDataTable** becomes invalid for a shape description if the shape description is geometrically modified by clipping, a transformation, and so on.

Constructors/Destructors

ccShapePerimDataTable

```
explicit ccShapePerimDataTable(
  const ccShape &shape = cc2Point(),
  const D & defaultData = D(),
```

```
const cmStd vector<ccPerimRange> &perimRanges =
                                    cmStd vector<ccPerimRange>(0),
const cmStd vector<D> &rangeData = cmStd vector<D>(0));
```

Constructs a shape data lookup table object with the given parameters.

Parameters

shape The shape description containing the perimeter ranges.

defaultData The data returned when a perimeter range position is not found See **get()** below.

perimRanges The shape perimeter ranges that represent the shape boundary. Elements of *perimRanges* must be valid for the *shape description* and perimeter ranges must not overlap.

rangeData Data values corresponding to *perimRanges*.

Throws

ccShapePerimDataDefs::BadParams
If any perimeter range values are detectably invalid for *shape description*,
or if the vectors *perimRanges* and *rangeData* vectors are not the same size,
or if the *shape description* is infinite and not a primitive.

Operators

operator==

```
virtual bool operator== (
  const ccShapePerimData<D> &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

get

```
virtual bool get(
  const ccPerimPos& perimPos,
  D &data) const;
```

Returns the associated shape data at the perimeter position. This function finds the first perimeter range in the range vector that includes the given perimeter position. If such a range is found, the corresponding data from the data vector is assigned to *data* and this function returns true. If such a range is not found, then this function returns false and the default data is assigned to *data*.

Perimeter ranges must not overlap.

This function overrides the **ccShapePerimData::get()**.

Parameters

perimPos	A perimeter position. *perimPos* must be valid for the shape description.
data	Where to put the data.

Throws

ccShapePerimDataDefs::BadParams
If *perimPos* is detectably invalid for the shape description.

setShapeAndVectors

```
void setShapeAndVectors(
  const ccShape &shape,
  const cmStd vector<ccPerimRange> &perimRanges,
  const cmStd vector<D> &rangeData);
```

Sets the shape description, shape perimeter range, and range data vectors.

Elements of *perimRanges* must be valid for the *shape description*.

Parameters

shape	The shape description containing the perimeter ranges.
perimRanges	A vector of perimeter ranges.
rangeData	A vector of range data corresponding to *perimRanges*.

Throws

ccShapePerimDataDefs::BadParams

If any range values are detectably invalid for *shape description,* or if *perimRanges* and *rangeData* vector sizes are not the same, or if the *shape description* is infinite and not a primitive.

Note: The state of this object remains unchanged if it throws.

shape

```
ccShapePtrh_const shape() const;
```

Returns the shape description of this object.

perimRanges

```
const cmStd vector<ccPerimRange> &perimRanges() const;
```

Returns the perimeter range vector of this object.

rangeData

```
const cmStd vector<D> &rangeData() const;
```

Returns the range data vector of this object.

Macros

cmShapePerimDataClone

```
cmShapePerimDataClone(
  ccShapePerimDataTable<D>, ccShapePerimData<D>);
```

Overrides **ccShapePerimData::clone()**.

Typedefs

ccShapeMaskTable

```
typedef ccShapePerimDataTable<ccShapeMaskValue>
                                              ccShapeMaskTable;
```

ccShapeTolTable

```
typedef ccShapePerimDataTable<ccBoundaryTol>
                                                ccShapeTolTable;
```

ccShapeTolStats

```
#include <ch_cvl/shapetol.h>

class ccShapeTolStats: public ccShapeTol
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccShapeTolStats is a class for estimating local shape boundary tolerances by training on images that contain non-defective boundaries. **ccShapeTolStats** is used with the Boundary Inspector tool.

When you train the Boundary Inspector tool you must provide a **ccShapeTol** object that specifies the allowed tolerances. Cognex provides this **ccShapeTolStats** tool for obtaining these tolerances automatically from good training images through statistical calculations. You can also provide your own tolerances if you wish to obtain them another way.

Constructors/Destructors

ccShapeTolStats

```
ccShapeTolStats();

ccShapeTolStats(
  const ccShape &modelBoundary,
  const cc2XformBase &clientFromImage,
  const ccBoundaryTol &defaultTol =
     ccBoundaryTol(ccRange::EmptyRange(), ccRadian(0.0)),
  const ccShapeTolStatsParams &statsParams =
                                    ccShapeTolStatsParams(),
  const ccShapeTolStatsModelParams &modelParams =
                                ccShapeTolStatsModelParams(),
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);

ccShapeTolStats(
  const ccShape &modelBoundary,
  const ccShapeMask &shapeMask,
  const cc2XformBase &clientFromImage,
  const ccBoundaryTol &defaultTol =
       ccBoundaryTol(ccRange::EmptyRange(), ccRadian(0.0)),
```

```
  const ccShapeTolStatsParams &statsParams =
                                        ccShapeTolStatsParams(),
  const ccShapeTolStatsModelParams &modelParams =
                                    ccShapeTolStatsModelParams(),
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);

ccShapeTolStats(const ccShapeTolStats &that);

~ccShapeTolStats();
```

Constructs a **ccShapeTolStats** object using the given parameters.

Boundaries or boundary portions without a defined tangent angle are ignored by this tool.

A valid clipping region is a closed, convex **ccPolyline** with at least 3 vertices.

- `ccShapeTolStats();`

  Constructs a default **ccShapeTolStats** object.

- ```
  ccShapeTolStats(
    const ccShape &modelBoundary,
    const cc2XformBase &clientFromImage,
    const ccBoundaryTol &defaultTol =
       ccBoundaryTol(ccRange::EmptyRange(), ccRadian(0.0)),
    const ccShapeTolStatsParams &statsParams =
                                        ccShapeTolStatsParams(),
    const ccShapeTolStatsModelParams &modelParams =
                                    ccShapeTolStatsModelParams(),
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0);
  ```

  Constructs a **ccShapeTolStats** object from the parameters provided. Does not use a shape mask.

  Parameters

modelBoundary	The shape description containing the model boundary.
clientFromImage	The transform from image space to client space.
defaultTol	Use this default if there is not enough information to compute a statistical tolerance.
statsParams	The statistical training parameters.
modelParams	The statistical model parameters.
  ```

obj A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccShapePerimDataDefs::BadParams
If the shape description is infinite and not a primitive, or if the shape description is infinite and *clipRegion* is not a closed polyline with at least 3 vertices.

-
```
ccShapeTolStats(
  const ccShape &modelBoundary,
  const ccShapeMask &shapeMask,
  const cc2XformBase &clientFromImage,
  const ccBoundaryTol &defaultTol =
      ccBoundaryTol(ccRange::EmptyRange(), ccRadian(0.0)),
  const ccShapeTolStatsParams &statsParams =
                                      ccShapeTolStatsParams(),
  const ccShapeTolStatsModelParams &modelParams =
                                  ccShapeTolStatsModelParams(),
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);
```

Constructs a **ccShapeTolStats** object from the parameters provided, including a shape mask.

Parameters

modelBoundary The shape description containing the model boundary.

shapeMask A mask applied to the shape boundary that selects only the boundary parts you wish to train.

clientFromImage The transform from image space to client space.

defaultTol Use this default if there is not enough information to compute a statistical tolerance.

statsParams The statistical training parameters.

modelParams The statistical model parameters.

obj A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccShapePerimDataDefs::BadParams
If the shape description is infinite and not a primitive,
or if the shape description is infinite and *clipRegion* is not a closed polyline with at least 3 vertices,
or if *shapeMask* is detectably invalid for the model boundary.

- `ccShapeTolStats(const ccShapeTolStats &that);`

  Copy constructor; performs a deep copy.

- `~ccShapeTolStats();`

  Destructor.

Operators

operator== `virtual bool operator==(const ccShapeTol &that) const;`

Equality operator. Returns true if the internal data members of this object are exactly equal to the internal data members of *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator==

```
virtual bool operator=(const ccShapeTol &that) const;
```

Deep copy assignment operator. Make this object a copy of *that*.

Public Member Functions

modelParams

```
ccShapeTolStatsModelParams modelParams() const;

void modelParams(
  const ccShapeTolStatsModelParams &modelParams);
```

The statistical model parameters determine how the data collected by training will be interpreted to estimate boundary tolerances.

The default *modelParams* is **ccShapeTolStatsModelParams()**.

- ```
  ccShapeTolStatsModelParams modelParams() const;
  ```

  Returns the current statistical model parameters.

- ```
  void modelParams(
    const ccShapeTolStatsModelParams &modelParams);
  ```

  Sets new statistical model parameters.

  Parameters

  modelParams The new parameters.

statsParams

```
ccShapeTolStatsParams statsParams() const;
```

Returns the statistical tolerance estimation parameters which are used for clipping the model boundary and determining the capture range between the model boundary and the image contours. The default is **ccShapeTolStatsParams()**.

ccShapeTolStats

defaultTol

```
ccBoundaryTol defaultTol() const;

void defaultTol(const ccBoundaryTol &defaultTol);
```

The default tolerance is returned for perimeter positions for which the statistical training process does not have enough information for a tolerance estimate.

The default is **ccBoundaryTol(ccRange::EmptyRange(), ccRadian(0.0))**.

- `ccBoundaryTol defaultTol() const;`

  Returns the current default boundary tolerance.

- `void defaultTol(const ccBoundaryTol &defaultTol);`

  Sets a new default boundary tolerance.

  Parameters

  defaultTol The new default boundary tolerance.

addImage

```
void addImage(
  const ccPelBuffer_const<c_UInt8> &image,
  const cc2XformBase &pose,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);

void addImage(
  const ccPelBuffer_const<c_UInt8> &image,
  const cc2XformBase &pose,
  const ccFeatureletFilter &featureletFilter,
  ccDiagObject* obj = 0,
  c_UInt32 diagFlags = 0);
```

Finds the image contours in the given image, filters the found contours with *featureletFilter* (if one is provided), and matches the remaining contours with the model boundary transformed by *pose*. The results from the matching operation are used to update the statistics about the local boundary tolerances.

The scaling factors of the transform pose should be close to 1.0 for best tool performance.

- ```
  void addImage(
    const ccPelBuffer_const<c_UInt8> &image,
    const cc2XformBase &pose,
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0);
  ```

  Adds an image without featurelet filtering.

  Parameters

image	The image to add.
pose	The model space to client space transform.
obj	A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

  Throws

  ccShapePerimDataDefs::BadParams
  If *image* is not bound.

  Note: The state of this object remains unchanged if it throws.

- ```
  void addImage(
    const ccPelBuffer_const<c_UInt8> &image,
    const cc2XformBase &pose,
    const ccFeatureletFilter &featureletFilter,
    ccDiagObject* obj = 0,
    c_UInt32 diagFlags = 0);
  ```

  Adds an image using featurelet filtering.

  The *featureletFilter* is applied to the image contours after the contours are transformed into the coordinate system in which the model boundary is defined.

Parameters

image	The image to add.
pose	The model space to client space transform.
featureletFilter	The featurelet filter to be applied to the image.
obj	A container class object that holds diagnostic records created during the inspection. *obj* must point to a valid memory location or it must be NULL. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

Throws

ccShapePerimDataDefs::BadParams
If *image* is not bound.

Note: The state of this object remains unchanged if it throws.

get

```
virtual bool get(
  const ccPerimPos& perimPos,
  ccBoundaryTol &tol) const;
```

Returns the associated shape tolerance estimated at the perimeter position. The tolerance estimation depends on the statistical model parameters. If there is enough statistical data collected for the given perimeter position, this function returns true and the estimated boundary tolerance is assigned to *tol*. Otherwise, this function returns false and default tolerance is assigned to *tol*.

This function overrides the **ccShapeTol::get()**.

Parameters

perimPos	The perimeter position where the shape tolerance is obtained.
tol	Where the shape tolerance is returned.

Throws

ccShapePerimDataDefs::BadParams

If *perimPos* is detectably invalid for **shape()**.

modelBoundary

```
ccShapePtrh_const modelBoundary() const;
```

Returns the model boundary. The default model boundary is **cc2Point()**.

clientFromImage

```
cc2XformBasePtrh_const clientFromImage() const;
```

Returns the client-from-image transform. The relationship between the client and image space of the boundary model is specified by this transform. The default is the identity transform.

shapeMask

```
ccShapeMaskPtrh_const shapeMask() const;
```

Returns the shape mask. The portions of the model boundary masked by this shape mask are ignored by this tool.

The default **ccShapeTolStats** object does not include a shape mask.

Throws

ccShapePerimDataDefs::NotAvailable

If a shape mask was not provided when this object was created.

Macros

cmShapePerimDataClone

```
cmShapePerimDataClone(ccShapeTolStats, ccShapeTol);
```

Overrides the **ccShapePerimData::clone()**.

ccShapeTolStats

ccShapeTolStatsModelParams

```
#include <ch_cvl/shapetol.h>

class ccShapeTolStatsModelParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccShapeTolStatsModelParams is a container class that includes parameters to be used in interpreting the statistical data collected by the **ccShapeTolStats** class. You pass in a **ccShapeTolStatsModelParams** object when you instantiate a **ccShapeTolStats** object.

There are two modes for interpreting the statistical data:

Normal Distribution Model assumes the data collected by **ccShapeTolStats** can be modeled by normal distribution. This mode requires that you provide a valid confidence level so that the boundary tolerances can be calculated from the collected data.

Non-parametric Model assumes that the data collected by **ccShapeTolStats** cannot be modeled by any parametric distribution. Only the observed maximal deviations from the model boundary and the *slack tolerances* you provide are used to estimate the boundary tolerances.

Constructors/Destructors

ccShapeTolStatsModelParams

```
explicit ccShapeTolStatsModelParams(
  StatisticalModel statsM =
                ccShapeTolStatsModelParams::kDefaultModel);
```

Constructs a **ccShapeTolStatsModelParams** object with the given parameter.

Parameters

statsM The statistical model. Must be one of the **StatisticalModel** enums.

Enumerations

StatisticalModel `enum StatisticalModel`

Defines the modes used in interpreting the statistical data.

Value	Meaning
eNormalDistribution = 0	The data can be modeled by normal distribution
eNonParametric = 1	The data cannot be modeled by any parametric distribution
kDefaultModel = *eNormalDistribution*	The default mode

Operators

operator==

```
bool operator== (
  const ccShapeTolStatsModelParams &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator!=

```
bool operator!= (
  const ccShapeTolStatsModelParams &that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

statsModel

```
ccShapeTolStatsModelParams::StatisticalModel statsModel()
                                                    const;
```

Returns the statistical model specified at construction time.

confidenceLevel

```
double confidenceLevel() const;
void confidenceLevel(double confidenceLevel);
```

The confidence level is used as the statistical confidence level in the statistical decision process of estimating boundary tolerances. The confidence level is a number in the range 0.5 through 1.0.

The default confidence level value is 0.95.

Notes

This function is used in Normal Distribution mode only.

- `double confidenceLevel() const;`

  Returns the current confidence level.

- `void confidenceLevel(double confidenceLevel);`

  Sets a new confidence level.

  Parameters

  confidenceLevel The new confidence level.

  Throws

  ccShapePerimDataDefs::BadParams

  If *confidenceLevel* < 0.5 or > 1.0.

  Note: The state of this object remains unchanged if it throws.

slackTol

```
ccBoundaryTol slackTol() const;
void slackTol(const ccBoundaryTol &slackTol);
```

A small additional tolerance added to the observed maximum tolerance to establish the tolerance range used during inspections. This extends the range slightly so that inspection computations are not made on the range boundaries.

The default slack tolerance is **ccBoundaryTol(ccRange::EmptyRange, ccRadian(0.0))**.

Notes

This function is used in Non-parametric Model mode only.

- `ccBoundaryTol slackTol() const;`

  Returns the slack tolerance.

- `void slackTol(const ccBoundaryTol &slackTol);`

  Sets the slack tolerance.

  Parameters

  slackTol The new slack tolerance.

ccShapeTolStatsParams

```
#include <ch_cvl/shapetol.h>

class ccShapeTolStatsParams
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

This is a container class that includes parameters to be used by the **ccShapeTolStats** class for statistical training of the Boundary Inspector tool. There are two parameters: *captureRange* and *clipRegion*.

The capture range specifies a tolerance range where you expect to find contours in training images. All contours outside this range are ignored when computing statistical tolerances. The clip region allows you to specify where on the model statistical tolerances are required.

Constructors/Destructors

ccShapeTolStatsParams

```
explicit ccShapeTolStatsParams(
  const ccBoundaryTol &captureRange =
        ccBoundaryTol(ccRange(-1., 1.), ccRadian(ckPI_4)),
  const ccPolyline &clipRegion = ccPolyline(true));
```

Constructs a **ccShapeTolStatsParams** object with the given parameters.

To enable clipping *clipRegion* must be a closed, convex polyline. Otherwise no clipping is performed.

Parameters

captureRange The capture range. Image contours found outside the capture range are ignored.

clipRegion The clipping region. A closed convex polyline that encloses all portions of the model where statistical boundary tolerances are required.

Throws

ccShapePerimDataDefs::BadParams
If the clipping region is open.

Operators

operator==

```
bool operator== (const ccShapeTolStatsParams &that) const;
```

Equality test operator. Returns true if this object is exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

operator!=

```
bool operator!= (const ccShapeTolStatsParams &that) const;
```

Inequality test operator. Returns true if this object is not exactly equal to *that*. Returns false otherwise.

Parameters

that The object to compare with this object.

Public Member Functions

clipRegion

```
const ccPolyline& clipRegion() const;

void clipRegion(const ccPolyline &clipRegion);
```

Defines the clipping region. To perform clipping, the clipping region must be a closed convex polyline. When clipping is performed, the model boundary is clipped by this region and boundary tolerances are estimated only for this clipped portion of the model.

No clipping is performed unless a valid clipping region is provided here. A valid clipping region is a closed, convex **ccPolyline** with at least 3 vertices.

The default clipping region is a closed polyline with no vertices (no clipping).

The clipping region is defined in the model coordinates of the model boundary.

- `const ccPolyline& clipRegion() const;`

  Returns the current clipping region.

- `void clipRegion(const ccPolyline &clipRegion);`

  Sets a new clipping region.

  Parameters

  clipRegion The new clipping region.

Throws

ccShapePerimDataDefs::BadParams
If the clipping region is open.

captureRange

```
ccBoundaryTol captureRange() const;
void captureRange(const ccBoundaryTol &captureRange);
```

No valid image contours from training images are expected to be outside the capture range you specify. If there are such contours, they will be ignored in the statistical estimation of boundary tolerances.

The default capture range is **ccBoundaryTol(ccRange(-1.0, 1.0), ccRadian(ckPI_4))**.

- `ccBoundaryTol captureRange() const;`

  Returns the current capture range.

- `void captureRange(const ccBoundaryTol &captureRange);`

  Sets a new capture range.

  Parameters

  captureRange The new capture range.

ccShapeTolStatsParams

ccShapeTree

```
#include <ch_cvl/shaptree.h>

class ccShapeTree : public ccShape;
```

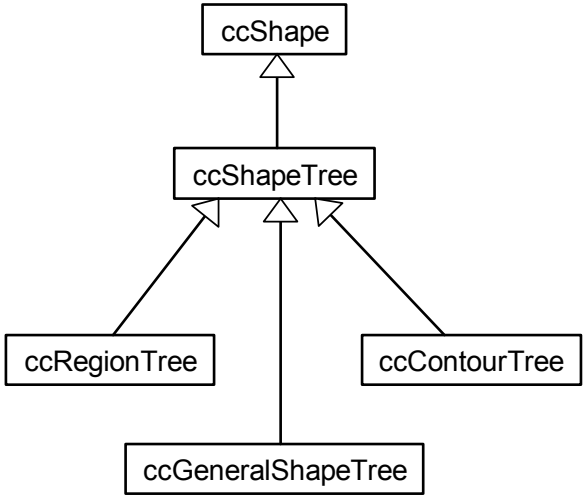
Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

The **ccShapeTree** class is the abstract base class for all hierarchical shapes. A **ccShapeTree** may have any number of **ccShape** children. Any of these children can themselves be **ccShapeTree**s, as **ccShapeTree** derives from **ccShape**.

Notes

A *primitive* shape is a **ccShape** that does not derive from **ccShapeTree**, such as a **ccLineSeg** or **ccCircle**.



The above figure shows the **ccShapeTree** class inheritance hierarchy.

Shared Children, Copying and Transforming Trees

Shape trees and classes derived from them are implemented with internal pointer handles to children. These pointer handles are **const** (that is, **ccShapePtrh_const**), so it is impossible to modify children objects through their parent, even if the parent is not **const**. It follows then that no object in a tree can be modified once it is placed into the tree.

Copying and cloning always use shallow copying of children. Thus, the original and the copy point to the same set of children objects; the copy is achieved by copying pointer handles. Trees cannot be modified in place. Instead, a tree modification is accomplished by creating a new tree using parts of the old one, possibly re-arranged and modified. Every modification of a tree node generates a new tree node. Nodes that don't change are simply copied or cloned. As they are shallow, copying and cloning are fast operations. This is the most efficient approach.

As an example, consider the following algorithm for mapping an entire tree by an affine transform. This function takes an original tree *T* and an affine transform *X*, and returns a new tree *T'* that is the transform of the original.

1. Recursively map the children of *T*, obtaining a set of new, transformed children.
2. Set *T'* to be a clone of *T*. This is a fast operation as it is involves a shallow copy. After this operation, *T'* and *T* share the same children.
3. Replace the children of *T'* with the set of transformed children computed in step 1. The children of *T* remain unchanged.
4. Return *T'*.

Copy Insertion versus Direct Insertion

Insertions of children into trees are typically done by *copy insertion*, that is, a copy of the object to be inserted is generated using **clone()**, and this copy is inserted into the tree. Since **clone()** is shallow, this is still a fast operation.

The alternative is *direct insertion*. You can insert a pointer handle directly into the list of children of a tree without copying anything but a single pointer handle. However, it is critical that objects added by direct insertion are never subsequently modified. Doing so violates the assumptions of the shape tree framework and can cause undefined behavior. For this reason, and because the efficiency gains are typically slight, Cognex strongly discourages the use of direct insertion.

There are two situations in which direct insertion may be substantially faster than copy insertion. The first is when the child to be inserted is a **ccShapeTree** with N children, where N is very large, for example a thousand or more. Direct insertion requires one pointer handle copy; copy insertion requires N pointer handle copies. The second case is when the child to be inserted is a very large primitive shape, such as a **ccPolyline** with thousands of vertices. Copy insertion copies this large object; direct insertion does not. If either of these cases exist in an inner loop, direct insertion might be worthwhile.

Finally, direct insertion is useful in the implementation of optimized classes derived from **ccShapeTree**, where correct usage can be assured.

The same distinction applies to replacing children in trees. The new child is either copied into the tree or directly placed into it by a single pointer handle assignment. The trade-offs and caveats are the same as for insertion.

Constructors/Destructors

ccShapeTree `ccShapeTree();`

Default constructor. Constructs a **ccShapeTree** containing no children.

Notes

Copies are shallow, that is, they are achieved by copying pointer handles. Hence, copy construction leads to sharing of children between different **ccShapeTree**s.

Only derived classes call this constructor, as **ccShapeTree** is an abstract base class and is never instantiated directly.

Operators

operator= `ccShapeTree& operator=(const ccShapeTree &rhs);`

Assign *rhs* to this **ccShapeTree**.

Parameters

rhs	The **ccShapeTree** to assign to this one.

Notes

Assignments are shallow, that is, they are achieved by copying pointer handles. Hence, assignment leads to sharing of children between different **ccShapeTree**s.

This method is protected to disallow assignment of shapes through references to the base class.

operator== `bool operator==(const ccShapeTree &rhs) const;`

Returns true if and only if this **ccShapeTree** is equal to *rhs*. Two **ccShapeTree**s are equal if their hierarchical structures are the same, and all of the corresponding primitive shapes are equal, under those primitives shapes' own **operator==()**.

Parameters

rhs	The other **ccShapeTree**.

operator!= `bool operator!=(const ccShapeTree &rhs) const;`

Returns true if and only if this **ccShapeTree** is not equal to *rhs*.

Parameters

rhs	The other **ccShapeTree**.

Public Member Functions

numChildren `c_Int32 numChildren() const;`

Returns the number of children of this **ccShapeTree**.

isLeaf `bool isLeaf() const;`

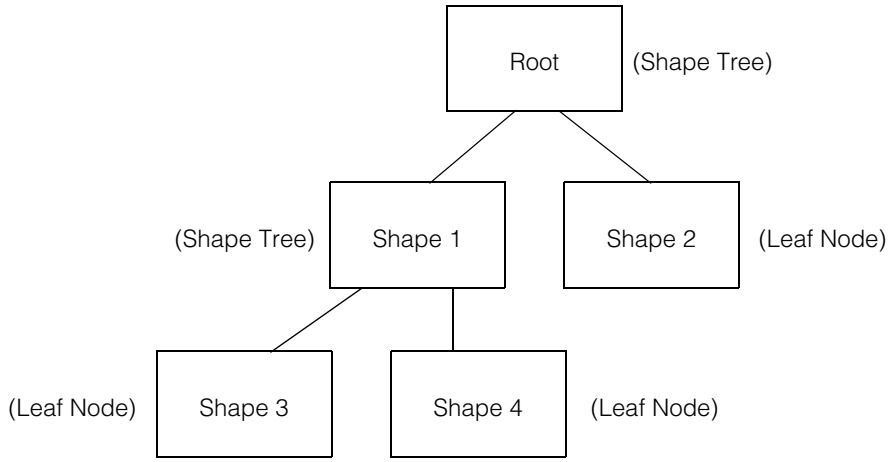
Returns true if and only if this **ccShapeTree** is a leaf node, that is, has no children.

size `c_Int32 size(bool primitivesOnly = false) const;`

Returns the number of descendants of this **ccShapeTree**, including the root node.

Parameters

primitivesOnly	If true, only primitive shapes are counted; otherwise all shapes in the hierarchy are counted. When *primitivesOnly* is true, only primitives that are leaf nodes are counted; primitives that are boundaries of **ccRegionTree**s are not counted. Therefore, this function always returns zero when invoked on a ccRegionTree with *primitivesOnly* set to true. This is the case because region trees have no primitive leaves.



The **ccShapeTree** structure shown above has four children. The **size()**, or number of nodes including the root, of this shape tree is five when the *primitivesOnly* flag is false; when *primitivesOnly* is true, the size is three. The **height()**, or longest path from the root to a leaf, of this shape tree is two.

height

```
c_Int32 height() const;
```

Returns the length of the longest path from the root of this **ccShapeTree** to a leaf. Leaf nodes have a height of zero.

child

```
const ccShape &child(c_Int32 idx) const;
```

Returns the indexed child of this **ccShapeTree**.

Parameters

idx The index.

Throws

ccShapesError::BadIndex

idx is less than zero or greater than or equal to **numChildren()**.

children

```
const cmStd vector<ccShapePtrh_const> &children() const;
```

Returns the children of this **ccShapeTree**. The returned object is a vector of pointer handles to the **ccShape** children.

insertChild

```
virtual void insertChild(c_Int32 idx,
  const ccShape &child);

virtual void insertChild(c_Int32 idx,
  const ccShapePtrh_const &child, bool direct = false);
```

- ```
  virtual void insertChild(c_Int32 idx,
    const ccShape &child);
  ```

  Inserts the **ccShape** referenced or pointed to by *child* as a new child of this **ccShapeTree**. The shape is inserted into the list of children so that after the insertion, it has index *idx*. Use an *idx* of 0 to insert the child at the front of the list, and use **numChildren()** to append it to the end of the list.

  Parameters

  idx — The index.

  child — The child to insert.

  Throws

  ccShapesError::BadIndex
  idx is less than zero or greater than **numChildren()** before insertion.

  ccShapesError::BadGeom
  Inserting the child would produce an invalid configuration of children. The default method never throws this exception.

- ```
  virtual void insertChild(c_Int32 idx,
    const ccShapePtrh_const &child, bool direct = false);
  ```

  Inserts the **ccShape** referenced or pointed to by *child* as a new child of this **ccShapeTree**. The shape is inserted into the list of children so that after the insertion, it has index *idx*. Use an *idx* of 0 to insert the child at the front of the list, and use **numChildren()** to append it to the end of the list.

  Parameters

  idx — The index.

  child — The child to insert.

  direct — If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

Notes

Inserting a child will change the indices of all existing children whose indices prior to the insertion are greater than or equal to *idx*.

A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw *ccShapesError::BadGeom* if the insertion would result in an invalid configuration of children.

The shape tree framework assumes that there are no cycles in the hierarchy, although it doesn't explicitly check this. Undefined behavior will result if *child* is an ancestor of this **ccShapeTree**.

Throws

ccShapesError::BadIndex
: *idx* is less than zero or greater than **numChildren()** before insertion.

ccShapesError::BadGeom
: Inserting the child would produce an invalid configuration of children. The default method never throws this exception.

insertChildren

```
virtual void insertChildren(c_Int32 idx,
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Inserts a set of **ccShape**s as children of this **ccShapeTree**. The shapes are inserted into the list of children contiguously so that after the insertion, they have indices *idx* through *idx* + **children.size()** - 1.

Parameters

idx	The index. Use an *idx* of zero to insert at the front of the list, use **numChildren()** to append at the end of the list.
children	The vector of children to insert.
direct	If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

Notes

Inserting children will change the indices of all existing children whose indices prior to the insertion are greater than or equal to idx.

A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw *ccShapesError::BadGeom* if the insertion would result in an invalid configuration of children. If such an exception is thrown, none of the children are inserted, even if some of them would be valid insertions.

The shape tree framework assumes that there are no cycles in the hierarchy, although it doesn't explicitly check this. Undefined behavior will result if any of the individual *children* is an ancestor of this **ccShapeTree**.

Throws

ccShapesError::BadIndex
: *idx* is less than zero or greater than **numChildren()** before insertion.

ccShapesError::BadGeom
: Inserting *children* would produce an invalid configuration of children. The default method never throws this exception.

---

addChild

```
virtual void addChild(const ccShape &child);

virtual void addChild(const ccShapePtrh_const &child,
  bool direct = false);
```

- `virtual void addChild(const ccShape &child);`

Convenience function for appending a shape to the end of this **ccShapeTree**'s list of children. Functionally equivalent to invoking **insertChild()** with *idx* equal to **numChildren()**.

Parameters

child The child to add.

Throws

ccShapesError::BadGeom
: Inserting the child would produce an invalid configuration of children. The default method never throws this exception.

- ```
  virtual void addChild(const ccShapePtrh_const &child,
    bool direct = false);
  ```

  Convenience function for appending a shape to the end of this **ccShapeTree**'s list of children. Functionally equivalent to invoking **insertChild()** with *idx* equal to **numChildren()**.

  Parameters

  child — The child to add.

  direct — If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

  Throws

  ccShapesError::BadGeom

  Inserting the child would produce an invalid configuration of children. The default method never throws this exception.

addChildren

```
virtual void addChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Convenience function for inserting a set of shapes at the end of this **ccShapeTree**'s list of children. Functionally equivalent to invoking **insertChildren()** with *idx* equal to **numChildren()**.

Parameters

children — The children to add.

direct — If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

Throws

ccShapesError::BadGeom

Inserting *children* would produce an invalid configuration of children. The default method never throws this exception.
```

replaceChild

```
virtual void replaceChild(c_Int32 idx,
 const ccShape &child);

virtual void replaceChild(c_Int32 idx,
 const ccShapePtrh_const &child, bool direct = false);
```

- ```
  virtual void replaceChild(c_Int32 idx,
   const ccShape &child);
  ```

  Replaces the indexed child of this **ccShapeTree** with the given shape.

  Parameters

  idx The index.

  child The child replacing the indexed child.

- ```
  virtual void replaceChild(c_Int32 idx,
   const ccShapePtrh_const &child, bool direct = false);
  ```

  Replaces the indexed child of this **ccShapeTree** with the given shape.

  Parameters

  idx The index.

  child The child replacing the indexed child.

  direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

  Notes

  A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw *ccShapesError::BadGeom* if the replacement would result in an invalid configuration of children.

  The shape tree framework assumes that there are no cycles in the hierarchy, although it doesn't explicitly check this. Undefined behavior will result if *child* is an ancestor of this **ccShapeTree**.

  Throws

  ccShapesError::BadIndex

  idx is less than zero or greater than or equal to **numChildren()**.

  ccShapesError::BadGeom

  Inserting the child would produce an invalid configuration of children. The default method never throws this exception.

replaceChildren

```
virtual void replaceChildren(
  const cmStd vector<ccShapePtrh_const> &children,
  bool direct = false);
```

Replace the children of this **ccShapeTree** with the given set of children.

Parameters

children The vector of children replacing the current children.

direct If false (the default), copy insertion is performed; if true, direct insertion is performed. Cognex recommends always using copy insertion unless there is a compelling reason not to use it. See *Copy Insertion versus Direct Insertion* on page 2976 for details.

Notes

A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw *ccShapesError::BadGeom* if the replacement would result in an invalid configuration of children. In this case, this **ccShapeTree** is left unchanged.

The shape tree framework assumes that there are no cycles in the hierarchy, although it doesn't explicitly check this. Undefined behavior will result if any of the individual children is an ancestor of this **ccShapeTree**.

Throws

ccShapesError::BadGeom

Replacing the children would produce an invalid configuration of children. The default method never throws this exception.

removeChild

```
virtual void removeChild(c_Int32 idx);
```

Removes the indexed child of this **ccShapeTree**.

Parameters

idx The index.

Notes

Removing a child will change the indices of all remaining children whose indices prior to the removal are greater than *idx*.

A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw ccShapesError::BadGeom if the removal would result in an invalid configuration of children.

Throws

ccShapesError::BadIndex

idx is less than zero or greater than or equal to **numChildren()** before removal.

ccShapesError::BadGeom

Removing the child would produce an invalid configuration of children. The default method never throws this exception.

removeChildren

```
virtual void removeChildren();
```

Removes all children of this **ccShapeTree**.

Notes

A derived class may override this method to place constraints on the types of children it may have. An overload of this method may throw *ccShapesError::BadGeom* if the derived type must have at least one child.

Throws

ccShapesError::BadGeom

Removing the children would produce an invalid configuration of children. The default method never throws this exception.

flatten

```
ccShapeTreePtrh flatten(bool preserveContours = false)
  const;
```

Computes and returns a flattened version of this shape tree. The flattened tree contains all the primitive shapes of the original tree, including the primitives defining the boundaries of region trees. These primitives are all arranged as direct children of the root node, which is the only shape tree node in the flattened tree unless the *preserveContours* argument is true.

If this tree is a contour tree, then the returned tree is also a contour tree. Otherwise, the returned tree is a general shape tree.

Parameters

preserveContours

Whether contours should be preserved when flattening this shape tree.

Notes

If *preserveContours* is true, the connectivity of shapes within contour tree descendants of this shape is preserved when the tree is flattened. That is, if C is a contour tree that is a proper descendant of this shape tree and C's parent is not a contour tree, then the returned tree will contain a flattened version of C as a child. The same would apply if C were the boundary of a region tree. In either case, the returned tree will not be completely flat, as it may contain contour tree children.

However, such children will have only primitives as their own children. In other words, the returned tree can have a height of at most two. The preserve contours mode is useful when a tree should be flattened to the fullest extent possible without losing connectivity information along the contours.

The order of the primitives in the flattened tree is the order in which they are encountered in a standard depth-first, pre-order traversal of this tree. The distinction between pre-, and post-order traversal is significant only when there are primitives as internal nodes, as is the case, for example, when region trees are present.

isEmpty `virtual bool isEmpty() const;`

Returns true if and only if all primitive shapes in the hierarchy are empty.

Notes

A **ccContourTree** or **ccGeneralShapeTree** is empty if and only if it contains no children, or all of its children are empty. A **ccRegionTree** can never be empty, because it must contain a boundary that is a region and region shapes are never empty.

See **ccShape::isEmpty()** for more information.

hasTangent `virtual bool hasTangent() const;`

Returns true if and only if any of the primitive shapes in the hierarchy has a tangent. See **ccShape::hasTangent()** for more information.

isDecomposed `virtual bool isDecomposed() const;`

Returns true if all primitive shapes in the hierarchy are already decomposed. See **ccShape::isDecomposed()** for more information.

boundingBox `virtual ccRect boundingBox() const;`

Returns the enclosing rectangle of this **ccShapeTree**.

Notes

The enclosing rectangle of this **ccShapeTree** is the smallest rectangle that encloses all of its component primitives.

See **ccShape::boundingBox()** for more information.

perimeter

```
virtual double perimeter() const;
```

Returns the perimeter of this shape tree.

See **ccShape::perimeter()** for more information.

nearestPerimPos

```
virtual ccPerimPos nearestPerimPos(const ccShapeInfo& info,
  const cc2Vect& point) const;
```

Returns the nearest perimeter position on this shape tree to the given point, as determined by **nearestPoint()**.

Parameters

info	Shape information for this shape tree.
point	The point.

See **ccShape::nearestPerimPos()** for more information.

mapShape

```
virtual ccShapePtrh mapShape(const cc2Xform& X) const;
```

Returns this ccShapeTree mapped by X.

Parameters

X	The transformation object.

Notes

Generates a new **ccShapeTree** that is an hierarchical refinement of the original. That is, the original hierarchy is replicated up to the leaf nodes. All primitive shapes in the original are mapped by *X*, and this mapping may convert the primitives themselves to subhierarchies.

decompose

```
virtual ccShapePtrh decompose() const;
```

Returns a new shape tree describing the same geometry as this **ccShapeTree**, but using only a subset of shape primitives. See **ccShapeTree::decompose()** for more information.

ccSharpnessParams

```
#include <ch_cvl/imgsharp.h>

class ccSharpnessParams
```

This class encapsulates parameters passed to the **cfImageSharpness()** global function that specify how the function determines a sharpness score for an image.

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

Constructors/Destructors

ccSharpnessParams

```
ccSharpnessParams();
```

Default constructor for sharpness parameters. The following defaults are set:

Parameter	Default value
algorithm	*eAutoCorrelation*
sx	1
sy	1
freqBand	0.25 through 0.45
noiseLevel	0.0
lowPassSmoothing	0

Enumerations

Algorithm `enum Algorithm`

This enumeration defines the sharpness algorithms.

Value	Meaning	Parameter used
eAutoCorrelation = 1	Autocorrelation algorithm	*noiseLevel*
eAbsDiff	Absolute difference algorithm	*sx, sy*
eEdgeGradient	Edge gradient algorithm **Note**: This algorithm is deprecated	
eBandPass	Frequency band response algorithm	*freqBand*
eGradientEnergy[1]	Gradient energy	*lowPassSmoothing*

(1) Most applications achieve the best results using this algorithm.

Public Member Functions

algorithm

```
ccSharpnessParams::Algorithm algorithm() const;
void algorithm(ccSharpnessParams::Algorithm algorithm);
```

Specifies the algorithm to be used by the **cfImageSharpness()** global function.

- `ccSharpnessParams::Algorithm algorithm() const;`

  Returns the current algorithm parameter.

- `void algorithm(ccSharpnessParams::Algorithm algorithm);`

  Sets a new algorithm parameter.

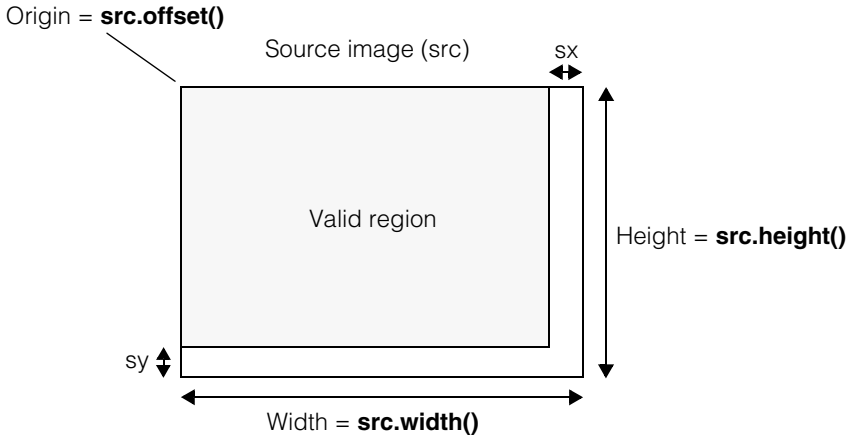
  Parameters

  algorithm The new algorithm.

sx

```
c_UInt32 sx() const;
void sx(c_UInt32 sx);
```

sx and **sy** specify the x and y separation of image samples (in pixels) used by **cfImageSharpness()** to determine image sharpness when the *eAbsDiff* mode is used. See the following diagram where *src* is the source image.



Notes

sx and **sy** are used only with the algorithm *eAbsDiff*.

- `c_UInt32 sx() const;`

  Returns the current value of **sx**.

- `void sx(c_UInt32 sx);`

  Sets a new **sx** value.

  Parameters

  sx The new **sx** value.

sy

```
c_UInt32 sy() const;
void sy(c_UInt32 sy);
```

sx and **sy** specify the x and y separation of image samples (in pixels) used by **cfImageSharpness()** to determine image sharpness when the *eAbsDiff* mode is used.

Notes

sx and **sy** are used only with the algorithm *eAbsDiff*.

- `c_UInt32 sy() const;`

  Returns the current value of **sy**.

- `void sy(c_UInt32 sy);`

  Sets a new **sy** value.

  Parameters

  sy The new **sy** value.

---

freqBand

```
const ccRange& freqBand() const;
void freqBand(const ccRange& freqBand);
```

Image grey scale patterns can be described in terms of frequency where sharp edges in the patterns represent high frequencies, and blurred edges represent a low frequencies. The total frequency range is expressed as 0 through 0.5 (lowest frequency to highest).

When the algorithm is *eBandPass*, this parameter specifies a frequency band used by **cfImageSharpness()** to determine image sharpness. **cfImageSharpness()** uses only frequencies occurring in this band and reports the average of these found frequencies as the image sharpness score.

The default frequency range is 0.25 through 0.45. All images contain some noise which has a very high frequency. Exclude the top of the frequency range (near 0.5) as we have done with the defaults to exclude noise from the sharpness calculation.

Notes

This parameter is used only when the algorithm is *eBandPass*.

- `const ccRange& freqBand() const;`

  Returns the current frequency band.

- `void freqBand(const ccRange& freqBand);`

  Sets a new frequency band.

  Parameters

  freqBand The new frequency band.

Throws

ccImageSharpnessDefs::BadParams
If the low cutoff frequency is less than zero, or if the high cutoff frequency is greater than 0.5.

noiseLevel

```
double noiseLevel() const;

void noiseLevel( double nLevel );
```

Get/Set the strength of the noise present in the image. As the focus is adjusted the image contrast can change. When the contrast is very low sensor noise can dominate, which can result in artificially high sharpness scores. This parameter makes the *eAutoCorrelation* sharpness function more robust to this effect. Ideally you should set this to a value below the contrast of the image at about the sensor noise level. The default is 0.

- `double noiseLevel() const;`

  Returns the current image noise level setting.

- `void noiseLevel( double nLevel );`

  Sets the image noise level.

  Parameters

  nLevel The new image noise level.

  Throws

  ccImageSharpnessDefs::BadParams
  If *nLevel* is < 0.0.

  Notes

  This parameter is used only by algorithm *eAutoCorrelation*

lowPassSmoothing

```
c_Int32 lowPassSmoothing() const;

void lowPassSmoothing(c_Int32 lowPassSmoothing);
```

Get/Set the low-pass smoothing value. The image is processed using Gaussian smoothing before sharpness is measured. The default value is 0 (no smoothing).

- `c_Int32 lowPassSmoothing() const;`

  Returns the current low-pass smoothing value setting.

- `void lowPassSmoothing(c_Int32 lowPassSmoothing);`

  Sets the low-pass smoothing value.

  Parameters

  lowPassSmoothing
  The new low-pass smoothing value.

  Throws

  ccImageSharpnessDefs::BadParams
  If *lowPassSmoothing* is < 0.

  Notes

  For most images, use a low-pass smoothing value of 0 (no smoothing).

  This parameter is used only by algorithm *eGradientEnergy*.

ccStatistics

```
#include <ch_cvl/stats.h>

class ccStatistics;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a population of samples of type **double**. The class include members that allow you to obtain basic statistical measures of the population.

Constructors/Destructors

ccStatistics

```
ccStatistics();

ccStatistics(const cmStd vector<double>& data);
```

- `ccStatistics();`

  Constructs an object with no samples.

- `ccStatistics(const cmStd vector<double>& data);`

  Constructs an object with the side population of samples.

  Parameters

  data The population.

Public Member Functions

reset

```
void reset();
```

Removes all samples from this object.

clear

```
void clear();
```

Removes all samples from this object.

add

```
void add(double val);
void add(const cmStd vector<double> &vals);
void add(const double *vals, c_Int32 numVals);
```

- `void add(double val);`

  Adds a new value to the population. Calling this function increases **n()** by 1.

  Parameters

val	The value to add.

- `void add(const cmStd vector<double> &vals);`

  Adds a vector of new values to the population. Calling this function increases **n()** by *vals.size()*.

  Parameters

vals	The values to add.

- `void add(const double *vals, c_Int32 numVals);`

  Adds the specified range of values from the supplied vector to the population. The values *vals[0]* through *vals[numVals-1]* are added. Calling this function increases **n()** by *numVals*.

  Parameters

vals	The values.
numVals	How many elements of *vals* to add.

n

```
c_Int32 n() const;
```

The number of samples in this population.

mean

```
double mean() const;
```

Returns the mean value of the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

statMin

```
double statMin() const;
```

Returns the minimum value in the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

statMax

```
double statMax() const;
```

Returns the maximum value in the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

sum

```
double sum() const;
```

Returns the sum of the values in the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

variance

```
double variance() const;
```

Returns the variance of the values in the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

stdDev

```
double stdDev() const;
```

Returns the standard deviation of the values in the population. **n()** must be greater than 0.

Throws
ccStatistics::NoSamples
The population has 0 samples.

rms `double rms() const;`

Returns the square root of the mean of the squares of the values in the population. **n()** must be greater than 0.

Throws

ccStatistics::NoSamples
The population has 0 samples.

Operators

operator+
```
ccStatistics operator+(const ccStatistics& lhs,
   const ccStatistics& rhs);
```

Adds the two populations and returns the result as a new **ccStatistics** object.

Parameters

lhs The first object to add.

rhs The second object to add.

operator+= `ccStatistics& operator+=(const ccStatistics& s);`

Adds the supplied population to this one.

Parameters

s The population to add.

operator+= `ccStatistics& operator+=(double d);`

Adds the supplied value to this population.

Parameters

d The value to add.

operator== `bool operator==(const ccStatistics& that) const;`

Returns true if the supplied **ccStatistics** object has the same statistical values as this one, false otherwise.

Notes

While the equality operator does not specifically require that the orders of the values in the two populations be the same, as a practical matter if the populations include floating point values, this operator will return true only if the orders of values in the two populations are the same.

Parameters

that	The object to compare to this one.

ccStatistics

ccStdGreyAcqFifo

```
#include <ch_cvl/acq.h>

class ccStdGreyAcqFifo : public ccGreyAcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This is a concrete class that describes acquisition FIFO queues for a standard grey-scale camera such as the Sony XC-75.

Notes

There is no need for you to create objects of this type in your program. When you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()** it returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccStdGreyAcqFifo

```
ccStdGreyAcqFifo(const ccVideoFormat& vf,
  ccFrameGrabber& fg);

~ccStdGreyAcqFifo();
```

- ```
  ccStdGreyAcqFifo(const ccVideoFormat& vf,
    ccFrameGrabber& fg);
  ```

  Creates an idle acquisition FIFO suitable for capturing grey-scale images of the format *vf* from the frame grabber *fg*.

  Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.
  ```

- `~ccStdGreyAcqFifo();`

  Destructor.

Public Member Functions

properties `virtual ccAnalogAcqProps& properties();`

Returns a reference to the FIFO's properties object.

videoFormat `virtual const ccVideoFormat& videoFormat() const;`

Returns the video format for which this FIFO was constructed.

frameGrabber `virtual ccFrameGrabber& frameGrabber() const;`

Returns the frame grabber for which this FIFO was constructed.

ccStdGreyVideoFormat

```
#include <ch_cvl/vidfmt.h>

class ccStdGreyVideoFormat : public ccGreyVideoFormat;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This is a concrete class that generates acquisition FIFOs of type **ccStdGreyAcqFifo** used by grey-scale cameras.

The acquisition software creates a single object of class **ccStdVideoFormat** (see page 3009) for each camera type and image size. You use these video format objects to create an acquisition FIFO that is appropriate for the camera and frame grabber that your application uses.

To get a video format, you use **ccStdVideoFormat::getFormat()** described on page 3012.

Notes

There is no need for you to use this class directly in your code. Use the **ccStdVideoFormat** class for all of your format programming.

Constructors/Destructors

The acquisition software creates one object for each supported video format. Use the functions listed at the end of the description of **ccStdVideoFormat** on page 3009 to get a reference to the appropriate video format

Public Member Functions

newAcqFifo

```
ccStdGreyAcqFifo* newAcqFifo(ccFrameGrabber& fg) const;
```

Creates and returns a new acquisition FIFO suitable for acquiring images of this format from the frame grabber *fg*.

Parameters

fg	The frame grabber to use to acquire images.

Throws

ccVideoFormat::NotSupported
The specified frame grabber does not support this video format.

ccStdRGB16AcqFifo

```
#include <ch_cvl/acq.h>

class ccStdRGB16AcqFifo : public ccRGB16AcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This is a concrete class that describe acquisition FIFO queues for a standard color camera such as the Sony XC-003.

Notes

There is no need for you to create objects of this type in your program. When you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()** it returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccStdRGB16AcqFifo

```
ccStdRGB16AcqFifo (const ccVideoFormat& vf,
  ccFrameGrabber& fg);

~ccStdRGB16AcqFifo();
```

- ```
  ccStdRGB16AcqFifo (const ccVideoFormat& vf,
    ccFrameGrabber& fg);
  ```

  Creates an idle acquisition FIFO suitable for capturing grey-scale images of the format *vf* from the frame grabber *fg*.

  Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.
  ```

- `~ccStdRGB16AcqFifo();`

  Destructor.

Public Member Functions

properties `ccAnalogAcqProps& properties();`

Returns a reference to the FIFO's properties object.

videoFormat `virtual const ccVideoFormat& videoFormat() const;`

Returns the video format for which this FIFO was constructed.

frameGrabber `virtual ccFrameGrabber& frameGrabber() const;`

Returns the frame grabber for which this FIFO was constructed.

ccStdRGB32AcqFifo

```
#include <ch_cvl/acq.h>

class ccStdRGB32AcqFifo : public ccRGB32AcqFifo;
```

Class Properties

Copyable	No
Derivable	Cognex-supplied classes only
Archiveable	No

This is a concrete class that describe acquisition FIFO queues for a standard color camera such as the Sony XC-003.

Notes

There is no need for you to create objects of this type in your program. When you create an acquisition FIFO with **ccStdVideoFormat::newAcqFifoEx()** it returns a **ccAcqFifo** base class pointer which you use to access **ccAcqFifo** methods to acquire images.

Constructors/Destructors

ccStdRGB32AcqFifo

```
ccStdRGB32AcqFifo (const ccVideoFormat& vf,
  ccFrameGrabber& fg);

~ccStdRGB32AcqFifo();
```

- ```
  ccStdRGB32AcqFifo (const ccVideoFormat& vf,
    ccFrameGrabber& fg);
  ```

  Creates an idle acquisition FIFO suitable for capturing grey-scale images of the format *vf* from the frame grabber *fg*.

  Parameters

vf	The video format of the images to be acquired.
fg	The frame grabber to use to acquire images.
  ```

- `~ccStdRGB32AcqFifo();`

  Destructor.

Public Member Functions

properties `ccAnalogAcqProps& properties();`

Returns a reference to the FIFO's properties object.

videoFormat `virtual const ccVideoFormat& videoFormat() const;`

Returns the video format for which this FIFO was constructed.

frameGrabber `virtual ccFrameGrabber& frameGrabber() const;`

Returns the frame grabber for which this FIFO was constructed.

ccStdVideoFormat

```
#include <ch_cvl/vidfmt.h>

class ccStdVideoFormat: public ccStdGreyVideoFormat;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This is a concrete class that the acquisition software uses to describe operations on video formats. The acquisition software defines a video format as the pairing of a particular camera type with a particular image size.

The acquisition software creates a single object of type **ccStdVideoFormat** for each camera type and image size. You use these video format objects to create an acquisition FIFO that is appropriate for the camera and frame grabber that your application uses. To get a video format, you call **ccStdVideoFormat::getFormat()** described in this reference page.

Video formats are either built in to the CVL code or are available though Camera Configuration Files (CCFs). Some frame grabbers can use only built-in video formats, while others use CCF-based video formats. For CVL versions prior to 6.0, CCFs are located in the directory specified by the environment variable *COGNEX_CCF_PATH* (usually *C:\vision\ccf)*. For CVL 6.0 and later versions, CCFs are located in *%VISION_ROOT%\bin\win32\cvl*.

Frame grabber/CVM combinations that use CCFs, such as the MVS-8120/CVM1 and the MVS-8120/CVM6 can also use the built-in formats in a compatibility mode. For example, if you specify the video format “Sony XC75 640x480”, CVL will actually use the corresponding CCF for the sync model you specify. If you are using a frame grabber/CVM combination that supports CCFs, use the CCF formats in preference to the built-in formats.

The *CVL Supported Cameras* HTML file lists the camera formats available for all of the frame grabbers supported in the current release. CCF-based formats have names that end in “CCF,” while built-in formats do not. You can also use the function **ccVideoFormat::filterList()** on page 3403 to determine which video formats are available for a given frame grabber.

Constructors/Destructors

ccStdVideoFormat

```
~ccStdVideoFormat();
```

Destructor.

The acquisition software creates one object for each supported video format. Use the functions listed at the end of this class to get a reference to the appropriate video format.

Enumerations

ceRGB16Pack

```
typedef enum { ckRGB16 = 16 } ceRGB16Pack;
```

The single constant for this enumeration, *ckRGB16*, is used as a parameter to **newAcqFifo()** to specify that it should return a 16-bit RGB acquisition FIFO.

ceRGB32Pack

```
typedef enum { ckRGB32 = 32 } ceRGB32Pack;
```

The single constant for this enumeration, *ckRGB32*, is used as a parameter to **newAcqFifo()** to specify that it should return a 32-bit RGB acquisition FIFO.

Public Member Functions

newAcqFifo

```
ccStdGreyAcqFifo* newAcqFifo(ccFrameGrabber& fg) const;

ccStdRGB16AcqFifo* newAcqFifo(ccFrameGrabber& fg,
  ceRGB16Pack packing) const;

ccStdRGB32AcqFifo* newAcqFifo(ccFrameGrabber& fg,
  ceRGB32Pack packing) const;
```

- `ccStdGreyAcqFifo* newAcqFifo(ccFrameGrabber& fg) const;`

  Creates and returns a new acquisition FIFO suitable for acquiring grey-scale from the frame grabber *fg*.

  Parameters

  fg — The frame grabber to use to acquire images.

  Throws

  ccVideoFormat::NotSupported — The specified frame grabber does not support this video format.

- ```
  ccStdRGB16AcqFifo* newAcqFifo(ccFrameGrabber& fg,
    ceRGB16Pack packing) const;
  ```

  Creates and returns a new acquisition FIFO suitable for acquiring 16-bit RGB images from the frame grabber *fg*.

  Parameters

  fg — The frame grabber to use to acquire images.

  packing — The packing scheme of each pixel. For a 16-bit RGB acquisition FIFO, this parameter must be

  ccStdVideoFormat::ckRGB16

  Throws

  ccVideoFormat::NotSupported
  The specified frame grabber does not support this video format.

- ```
  ccStdRGB32AcqFifo* newAcqFifo(ccFrameGrabber& fg,
    ceRGB32Pack packing) const;
  ```

  Creates and returns a new acquisition FIFO suitable for acquiring 32-bit RGB images from the frame grabber *fg*.

  Parameters

  fg — The frame grabber to use to acquire images.

  packing — The packing scheme of each pixel. For a 32-bit RGB acquisition FIFO, this parameter must be

  ccStdVideoFormat::ckRGB32

  Throws

  ccVideoFormat::NotSupported
  The specified frame grabber does not support this video format.

newAcqFifoEx

```
ccAcqFifo* newAcqFifoEx(
  ccFrameGrabber& fg,
  ceImageFormat fmt = ceImageFormat_Unknown) const;
```

Create and return a **ccAcqFifo**. This is the recommended way to create a **ccAcqFifo**.

Parameters

fg — The frame grabber to use to acquire images.

fmt — The image format.

Notes

The image format of a CCF is the format of a camera, while the image format of a **ccAcqFifo** is the format of images acquired into system memory. Use *fmt* = *ceImageFormat_Unknown*, when you intend to acquire images in the native format that the camera outputs. There is no format conversion of any kind during image acquisition.

fullList

```
static const cmStd vector<const ccStdVideoFormat*>&
  fullList();
```

Returns a vector of pointers to all supported **ccVideoFormat** objects.

filterList

```
static cmStd vector<const ccStdVideoFormat*> filterList(
  const cmStd vector<const ccStdVideoFormat*>& list,
  ccFrameGrabber& fg);
```

Returns a vector of pointers to **ccVideoFormat** objects supported by the given **ccVideoFormat** within the given vector of pointers to **ccVideoFormat** objects.

Parameters

list	List of **ccVideoFormat** objects.
fg	The specified frame grabber.

Example:

```
cmStd vector<const ccVideoFormat*> myVidFmts =
  ccVideoFormat::filterList(ccVideoFormat::fullList(), fg);
```

Where *fg* is a particular **ccFrameGrabber**. The function returns the complete list of **ccVideoFormat** objects which are support on frame grabber *fg*.

Static Functions

getFormat

```
static const ccStdVideoFormat& getFormat(
  ccCvlString& name);
```

If the named format is one of the built-in camera formats, or is available through a Camera Configuration File (CCF), this function returns the appropriate **ccStdVideoFormat** object.

Parameters

name	The name of the video format. Must match exactly the string returned by **ccVideoFormat::name()** for a particular video format.

Example

This is how you would get a video format for a Sony XC75 camera:

```
const ccStdVideoFormat& fmt =
        ccStdVideoFormat::getFormat(cmT("Sony XC75 640x480"))
```

Notes

The function **ccVideoFormat::fullList()** on page 3403 returns a vector of pointers to video format objects for all of the supported video formats. The function **ccVideoFormat::filterList()** returns a vector of pointers to all of the video formats supported by a particular frame grabber. Not all video formats are supported on all Cognex frame grabbers. Please consult the *Release Notes* of the specific CVL release you are using for a complete list of supported video formats.

Before CVL 5.5, Cognex recommended using the functions described in the next section to obtain video formats. While these functions are retained for backward compatibility, their use is no longer recommended.

Some cameras or frame grabbers are unable to supply images with the exact dimensions specified in the video format. To determine the actual image size, use the functions **ccPelBuffer::height()** and **ccPelBuffer:width()**. The functions **ccVideoFormat::height()** and **ccVideoFormat::width()** return the nominal size of the image as described in the format names, not the actual image sizes.

Throws

ccVideoFormat::NotFound

name does not match a known format name.

Functions

These functions are retained for compatibility with programs written with earlier versions of CVL. Instead of using these functions to obtain a video format object, you should use **ccStdVideoFormat::getFormat()**.

Each of these functions returns a unique **ccStdVideoFormat** object for the specified video format.

Not all video formats are supported on all Cognex frame grabbers. Please consult the *Release Notes* of the specific CVL release you are using for a complete list of supported video formats.

cfCvc1000_640x480

```
const ccStdVideoFormat& cfCvc1000_640x480();
```

Returns a video format object for a Cognex CVC-1000 high-speed analog camera with a full resolution image size of 640x480.

ccStdVideoFormat

cfKpf100_1280x1024

```
const ccStdVideoFormat& cfKpf100_1280x1024();
```

Returns a video format object for a Hitachi KP-F100 digital camera with a full resolution image size of 1280x1024.

cfLSFth_2048

```
const ccStdVideoFormat& cfLSFth_2048();
```

Returns a video format object for an NED FTH 20 MHz analog line scan camera.

cfLSScd_2048

```
const ccStdVideoFormat& cfLSScd_2048();
```

Returns a video format object for a Mitsubishi SCD-2048 20 MHz analog line scan camera.

cfLSTest_2048()

```
const ccStdVideoFormat& cfLSTest_2048();
```

Returns a video format for a virtual line scan camera used for troubleshooting. Images acquired through this camera consist of eight 256-pixel-wide light-to-dark gradients.

cfTm9700_640x480

```
const ccStdVideoFormat& cfTm9700_640x480();
```

Returns a video format object for a Pulnix TM-9701 RS-170 rapid reset camera with a full resolution image size of 640x480.

cfIk542_640x480

```
const ccStdVideoFormat& cfIk542_640x480();
```

Returns a video format object for a Toshiba IK-542 RS-170 rapid reset camera with a full resolution image size of 640x480.

cfIkm41ma_320x240

```
const ccStdVideoFormat& cfIkm41ma_320x240();
```

Returns a video format object for a Toshiba IK-M41MA RS-170 rapid reset camera with a half resolution image size of 320x240.

cfTm6cn_760x574

```
const ccStdVideoFormat& cfTm6cn_760x574();
```

Returns a video format object for a Pulnix TM-6CN CCIR camera with a full resolution image size of 760x574. The TM-6CN provides synchronization signals to the frame grabber.

cfTm7ex_640x480

```
const ccStdVideoFormat& cfTm7ex_640x480();
```

Returns a video format object for a Pulnix TM-7EX RS-170 camera with a full resolution image size of 640x480.

cfTm7ex_320x240

```
const ccStdVideoFormat& cfTm7ex_320x240();
```

Returns a video format object for a Pulnix TM-7EX RS-170 camera with a half resolution image size of 320x240.

cfTm7ex_640x240

```
const ccStdVideoFormat& cfTm7ex_640x240();
```

Returns a video format object for a Pulnix TM-7EX RS-170 camera with a single field image size of 640x240.

cfXc55_640x480 `const ccStdVideoFormat& cfXc55_640x480();`

Returns a video format object for a Sony XC-55 RS-170 rapid reset camera with a full resolution image size of 640x480.

cfXc75_640x480 `const ccStdVideoFormat& cfXc75_640x480();`

Returns a video format object for a Sony XC-75 RS-170 camera with a full resolution image size of 640x480.

cfXc75_640x240 `const ccStdVideoFormat& cfXc75_640x240();`

Returns a video format object for a Sony XC-75 RS-170 camera with a single field image size of 640x240.

cfXc75_320x240 `const ccStdVideoFormat& cfXc75_320x240();`

Returns a video format object for a Sony XC-75 RS-170 camera with a half resolution image size of 320x240.

cfXc75rr_320x240

```
const ccStdVideoFormat& cfXc75rr_320x240();
```

Returns a video format object for a Sony XC-75 RR RS-170 rapid reset camera with a half resolution image size of 320x240.

cfXc75cerr_380x287

```
const ccStdVideoFormat& cfXc75cerr_380x287();
```

Returns a video format object for a Sony XC-75CE RR CCIR rapid reset camera with a half resolution image size of 380x287.

cfXc75ce_760x574

```
const ccStdVideoFormat& cfXc75ce_760x574();
```

Returns a video format object for a Sony XC-75CE CCIR camera with a full resolution image size of 760x574.

cfXc75ce_760x287

```
const ccStdVideoFormat& cfXc75ce_760x287();
```

Returns a video format object for a Sony XC-75CE CCIR camera with a single field image size of 760x287.

cfXc75ce_380x287

```
const ccStdVideoFormat& cfXc75ce_380x287();
```

Returns a video format object for a Sony XC-75CE CCIR camera with a half resolution image size of 380x287.

cfXc7500_640x480

```
const ccStdVideoFormat& cfXc7500_640x480();
```

Returns a video format object for a Sony XC-7500 dual tap rapid reset RS-170 camera with a full resolution image size of 640x480.

cfXc003_640x480

```
const ccStdVideoFormat& cfXc003_640x480();
```

Returns a video format object for a Sony XC-003 NTSC color camera with a full resolution image size of 640x480.

cfXc003p_760x574

```
const ccStdVideoFormat& cfXc003p_760x574();
```

Returns a video format object for a Sony XC-003P PAL color camera with a full resolution image size of 760x574.

cfDLSScd_2048x2048

```
const ccStdVideoFormat& cfDLSScd_2048x2048();
```

Returns a video format object for a Mitsubishi SCD-2048 40 MHz digital line scan camera with an image size up to 2048 pixels wide and up to 2048 lines high. The default image size is 2048x2048.

Use the ROI property to set the exact dimensions of the image. (See **ccRoiProp** on page 2763.)

cfDLSScd_1024x4096

```
const ccStdVideoFormat& cfDLSScd_1024x4096();
```

Returns a video format object for a Mitsubishi SCD-1024 40 MHz digital line scan camera with an image size up to 1024 pixels wide and up to 4096 lines high. The default image size is 1024x4096.

Use the ROI property to set the exact dimensions of the image. (See **ccRoiProp** on page 2763.)

cfDLSSpy_2048x2048

```
const ccStdVideoFormat& cfDLSSpy_2048x2048();
```

Returns a video format object for a Dalsa Spyder 40 MHz digital line scan camera with an image size up to 2048 pixels wide and up to 2048 lines high. The default image size is 2048x2048.

Use the ROI property to set the exact dimensions of the image. (See **ccRoiProp** on page 2763.)

cfDLSSpy_1024x4096

```
const ccStdVideoFormat& cfDLSSpy_1024x4096();
```

Returns a video format object for a Dalsa Spyder 40 MHz digital line scan camera with an image size up to 1024 pixels wide and up to 4096 lines high. The default image size is 1024x4096.

Use the ROI property to set the exact dimensions of the image. (See **ccRoiProp** on page 2763.)

ccStdVideoFormat

ccStrobeDelayProp

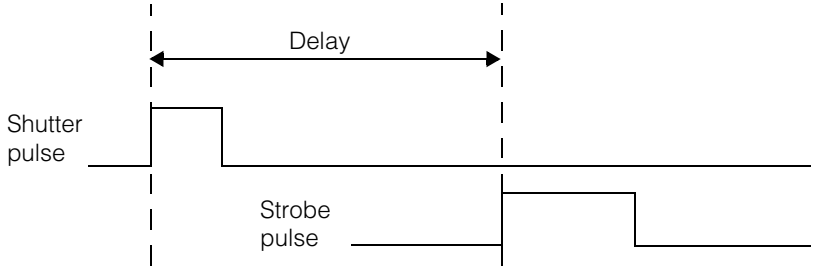
```
#include <ch_cvl/prop.h>

class ccStrobeDelayProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes a property that controls the strobe delay associated with an acquisition FIFO. Strobe delay is the delay time in seconds between the shutter pulse and the strobe firing.



Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccStrobeDelayProp

```
ccStrobeDelayProp();
explicit ccStrobeDelayProp(double delay);
virtual ~ccStrobeDelayProp() {};
```

- `ccStrobeDelayProp();`

  Default constructor. Default strobe delay = 0.

- `explicit ccStrobeDelayProp(double delay);`

  Constructor specifying strobe delay.

  Parameters

  delay Strobe delay in seconds.

- `virtual ~ccStrobeDelayProp() {};`

  Destructor.

Public Member Functions

strobeDelay

```
void strobeDelay(double delay);
double strobeDelay() const;
```

Specifies the strobe delay for acquisitions. The strobe delay is the time in seconds between the shutter pulse and the strobe pulse. The default value is 0.

- `void strobeDelay(double delay);`

  Sets a new strobe delay.

  Parameters

  delay The new strobe delay in seconds.

- `double strobeDelay() const;`

  Returns the current strobe delay.

Constants

defaultStrobeDelay

```
static const double defaultStrobeDelay;
```

The default is 0.

ccStrobeDelayProp

ccStrobeProp

```
#include <ch_cvl/prop.h>

class ccStrobeProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes the strobe property of an acquisition FIFO queue. The strobe property determines whether an acquisition uses a strobe or ambient lighting.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccStrobeProp

```
ccStrobeProp();

explicit ccStrobeProp(bool enabled);
```

- `ccStrobeProp();`

  Create a new strobe property not associated with any FIFO. Strobing is initially disabled.

- `explicit ccStrobeProp(bool enabled);`

  Create a new strobe property not associated with any FIFO. Strobing is initially enabled or disabled as specified.

  Parameters

  enabled — True if strobing is enabled; false if acquisitions use ambient lighting.

Public Member Functions

strobeEnable

```
bool strobeEnable() const;
void strobeEnable(bool enable);
```

- `bool strobeEnable() const;`

  Returns true if strobing is enabled or false if acquisition uses ambient lighting.

- `void strobeEnable(bool enable);`

  Enable or disable strobing.

  Parameters

  enabled — True if strobing is enabled, false if acquisitions use ambient lighting.

strobePulseDuration

```
double strobePulseDuration() const;
void strobePulseDuration(double seconds);
```

The strobe pulse duration is the pulse width used to fire the strobe. It is not necessarily the duration of the strobe flash.

- `double strobePulseDuration() const;`

  Return the strobe output line duration.

- `void strobePulseDuration(double seconds);`

  Set the strobe pulse duration. The strobe pulse is used to initiate a strobe flash. Check your strobe specifications to determine the strobe pulse width requirements.

  Parameters

  seconds — The width of the strobe pulse in seconds. A value of 0 means to use the shortest possible strobe pulse width. On most platforms, pulse width has a granularity between one millisecond and one microsecond.

  Throws

  ccStrobeProp::BadParams
  seconds was less than 0.

Notes

strobePulseDuration() applies to the MVS-8100L and frame grabbers that support CCF style video formats, including the MVS-8100M+, MVS-8120, and the MVS-8500 series.

strobePulseDuration() has no effect on MVS-8100M, MVS-8100C, and MVS-8100C/CPCI.

strobeHigh

```
bool strobeHigh() const;
void strobeHigh(bool polarity);
```

- `double strobeHigh() const;`

Returns the polarity of the strobe pulse.

- `void strobeHigh(bool polarity);`

Sets the polarity of the strobe pulse. The default value is true (high polarity). Consult your hardware's documentation for the appropriate setting of strobe polarity.

Parameters

polarity	If true, set the active pulse to high. If false, sets the active pulse to low.

ccStrobeProp

ccSymbologyParamsUPCEAN

```
#include <ch_cvl/id.h>

class ccSymbologyParamsUPCEAN;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the UPC/EAN symbology.

Enumerations

UPCEANType

```
enum UPCEANType;
```

This enumeration defines the UPC/EAN symbol types. The values in this enumeration are returned by **ccIDDecodeResult::symbologySubtype()**.

Value	meaning
eUPC_A	UPC-A.
eUPC_E	UPC-E
eEAN_8	EAN-8
eEAN_13	EAN-13
eAddOn5	5-digit EAN add-on
eAddOn2	2-digit EAN add-on

Constructors/Destructors

ccSymbologyParamsUPCEAN

```
ccSymbologyParamsUPCEAN();
```

Constructs an object with the following values:.

isAddOnEnabled: true
isEAN8AddOnValid: false
isUPCE1Enabled: false
isUPCEExpanded: true

Public Member Functions

isAddOnEnabled

```
bool isAddOnEnabled() const;

void isAddOnEnabled(bool isAddOnEnabled);
```

- `bool isAddOnEnabled() const;`

  Returns true if reading of UPC/EAN symbols with 2- or 5-digit add-on component is enabled, false otherwise.

- `void isAddOnEnabled(bool isAddOnEnabled);`

  Determines whether the reading of UPC/EAN symbols with 2- or 5-digit add-on component is enabled.

  Parameters

  isAddOnEnabled

  Specify true to enable reading of add-on components, false to disable reading of add-on components.

isUPCE1Enabled

```
bool isUPCE1Enabled() const;

void isUPCE1Enabled(bool isUPCE1Enabled);
```

- `bool isUPCE1Enabled() const;`

  Returns true if reading UPC-E symbols is enabled, false otherwise.

- `void isUPCE1Enabled(bool isUPCE1Enabled);`

  Sets whether reading UPC-E symbols is enabled.

  Parameters

  isUPCE1Enabled

  Specify true to enable reading UPC-E symbols, false to disable it.

  Notes

  UPC-E is applicable only to number system 0, and is referred as UPC-E0. UPC-E1 is a non-standard variation of UPC-E with number system 1. It is created by inverting the parity pattern for the implicit modulo check character. When isUPCE1Enabled is set to true, all UPC-E parameters apply to both UPC-E0 and UPC-E1 symbols.

isUPCEExpanded

```
bool isUPCEExpanded() const;

void isUPCEExpanded(bool isUPCEExpanded);
```

- `bool isUPCEExpanded() const;`

  Returns true if the expansion of decoded UPC-E strings to the 13-digit EAN-13 representation is enabled, false if it is disabled.

- `void isUPCEExpanded(bool isUPCEExpanded);`

  Sets the expansion of decoded UPC-E strings to the 13-digit EAN-13 representation.

  Parameters

  isUPCEExpanded

  Specify true to enable expansion, false to disable it.

  Notes

  When this flag is set to false, the decoded string of a UPC-E symbol is returned as <number system> + 6 digits + implicit check. When this flag is set to true, the decoded string is returned in 13 digit EAN-13 format.

  The standard UPC-E symbol identifier is used regardless of whether UPC-E is expanded or not. Since it can not indicate a UPC-E string transmitted in non-expanded format, number of bytes in the result's decoded string shall be used to determine this information.

isEAN8AddOnValid

```
bool isEAN8AddOnValid() const;

void isEAN8AddOnValid(bool isEAN8AddOnValid);
```

- `bool isEAN8AddOnValid() const;`

  Returns true if the tool will treat EAN-8 symbols with 2- or 5-digit add-on symbols as valid, false otherwise.

- `void isEAN8AddOnValid(bool isEAN8AddOnValid);`

  Sets whether or not the tool will treat EAN-8 symbols with 2- or 5-digit add-on symbols as valid, false otherwise.

  Parameters
  isEAN8AddOnValid

  Notes

  A standard EAN-8 symbol is not allowed to have add-on symbols. Enabling this flag allows reading of non-standard EAN-8 symbols where an add-on symbol is used.

  The decoded EAN-8 string is returned aa 8 digits (no add-on), 10 digits (2 digit add-on), or 13 digits (5-digit add-on).

  Notes
  This flag has no effect when **isAddOnEnabled** is set to false.

Operators

operator==

```
bool operator== (const ccSymbologyParamsUPCEAN& that)
const;
```

Returns true if the supplied object is equal to this one.

Parameters

that	The object to compare to this one.

Notes
Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsCodabar

```
#include <ch_cvl/id.h>

class ccSymbologyParamsCodabar;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the Codabar symbology.

Constructors/Destructors

ccSymbologyParamsCodabar

```
ccSymbologyParamsCodabar();
```

Constructs an object with the following values:

transmitStartStop: false
hasCheckChar: false
transmitCheckChar: false
lengthMin: 3
lengthMax: 40

Public Member Functions

transmitStartStop

```
bool transmitStartStop() const;

void transmitStartStop(bool transmitStartStop);
```

- `bool transmitStartStop() const;`

  Returns true if the tool includes start and stop characters in the returned decoded string, false otherwise.

- `void transmitStartStop(bool transmitStartStop);`

  Sets whether the tool includes start and stop characters in the returned decoded string.

Parameters

transmitStartStop

Specify true to include start and stop characters, false to not include them.

hasCheckChar

```
bool hasCheckChar() const;
void hasCheckChar(bool hasCheckChar);
```

- `bool hasCheckChar() const;`

Returns true if the tool requires that the symbol include a valid embedded checksum character, false if no checksum character is expected.

- `void hasCheckChar(bool hasCheckChar);`

Sets whether the tool requires that the symbol include a valid embedded checksum character.

Parameters

hasCheckChar Specify true to require an embedded checksum character, false to not require a checksum character.

Notes

When this flag is set to true, the checksum is validated before the result is reported.

transmitCheckChar

```
bool transmitCheckChar() const;
void transmitCheckChar(bool transmitCheckChar);
```

- `bool transmitCheckChar() const;`

Returns true if the tool includes the embedded checksum character in the returned decoded string, false if the tool does not include the checksum character.

- `void transmitCheckChar(bool transmitCheckChar);`

Sets whether the tool includes the embedded checksum character in the returned decoded string.

Parameters

transmitCheckChar

Specify true to have the tool include the checksum character.

Notes

If **hasCheckChar()** has a value of false, this property has no effect on the tool.

lengthMin

```
c_Int32 lengthMin() const;
```

Returns the minimum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes fewer bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

lengthMax

```
c_Int32 lengthMax() const;
```

Returns the maximum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes more bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

setLengthRange

```
void setLengthRange(c_Int32 lengthMin, c_Int32 lengthMax);
```

Sets the minimum and maximum number of bytes that are expected to be encoded in the symbol. If the number of bytes in the decoded symbol is outside of the specified range, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

Parameters

lengthMin The minimum number of bytes.

lengthMax The maximum number of bytes.

Throws

ccIDDefs::BadParams

lengthMin is less than *ccIDDefs::kLinearLengthMin*, *lengthMax* is greater than *ccIDDefs::kLinearLengthMax*, or *lengthMin* is greater than *lengthMax*.

Operators

operator==

```
bool operator== (const ccSymbologyParamsCodabar& that)
   const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsCode39

```
#include <ch_cvl/id.h>

class ccSymbologyParamsCode39;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the Code 39 symbology.

Constructors/Destructors

ccSymbologyParamsCode39

```
ccSymbologyParamsCode39();
```

Constructs an object with the following values:

fullASCIIMode: false
hasCheckChar: false
transmitCheckChar: false
lengthMin: 3
lengthMax: 40

Public Member Functions

fullASCIIMode

```
bool fullASCIIMode() const;

void fullASCIIMode(bool fullASCIIMode);
```

- ```
  bool fullASCIIMode() const;
  ```

  Returns true if the tool interprets the decoded string as full ASCII characters, false if only the 44-character subset is interpreted (A-Z; 0-9; *-$% ./+).
  ```

- `void fullASCIIMode(bool fullASCIIMode);`

  Gets/sets fullASCIIMode flag.

  Determines whether the tool interprets the decoded string as full ASCII characters or only the 44-character subset (A-Z; 0-9; *-$% ./+).

  Parameters

  fullASCIIMode Specify true to interpret full ASCII, false for the 44-character subset.

hasCheckChar

```
bool hasCheckChar() const;
void hasCheckChar(bool hasCheckChar);
```

- `bool hasCheckChar() const;`

  Returns true if the tool requires that the symbol include a valid embedded checksum character, false if no checksum character is expected.

- `void hasCheckChar(bool hasCheckChar);`

  Sets whether the tool requires that the symbol include a valid embedded checksum character.

  Parameters

  hasCheckChar Specify true to require an embedded checksum character, false to not require a checksum character.

  Notes

  When this flag is set to true, the checksum is validated before the result is reported.

transmitCheckChar

```
bool transmitCheckChar() const;
void transmitCheckChar(bool transmitCheckChar);
```

- `bool transmitCheckChar() const;`

  Returns true if the tool includes the embedded checksum character in the returned decoded string, false if the tool does not include the checksum character.

- `void transmitCheckChar(bool transmitCheckChar);`

  Sets whether the tool includes the embedded checksum character in the returned decoded string.

  Parameters

  transmitCheckChar

  Specify true to have the tool include the checksum character.

  Notes

  If **hasCheckChar()** has a value of false, this property has no effect on the tool.

lengthMin `c_Int32 lengthMin() const;`

Returns the minimum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes fewer bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

lengthMax `c_Int32 lengthMax() const;`

Returns the maximum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes more bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

setLengthRange

`void setLengthRange(c_Int32 lengthMin, c_Int32 lengthMax);`

Sets the minimum and maximum number of bytes that are expected to be encoded in the symbol. If the number of bytes in the decoded symbol is outside of the specified range, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

Parameters

lengthMin The minimum number of bytes.

lengthMax The maximum number of bytes.

Throws

ccIDDefs::BadParams

lengthMin is less than *ccIDDefs::kLinearLengthMin*, *lengthMax* is greater than *ccIDDefs::kLinearLengthMax*, or *lengthMin* is greater than *lengthMax*.

Operators

operator==

```
bool operator== (const ccSymbologyParamsCode39& that)
  const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsCode93

```
#include <ch_cvl/id.h>

class ccSymbologyParamsCode93;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the Code 93 symbology.

Constructors/Destructors

ccSymbologyParamsCode93

```
ccSymbologyParamsCode93();
```

Constructs an object with the following values:.

lengthMin: 3
lengthMax: 40

Public Member Functions

lengthMin

```
c_Int32 lengthMin() const;
```

Returns the minimum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes fewer bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

lengthMax

```
c_Int32 lengthMax() const;
```

Returns the maximum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes more bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

setLengthRange

```
void setLengthRange(c_Int32 lengthMin, c_Int32 lengthMax);
```

Sets the minimum and maximum number of bytes that are expected to be encoded in the symbol. If the number of bytes in the decoded symbol is outside of the specified range, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

Parameters

lengthMin The minimum number of bytes.

lengthMax The maximum number of bytes.

Throws

ccIDDefs::BadParams

lengthMin is less than *ccIDDefs::kLinearLengthMin*, *lengthMax* is greater than *ccIDDefs::kLinearLengthMax*, or *lengthMin* is greater than *lengthMax*.

Operators

operator==

```
bool operator== (const ccSymbologyParamsCode93& that)
   const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsCode128

```
#include <ch_cvl/id.h>

class ccSymbologyParamsCode128;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the Code 128 symbology.

Constructors/Destructors

ccSymbologyParamsCode128

```
ccSymbologyParamsCode128();
```

Constructs an object with the following values:.

lengthMin: 3
lengthMax: 40

Public Member Functions

lengthMin

```
c_Int32 lengthMin() const;
```

Returns the minimum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes fewer bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

lengthMax

```
c_Int32 lengthMax() const;
```

Returns the maximum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes more bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

setLengthRange

```
void setLengthRange(c_Int32 lengthMin, c_Int32 lengthMax);
```

Sets the minimum and maximum number of bytes that are expected to be encoded in the symbol. If the number of bytes in the decoded symbol is outside of the specified range, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

Parameters

lengthMin The minimum number of bytes.

lengthMax The maximum number of bytes.

Throws

ccIDDefs::BadParams

lengthMin is less than *ccIDDefs::kLinearLengthMin*, *lengthMax* is greater than *ccIDDefs::kLinearLengthMax*, or *lengthMin* is greater than *lengthMax*.

Operators

operator==

```
bool operator== (const ccSymbologyParamsCode128& that)
   const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsComposite

```
#include <ch_cvl/id.h>

class ccSymbologyParamsComposite;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for composite symbols.

Constructors/Destructors

ccSymbologyParamsComposite

```
ccSymbologyParamsComposite();
```

Constructs an object with the following values:

type: *ccSymbologyParamsComposite::kDefaultComponent2DType*
combineResults: false
transmissionMode: *ccSymbologyParamsComposite::kDefaultDataTransmissionMode*

Enumerations

Component2DType

```
enum Component2DType;
```

This enumeration defines the component symbology types supported by the ID tool. The values in this enumeration are returned by **ccIDDecodeResult::symbologySubtype()**.

Value	meaning
eComponent2DTypeCCA	CC-A
eComponent2DTypeCCB	CC-B
kDefaultComponent2DType	The default type, as defined in id.h.

DataTransmissionMode

```
enum DataTransmissionMode;
```

This enumeration defines the data transmission modes supported for composite symbols.

Value	meaning
eDataTransmissionModeStandard	Both the linear and 2D components of a composite symbol are returned.
eDataTransmissionModeLinearOnly	Only the linear component of a composite symbol is returned.
kDefaultDataTransmissionMode	The default mode, as defined in id.h.

Public Member Functions

type2D

```
c_UInt32 type2D() const;

void type2D(c_UInt32 type);
```

- `c_UInt32 type2D() const;`

  Returns the type of 2D component that the tool will decode. The returned value is formed by ORing together one or more of the values defined in the **ccSymbologyParamsComposite::Component2DType** enumeration.

- `void type2D(c_UInt32 type);`

  Sets the type of 2D component that the tool will decode.

  Parameters

  type The 2D types to decode. This value must be formed by ORing together one or more of the following values:

  ccSymbologyParamsComposite::eDataTransmissionModeStandard
  ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly

  Throws

  ccIDDefs::BadParams

  type is not the result of ORing together one or more values from the **ccSymbologyParamsComposite::Component2DType** enumeration.

combineResults

```
bool combineResults() const;

void combineResults(bool combineResults);
```

- `bool combineResults() const;`

  If true, the tool combines the two decoded components of a composite symbol and returns a single result. If false, the tool reports separate subresuilts.

- `void combineResults(bool combineResults);`

  Controls whether the tool combines the two decoded components of a composite symbol and returns a single result or reports separate subresuilts for the components.

  If the tool combines results, the **decodedString()** and **decodedElementString()** values are concatenated.

  Parameters

  combineResults Specify true to combine results, false to report separate results.

  Notes

  This flag has no effect if the **dataTransmissionMode** is set to *ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly*.

dataTransmissionMode

```
DataTransmissionMode dataTransmissionMode() const;

void dataTransmissionMode(DataTransmissionMode mode);
```

- `DataTransmissionMode dataTransmissionMode() const;`

  Returns the current data transmission mode. The transmission mode controls which results the tool returns.

  If the mode is *ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly*, then only the linear component is returned. If the mode is *ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly*, then both components are returned. **combineResults()** determines how the results are returned.

- `void dataTransmissionMode(DataTransmissionMode mode);`

  Sets the current data transmission mode. The transmission mode controls which results the tool returns.

  If you specify *ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly*, then only the linear component is returned. If you specify *ccSymbologyParamsComposite::eDataTransmissionModeLinearOnly*, then both components are returned. **combineResults()** determines how the results are returned.

  Parameters

  mode The transmission mode to set.

  Throws

  ccIDDefs::BadParams
  mode is invalid.

Operators

operator==

```
bool operator== (
   const ccSymbologyParamsComposite& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsI2of5

```
#include <ch_cvl/id.h>

class ccSymbologyParamsI2of5;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the 2 of 5 symbology.

Constructors/Destructors

ccSymbologyParamsI2of5

```
ccSymbologyParamsI2of5();
```

Constructs an object with the following values:

hasCheckChar: false
transmitCheckChar: false
lengthMin: 6
lengthMax: 40

Public Member Functions

hasCheckChar

```
bool hasCheckChar() const;

void hasCheckChar(bool hasCheckChar);
```

- `bool hasCheckChar() const;`

  Returns true if the tool requires that the symbol include a valid embedded checksum character, false if no checksum character is expected.

- `void hasCheckChar(bool hasCheckChar);`

  Sets whether the tool requires that the symbol include a valid embedded checksum character.

Parameters

hasCheckChar Specify true to require an embedded checksum character, false to not require a checksum character.

Notes

When this flag is set to true, the checksum is validated before the result is reported.

transmitCheckChar

```
bool transmitCheckChar() const;

void transmitCheckChar(bool transmitCheckChar);
```

- `bool transmitCheckChar() const;`

  Returns true if the tool includes the embedded checksum character in the returned decoded string, false if the tool does not include the checksum character.

- `void transmitCheckChar(bool transmitCheckChar);`

  Sets whether the tool includes the embedded checksum character in the returned decoded string.

  Parameters

  transmitCheckChar
  Specify true to have the tool include the checksum character.

  Notes

  If **hasCheckChar()** has a value of false, this property has no effect on the tool.

lengthMin `c_Int32 lengthMin() const;`

Returns the minimum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes fewer bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

lengthMax `c_Int32 lengthMax() const;`

Returns the maximum number of bytes that are expected to be encoded in the symbol. If the decoded symbol includes more bytes, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

setLengthRange

```
void setLengthRange(c_Int32 lengthMin, c_Int32 lengthMax);
```

Sets the minimum and maximum number of bytes that are expected to be encoded in the symbol. If the number of bytes in the decoded symbol is outside of the specified range, **ccIDResult::isDecoded()** returns false and **ccIDResult::failureCode()** is set to *ccIDDefs::eFailureUnexpectedStringLength*.

Parameters

lengthMin The minimum number of bytes.

lengthMax The maximum number of bytes.

Throws

ccIDDefs::BadParams

lengthMin is less than *ccIDDefs::kLinearLengthMin*, *lengthMax* is greater than *ccIDDefs::kLinearLengthMax*, or *lengthMin* is greater than *lengthMax*.

Operators

operator==

```
bool operator== (const ccSymbologyParamsI2of5& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsI2of5

ccSymbologyParamsPDF417

```
#include <ch_cvl/id.h>

class ccSymbologyParamsPDF417;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the PDF417 symbology.

Enumerations

PDF417Type

```
enum PDF417Type;
```

This enumeration defines the PDF417 symbol types. The values in this enumeration are returned by **cclIDDecodeResult::symbologySubtype()**.

Value	meaning
ePDF417	PDF417 code
eMicroPDF417	Micro-PDF417 code
kDefaultPDFType	The default type, as defined in id.h

Constructors/Destructors

ccSymbologyParamsPDF417

```
ccSymbologyParamsPDF417();
```

Constructs an object with the following values:

type: *ccSymbologyParamsPDF417::kDefaultPDFType*

Public Member Functions

type

```
c_UInt32 type() const;

void type(c_UInt32 type);
```

- `c_UInt32 type() const;`

  Returns the PDF417 subtype that the tool will decode. The returned value will be formed by ORing together 1 or more of the following values:

  ccSymbologyParamsPDF417::ePDF417
  ccSymbologyParamsPDF417::eMicroPDF417

- `void type(c_UInt32 type);`

  Sets the PDF417 subtypes that the tool will decode.

  type — The types to decode. *type* must be formed by ORing together 1 or more of the following values:

  ccSymbologyParamsPDF417::ePDF417
  ccSymbologyParamsPDF417::eMicroPDF417

  Throws

  ccIDDefs::BadParams

  type is not the result of ORing together one or more of the values from the not set to a valid bitwise combination of any of the **ccSymbologyParamsPDF417::PDF417Type** enumeration values.

Operators

operator==

```
bool operator== (const ccSymbologyParamsPDF417& that)
   const;
```

Returns true if the supplied object is equal to this one.

Parameters

that — The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsPostal

```
#include <ch_cvl/id.h>

class ccSymbologyParamsPostal;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the Postal symbologies.

Enumerations

PostalType

```
enum PostalType;
```

This enumeration defines the Postal symbol subtypes. The values in this enumeration are returned by **ccIDDecodeResult::symbologySubtype()**.

Value	meaning
ePostal4StateJapanPost	4-state Japan Post code
ePostal4StateAustraliaPost	4-state Australia Post code
ePostal4StateUPU	4-state UPU code
ePostal4StateUSPS	4-state USPS code
ePostalUSPostnet	Postnet code
ePostalUSPlanet	Planet code
ePostalCepnet	CEPNet code
kDefaultPostalType	The default codes, as defined in id.h

Constructors/Destructors

ccSymbologyParamsPostal

```
ccSymbologyParamsPostal();
```

Constructs an object with the following values:

type: *ccSymbologyParamsPostal::kDefaultPostalType*
transmitCheckChar: *false*

Public Member Functions

type

```
c_UInt32 type() const;

void type(c_UInt32 type);
```

- `c_UInt32 type() const;`

  Returns the Postal subtypes that this tool is configured to decode. The returned value is formed by ORing together one or more of the following values:

  ccSymbologyParamsPostal::ePostal4StateJapanPost
  ccSymbologyParamsPostal::ePostal4StateAustraliaPost
  ccSymbologyParamsPostal::ePostal4StateUPU
  ccSymbologyParamsPostal::ePostal4StateUSPS
  ccSymbologyParamsPostal::ePostalUSPostnet
  ccSymbologyParamsPostal::ePostalUSPlanet
  ccSymbologyParamsPostal::ePostalCepnet

- `void type(c_UInt32 type);`

  Sets the Postal subtypes that the tool will decode.

  Parameters

  type — The subtypes to decode. *type* must be formed by ORing together one or more of the following values:

  ccSymbologyParamsPostal::ePostal4StateJapanPost
  ccSymbologyParamsPostal::ePostal4StateAustraliaPost
  ccSymbologyParamsPostal::ePostal4StateUPU
  ccSymbologyParamsPostal::ePostal4StateUSPS
  ccSymbologyParamsPostal::ePostalUSPostnet
  ccSymbologyParamsPostal::ePostalUSPlanet
  ccSymbologyParamsPostal::ePostalCepnet

Throws

ccIDDefs::BadParams

type is not formed by ORing together one or more values from the **ccSymbologyParamsPostal::PostalType** enumeration.

transmitCheckChar

```
bool transmitCheckChar(PostalType type) const;

void transmitCheckChar(PostalType type,
   bool transmitCheckChar);
```

- `bool transmitCheckChar(PostalType type) const;`

Returns true if the tool includes the embedded checksum character in the returned decoded string for the specified symbology subtype, false if the tool does not include the checksum character.

Parameters

type The Postal code type for which to obtain the checksum flag. *type* must be one of the following values:

ccSymbologyParamsPostal::ePostalUSPostnet
ccSymbologyParamsPostal::ePostalUSPlanet

For CEPNet, use *ccSymbologyParamsPostal::ePostalUSPostnet*

- `void transmitCheckChar(PostalType type, bool transmitCheckChar);`

Sets whether the tool includes the embedded checksum character in the returned decoded string for the supplied symbology subtype.

Parameters

type The Postal code type for which to set the checksum flag. *type* must be one of the following values:

ccSymbologyParamsPostal::ePostalUSPostnet
ccSymbologyParamsPostal::ePostalUSPlanet

For CEPNet, use *ccSymbologyParamsPostal::ePostalUSPostnet*

transmitCheckChar

Specify true to return the checksum, false to not return the checksum.

Throws

ccIDDefs::BadParams

type is not *ccSymbologyParamsPostal::ePostalUSPostnet* or *ccSymbologyParamsPostal::ePostalUSPlanet*.

decodePostnetAsCepnet

```
bool decodePostnetAsCepnet() const;

void decodePostnetAsCepnet(bool value);
```

- `bool decodePostnetAsCepnet() const;`

  Returns the flag whether to enable CEPNet decoding.

- `void decodePostnetAsCepnet(bool value);`

  Sets the flag whether to enable CEPNet decoding.

  Parameters

  value Whether to enable CEPNet decoding.

  The default is false.

  Notes

  CEPNet and Postnet use the same symbol character set and checksum algorithm but the lengths are different. When this flag is set to true, the US-Postnet codes will be treated as CEPNet codes.

Operators

operator==

```
bool operator== (const ccSymbologyParamsPostal& that)
   const;
```

Returns true if the supplied object is equal to this one.

Parameters

that The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsRSS

```
#include <ch_cvl/id.h>

class ccSymbologyParamsRSS;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class containing the symbology-specific parameters for the RSS symbology.

Enumerations

RSSType

```
enum RSSType;
```

This enumeration defines the RSS symbol subtypes. The values in this enumeration are returned by **ccIDDecodeResult::symbologySubtype()**.

Value	meaning
eRSS14	RSS - 14
eRSSLimited	RSS - Limited
kDefaultRSSType	The default type, as defined in id.h

Constructors/Destructors

ccSymbologyParamsRSS

```
ccSymbologyParamsRSS();
```

Constructs an object with the following values:

type: *ccSymbologyParamsRSS::kDefaultRSSType*

Public Member Functions

type

```
c_UInt32 type() const;

void type(c_UInt32 type);
```

- `c_UInt32 type() const;`

  Returns the RSS subtypes that this tool is configured to decode. The returned value is formed by ORing together one or more of the following values:

  ccSymbologyParamsRSS::eRSS14
  ccSymbologyParamsRSS::eRSSLimited

- `void type(c_UInt32 type);`

  Sets the RSS subtypes that the tool will decode.

  Parameters

  type — The subtypes to decode. *type* must be formed by ORing together one or more of the following values:

  ccSymbologyParamsRSS::eRSS14
  ccSymbologyParamsRSS::eRSSLimited

  Notes

  This must be a bitwise combination of any of the

  RSSType enum values.

  Throws

  ccIDDefs::BadParams
  type is not formed by ORing together one or more values from the **ccSymbologyParamsRSS::RSSType** enumeration.

Operators

operator==

```
bool operator== (const ccSymbologyParamsRSS& that) const;
```

Returns true if the supplied object is equal to this one.

Parameters

that — The object to compare to this one.

Notes

Two objects are considered equal if all their corresponding data members are exactly equal.

ccSymbologyParamsRSS

ccSynFont

```
#include <ch_cvl/synfont.h>

class ccSynFont : public virtual ccRepBase,
                  public virtual ccPersistent
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

The **ccSynFont** class represents a font, which is a specification for a set of characters. A font can be used to generate rendered images of individual characters or strings, as well as to generate outline shapes and metrics.

A font can be imported either from a set of character bitmaps (a **ccImageFont**) or from a font file, in any one of a variety of supported font file formats.

Constructors/Destructors

ccSynFont

```
ccSynFont();

ccSynFont(const ccSynFont& rhs);

~ccSynFont();
```

- `ccSynFont();`

  Constructs an unimported object.

- `ccSynFont(const ccSynFont& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

- `~ccSynFont();`

  Destructor.

Enumerations

FontType `enum FontType;`

Types of fonts.

The type of a font indicates a broad category of how fonts are internally represented.

Value	Meaning
eNone	No font type (note: not currently used)
eOutline	Outline font (for example, TrueType)
eRaster	Raster font (for example, VideoJet, Markem, Imaje, Zebra, Xymark)
eStroke	Stroke font (for example, Xymark, Domino)
eImage	Image font (character bitmaps; for example, **ccImageFont**)

Operators

operator= `ccSynFont& operator=(const ccSynFont& rhs);`

Assignment operator.

Parameters

rhs The assignment source.

operator== `bool operator==(const ccSynFont& other) const;`

Returns true if and only if this object is equal to the specified other object.

Parameters

other The object with which to compare for equality.

Public Member Functions

import

```
void import(const ccCvlString& filename,
  const ccCvlString& fontname = ccCvlString());

void import(const ccImageFont& imageFont);
```

- ```
  void import(const ccCvlString& filename,
    const ccCvlString& fontname = ccCvlString());
  ```

  Load font from file. Resets all settable values such as *spotSize* and *leading*.

  Parameters

  filename The name of the file.

- ```
  void import(const ccImageFont& imageFont);
  ```

  Load font from the image font. Resets all settable values such as *spotSize* and *leading*.

  Parameters

  imageFont The image font.

  Notes

  A font that is imported this way cannot currently be saved by archiving.

isImported

```
bool isImported() const;
```

Returns whether the font has been imported.

All other functions will throw **ccSynFontDefs::NotImported** if the font has not been imported.

name

```
ccCvlString name() const;
```

Gets the name of the font.

usesSpotSize

```
bool usesSpotSize() const;
```

Returns whether the font is a type that uses *spotSize*, that is, *eRaster* or *eStroke*.

spotSize

```
double spotSize() const;

void spotSize(double diam);
```

- `double spotSize() const;`

  Gets the spot size (diameter) of the laser.

- `void spotSize(double diam);`

  Sets the spot size (diameter) of the laser.

  Parameters

  diam The spot size of the laser in diameter.

  Throws

  ccSynFontDefs::NotImplemented
  usesSpotSize is false.

  ccSynFontDefs::BadParams
  diam is negative.

usesSpotSpacing

```
bool usesSpotSpacing() const;
```

Returns whether the font is a type that is affected by *spotSpacingXScale* and *spotSpacingYScale* in the params.

Notes

Typically, spot and stroke fonts can use spot spacing, while outline fonts cannot.

leading

```
cc2Vect leading(const ccSynFontCharRenderParams&
  charParams = ccSynFontCharRenderParams()) const;

void leading(const cc2Vect& leading);
```

- `cc2Vect leading(const ccSynFontCharRenderParams& charParams = ccSynFontCharRenderParams()) const;`

  Gets the leading, which is the origin-to-origin displacement between the first characters of lines.

  Parameters

  charParams The character rendering parameters.

- `void leading(const cc2Vect& leading);`

  Sets the leading, which is the origin-to-origin displacement between the first characters of lines.

  Typically, **leading.x()** is 0 and **leading.y()** is a positive number.

  Parameters
  leading The new leading value.

  Notes

  Leading is pronounced "ledding."

isKnown `bool isKnown(c_Int32 charCode) const;`

Returns whether or not the given character code is recognized by this font.

Parameters
charCode The given character code.

areKnown

```
bool areKnown(const cmStd vector<c_Int32>& chars) const;
bool areKnown(const ccCvlString& str) const;
```

- `bool areKnown(const cmStd vector<c_Int32>& chars) const;`

  Returns whether or not all the given character codes are recognized by this font.

  Parameters
  chars The given character codes.

- `bool areKnown(const ccCvlString& str) const;`

  Returns whether or not all the given character codes are recognized by this font.

  Parameters
  str The given character codes.

isBlank `bool isBlank(c_Int32 key) const;`

Returns whether or not the given character is a blank (space).

Parameters
key The given character.

Throws

ccSynFontDefs::UnknownChar
key is not in the font.

cellRect

```
ccRect cellRect(c_Int32 charCode,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;
```

Gets the cell rectangle of one character.

Parameters

charCode The code of the character.

charParams The character rendering parameters.

encloseCellRect

```
ccRect encloseCellRect(const cmStd vector<c_Int32>
  &charList,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;

ccRect encloseCellRect( const cmStd vector<cmStd
  vector<c_Int32> >&charLineList,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;

ccRect encloseCellRect(const ccSynFontCharRenderParams&
  charParams = ccSynFontCharRenderParams()) const;
```

-
```
ccRect encloseCellRect(const cmStd vector<c_Int32>
  &charList,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;
```

Gets the enclosing cell rectangle of multiple characters.

Parameters

charList The list of characters.

charParams The character rendering parameters.

- ```
  ccRect encloseCellRect( const cmStd vector<cmStd
    vector<c_Int32> >&charLineList,
    const ccSynFontCharRenderParams& charParams =
    ccSynFontCharRenderParams()) const;
  ```

  Gets the enclosing cell rectangle of multiple characters (in a form convenient for multiple lines).

  Parameters

  charLineList The list of characters.

  charParams The character rendering parameters.

- ```
  ccRect encloseCellRect(const ccSynFontCharRenderParams&
    charParams = ccSynFontCharRenderParams()) const;
  ```

  Gets the enclosing cell rectangle of all characters.

  Parameters

  charParams The character rendering parameters.

markRect

```
ccRect markRect(c_Int32 charCode,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;
```

Gets the mark rectangle of one character.

Parameters

charCode The character code.

charParams The character rendering parameters.

encloseMarkRect

```
ccRect encloseMarkRect(const cmStd vector<c_Int32>
  &charList,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;

ccRect encloseMarkRect( const cmStd vector<cmStd
  vector<c_Int32> >&charLineList,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;

ccRect encloseMarkRect(const ccSynFontCharRenderParams&
  charParams = ccSynFontCharRenderParams()) const;
```

- ```
  ccRect encloseMarkRect(const cmStd vector<c_Int32>
    &charList,
    const ccSynFontCharRenderParams& charParams =
    ccSynFontCharRenderParams()) const;
  ```

  Gets the enclosing mark rectangle of multiple characters.

  Parameters

  charList The list of characters.

  charParams The character rendering parameters.

- ```
  ccRect encloseMarkRect( const cmStd vector<cmStd
    vector<c_Int32> >&charLineList,
    const ccSynFontCharRenderParams& charParams =
    ccSynFontCharRenderParams()) const;
  ```

  Gets the enclosing mark rectangle of multiple characters (in a form convenient for multiple lines).

  Parameters

  charLineList The list of characters.

  charParams The character rendering parameters.

- ```
  ccRect encloseMarkRect(const ccSynFontCharRenderParams&
    charParams = ccSynFontCharRenderParams()) const;
  ```

  Gets the enclosing mark rectangle of all characters.

  Parameters

  charParams The character rendering parameters.
  ```

renderMetrics

```
void renderMetrics(c_Int32 charCode,
  const ccSynFontRenderParams& params,
  c_UInt32 requestedMetrics,
  ccSynFontRenderMetrics& metrics) const;

void renderMetrics(const cmStd vector<c_Int32>& chars,
  const ccSynFontRenderParams& params,
  c_UInt32 requestedMetrics,
  ccSynFontRenderMetrics& metrics) const;

void renderMetrics(const ccCvlString& str,
  const ccSynFontRenderParams& params,
  c_UInt32 requestedMetrics,
  ccSynFontRenderMetrics& metrics) const;

void renderMetrics(const cmStd vector<cmStd vector<c_Int32>
  >& charLines,
  const ccSynFontRenderParams& params,
  c_UInt32 requestedMetrics,
  ccSynFontRenderMetrics& metrics) const;

void renderMetrics(const cmStd vector<ccCvlString>&
  strLines,
  const ccSynFontRenderParams& params,
  c_UInt32 requestedMetrics,
  ccSynFontRenderMetrics& metrics) const;
```

- ```
  void renderMetrics(c_Int32 charCode,
    const ccSynFontRenderParams& params,
    c_UInt32 requestedMetrics,
    ccSynFontRenderMetrics& metrics) const;
  ```

  Gets the metrics for a single character as the characters are rendered.

  Parameters

  charCode The code of the character.

  params Font rendering parameters.

  requestedMetrics The requested metrics.

  metrics The metrics.

  Throws

  ccSynFontDefs::UnknownChar Any character has **isKnown()** false.
  ```

- ```
  void renderMetrics(const cmStd vector<c_Int32>& chars,
    const ccSynFontRenderParams& params,
    c_UInt32 requestedMetrics,
    ccSynFontRenderMetrics& metrics) const;
  ```

  Gets the metrics for a single line of characters as the characters are rendered.

  Parameters

  chars The characters.

  params Font rendering parameters.

  requestedMetrics
  The requested metrics.

  metrics The metrics.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  void renderMetrics(const ccCvlString& str,
    const ccSynFontRenderParams& params,
    c_UInt32 requestedMetrics,
    ccSynFontRenderMetrics& metrics) const;
  ```

  Gets the metrics for a single line of characters represented as a string as the characters are rendered.

  Parameters

  str The string.

  params Font rendering parameters.

  requestedMetrics
  The requested metrics.

  metrics The metrics.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  void renderMetrics(const cmStd vector<cmStd vector<c_Int32>
    >& charLines,
    const ccSynFontRenderParams& params,
    c_UInt32 requestedMetrics,
    ccSynFontRenderMetrics& metrics) const;
  ```

  Gets the metrics for multiple lines of characters represented as a string as the characters are rendered.

  Parameters

  charLines The string of multiple lines of characters.

  params Font rendering parameters.

  requestedMetrics The requested metrics.

  metrics The metrics.

  Throws

  ccSynFontDefs::UnknownChar Any character has **isKnown()** false.

- ```
  void renderMetrics(const cmStd vector<ccCvlString>&
    strLines,
    const ccSynFontRenderParams& params,
    c_UInt32 requestedMetrics,
    ccSynFontRenderMetrics& metrics) const;
  ```

  Gets the metrics for multiple lines of characters represented as strings as the characters are rendered.

  Parameters

  strLines The strings of multiple lines of characters.

  params Font rendering parameters.

  requestedMetrics The requested metrics.

  metrics The metrics.

  Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

No rendering is actually performed. This function is typically used to determine the bounding rectangle of the string and to learn nominal positions of characters for use in training OCR and OCV.

Metrics vectors are ordered first by line and then by position, that is, all the metrics for the first line come first, followed by all the metrics for the second line, and so on.

renderRect

```
ccPelRect renderRect( c_Int32 charCode,
  const ccSynFontRenderParams& params,
  const cc2XformLinear& clientFromImage = cc2XformLinear())
  const;

ccPelRect renderRect( const cmStd vector<c_Int32>& chars,
  const ccSynFontRenderParams& params,
  const cc2XformLinear& clientFromImage = cc2XformLinear())
  const;

ccPelRect renderRect( const ccCvlString &str,
  const ccSynFontRenderParams& params,
  const cc2XformLinear& clientFromImage = cc2XformLinear())
  const;

ccPelRect renderRect( const cmStd vector<cmStd
  vector<c_Int32> >& charLines,
  const ccSynFontRenderParams& params,
  const cc2XformLinear& clientFromImage = cc2XformLinear())
  const;

ccPelRect renderRect( const cmStd vector<ccCvlString>&
  strLines,
  const ccSynFontRenderParams& params,
  const cc2XformLinear& clientFromImage = cc2XformLinear())
  const;
```

- ```
  ccPelRect renderRect( c_Int32 charCode,
    const ccSynFontRenderParams& params,
    const cc2XformLinear& clientFromImage = cc2XformLinear())
    const;
  ```

  Returns for a single character the rect that encloses all of the cell and mark rects of the character, padded as specified by *params*.The returned rect can then be used to pre-allocate an image to be used for rendering.
  ```

Parameters

charCode The code of the character.

params The parameters.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  ccPelRect renderRect( const cmStd vector<c_Int32>& chars,
    const ccSynFontRenderParams& params,
    const cc2XformLinear& clientFromImage = cc2XformLinear())
    const;
  ```

  Returns for a single line of characters the rect that encloses all of the cell and mark rects of the characters, padded as specified by *params*.The returned rect can then be used to pre-allocate an image to be used for rendering.

  Parameters

  chars The characters.

  params The parameters.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  ccPelRect renderRect( const ccCvlString &str,
    const ccSynFontRenderParams& params,
    const cc2XformLinear& clientFromImage = cc2XformLinear())
    const;
  ```

  Returns for a single line of characters represented as a string the rect that encloses all of the cell and mark rects of the characters, padded as specified by *params*.The returned rect can then be used to pre-allocate an image to be used for rendering.

  Parameters

  str The characters.

  params The parameters.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  ccPelRect renderRect( const cmStd vector<cmStd
    vector<c_Int32> >& charLines,
    const ccSynFontRenderParams& params,
    const cc2XformLinear& clientFromImage = cc2XformLinear())
    const;
  ```

  Returns for multiple lines of characters the rect that encloses all of the cell and mark rects of the characters, padded as specified by *params*.The returned rect can then be used to pre-allocate an image to be used for rendering.

  Parameters

  charLines The characters.

  params The parameters.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  ccPelRect renderRect( const cmStd vector<cccCvlString>&
    strLines,
    const ccSynFontRenderParams& params,
    const cc2XformLinear& clientFromImage = cc2XformLinear())
    const;
  ```

  Returns for multiple lines of characters represented as strings the rect that encloses all of the cell and mark rects of the characters, padded as specified by *params*.The returned rect can then be used to pre-allocate an image to be used for rendering.

  Parameters

  strLines The characters.

  params The parameters.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

render

```
void render(ccPelBuffer<c_UInt8>& image,
  c_Int32 charCode,
  const ccSynFontRenderParams& params) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<c_Int32>& chars,
  const ccSynFontRenderParams& params) const;

void render(ccPelBuffer<c_UInt8>& image,
  const ccCvlString& str,
  const ccSynFontRenderParams& params) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<cmStd vector<c_Int32> >& chars,
  const ccSynFontRenderParams& params) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<ccCvlString>& str,
  const ccSynFontRenderParams& params) const;

void render(ccPelBuffer<c_UInt8>& image,
  c_Int32 charCode,
  const ccSynFontRenderParams& params,
  ccSynFontRenderResult& result) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<c_Int32>& chars,
  const ccSynFontRenderParams& params,
  ccSynFontRenderResult& result) const;

void render(ccPelBuffer<c_UInt8>& image,
  const ccCvlString& str,
  const ccSynFontRenderParams& params,
  ccSynFontRenderResult& result) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<cmStd vector<c_Int32> >& chars,
  const ccSynFontRenderParams& params,
  ccSynFontRenderResult& result) const;

void render(ccPelBuffer<c_UInt8>& image,
  const cmStd vector<ccCvlString>& str,
  const ccSynFontRenderParams& params,
  ccSynFontRenderResult& result) const;
```

-
```
void render(ccPelBuffer<c_UInt8>& image,
  c_Int32 charCode,
  const ccSynFontRenderParams& params) const;
```

  Renders a character into pelbuffer using the specified parameters.

If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

Parameters

image The image.

charCode The code of the character.

params The parameters.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<c_Int32>& chars,
    const ccSynFontRenderParams& params) const;
  ```

Renders a single line of characters into pelbuffer using the specified parameters.

If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

Parameters

image The image.

chars The characters.

params The parameters.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const ccCvlString& str,
    const ccSynFontRenderParams& params) const;
  ```

Renders a single line of characters represented as a string into pelbuffer using the specified parameters.

If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

Parameters

image The image.

str The characters.

params The parameters.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<cmStd vector<c_Int32> >& chars,
    const ccSynFontRenderParams& params) const;
  ```

  Renders multiple lines of characters into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  chars The characters.

  params The parameters.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<ccCvlString>& str,
    const ccSynFontRenderParams& params) const;
  ```

  Renders multiple lines of characters represented as strings into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  str The characters.

params The parameters.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    c_Int32 charCode,
    const ccSynFontRenderParams& params,
    ccSynFontRenderResult& result) const;
  ```

  Renders a single character into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  charCode The code of the character.

  params The parameters.

  result The result.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<c_Int32>& chars,
    const ccSynFontRenderParams& params,
    ccSynFontRenderResult& result) const;
  ```

  Renders a single line of characters into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  chars The characters.

  params The parameters.

  result The result.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const ccCvlString& str,
    const ccSynFontRenderParams& params,
    ccSynFontRenderResult& result) const;
  ```

  Renders a single line of characters represented as a string into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  str The characters.

  params The parameters.

  result The result.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<cmStd vector<c_Int32> >& chars,
    const ccSynFontRenderParams& params,
    ccSynFontRenderResult& result) const;
  ```

  Renders multiple lines of characters into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

  image The image.

  chars The characters.

  params The parameters.

  result The result.

Throws

ccSynFontDefs::UnknownChar
Any character has **isKnown()** false.

- ```
  void render(ccPelBuffer<c_UInt8>& image,
    const cmStd vector<ccCvlString>& str,
    const ccSynFontRenderParams& params,
    ccSynFontRenderResult& result) const;
  ```

  Renders multiple lines of characters represented as strings into pelbuffer using the specified parameters.

  If the image is unbound, it will be allocated using **renderRect()** with identity client coordinates. If the image is bound, it should initially have been set to the background color by the user.

  Parameters

image	The image.
str	The characters.
params	The parameters.
result	The result.

  Throws

  ccSynFontDefs::UnknownChar
  Any character has **isKnown()** false.

availableChars

```
const cmStd vector<c_Int32>& availableChars(bool
  includeAllBlanks = false) const;
```

Gets a list of characters available in the font.

If *includeAllBlanks* is true and the font has multiple blank characters, then all the blanks will be included; if *includeAllBlanks* is false, then only the **defaultBlank()** blank character will be included.

The list includes all printable characters plus the space character (if present).

Parameters

includeAllBlanks
```

availableNonblankChars

```
const cmStd vector<c_Int32>& availableNonblankChars()
  const;
```

Gets a list of characters available in the font. The list includes all printable characters.

availableBlankChars

```
const cmStd vector<c_Int32>& availableBlankChars() const;
```

Gets a list of blank (that is, space) characters available in the font.

hasBlank

```
bool hasBlank() const;
```

Returns whether this font contains at least one blank character.

defaultBlank

```
c_Int32 defaultBlank() const;
```

Returns the default blank character for this font.

Throws

ccSynFontDefs::UnknownChar
The **hasBlank()** operation returned false.

advance

```
cc2Vect advance(c_Int32 charCode,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;
```

Returns the advance for the specified character.

Parameters

charCode The code of the character.

charParams The character rendering parameters.

Notes

The total advance from one character to the next:

advance(a) + **kerning(a, b)** + **tracking()**

renderMetrics() is often a more convenient way to get this information for a particular string.

Throws

ccSynFontDefs::UnknownChar
The **isKnown(***charCode***)** operation returned false.

kerning

```
cc2Vect kerning(c_Int32 firstCharCode,
  c_Int32 secondCharCode,
  const ccSynFontCharRenderParams& charParams =
  ccSynFontCharRenderParams()) const;
```

Returns the kerning between the specified ordered pair of characters.

Parameters

firstCharCode The code of the first character.

secondCharCode
The code of the second character.

charParams The character rendering parameters.

Notes

The total advance from one character to the next:

advance(a) + **kerning(a, b)** + **tracking()**

renderMetrics() is often a more convenient way to get this information for a particular string.

Throws

ccSynFontDefs::UnknownChar
The **isKnown(***charCode***)** operation returned false.

isProportional

```
bool isProportional() const;
```

Returns whether this font is a proportional font.

fontType

```
FontType fontType() const;
```

Gets the type of the font as one of the following types:

eNone, *eRaster*, *eStroke*, *eOutline*, or *eImage*

isImageFont

```
bool isImageFont() const;
```

Returns whether the font is an image font; that is, whether it is based on stored bitmaps of characters rather than on synthetic descriptions of characters.

Notes

A font whose *fontType* is *eImage* will always be an image font, but it is also possible (confusingly) to have a font whose type is *eOutline* be an image font.

canMoveImageFontCharOrigins

```
bool canMoveImageFontCharOrigins() const;
```

Returns whether the font is an image font whose characters can have their origins moved using **moveImageFontCharOrigins()**.

moveImageFontCharOrigins

```
bool moveImageFontCharOrigins( ccImageFontChar::Origin
  origin = ccImageFontChar::eDetectedMarkLowerLeft);
```

Moves the origins as specified if the font is an image font.

Parameters

origin The origin.

Returns true if the move request could be fulfilled; that is, if the font was an image font.

Notes

Only fonts whose font type is *eImage* can be modified this way; the *eOutline* fonts that are image fonts cannot be modified like this (and typically do not need to be).

fontNames

```
static void fontNames(const ccCvlString& filename,
  cmStd vector<ccCvlString>& fontNames);
```

Gets names of all fonts present in the font file.

Parameters

filename The name of the font file.

fontNames The names of the fonts present in the font file.

Deprecated Members

The following member functions are deprecated. Use the overloads that take a **ccSynFontCharRenderParams** instead.

markRect

```
ccRect markRect(c_Int32 charCode,
  double spotSizeFactor,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0) const;
```

Gets the mark rectangle of one character.

Parameters

charCode The code of the character.

spotSizeFactor The *spotSize* factor.

extraStrokeWidth The increase of the stroke width of the font.

spotSpacingXScale
The x-coordinate spot spacing factor.

spotSpacingYScale
The y-coordinate spot spacing factor.

encloseMarkRect

```
ccRect encloseMarkRect(const cmStd vector<c_Int32>
  &charList,
  double spotSizeFactor,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0) const;

ccRect encloseMarkRect( const cmStd vector<cmStd
  vector<c_Int32> >&charLineList,
  double spotSizeFactor,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0) const;

ccRect encloseMarkRect(double spotSizeFactor,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0) const;
```

-
```
ccRect encloseMarkRect(const cmStd vector<c_Int32>
  &charList,
  double spotSizeFactor,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0) const;
```

Gets the enclosing mark rectangle of multiple characters.

Parameters

charList The characters.

spotSizeFactor The *spotSize* factor.

extraStrokeWidth The increase of the stroke width of the font.

spotSpacingXScale
The x-coordinate spot spacing factor.

spotSpacingYScale
The y-coordinate spot spacing factor.

- ```
  ccRect encloseMarkRect( const cmStd vector<cmStd
    vector<c_Int32> >&charLineList,
    double spotSizeFactor,
    double extraStrokeWidth = 0.,
    double spotSpacingXScale = 1.0,
    double spotSpacingYScale = 1.0) const;
  ```

  Gets the enclosing mark rectangle of multiple characters (in a form convenient for multiple lines).

  Parameters

  charLineList The characters.

  spotSizeFactor The *spotSize* factor.

  extraStrokeWidth The increase of the stroke width of the font.

  spotSpacingXScale
  The x-coordinate spot spacing factor.

  spotSpacingYScale
  The y-coordinate spot spacing factor.

- ```
  ccRect encloseMarkRect(double spotSizeFactor,
    double extraStrokeWidth = 0.,
    double spotSpacingXScale = 1.0,
    double spotSpacingYScale = 1.0) const;
  ```

  Get the enclosing mark rectangle of all characters.

  Parameters

  spotSizeFactor The *spotSize* factor.

  extraStrokeWidth The increase of the stroke width of the font.

  spotSpacingXScale
  The x-coordinate spot spacing factor.

  spotSpacingYScale
  The y-coordinate spot spacing factor.

ccSynFont

ccSynFontCharRenderParams

```
#include <ch_cvl/synfont.h>

class ccSynFontCharRenderParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccSynFontCharRenderParams** class specifies parameters that control the rendering of individual characters.

Constructors/Destructors

ccSynFontCharRenderParams

```
explicit ccSynFontCharRenderParams(double spotSizeFactor =
  1.0,
  double extraStrokeWidth = 0.,
  double spotSpacingXScale = 1.0,
  double spotSpacingYScale = 1.0):
    spotSizeFactor_(spotSizeFactor),
    extraStrokeWidth_(extraStrokeWidth),
    spotSpacingXScale_(spotSpacingXScale),
    spotSpacingYScale_(spotSpacingYScale);
```

Contstructs a default character render parameters object.

Notes

The default copy constructor, assign operator, and destructor are used.

Parameters

spotSizeFactor The *spotSize* factor.

extraStrokeWidth The increase of the stroke width of the font.

spotSpacingXScale
The x-coordinate spot spacing factor.

spotSpacingYScale
The y-coordinate spot spacing factor.

spotSizeFactor The *spotSize* factor.

extraStrokeWidth The increase of the stroke width of the font.

spotSpacingXScale
The x-coordinate spot spacing factor.

spotSpacingYScale
The y-coordinate spot spacing factor.

Public Member Functions

spotSizeFactor

```
double spotSizeFactor() const;

void spotSizeFactor(double s);
```

- `double spotSizeFactor() const;`

Gets a factor to be used as a multiplier on the font's *spotSize* value.

- `void spotSizeFactor(double s);`

Sets a factor to be used as a multiplier on the font's *spotSize* value.

Parameters
s The new *spotSize* factor value.

spotSize determines the size of the spots for raster fonts and the width of the stroke for stroke fonts.

Has no effect on outline fonts.

Throws
ccSynFontDefs::BadParams
spotSizeFactor is negative.

extraStrokeWidth

```
double extraStrokeWidth() const;

void extraStrokeWidth(double e);
```

- `double extraStrokeWidth() const;`

Gets the amount by which to change the stroke width of the given font, using morphology.

- `void extraStrokeWidth(double e);`

  Sets the amount by which to change the stroke width of the given font, using morphology.

  Parameters

  e The increase of the stroke width of the font.

  Using **spotSizeFactor()** is usually preferable, but this function may be needed for outline fonts.

  Notes

  The *extraStrokeWidth* value may be negative to indicate stroke width should be decreased.

spotSpacingXScale

```
double spotSpacingXScale() const;
void spotSpacingXScale(double xScale);
```

- `double spotSpacingXScale() const;`

  Gets the x-coordinate spot spacing factor.

- `void spotSpacingXScale(double xScale);`

  Sets the x-coordinate spot spacing factor.

  Parameters

  xScale The new x-coordinate spot spacing factor.

  spotSpacingXScale() specifies a factor by which to change the x-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Throws

  ccSynFontDefs::BadParams

  xScale is less than or equal to 0.

spotSpacingYScale

```
double spotSpacingYScale() const;

void spotSpacingYScale(double yScale);
```

- `double spotSpacingYScale() const;`

  Gets the y-coordinate spot spacing factor.

- `void spotSpacingYScale(double yScale);`

  Sets the y-coordinate spot spacing factor.

  spotSpacingYScale() specifies a factor by which to change the y-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Parameters

  yScale The new y-coordinate spot spacing factor.

  Throws

  ccSynFontDefs::BadParams

  yScale is less than or equal to 0.

ccSynFontDefs

```
#include <ch_cvl/synfont.h>

class ccSynFontDefs;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

The **ccSynFontDefs** class contains all of the enumerations specific to the ccSynFont class and its supporting classes.

Enumerations

Polarity

```
enum Polarity;
```

Polarity types for characters to specify the appearance of the character relative to its nearby background in the image.

Value	Meaning
eDarkOnLight = 0	Dark characters on light background
eLightOnDark	Light characters on dark background
eUnknown	Unknown polarity

ccSynFontDefs

ccSynFontRenderMetrics

```
#include <ch_cvl/synfont.h>

class ccSynFontRenderMetrics;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccSynFontRenderMetrics** class contains metrics (such as bounding boxes and origins) resulting from rendering one or more characters.

Constructors/Destructors

ccSynFontRenderMetrics

```
ccSynFontRenderMetrics();
```

Default constructor, defaults to all false.

Notes

The default copy constructor, assign operator, and destructor are used.

Enumerations

Metrics

```
enum Metrics;
```

Types of metrics for rendered characters.

Value	Meaning
ePose = 0x01	Character pose
eCellRect = 0x02	Character cell rect
eMarkRect = 0x04	Character mark rect
eUnionRect = 0x08	Encloses cell rect and mark rect
eOrigin = 0x10	Character origin

Value	Meaning
eEncloseCellRect = 0x20	Character enclose cell rect
ePolarity = 0x40	Character polarity

Public Member Functions

reset

```
void reset();
```

Resets all metrics to being not computed (all values to false).

hasPoses

```
bool hasPoses() const;
void hasPoses(bool h);
```

- `bool hasPoses() const;`

  Gets whether or not the object has a valid poses value.

- `void hasPoses(bool h);`

  Sets whether or not the object has a valid poses value.

  Parameters

  h — If true, the object has a valid poses value.

poses

```
const cmStd vector<cc2Xform>& poses() const;
void poses(const cmStd vector<cc2Xform>& poses);
```

- `const cmStd vector<cc2Xform>& poses() const;`

  Gets the vector of character poses.

  Throws

  ccSynFontDefs::NotComputed
  The **hasPoses()** operation returned false.

- `void poses(const cmStd vector<cc2Xform>& poses);`

  Sets the vector of character poses.

Parameters
poses The new vector of character poses.

hasCellRects

```
bool hasCellRects() const;

void hasCellRects(bool h);
```

- `bool hasCellRects() const;`

  Gets whether or not the object has a valid *cellRects* value.

- `void hasCellRects(bool h);`

  Sets whether or not the object has a valid *cellRects* value.

  Parameters
  h If true, the object has a valid *cellRects* value.

cellRects

```
const cmStd vector<ccAffineRectangle>& cellRects() const;

void cellRects(const cmStd vector<ccAffineRectangle>&
  cellRects);
```

- `const cmStd vector<ccAffineRectangle>& cellRects() const;`

  Gets the vector of character cellrects.

  Throws
  ccSynFontDefs::NotComputed
  The **hasCellRects()** operation returned false.

- `void cellRects(const cmStd vector<ccAffineRectangle>& cellRects);`

  Sets the vector of character cellrects.

  Parameters
  cellRects The new vector of character cellrects.

hasMarkRects

```
bool hasMarkRects() const;

void hasMarkRects(bool h);
```

- `bool hasMarkRects() const;`

  Gets whether or not the object has a valid *markRects* value.

- `void hasMarkRects(bool h);`

  Sets whether or not the object has a valid *markRects* value.

  Parameters

  h If true, the object has a valid *markRects* value.

markRects

```
const cmStd vector<ccAffineRectangle>& markRects() const;

void markRects(const cmStd vector<ccAffineRectangle>&
 markRects);
```

- `const cmStd vector<ccAffineRectangle>& markRects() const;`

  Gets the vector of character markrects.

  Throws

  ccSynFontDefs::NotComputed
  The **hasMarkRects()** operation returned false.

- `void markRects(const cmStd vector<ccAffineRectangle>& markRects);`

  Sets the vector of character markrects.

  Parameters

  markRects The new vector of character markrects.

hasUnionRects

```
bool hasUnionRects() const;

void hasUnionRects(bool h);
```

- `bool hasUnionRects() const;`

  Gets whether or not the object has a valid *unionRects* value.

- `void hasUnionRects(bool h);`

  Sets whether or not the object has a valid *unionRects* value.

  Parameters

  h If true, the object has a valid *unionRects* value.

unionRects

```
const cmStd vector<ccAffineRectangle>& unionRects() const;

void unionRects(const cmStd vector<ccAffineRectangle>&
unionRects);
```

- `const cmStd vector<ccAffineRectangle>& unionRects() const;`

  Gets the vector of character unionrects.

  Throws

  ccSynFontDefs::NotComputed
  The **hasUnionRects()** operation returned false.

- `void unionRects(const cmStd vector<ccAffineRectangle>& unionRects);`

  Sets the vector of character unionrects.

  Parameters

  unionRects The new vector of character unionrects.

hasOrigins

```
bool hasOrigins() const;

void hasOrigins(bool h);
```

- `bool hasOrigins() const;`

  Gets whether or not the object has a valid origins value.

- `void hasOrigins(bool h);`

  Sets whether or not the object has a valid origins value.

  Parameters

  h If true, the object has a valid origins value.

origins

```
const cmStd vector<cc2Vect>& origins() const;
void origins(const cmStd vector<cc2Vect>& origins);
```

- `const cmStd vector<cc2Vect>& origins() const;`

  Gets the vector of character origins.

  Throws
  ccSynFontDefs::NotComputed
  The **hasOrigins()** operation returned false.

- `void origins(const cmStd vector<cc2Vect>& origins);`

  Sets the vector of character origins.

  Parameters
  origins The new vector of character origins.

hasEncloseCellRects

```
bool hasEncloseCellRects() const;
void hasEncloseCellRects(bool h);
```

- `bool hasEncloseCellRects() const;`

  Gets whether or not the object has a valid *encloseCellRects* value.

- `void hasEncloseCellRects(bool h);`

  Sets whether or not the object has a valid *encloseCellRects* value.

  Parameters
  h If true, the object has a valid *encloseCellRects* value.

encloseCellRects

```
const cmStd vector<ccRect>& encloseCellRects() const;

void encloseCellRects(const cmStd vector<ccRect>&
encloseCellRects);
```

- `const cmStd vector<ccRect>& encloseCellRects() const;`

  Gets the vector of character enclosing cellrects.

  Throws

  ccSynFontDefs::NotComputed

  The **hasEncloseCellRects()** operation returned false.

- `void encloseCellRects(const cmStd vector<ccRect>& encloseCellRects);`

  Sets the vector of character enclosing cellrects.

  Parameters

  encloseCellRects

  The new vector of character enclosing cellrects.

hasPolarities

```
bool hasPolarities() const;

void hasPolarities(bool h);
```

- `bool hasPolarities() const;`

  Gets whether or not the object has a valid polarities value.

- `void hasPolarities(bool h);`

  Sets whether or not the object has a valid polarities value.

  Parameters

  h If true, the object has a valid polarities value.

polarities

```
const cmStd vector<ccSynFontDefs::Polarity>& polarities()
  const;

void polarities(const cmStd
  vector<ccSynFontDefs::Polarity>& p);
```

- ```
  const cmStd vector<ccSynFontDefs::Polarity>& polarities()
    const;
  ```

  Gets the vector of polarities.

- ```
  void polarities(const cmStd
    vector<ccSynFontDefs::Polarity>& p);
  ```

  Sets the vector of polarities.

  Parameters

p	The new vector of polarities.

ccSynFontRenderOutline

```
#include <ch_cvl/synfont.h>

class ccSynFontRenderOutline;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccSynFontRenderOutline** class represents a character or set of characters as a shape and as a graphic object. The outline has a hierarchical structure, with the top level of the structure corresponding to individual characters.

Constructors/Destructors

ccSynFontRenderOutline

```
ccSynFontRenderOutline();

ccSynFontRenderOutline(const ccSynFontRenderOutline& rhs);
```

- `ccSynFontRenderOutline();`

  Constructs a default (empty) outline.

- `ccSynFontRenderOutline(const ccSynFontRenderOutline& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

Operators

operator=

```
ccSynFontRenderOutline& operator=(const
  ccSynFontRenderOutline& rhs);
```

Assignment operator.

Parameters

rhs The assignment source.

Notes

The default destructor is used.

Public Member Functions

reset

```
void reset();
```

Resets the outline to a default (empty) state.

hasShape

```
bool hasShape() const;
```

Gets whether the outline has a representation as a shape.

shape

```
ccShapePtrh_const shape() const;
```

Gets the outline represented as a shape.

Throws

ccSynFontDefs::NotComputed
The **hasShape()** operation returned false.

hasGraphics

```
bool hasGraphics() const;
```

Gets whether the outline has a representation as a graphic object.

graphics

```
ccGraphicPtrh_const graphics() const;
```

Gets the outline represented as a graphic object.

Throws

ccSynFontDefs::NotComputed
The **hasGraphics()** operation returned false.

draw

```
void draw(ccGraphicList& glist) const;
```

Draws the outline into the graphic list.

Note There is no effect if **hasGraphics()** is false.

Parameters

glist The graphic list.

numChildren

```
c_Int32 numChildren() const;
```

Returns the number of children.

children

```
const cmStd vector<ccSynFontRenderOutline>& children()
  const;

void children(const cmStd vector<ccSynFontRenderOutline>&
  children);
```

- ```
  const cmStd vector<ccSynFontRenderOutline>& children()
    const;
  ```

  Gets the children of this outline.

- ```
  void children(const cmStd vector<ccSynFontRenderOutline>&
    children);
  ```

  Sets the children of this outline, and updates **shape()** and **graphics()** to represent the combination of all of them.

  Parameters

  children The new children of this outline.

takeChildren

```
void takeChildren(cmStd vector<ccSynFontRenderOutline>&
  children);
```

Sets the children of this outline, and updates **shape()** and **graphics()** to represent the combination of all of them; takes ownership of the vector, which will be empty after calling this function.

Parameters

children The new children of this outline.

isNull

```
bool isNull() const;
```

Returns whether this outline is null; for example, will not draw anything.

Notes

The outline for a blank character will always be null.

ccSynFontRenderOutline

props

```
const ccGraphicProps& props() const;
void props(const ccGraphicProps& p);
```

- `const ccGraphicProps& props() const;`

  Gets the graphic properties.

- `void props(const ccGraphicProps& p);`

  Sets the graphic properties.

  Parameters

  p The new graphic properties.

  Notes

  It is possible for an outline to have multiple properties; the getter will return the properties of the first non-null child, if there is one.

color

```
ccColor color() const;
void color(const ccColor& color);
```

- `ccColor color() const;`

  Gets the color.

- `void color(const ccColor& color);`

  Sets the color.

  Parameters

  color The new color.

  Notes

  It is possible for an outline to have multiple colors; the getter will return the color of the first non-null child, if there is one.

ccSynFontRenderParams

```
#include <ch_cvl/synfont.h>

class ccSynFontRenderParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccSynFontRenderParams** class specifies parameters that control the rendering of one or more characters as well as specifying which results are requested by a rendering operation.

Constructors/Destructors

ccSynFontRenderParams

```
ccSynFontRenderParams(): tracking_(cc2Vect(0, 0)),
  foreground_(10),
  background_(200),
  padding_(0),
  preserveImageCharacterGraylevels_(false),
  requestedResults_(eImage),
  requestedMetrics_(0),
  doSimplifyOutline_(false),
  outlineProps_(ccColor::greenColor());
```

Constructs a default font render parameters object.

Notes

The default copy constructor, assignment operator, and destructor are used.

Enumerations

Results

```
enum Results;
```

Value	Meaning
eImage = 0x0100	Produces the rendered image.
eMetrics = 0x0200	Produces the metrics specified by **requestedMetrics()**
eRenderedRects = 0x0400	Produces the rects for the characters.
eRenderedMasks = 0x0800	Produces the masks for the characters.
eOutline = 0x1000	Produces an outline for the set of characters.

Public Member Functions

tracking

```
cc2Vect tracking() const;
void tracking(const cc2Vect& t);
```

- `cc2Vect tracking() const;`

  Gets the tracking value, the distance between the origins of adjacent characters on a line.

- `void tracking(const cc2Vect& t);`

  Sets the tracking value, the distance between the origins of adjacent characters on a line.

  Parameters

  t The new tracking value.

extraLeading

```
cc2Vect extraLeading() const;
void extraLeading(const cc2Vect& e);
```

- `cc2Vect extraLeading() const;`

  Gets the amount to add to the font's leading value, the distance between the origins of sequential lines.

- `void extraLeading(const cc2Vect& e);`

  Sets the amount to add to the font's leading value, the distance between the origins of sequential lines.

  Parameters

  e The new amount to add to the font's leading value.

charParams

```
const ccSynFontCharRenderParams& charParams() const;
void charParams(const ccSynFontCharRenderParams& c);
```

- `const ccSynFontCharRenderParams& charParams() const;`

  Gets all character rendering parameters as a set.

- `void charParams(const ccSynFontCharRenderParams& c);`

  Sets all character rendering parameters as a set.

  Parameters

  c The new character rendering parameters as a set.

spotSizeFactor

```
double spotSizeFactor() const;
void spotSizeFactor(double s);
```

- `double spotSizeFactor() const;`

  Gets a factor to be used as a multiplier on the font's *spotSize* value.

- `void spotSizeFactor(double s);`

  Sets a factor to be used as a multiplier on the font's *spotSize* value.

  Parameters

  s The new *spotSize* factor value.

  spotSize determines the size of the spots for raster fonts and the width of the stroke for stroke fonts.

  Has no effect on outline fonts.

  Throws

  ccSynFontDefs::BadParams
  spotSizeFactor is negative.

extraStrokeWidth

```
double extraStrokeWidth() const;
void extraStrokeWidth(double e);
```

- `double extraStrokeWidth() const;`

  Gets the increase of the stroke width of the font.

- `void extraStrokeWidth(double e);`

  Sets the increase of the stroke width of the font.

  Parameters

  e The increase of the stroke width of the font.

  extraStrokeWidth() increases the stroke width of the given font, using morphology.

  Using **spotSizeFactor()** is usually preferable, but this function may be needed for outline fonts.

  Notes

  The *extraStrokeWidth* value may be negative to indicate stroke width should be decreased.

spotSpacingXScale

```
double spotSpacingXScale() const;
void spotSpacingXScale(double xScale);
```

- `double spotSpacingXScale() const;`

  Gets the x-coordinate spot spacing factor.

- `void spotSpacingXScale(double xScale);`

  Sets the x-coordinate spot spacing factor.

  Parameters
  xScale The new x-coordinate spot spacing factor.

  spotSpacingXScale() specifies a factor by which to change the x-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Throws
  BadParams
  xScale is less than or equal to 0.

spotSpacingYScale

```
double spotSpacingYScale() const;
void spotSpacingYScale(double yScale);
```

- `double spotSpacingYScale() const;`

  Gets the y-coordinate spot spacing factor.

- `void spotSpacingYScale(double yScale);`

  Sets the y-coordinate spot spacing factor.

  spotSpacingYScale() specifies a factor by which to change the y-coordinate of spots relative to each other; also changes the endpoints of strokes.

  Parameters
  yScale The new y-coordinate spot spacing factor.

  Throws
  BadParams
  yScale is less than or equal to 0.

clientFromFontXform

```
cc2Xform clientFromFontXform() const;
void clientFromFontXform(const cc2Xform& x);
```

- `cc2Xform clientFromFontXform() const;`

  Gets the client-from-font xform to be used for rendering.

- `void clientFromFontXform(const cc2Xform& x);`

  Sets the client-from-font xform to be used for rendering.

  Parameters

  x The new client-from-font xform to be used for rendering.

foreground

```
c_UInt8 foreground() const;
void foreground(c_UInt8 f);
```

- `c_UInt8 foreground() const;`

  Gets the foreground color to be used for rendering.

- `void foreground(c_UInt8 f);`

  Sets the foreground color to be used for rendering.

  Parameters

  f The new foreground color to be used for rendering.

background

```
c_UInt8 background() const;
void background(c_UInt8 b);
```

- `c_UInt8 background() const;`

  Gets the background color to be used for rendering.

- `void background(c_UInt8 b);`

  Sets the background color to be used for rendering.

Parameters

b The new background color to be used for rendering.

preserveImageCharacterGraylevels

```
bool preserveImageCharacterGraylevels() const;

void preserveImageCharacterGraylevels(bool p);
```

- `bool preserveImageCharacterGraylevels() const;`

  Gets whether to preserve the graylevels if the font is an image font, instead of trying to map the graylevels to the requested foreground/background range.

- `void preserveImageCharacterGraylevels(bool p);`

  Sets whether to preserve the graylevels if the font is an image font, instead of trying to map the graylevels to the requested foreground/background range.

  Parameters

  p If true, graylevels are preserved if the font is an image font.

  However, the foreground/background values will still indicate whether the image should be inverted.

padding

```
c_Int32 padding() const;

void padding(c_Int32 p);
```

- `c_Int32 padding() const;`

  Gets the uniform padding amount to surround the rendering.

- `void padding(c_Int32 p);`

  Sets the uniform padding amount to surround the rendering.

  Parameters

  p The new uniform padding amount to surround the rendering.

requestedResults

```
c_UInt32 requestedResults() const;
void requestedResults(c_UInt32 r);
```

- `c_UInt32 requestedResults() const;`

  Gets the types of results that the rendering operation should produce as a bitwise-OR of values from **ccSynFontRenderParams::Results**.

- `void requestedResults(c_UInt32 r);`

  Sets the types of results that the rendering operation should produce as a bitwise-OR of values from **ccSynFontRenderParams::Results**.

  The following types are possible:

  eImage – produces the rendered image.

  eMetrics – produces the metrics specified by **requestedMetrics()**

  eRenderedRects – produces the rects for the characters.

  eRenderedMasks – produces the masks for the characters.

  eOutline – produces an outline for the set of characters.

  The specified types of results will be stored in a **ccSynFontRenderResult** object.

  Parameters

r	The result type.

requestedMetrics

```
c_UInt32 requestedMetrics() const;
void requestedMetrics(c_UInt32 r);
```

- `c_UInt32 requestedMetrics() const;`

  Gets the types of metrics that the rendering operation should produce as a bitwise-OR of values from **ccSynFontRenderMetrics::Metrics**.

- `void requestedMetrics(c_UInt32 r);`

  Sets the types of metrics that the rendering operation should produce as a bitwise-OR of values from **ccSynFontRenderMetrics::Metrics**.

  Notes

  The **requestedResults()** must also specify *eMetrics* to actually compute any of the requested metrics. Each metric corresponds to the similarly-named accessor in a **ccSynFontRenderMetrics** object.

  Parameters

r	The types of metrics.

doSimplifyOutline

```
bool doSimplifyOutline() const;
void doSimplifyOutline(bool s);
```

- `bool doSimplifyOutline() const;`

  Gets whether to simplify the outline if one is requested.

- `void doSimplifyOutline(bool s);`

  Sets whether to simplify the outline if one is requested.

  If false, then the outlines will be the results of edge detection; if it is true, then simpler, smoother contours will be produced.

  Parameters

s	If true, the outline is simplified if one is requested.

outlineProps

```
const ccGraphicProps& outlineProps() const;
void outlineProps(const ccGraphicProps& p);
```

- `const ccGraphicProps& outlineProps() const;`

  Gets the graphic properties for the outline.

- `void outlineProps(const ccGraphicProps& p);`

  Sets the graphic properties for the outline.

Note The color is part of the outline properties, so changes to the outline color (see **outlineColor()** below) will change the color stored in the properties.

Parameters

p The graphic properties for the outline.

outlineColor

```
ccColor outlineColor() const;
void outlineColor(const ccColor& c);
```

- `ccColor outlineColor() const;`

  Gets the color for the outline.

- `void outlineColor(const ccColor& c);`

  Sets the color for the outline.

  Note The color is part of the outline properties, so changes to the properties (See **outlineProps()** above) will also affect the outline color.

  Parameters

  c The color for the outline.

ccSynFontRenderResult

```
#include <ch_cvl/synfont.h>

class ccSynFontRenderResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

The **ccSynFontRenderResult** class contains the result of a rendering operation, which can include the rendered image, an outline, and/or various metrics.

Constructors/Destructors

ccSynFontRenderResult

```
ccSynFontRenderResult();

ccSynFontRenderResult(const ccSynFontRenderResult& rhs);
```

- `ccSynFontRenderResult();`

  Constructs a default (empty) render result.

- `ccSynFontRenderResult(const ccSynFontRenderResult& rhs);`

  Copy constructor.

  Parameters

  rhs The source of the copy.

  Notes

  The default destructor is used.

Operators

operator=

```
ccSynFontRenderResult& operator=(const
  ccSynFontRenderResult& rhs);
```

Assignment operator.

Parameters

rhs The assignment source.

Public Member Functions

reset

```
void reset();
```

Resets result to be empty.

hasImage

```
bool hasImage() const;
```

Gets whether the result contains an image.

image

```
ccPelBuffer_const<c_UInt8> image() const;
```

Gets the rendered image.

Notes

For efficiency, the image stored in the result is a shallow copy of the image passed to **render()**, so any changes the user may make to the pels of that image will also be made to the pels of the image stored in this result.

Throws

ccSynFontDefs::NotComputed
The **hasImage()** operation returned false.

hasMetrics

```
bool hasMetrics() const;
```

Gets whether the result contains metrics.

metrics

```
const ccSynFontRenderMetrics& metrics() const;
```

Gets the rendered metrics.

Throws

ccSynFontDefs::NotComputed
The **hasMetrics()** operation returned false.

hasRenderedRects

```
bool hasRenderedRects() const;
```

Gets whether the result contains rendered character rectangles.

renderedRects

```
const cmStd vector<ccPelRect>& renderedRects() const;
```

Gets the rendered character rectangles. Each rectangle specifies the image-coordinate rectangle of pixels that enclose the rendered pixels for one character.

Throws

ccSynFontDefs::NotComputed
The **hasRenderedRects()** operation returned false.

hasRenderedMasks

```
bool hasRenderedMasks() const;
```

Gets whether the result contains rendered masks.

renderedMasks

```
const cmStd vector<ccPelBuffer_const<c_UInt8> >&
  renderedMasks() const;
```

Gets the rendered character masks. Each mask is an image whose window is the corresponding rendered rect and which contains a 255 for any pixel touched by rendering this character and a zero otherwise.

Throws

ccSynFontDefs::NotComputed
The **hasRenderedMasks()** operation returned false.

hasOutline

```
bool hasOutline() const;
```

Gets whether the result contains an outline.

outline

```
const ccSynFontRenderOutline& outline() const;
```

Gets the outline.

Throws

ccSynFontDefs::NotComputed
The **hasOutline()** operation returned false.

ccSynFontRenderResult

ccThreadID

```
#include <ch_cvl/threads.h>

class ccThreadID: public cc_PtrHandleBase_RepAccessor;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	No

A platform-independent thread handle. You can obtain a **ccThreadID** when you create a thread by calling **cfCreateThread()**, or by when you call **cfGetCurrentThreadID()**.

Constructors/Destructors

ccThreadID

```
ccThreadID();
```

You should not construct this class directly.

Operators

operator=

```
ccThreadID& operator=(const ccThreadID& rhs);
```

Assigns one **ccThreadID** to another.

Parameters

rhs The **ccThreadID** from which to assign.

operator const void*

```
operator const void* () const;
```

Returns zero if this is a default constructed **ccThreadID**, a nonzero value otherwise.

operator!

```
bool operator!() const;
```

Returns true if this is a non-default constructed **ccThreadID**, false otherwise.

operator==

```
bool operator==(const ccThreadID& rhs) const;
```

Returns true if this **ccThreadID** is equivalent to the supplied **ccThreadID**.

Parameters

rhs The **ccThreadID** to compare to this one.

operator!=

```
bool operator!=(const ccThreadID& rhs) const;
```

Returns false if this **ccThreadID** is equivalent to the supplied **ccThreadID**.

Parameters

rhs The **ccThreadID** to compare to this one.

Public Member Functions

osDependentThreadId

```
c_UInt32 osDependentThreadId() const;
```

Return the underlying operating system's thread identifier.

osDependentThreadHandle

```
void *osDependentThreadHandle() const;
```

Return the underlying operating system's thread representation.

atexit

```
void atexit(void (*func)
  (const ccThreadID&, void *arg), void *arg) const;
```

Registers a function which will be called after this thread exits. The supplied function must have the following signature:

```
void function(const ccThreadID& thr, void *arg);
```

where *thr* is the thread calling the function and *arg* is the argument you supply when you call **atexit()**.

You cannot call this function if this **ccThreadID** refers to the main program thread; use the C runtime function **atexit()** instead.

Parameters

func The function to call on exit

arg A value that will be supplied as the second argument to *func* when it is called.

Throws

ccThreadID::CouldNotRegister

The function could not be registered. Make sure that this **ccThreadID** does not refer to the main program thread and that you have not attempted to register more than 16 functions.

Notes

This function will be run in the context of the calling thread.

Static Functions

mainThreadID

```
static ccThreadID mainThreadID();
```

Returns a **ccThreadID** representing this program's main thread.

ccThreadID

ccThreadLocal

```
#include <ch_cvl/threads.h>

template <class T>class ccThreadLocal: public cc_ThreadLocal;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A templated class that implements thread-safe global storage.

You can instantiate any number of **ccThreadLocal** objects as static or global variables. Each thread that later accesses the contents of a **ccThreadLocal** object gets its own instance of the object. The **ccThreadLocal** class includes functions that let you set and get the value of the object.

You specify the type for a **ccThreadLocal** object on construction, as shown below:

```
ccThreadLocal<ccIPair> resultLocation;
```

The class you specify must support copy construction.

Constructors/Destructors

ccThreadLocal `ccThreadLocal();`

Constructs a **ccThreadLocal** object of a given type. You should only construct **ccThreadLocal** objects at STI time. You should not create automatic **ccThreadLocal** objects or dynamically allocated **ccThreadLocal** objects.

Public Member Functions

value

```
T* value();

const T* value() const;

void value(const T& val);
```

- `T* value();`

  Returns a pointer to the object stored in this **ccThreadLocal**. If the value of this **ccThreadLocal** has not been set, this function returns 0.

- `const T* value() const;`

  Returns a **const** pointer to the object stored in this **ccThreadLocal**. If the value of this **ccThreadLocal** has not been set, this function returns 0.

- `void value(const T& val);`

  Sets the value of this **ccThreadLocal**. This function is thread-safe: each thread sets its own value for a given **ccThreadLocal** object.

  Parameters

val	A reference to the object to store in this **ccThreadLocal**. The object being referred to is copied into the **ccThreadLocal** object.

ccThresholdResult

```
#include <ch_cvl/thresh.h>

class ccThresholdResult;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class represents the results of running the Threshold tool.

Constructors/Destructors

ccThresholdResult

```
ccThresholdResult();
```

Constructs a threshold result object with no computed threshold or score.

Public Member Functions

isComputed

```
bool isComputed() const;
```

Returns true if the threshold was successfully computed; false otherwise.

threshold

```
c_Int32 threshold() const;
```

Returns the computed threshold.

Throws

ccThresholdDefs::NotComputed
The threshold was not computed.

score

```
double score() const;
```

Returns the score for the threshold computation. This score is a value in the range 0.0 through 1.0 that indicates the separation of the two groups of bins determined by the threshold. A greater score means more separation. The score is 0.0 if the partial histogram has only one nonzero bin.

Throws

ccThresholdDefs::NotComputed
The threshold was not computed.

ccTimeout

```
#include <ch_cvl/attent.h>

class ccTimeout : public ccAttentionClient ;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

The **ccTimeout** class implements a timeout facility for CVL Vision Tools. You use **ccTimeout** by constructing a **ccTimeout** with a specified value (in seconds), then calling a vision tool function. If the tool has not completed its operation within the specified period of time, the tool throws a *ccTimeout::Expired* exception.

The **ccTimeout**-based timeout mechanism is not supported by all CVL vision tools. Refer to the documentation for specific tools to determine if that tool supports **ccTimeout**-based timeouts.

Constructors/Destructors

ccTimeout

```
ccTimeout(double delay_s);
```

Constructs this **ccTimeout** object to wait the specified number of seconds, and then throw *ccTimeout::Expired*. The error is thrown from any CVL function that supports timeouts

Once this **ccTimeout** object expires and throws *ccTimeout::Expired*, this **ccTimeout** object is deactivated.

If this **ccTimeout** object is destroyed before its time elapses, no error is thrown.

Parameters

delay_s — The timeout value seconds. *delay_s* must be greater than or equal to 0.0.

Notes

The timeout is expressed in real elapsed time, not execution time of the tool. The timeout you specify is rounded down to the nearest value supported by **ccTimer**, based on **ccTimer** granularity.

ccTimeout

ccTimeoutProp

```
#include <ch_cvl/prop.h>

class ccTimeoutProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes the timeout property of an acquisition FIFO queue. The timeout property limits the amount of time an acquisition FIFO will wait to obtain any resources it needs to perform an acquisition. For example, if all available image buffers are in use, the acquisition FIFO will wait until the end of the timeout period for a buffer to become available. If a buffer does not become available within that time, the acquisition FIFO gives up and the acquisition fails. The failure is reported in a **ccAcqFailure** object: **ccAcqFailure::isTimeout()** returns true.

In manual mode and semi-automatic mode the timeout interval begins when you call **start()**. Note that if you queue several starts, their timeout timers run coincident with one another. For auto trigger mode acquisitions, the timeout interval begins when the previous acquisition completes, and queued request timeout timers run serially, in the order in which they were queued.

For an externally triggered acquisition, the acquisition FIFO will wait indefinitely for a hardware trigger once it has obtained all the necessary resources.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Note This class has been deprecated and is maintained for backward compatibility only. New code should use other methods to protect against extended blocking during image acquisition.

Constructors/Destructors

ccTimeoutProp

```
ccTimeoutProp();
explicit ccTimeoutProp(double);
```

- `ccTimeoutProp();`

  Creates a new timeout property not associated with any FIFO. The timeout period is set to *ccExposureProp::defaultTimeout*.

- `explicit ccTimeoutProp(double seconds);`

  Creates a new timeout property not associated with any FIFO. The timeout period is set to *seconds*.

  Parameters

  seconds — The timeout period in seconds. A value of zero means to time out if the acquisition cannot start immediately. A value of *HUGE_VAL* means that the acquisition never times out.

  Throws

  ccTimeoutProp::BadParams — *seconds* was less than zero.

Public Member Functions

timeout

```
void timeout(double seconds);
double timeout();
```

- `void timeout(double seconds);`

  Set the timeout duration to *seconds*.

  Parameters

  seconds — The timeout period in seconds. A value of zero means to time out if the acquisition cannot start immediately. A value of *HUGE_VAL* means that the acquisition never times out.

  Throws

  ccTimeoutProp::BadParams — *seconds* was less than zero.

- `double timeout();`

  Return the timeout period in seconds.

Constants

defaultTimeout `static const double defaultTimeout = HUGE_VAL;`

ccTimeoutProp

ccTimer

```
#include <ch_cvl/timer.h>

class ccTimer;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

A class that implements a simple stopwatch-style timer. You can use this class to measure how long operations take in real time.

Constructors/Destructors

ccTimer

```
ccTimer(bool running = false);
```

Constructs a **ccTimer**. The **ccTimer** is initialized to have an elapsed time of 0 and an iteration count of 1.

Parameters

running — If true, the **ccTimer** begins accumulating elapsed time when it is constructed. If false, the **ccTimer** needs to be started with a call to **start()**.

Public Member Functions

start

```
void start();
```

Starts accumulating elapsed time. Calling this function does not reset this **ccTimer**'s total elapsed time.

stop

```
void stop();
```

Stops accumulating elapsed time. Calling this function does not reset this **ccTimer**'s total elapsed time.

Notes

You can obtain the current elapsed time for a **ccTimer** while it is running.

running

```
bool running() const;
```

Returns true if this **ccTimer** is currently accumulating elapsed time, false if it is stopped.

reset

```
void reset();
```

Resets this **ccTimer**'s accumulated elapsed time to 0.

Notes

You do not need to stop a **ccTimer** to reset it; you can reset a running **ccTimer**.

count

```
c_Int32 count() const;
void count(c_Int32 loop);
```

- `c_Int32 count() const;`

Returns this **ccTimer**'s iteration count. The **ticks()**, **sec()**, **msec()**, and **usec()** functions all normalize their return values by dividing them by the iteration count.

- `void count(c_Int32 loop);`

Sets this **ccTimer**'s iteration count. The **ticks()**, **sec()**, **msec()**, and **usec()** functions all normalize their return values by dividing them by the iteration count.

On construction, a **ccTimer**'s iteration count is 1.

Parameters

loop	The iteration count. *loop* must be greater than 0.

ticks

```
double ticks() const;
```

Returns the accumulated elapsed time in ticks, divided by this **ccTimer**'s iteration count.

sec

```
double sec() const;
```

Returns the accumulated elapsed time in seconds, divided by this **ccTimer**'s iteration count.

msec

```
double msec() const;
```

Returns the accumulated elapsed time in milliseconds, divided by this **ccTimer**'s iteration count.

usec

```
double usec() const;
```

Returns the accumulated elapsed time in microseconds, divided by this **ccTimer**'s iteration count.

rawTicks

```
double rawTicks() const;
```

Reports this **ccTimer**'s current accumulated elapsed time in ticks. The value returned by this function is not normalized by the iteration count, and is not adjusted to correct for the overhead of starting and stopping the timer.

Call the **ticksPerSecond()** to determine the duration of a tick.

Notes

Raw ticks are represented internally using 53 bits. The raw tick count wraps each 2^{53} ticks.

Static Functions

resolution

```
static double resolution();
```

Returns this system's underlying timer resolution, in microseconds per raw tick.

sleep

```
static void sleep(double seconds);
```

Calling this function causes the current thread to block for the requested number of seconds, rounded up to the underlying timer facility's tick granularity.

Parameters

seconds	The number of seconds to block. *seconds* must be greater than or equal to 0.

Notes

If you specify a value of 0.0, the current thread relinquishes the remainder of its timeslice to any other thread of equal priority that is ready to run. If there are no other threads of equal priority ready to run, this function returns immediately, and the thread continues execution.

While **sleep()** is accurate to approximately 10 milliseconds, **ccTimer** itself is accurate to within a few microseconds.

ticksPerSecond

```
static c_UInt32 ticksPerSecond();
```

Returns this system's underlying timer resolution, in raw ticks per second.

readSystemTime `static double readSystemTime();`

Returns the current system time in raw ticks.

Macros

cmExecutionTime

`cmExecutionTime(tm, statement);`

Executes the supplied C++ expression one time and places the time required to execute it in the supplied **ccTimer**.

Parameters

tm	A **ccTimer**.
statement	A C++ expression.

cmTiming `cmTiming(tm, num, statement);`

Executes the supplied C++ expression the specified number of times and places the time required to execute it in the supplied **ccTimer**.

Parameters

tm	A **ccTimer**.
num	The number of times to execute *statement*.
statement	A C++ expression.

Notes

This time returned by this macro includes the overhead of executing a **for** loop.

cmAutoTime `cmAutoTime(tm, min_ticks, statement);`

Executes the supplied C++ expression until the specified number of timer ticks has elapsed.

Parameters

tm	A **ccTimer**.
min_ticks	The number of timer ticks.
statement	A C++ expression.

ccTriggerFilterProp

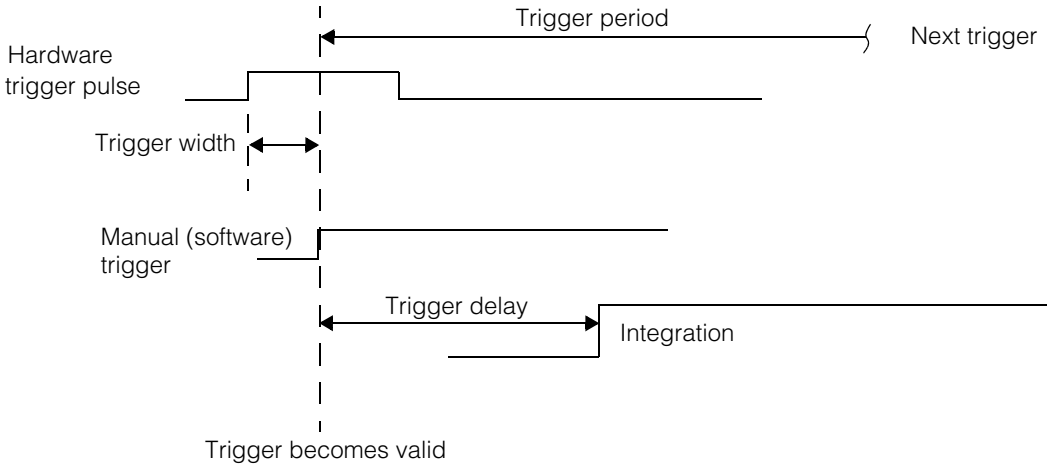
```
#include <ch_cvl/prop.h>

class ccTriggerFilterProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This object encapsulates the input trigger properties; trigger width, trigger period, and trigger delay. See the following diagram.

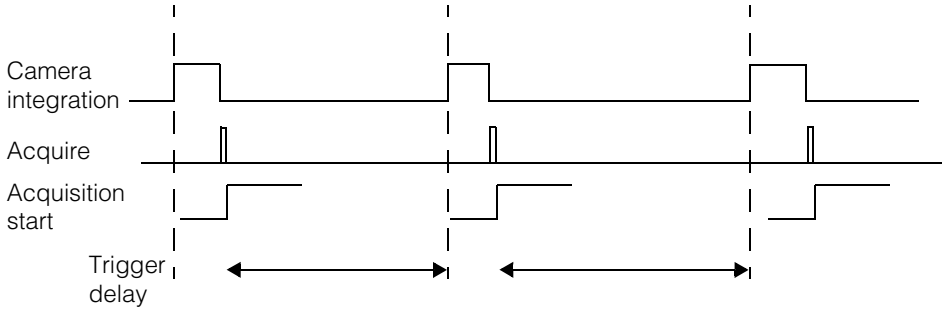


The example above shows both a hardware trigger and a manual trigger which is initiated by software. A hardware trigger pulse must satisfy the width requirement to become valid, while a manual trigger is effective immediately.

If you specify a trigger delay, camera integration is delayed by this amount after the trigger is effective.

For platforms such as the MVS-8600 and MVS-8600e that do not support setting variable steps-per-line for a test encoder, the trigger delay can be used with manual triggers to set the time between line scans for line scan camera applications. Without a trigger

delay the application would run at the camera frame rate, which may be faster than you wish. You can set a trigger delay to slow down the camera to the desired line rate. See the following diagram.



Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccTriggerFilterProp

```
ccTriggerFilterProp();

ccTriggerFilterProp(const ccTriggerFilterProp& that);

ccTriggerFilterProp(
  double width,
  double period,
  double delay);

virtual ~ccTriggerFilterProp() {};
```

- `ccTriggerFilterProp();`

  Default constructor.

- `ccTriggerFilterProp(const ccTriggerFilterProp& that);`

  Copy constructor.

Parameters

that	The object to copy.

- ```
  ccTriggerFilterProp(
    double width,
    double period,
    double delay);
  ```

  Constructs an object with the specified trigger width, period, and delay.

  Parameters

width	The hardware trigger width requirement in seconds. The trigger input signal must be asserted for at least this duration before it is recognized as a valid input trigger. If the trigger does not meet this width constraint, it is ignored.
period	The trigger input period requirement, in seconds. Only the first valid trigger within a *period* will initiate a camera integration cycle. Other valid triggers in that same period result in **isMissed()** errors. This can be used to help limit the camera acquisition rate. A zero specifies there is no period requirement.
delay	The delay in seconds, from an accepted trigger to camera integration start.

- ```
  virtual ~ccTriggerFilterProp() {};
  ```

  Destructor.

Operators

operator==

```
bool operator==(const ccTriggerFilterProp& that) const;
```

Comparison operator. Returns true is this object = *that*. Returns false otherwise.

Parameters

that	The other **ccTriggerFilterProp** object.

operator!=

```
bool operator!=(const ccTriggerFilterProp& that) const;
```

Comparison operator. Returns false is this object = *that*. Returns true otherwise.

Parameters

that The other **ccTriggerFilterProp** object.

Public Member Functions

triggerWidth

```
void triggerWidth(double);
double triggerWidth() const;
```

Note This method is not supported any longer.

The hardware trigger width requirement in seconds. The trigger input signal must be asserted for at least this duration before it is recognized as a valid input trigger. If the trigger does not meet this width constraint, it is ignored.

Notes

The latency between the edge transition of the trigger signal and the start of camera integration is computed as (triggerWidth + triggerDelay).

- `void triggerWidth(double);`

  Sets a new trigger width.

  Parameters

  double The new trigger width in seconds.

- `double triggerWidth() const;`

  Returns the current trigger width.

triggerPeriod

```
void triggerPeriod(double);
double triggerPeriod() const;
```

Note This method is not supported any longer.

The trigger input period requirement, in seconds. Only the first valid trigger within a *period* will initiate a camera integration cycle. Other valid triggers in that same period result in **isMissed(**) errors.

This can be used to help limit the camera acquisition rate. A zero specifies there is no period requirement.

- `void triggerPeriod(double);`

  Sets a new trigger period.

  Parameters

  double The new trigger period.

- `double triggerPeriod() const;`

  Returns the current trigger period.

triggerDelay

```
void triggerDelay(double delay);
double triggerDelay() const;
```

The delay in seconds, from an accepted trigger to camera integration start.

- `void triggerDelay(double);`

  Sets a new trigger delay.

  Parameters

  delay The new trigger delay in seconds.

  Notes

  On MVS-8600 and MVS-8600e frame grabbers using a linescan camera, the trigger delay property takes effect for every line instead of every frame as with area scan cameras. When using this property with linescan cameras it has a resolution of one horizontal line.

  For example, setting the delay to 1.0 adds a delay of one horizontal line time between acquisition of successive lines.

  This property may be used in conjunction with the built-in test encoder on the MVS-8600 to adjust the rate of acquisition of successive lines (line rate).

- `double triggerDelay() const;`

  Returns the current trigger delay.

ignoreMissedTrigger

```
void ignoreMissedTrigger(bool);

bool ignoreMissedTrigger() const;
```

- `void ignoreMissedTrigger(bool);`

  Returns true if a missed trigger does not generate an **isMissed** failure, false if a missed trigger does generate the failure.

  Parameters
  bool

- `bool ignoreMissedTrigger() const;`

  Set this value to false to cause a missed trigger to generate an **isMissed** failure when using an area scan camera. A missed trigger is a hardware trigger which failed to cause an acquisition to occur.

  See **ccAcqFailure** on page 209for conditions under which this failure may be generated.

  The default is true, which means that a missed trigger will not generate an **isMissed** failure.

  Notes
  Only the Rev 4 and above MVS-8602e supports this function. Rev 2 MVS-8602e does not support this function.

Constants

defaultTriggerWidth

```
static const double defaultTriggerWidth;
```

Default = 5e-6.

defaultTriggerPeriod

```
static const double defaultTriggerPeriod;
```

Default = 0.

defaultTriggerDelay

```
static const double defaultTriggerDelay;
```

Default = 0.

ccTriggerFilterProp

ccTriggerModel

```
#include <ch_cvl/trigmodl.h>

class ccTriggerModel;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This class describes the trigger models available for acquisition FIFO queues. The acquisition software creates trigger model objects that you can use as parameters to the **ccTriggerProp::triggerModel()** method. The following table summarizes the trigger models:

Trigger type	Also known as	Acquisition started by	Associated global function
Manual trigger	Software trigger	**ccAcqFifo::start()**	**cfManualTrigger()**
Auto trigger	Hardware trigger	External signal	**cfAutoTrigger()**
Semi trigger	n/a	**ccAcqFifo::start()**, then external signal	**cfSemiTrigger()**
Slave trigger	n/a	Same as master	**cfSlaveTrigger()**
Free run trigger	n/a	**ccAcqFifo:triggerEnable()** set to true	**cfFreeRunTrigger()**

If you are using a vision board that supports CVM11, you can specify encoder triggered acquisition. This is a special case of hardware (auto) triggering when using line scan cameras with CVM11. To use encoder triggering, set your trigger model as Auto or Semi, then use **ccEncoderProp::encoderTriggerEnabled()** as described on page 1363.

The relationship between the non-slave trigger models is summarized as follows:

	Needs external trigger	Does not need external trigger
Needs start()	Semi	Manual (software)
Does not need start()	Auto (hardware)	Free Run

Constructors/Destructors

The acquisition software creates one object for each trigger model.

Enumerations

ceBufferImages `enum ceBufferImages;`

This enumeration controls how the FIFO buffers completed images.

Value	Meaning
ckBuffer_Compatible	Images are buffered to the buffer capacity of the FIFO. This setting is appropriate for applications that must process all images. This is the default setting for all built-in trigger models.
ckBufferOnlyLatest	New images replace older images in the FIFO. This setting is appropriate for live video or applications that do not need to process every acquired image. Do not use this setting if **ccTriggerModel::startAction()** indicates that **start()** must be called, or with synchronous configurations. Replaced images are converted to **isMissed** errors, which are then handled according to the **missedErrorHandling()** setting. For example, if **ckIgnoreMissed** is set, replaced images are simply discarded. Take care when using callbacks with **ckBufferOnlyLatest** and **ckIgnoreMissed**. Because images are discarded, you will not be able to call **ccAcqFifo::complete()** as many times as your complete callback routine is called.

ceTriggerSource `enum ceTriggerSource;`

This enumeration specifies when the camera should acquire an image.

Value	Meaning
ckHardwareTrigger	Acquire an image when the hardware detects a trigger.
ckImmediateTrigger	Acquire an image as soon as the hardware is ready. This setting together with **ccTriggerModel::startAction(ckNotAllowed_Compatible)** causes the FIFO to "free run" or acquire images as fast as the acquisition hardware and camera will allow.
ckSoftwareTrigger	Wait until **ccAcqFifo::trigger()** is called before acquiring an image. This setting allows more precise control over when the image is captured than would be possible with **ccAcqFifo::start()**.

ceMissedErrorHandling
`enum ceMissedErrorHandling;`

This enumeration specifies whether the FIFO should report **isMissed** errors.

Value	Meaning
ckReportMissed_Compatible	Report all errors in a backward-compatible manner. This is the default setting for all built-in trigger models.
ckIgnoreMissed	Suppress reporting of **isMissed** errors; report all other errors as usual. This setting is useful when the video system is intentionally being triggered too fast.

ceStartAction `enum ceStartAction;`

This enumeration specifies whether acquisitions must be explicitly requested using **ccAcqFifo()::start()**, and determines how the start routine responds to error conditions.

Value	Meaning
ckRequestAcquire_Compatible	**ccAcqFifo::start()** must be called for every acquisition. This setting is the default for the manual and semi trigger models. If an acquisition cannot be requested because of insufficient resources, an **isMissed** error is queued and returned in sequence using **ccAcqFifo::complete()**. This setting is appropriate when property settings can be changed between acquisitions, or when multiple FIFOs are sharing a single camera.
ckNotAllowed_Compatible	Acquisitions can be started without a call to **ccAcqFifo::start()**. Calling this method will in fact cause a **ccAcqFifo::StartNotAllowed** exception to be thrown. This setting is the default for the auto and slave trigger models. This setting allows the FIFO to begin preparing the hardware for the next acquisition immediately upon completion of the preceding acquisition. This setting is appropriate for high-performance applications that use the same acquisition properties for every acquisition.
ckRequestAcquireOrFail	Similar to *ckRequestAcquire_Compatible*, but if a request fails, **ccAcqFifo::start()** returns false instead of queueing an **isMissed** error.
ckNotAllowedSilent	Similar to *ckNotAllowed_Compatible*, but calls to **ccAcqFifo::start()** are ignored instead of generating an exception.

ceHardwareTriggerAction

```
enum ceHardwareTriggerAction;
```

This enumeration specifies the choices you have for controlling image acquisition in response to a hardware trigger.

Value	Meaning
ckStartAcq_Compatible	Causes the acquisition fifo to acquire one image when an hardware trigger is input. Only one image is acquired for one hardware trigger. This is the default setting for Cognex hardware when using the built-in auto trigger model.
ckStartStopAcq	Causes the acquisition fifo to start acquiring images when a hardware trigger is input. The fifo will continue to acquire images as fast as possible until another hardware trigger is received at which point the fifo will stop acquiring. The fifo will wait for the next hardware trigger to occur to resume acquiring. Multiple images can be acquired from a single hardware trigger.
ckAcqOnTriggerHigh	Causes the acquisition fifo to start acquiring images and to continue acquiring images as long as the hardware trigger input signal is held high. The sense of the trigger input high setting depends upon the *triggerLowToHigh* property. Multiple images can be acquired from a single hardware trigger.
ckRestartAcq	This trigger model should be used with line scan cameras only. An initial trigger causes acquisition to begin at the start of the next image. Successive image acquisitions occur until the next trigger. The trigger can come any time, from immediately, to many images down stream. Each successive trigger causes acquisition to restart at the beginning of the next image. If a trigger occurs during an acquisition, the acquisition is terminated immediately and the image acquired up to that point is returned. Acquisition then restarts at the beginning of the next image.

Public Member Functions

name

```
const TCHAR* name() const;
```

Returns the name of this trigger model as a string. For example, “Manual” or “Automatic”.

copyForCustomization

```
ccTriggerModel* copyForCustomization() const;
```

Creates a user modifiable trigger model initialized with the settings of this trigger model. As all built-in CVL trigger models are **const**, you must call this method to customize any trigger model settings.

Notes

The returned trigger model is dynamically allocated using **new()**, therefore you must delete it when no longer needed to prevent memory leaks. A convenient way to do this is to use the reference-counted pointer handle version, **ccTriggerModelPtrh**. For example:

```
const ccTriggerModel tm1 = cfManualTrigger();
ccTriggerModelPtrh tm2Ptr(
  tm1.copyForCustomization());
// Now you can customize the copy pointed to by tm2Ptr
```

bufferImages

```
ceBufferImages bufferImages() const;

void bufferImages(ceBufferImages buffer);
```

- `ceBufferImages bufferImages() const;`

Retrieves the image buffer setting.

- `void bufferImages(ceBufferImages buffer);`

Sets how the FIFO buffers images.

Parameters

buffer The image buffer setting. Must be one of:

ccTriggerModel::ckBuffer_Compatible
ccTriggerModel::ckBufferOnlyLatest

Throws

ccTriggerModel::BadParams
buffer is not one of the allowed values.

triggerSource

```
ceTriggerSource triggerSource() const;
void triggerSource(ceTriggerSource source);
```

- `ceTriggerSource triggerSource() const;`

  Retrieves the trigger source setting.

- `void triggerSource(ceTriggerSource source);`

  Sets the trigger source to specify when the camera acquires an image.

  Parameters

  source The trigger source. Must be one of:

  ccTriggerModel::ckHardwareTrigger
  ccTriggerModel::ckImmediateTrigger
  ccTriggerModel::ckSoftwareTrigger

  Throws

  ccTriggerModel::BadParams
  source is not one of the allowed values.

missedErrorHandling

```
ceMissedErrorHandling missedErrorHandling() const;
void missedErrorHandling(ceMissedErrorHandling how);
```

- `ceMissedErrorHandling missedErrorHandling() const;`

  Retrieves the missed error setting, which determines how the FIFO reports **isMissed()** errors.

- `void missedErrorHandling(ceMissedErrorHandling how);`

  Sets how the FIFO reports **isMissed()** errors.

  Parameters

  how The missed error reporting setting. Must be one of:

  ccTriggerModel::ckReportMissed_Compatible
  ccTriggerModel::ckIgnoreMissed

Throws

ccTriggerModel::BadParams

how is not one of the allowed values.

hardwareTriggerAction

```
ceHardwareTriggerAction hardwareTriggerAction() const;

void hardwareTriggerAction(
                              ceHardwareTriggerAction action);
```

This setting controls how an external hardware trigger will affect acquisition. The choices are explained in the **ceHardwareTriggerAction** enum on page 3149.

- `ceHardwareTriggerAction hardwareTriggerAction() const;`

  Returns the current hardware trigger action setting.

- ```
  void hardwareTriggerAction(
                                ceHardwareTriggerAction action);
  ```

  Sets a new hardware trigger action. Must be one of the **ceHardwareTriggerAction** enums.

  Parameters

  action The new hardware trigger action.

  Notes

  hardwareTriggerAction() is only valid when you are using a hardware trigger, and **startAction()** is *ckNotAllowed_Compatible*.

  Only MVS-8600 frame grabbers operating with line scan cameras support this hardware trigger action functionality.

startAction

```
ceStartAction startAction() const;

void startAction(ceStartAction start);
```

- `ceStartAction startAction() const;`

  Retrieves the start action setting, which determines whether **ccAcqFifo::start()** must be called to start an acquisition.
```

- `void startAction(ceStartAction start);`

  Sets whether **ccAcqFifo::start()** must be called to start an acquisition. This setting also determines the response of the start routine to error conditions.

  Parameters

  start The start action setting. Must be one of:

  ccTriggerModel::ckRequestAcquire_Compatible
  ccTriggerModel::ckNotAllowed_Compatible
  ccTriggerModel::ckRequestAcquireOrFail
  ccTriggerModel::ckNotAllowedSilent

  Throws

  ccTriggerModel::BadParams
  start is not one of the allowed values.

bufferHardwareTrigger

```
bool bufferHardwareTrigger() const;

void bufferHardwareTrigger(bool enable);
```

- `bool bufferHardwareTrigger() const;`

  Retrieves the current enable/disable setting of the hardware trigger buffer feature.

- `void bufferHardwareTrigger(bool enable);`

  Controls whether triggers received during camera readout are accepted as a valid trigger without generating an **isMissed()** error. When enabled and such a trigger is received, the trigger is buffered until the acquisition is complete. At that time, the trigger is issued internally to initiate the next acquisition.

  Notes

  If multiple triggers occur during the readout, only the first is buffered. All other such triggers are ignored, and no **isMissed()** error is generated for these ignored triggers.

  If any triggers occur before the charge transfer interval, which precedes the camera readout phase, then an **isMissed()** error is generated.

  This feature is only supported on certain Cognex frame grabbers.

Deprecated Members

The following member functions are deprecated. They are provided for backward compatibility only.

isSlave

```
bool isSlave() const;
```

Returns whether this trigger model is slave.

usesInputLine

```
bool usesInputLine() const;
```

Returns whether this trigger model uses an input line to trigger acquisitions.

canStart

```
bool canStart() const;
```

Returns true if **ccAcqFifo::start()** can safely be called to start an acquisition with this trigger model. Returns false if calling **ccAcqFifo::start()** would throw an error.

Notes

This function returns true for **cfManualTrigger()** and **cfSemiTrigger()** and false for **cfAutoTrigger()** and **cfSlaveTrigger()**.

Typedefs

ccTriggerModelPtrh

```
typedef ccPtrHandle<ccTriggerModel> ccTriggerModelPtrh;
```

ccTriggerProp

```
#include <ch_cvl/prop.h>

class ccTriggerProp : virtual public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

This class describes the trigger property of an acquisition FIFO queue. Trigger models are described in **ccTriggerModel** on page 3145.

Since this class is one of the base classes of **ccAcqProps**, you do not need to create an instance of this class. All classes derived from **ccAcqFifo** can use **ccAcqFifo::properties()** to return a properties object that includes this property.

A table showing the acquisition hardware platforms that support this property is included in the *Acquiring Images* chapter of the *CVL User's Guide*.

Constructors/Destructors

ccTriggerProp

```
ccTriggerProp();

explicit ccTriggerProp(const ccTriggerModel& model,
  bool enable = true, bool lowToHigh = true,
  const ccPtrHandle<ccAcqFifo>& triggerMaster =
    ccPtrHandle<ccAcqFifo>());
```

- ```
  ccTriggerProp();
  ```

  Create a new trigger property object not associated with any FIFO. Triggering is enabled and default trigger model is **cfManualTrigger()**.

- ```
  explicit ccTriggerProp(const ccTriggerModel& model,
    bool enable = true, bool lowToHigh = true,
    const ccPtrHandle<ccAcqFifo>& triggerMaster =
      ccPtrHandle<ccAcqFifo>());
  ```

  Creates a new trigger not associated with any FIFO with the specified trigger model.

Parameters

model	The trigger model to use with this trigger property; one of **cfManualTrigger()**, **cfAutoTrigger()**, **cfSemiTrigger()** or **cfSlaveTrigger()**.
enable	True if triggered acquisitions are enabled. False if acquisitions should be immediate.
lowToHigh	True if a trigger signal is an input line transition from low to high. False means that a trigger signal is an input line transition from high to low
triggerMaster	If model is **cfSlaveTrigger()**, this is the slave's master acquisition FIFO.

Public Member Functions

triggerModel

```
void triggerModel(const ccTriggerModel& model);
const ccTriggerModel& triggerModel();
```

- `void triggerModel(const ccTriggerModel& model);`

  Set the trigger model for this trigger to *model*. The trigger model property determines the acquisition method. Changing the trigger model will temporarily disable triggers (if enabled) and flush the FIFO and all slaves.

  See **ccTriggerModel** on page 3145 for more information.

  Parameters

model	The trigger model to use with this trigger property; one of **cfManualTrigger()**, **cfAutoTrigger()**, **cfSemiTrigger()**, or **cfSlaveTrigger()**.

- `const ccTriggerModel& triggerModel();`

  Return this trigger property's trigger model.

triggerEnable

```
void triggerEnable(bool enable);
bool triggerEnable();
```

- `void triggerEnable(bool enable);`

  Enable or disable acquisitions as specified by the trigger model. The default is true. **triggerEnable()** affects all related master/slave FIFOs identically. For best results use the following recommendations:

  - Use **triggerEnable()** on a master only, if possible. In a multi-threaded master/slave application, undefined behavior can occur if two threads call **triggerEnable()** on separate, but related, FIFOs at the same time.
  - Disable triggers before changing trigger models, especially when setting up master/slave applications. This prevents extraneous disabling and enabling of triggers inside CVL functions during the master/slave setup.

  If an acquisition FIFO has slaves, changing the state of the master changes the states of all of the slaves.

  Parameters

  enabled — True if acquisitions can take place in all triggering models. False if acquisitions are to be queued (trigger model is **cfManualTrigger()**) or if transitions on the trigger input line are to be ignored (trigger model is **cfAutoTrigger()** or **cfSemiTrigger()**).

- `bool triggerEnable();`

  Return true if acquisitions are enabled for the specified trigger model.

triggerLowToHigh

```
void triggerLowToHigh(bool polarity);
bool triggerLowToHigh() const;
```

- `void triggerLowToHigh(bool polarity);`

  Sets the input trigger line polarity. The default is true: low to high transition.

  Parameters

  polarity — True means that a trigger signal is an input line transition from low to high. False means that a trigger signal is an input line transition from high to low.

Notes

Consult your hardware manual for proper connections and polarity.

- `bool triggerLowToHigh() const;`

Returns the input trigger line polarity.

triggerMaster

```
void triggerMaster(const ccPtrHandle<ccAcqFifo>& master);
const ccPtrHandle<ccAcqFifo>& triggerMaster() const;
```

- `void triggerMaster(const ccPtrHandle<ccAcqFifo>& master);`

Set the master of the acquisition FIFO to be *master*. This setting is relevant only when the trigger model is **cfSlaveTrigger()**.

Parameters

master The acquisition FIFO that is the master of this acquisition FIFO.

Throws

ccAcqFifo::InvalidMaster

This acquisition FIFO cannot be a slave to the specified master. See **couldSlaveTo()** on page 3158.

- `const ccPtrHandle<ccAcqFifo>& triggerMaster();`

Returns this acquisition FIFO's master.

couldSlaveTo

```
bool couldSlaveTo(const ccPtrHandle<ccAcqFifo>& master)
  const;
```

Returns true if this acquisition FIFO can be the slave of the specified acquisition FIFO. Returns false if these properties are not associated with a FIFO or if *master* is not a suitable master for this FIFO.

Parameters

master The acquisition FIFO to test.

Notes

ccTriggerProp::couldSlaveTo() indicates whether one FIFO can be a slave to another without taking into account current property settings. In particular, the master port property of the FIFOs must be set properly for master/slave configurations to work. If your master/slave configuration does not perform as expected, use

ccAcqFifo::isValid() to check each FIFOs configuration. If **isValid()** returns false, use **ccAcqProblem::hasInvalidMaster()** or **ccAcqProblem::hasInvalidSlave()** to determine whether the FIFO's master/slave configuration is supported.

ccTriggerProp

ccUIAffineRect

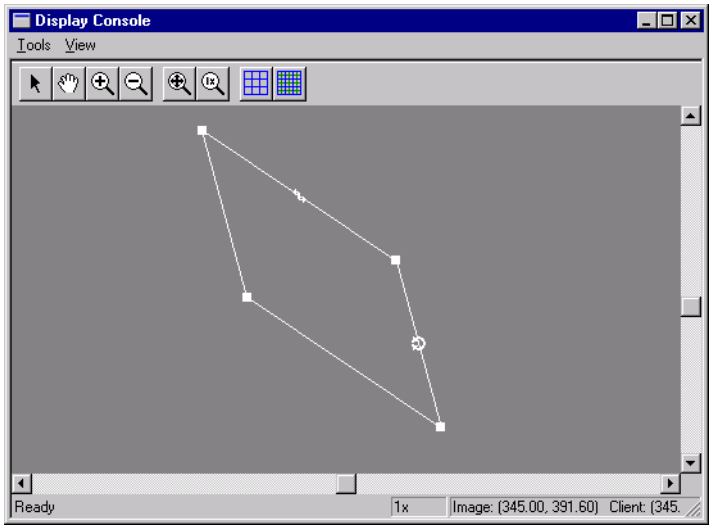
```
#include <ch_cvl/uishapes.h>

class ccUIAffineRect : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an affine rectangle (**ccAffineRectangle**) that you can manipulate. When you add a **ccUIAffineRect** object to a **ccDisplay** window an affine rectangle is displayed that can be moved about, resized, and rotated using your mouse. The following is an example of an affine rectangle that has been added to a **ccDisplayConsole** window.



ccUIAffineRect is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIAffineRect** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIAffineRect** has four resizing handles which all operate in the same way.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the object. The rotation handle is on the right-hand edge of the rectangle.
 Skew handle	Left-click on the skew handle holding the button down, and drag the handle to change the affine rectangle skew.

After manipulating an affine rectangle in a **ccDisplay** window, you will generally want to retrieve the final affine rectangle state and use it in some way. You can use code similar to the following to retrieve the manipulated affine rectangle.

```
ccAffineRectangle new_affineRect;
new_affineRect = ui_affineRect->affRect();
```

Where **ui_affineRect** is the manipulated **ccUIAffineRect** object.

Notes

ccUIAffineRect and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIAffineRect

```
ccUIAffineRect (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccAffineRectangle**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The rectangle's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eLock

This enumeration lets you specify which handles are not visible when the object is selected. By using these locks, you can prevent a shape from being modified along different degrees of freedom.

Value	Meaning
eNoLocks = 0	No locks. All manipulations allowed.
eSizeLock = 0x1	The object cannot be resized.
eRotLock = 0x2	The object cannot be rotated.
eSkewLock = 0x4	The object cannot be skewed.

Public Member Functions

affRect

```
void affRect(const ccAffineRectangle& r);

const ccAffineRectangle& affRect() const;
```

- `void affRect(const ccAffineRectangle&);`

  Associates a **ccAffineRectangle** with this manipulation object.

  Parameters

  r The affine rectangle to make manipulable.

- `const ccAffineRectangle& affRect() const;`

  Gets the **ccAffineRectangle** associated with this manipulation object.

updateHandles

```
virtual void updateHandles ();
```

Update all of my handles. Called when handles have been repositioned in the display.

showHandles `virtual void showHandles (bool show);`

Make my handles visible/invisible depending on *show*, and the DOF locks. If the handles aren't created yet, create them.

Parameters

show True = show handles. False = do not show handles.

freeHandles `virtual void freeHandles ();`

Deletes all handles.

locks

```
c_UInt32 locks() const;
void locks(c_UInt32 b);
```

- `c_UInt32 locks() const;`

  Returns the lock bits that indicate which resizing operations are not allowed for this object.

- `void locks(c_UInt32 b);`

  Sets the lock bits that indicate the resizing operations that are not allowed for this object.

  Parameters

  b The lock bits. May be any of the following ORed together:

  ccUIAffineRect::eNoLocks
  ccUIAffineRect::eSizeLock
  ccUIAffineRect::eRotLock
  ccUIAffineRect::eSkewLock

  These lock values are described in *Enumerations* on page 3163.

setLocks `void setLocks(c_UInt32 b);`

ORs the specified locks to the current locks.

Parameters

b The lock bits. May be any of the following ORed together:

ccUIAffineRect::eNoLocks
ccUIAffineRect::eSizeLock
ccUIAffineRect::eRotLock
ccUIAffineRect::eSkewLock

These lock values are described in *Enumerations* on page 3163.

clrLocks `void clrLocks(c_UInt32 b);`

Clears the locks specified in *b*. (ANDs the current locks with the complement of *b*)

Parameters

b The lock bits. May be any of the following ORed together:

ccUIAffineRect::eNoLocks
ccUIAffineRect::eSizeLock
ccUIAffineRect::eRotLock
ccUIAffineRect::eSkewLock

These lock values are described in *Enumerations* on page 3163.

isTouched `virtual bool isTouched (const cc2Vect& pt, double scale);`

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt The position to test in the coordinate system used to draw the shape.

scale The scale to convert *pt* to pixels.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;
virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the center location of the affine rectangle relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center location of the affine rectangle relative to its parent, in tablet coordinates.

  Parameters

  pos The new center location.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the affine rectangle in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

Static Functions

touchDist

```
static float touchDist();
static void touchDist(float d);
```

- `static float touchDist();`

Gets the distance from all instance of this object that is still considered a click on the object. The distance is in display coordinates.

- `static void touchDist (float d);`

Sets the distance from all instance of this object that is still considered a click on the object. The distance is in display coordinates.

Parameters

d	The distance from the object.

ccUICircle

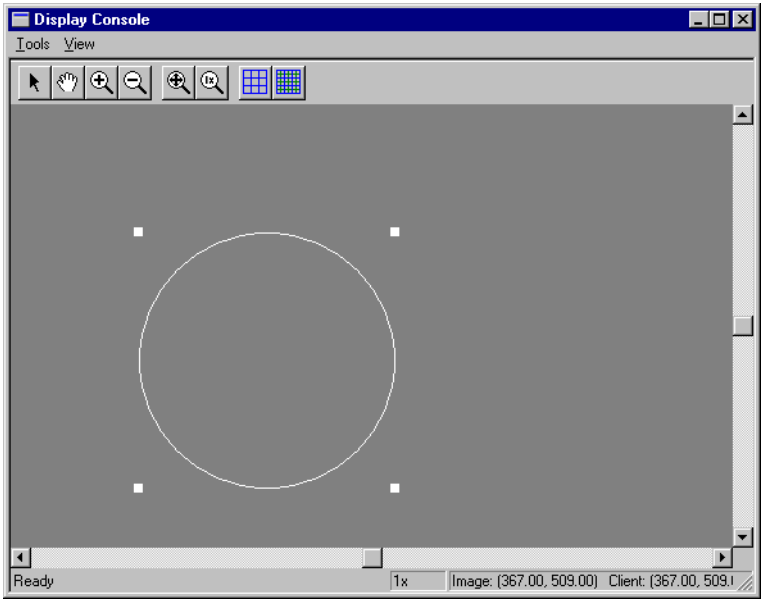
```
#include <ch_cvl/uishapes.h>

class ccUICircle : public ccUIGenRect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a circle (**ccCircle**) that you can manipulate. When you add a **ccUICircle** object a **ccDisplay** window a circle is displayed that can be moved about and resized using your mouse. The following is an example of a circle that has been added to a **ccDisplayConsole** window:



ccUICircle is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUICircle** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUICircle** has four resizing handles which all operate in the same way.

After manipulating a circle in a **ccDisplay** window, you will generally want to retrieve the final circle state and use it in some way. You can use code similar to the following to retrieve the manipulated circle.

```
ccCircle new_circle;
new_circle = ui_circle->circle();
```

Where **ui_circle** is the manipulated **ccUICircle** object.

Notes

ccUICircle and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUICircle

```
ccUICircle(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccCircle**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent	The circle's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

circle

```
void circle(const ccCircle& c);
ccCircle circle() const;
```

- Associates a **ccCircle** with this manipulation object.

  Parameters

  c The circle to make manipulable.

- `ccCircle circle() const;`

  Gets the **ccCircle** associated with this manipulation object.

ccUICircle

ccUICoordAxes

```
#include <ch_cvl/uishapes.h>

class cmImport_cogdisp ccUICoordAxes : public ccUIManShape;
```

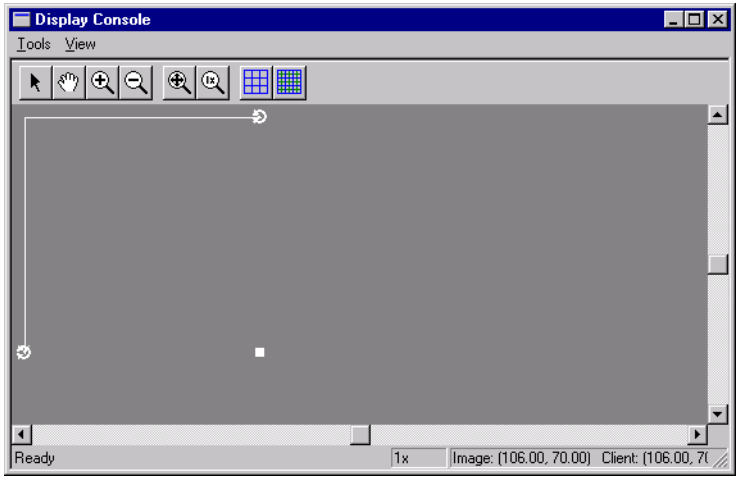
Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an x,y coordinate frame (**ccCoordAxes**) that you can manipulate. When you add a **ccUICoordAxes** object to a **ccDisplay** window an x,y coordinate frame is displayed that can be moved about, resized, and rotated using your mouse. You can lock specific degrees of freedom of the coordinate frame such as skew and rotation so that they cannot be changed with the mouse. See **ccUICoordAxes::locks()**.

The displayed coordinate frame is represented by a **cc2Xform** that maps user coordinates to client-specified base coordinates. Base coordinates are defined by a **cc2Xform** that maps base coordinates to tablet coordinates (*eDisplayCoords*, *eImageCoords*, or *eClientCoords* for **ccDisplay** objects). The full transform from user coordinates to tablet coordinates is obtained by multiplying the **ccUICoordAxes::tabletFromBase()** and **ccUICoordAxes::baseFromUser()** transforms.

The following is an example of a **ccUICoordAxes** coordinate frame that has been added to a **ccDisplayConsole** window.



ccUICoordAxes is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUICoordAxes** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the **ccUICoordAxes** object.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the object. Each axis has its own rotation handle. The axes rotate independently.

After manipulating a coordinate frame in a **ccDisplay** window, you will generally want to retrieve the final coordinate frame state and use it in some way. You can use code similar to the following to retrieve the manipulated coordinate frame.

```
ccCoordinageAxes new_coordAxes;
new_coordAxes = ui_coordAxes->coordAxes();
```

Where **ui_coordAxes** is the manipulated **ccUICoordAxes** object.

Notes

ccUICoordAxes and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUICoordAxes

```
ccUICoordAxes (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccCoordAxes** with an identity transformation, default locks, and default axes with length 0.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The coordinate axes parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eLock

The following enumerations let you specify which handles are not visible when the object is selected. By using these locks, you can prevent the object from being modified along different degrees of freedom. You can OR these values together to lock multiple degrees of freedom. For example, to prevent resizing of any of the axes, call **locks(ccUICoordAxes::eScaleLock | ccUICoordAxes::eAxesLenLock)**.

Value	Meaning
eNoLocks = 0	No locks are set. All manipulations allowed.
ePosLock = 0x1	Locks position. *Dragable* is FALSE when position is locked.
eScaleLock = 0x2	Locks scale. The object cannot be scaled. If scale is locked, aspect ratio is locked. Applies only to the X and Y coordinate axes adjustment handles, preventing scaling of the axes.
eAspectLock = 0x4	Locks aspect ratio. The object keeps the same aspect ratio when resized. The aspect ratio is locked regardless of *aspectLock* flag.
eRotLock = 0x8	Locks rotation. The object cannot be rotated. If rotation is locked, skew is locked
eSkewLock = 0x10	Locks skew. Object cannot be skewed. Skew is locked regardless of *skewLock* flag
eAxesLenLock = 0x20	Locks axes length independent of scale lock. Applies only to the coordinate axes size handles, preventing resizing of the axes.
eAllLock = 0x3F	All locks are set. No manipulations allowed

Public Member Functions

baseFromUser

```
const cc2Xform& baseFromUser () const;
void baseFromUser (const cc2Xform&);
```

- `const cc2Xform& baseFromUser () const;`

  Returns the base coordinates from user coordinates transformation object.

- `void baseFromUser (const cc2Xform& form);`

  Sets the base coordinates from user coordinates transformation object.

  Parameters

  form The transformation object

tabletFromBase

```
const cc2Xform& tabletFromBase () const;
void tabletFromBase (const cc2Xform&);
```

- `const cc2Xform& tabletFromBase () const;`

  Returns tablet coordinates from base coordinates transformation object.

- `void tabletFromBase (const cc2Xform& form);`

  Sets tablet coordinates from base coordinates transformation object.

  Parameters

  form The transformation object.

tabletFromUser

```
const cc2Xform& tabletFromUser () const;
```

Returns the full tablet coordinates from user coordinates transformation object. This is equivalent to multiplying the **tabletFromBase()** and **baseFromUser()** transformation objects.

axesLen

```
double axesLen () const;

void axesLen (double len);
```

- `double axesLen () const;`

  Returns the length of the displayed coordinate axes.

- `void axesLen (double len);`

  Sets the length of the displayed coordinate axes.

  Parameters

len	*len* > 0, sets length in user coordinates. *len*= 0: sets length to default value (-50). *len* < 0: sets length of x axis in tablet coordinates to the absolute of the value given. The length of y axis is determined by the aspect ratio of transform.

  Notes

  When the user manipulates the coordinate axes length by dragging the appropriate handle, **axesLen()** will be set positive in user coordinates, regardless of previous setting.

axesULen

```
double axesULen () const;
```

Returns the displayed length of the coordinate axes in user coordinates.

coordAxes

```
void coordAxes(const ccCoordAxes& ax, double xLen = 1,
  double yLen = 1);

const ccCoordAxes& coordAxes() const;
```

- `void coordAxes(const ccCoordAxes& axes, double xLen = 1, double yLen = 1);`

  Sets the coordinate axes representation in tablet coordinates. The transforms are modified, **tabletFromBase()** is set to the identity transform, and **baseFromUser(**) is computed from the coordinate axes and the specified x and y axes lengths in user coordinates. The axes lengths are used to compute x and y scale.

  Parameters

axes	The coordinate axes object.
xLen	Length in x direction.

yLen Length in y direction.

Notes

This setter requires that the coordinate *axes* input not be degenerate.

- `const ccCoordAxes& coordAxes() const;`

Returns the coordinate axes representation in tablet coordinates.

updateHandles `virtual void updateHandles ();`

Tells all handles to update themselves because of a change.

showHandles `virtual void showHandles (bool b);`

Make handles visible or invisible. If the handles aren't created yet, this function creates them.

Parameters

b True sets handles to visible. False sets handles to invisible.

freeHandles `virtual void freeHandles ();`

Deletes all handles.

locks

```
c_UInt32 locks () const;
void locks (ccUICoordAxes::eLocks = b);
```

- `c_UInt32 locks () const;`

Returns the lock bits that indicate which resizing operations are not allowed for this object.

- `void locks (c_UInt32 b);`

Sets the lock bits that indicate the resizing operations that are not allowed for this object.

Parameters

b The lock bits. May be any of the following ORed together:

ccUICoordAxes::eNoLocks
ccUICoordAxes::ePosLock
ccUICoordAxes::eScaleLock

ccUICoordAxes::eRotLock
ccUICoordAxes::AspectLock
ccUICoordAxes::SkewLock
ccUICoordAxes::AxesLenLock
ccUICoordAxes::AllLock

These lock values are described on page 3173

setLocks `void setLocks (c_UInt32 b);`

ORs the specified locks to the current locks.

Parameters

b The locks to OR with the current locks. May be any of the following ORed together:

ccUICoordAxes::eNoLocks
ccUICoordAxes::ePosLock
ccUICoordAxes::eScaleLock
ccUICoordAxes::eRotLock
ccUICoordAxes::AspectLock
ccUICoordAxes::SkewLock
ccUICoordAxes::AxesLenLock
ccUICoordAxes::AllLock

These lock values are described on page 3173.

clrLocks `void clrLocks (c_UInt32 b);`

Clears the locks specified in *b*. (ANDs the current locks with the complement of *b*)

Parameters

b The locks to clear. May be any of the following ORed together:

ccUICoordAxes::eNoLocks
ccUICoordAxes::ePosLock
ccUICoordAxes::eScaleLock
ccUICoordAxes::eRotLock
ccUICoordAxes::AspectLock
ccUICoordAxes::SkewLock
ccUICoordAxes::AxesLenLock
ccUICoordAxes::AllLock

These lock values are described on page 3173.

isTouched

```
virtual bool isTouched (const cc2Vect& pt,
  double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the position of the coordinate frame origin relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the position of the coordinate frame origin relative to its parent, in tablet coordinates.

  Parameters

pos	The new position.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the coordinate frame in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.

m The drawing mode. Must be one of:
ccUIShapes::drawNormal
ccUIShapes::drawAbridged
ccUIShapes::drawDrag

Static Functions

touchDist

```
static float touchDist();
static void touchDist(float d);
```

- `static float touchDist();`

  Gets the distance from all instances of this object that is still considered to be a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instances of this object that is still considered to be a click on the object. The distance is specified in display coordinates.

  Parameters

  d The distance from the object.

ccUICoordAxes

ccUIEllipse

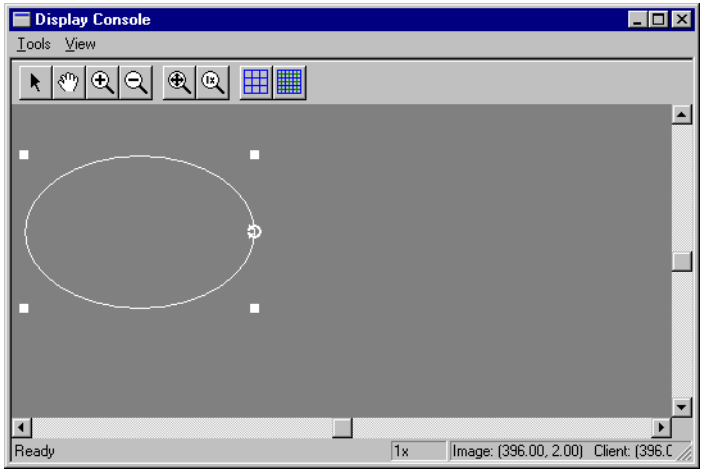
```
#include <ch_cvl/uishapes.h>

class ccUIEllipse : public ccUIGenRect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an ellipse (**ccEllipse2**) that you can manipulate. When you add a **ccUIEllipse** to a **ccDisplay** window an ellipse is displayed that can be moved about, reshaped, resized, and rotated using your mouse. The following is an example of an ellipse that has been added to a **ccDisplayConsole** window:



ccUIEllipse is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIEllipse** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIEllipse** has four resizing handles which all operate in the same way.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the ellipse. The rotation handle is on the ellipse right-hand edge.

After manipulating an ellipse in a **ccDisplay** window, you will generally want to retrieve the final ellipse state and use it in some way. You can use code similar to the following to retrieve the manipulated ellipse.

```
ccEllipse new_ellipse;
new_ellipse = ui_ellipse->ellipse();
```

Where **ui_ellipse** is the manipulated **ccUIEllipse** object.

Notes

ccUIEllipse and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIEllipse

```
ccUIEllipse(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccEllipse2**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The ellipse's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

ellipse2

```
void ellipse2(const ccEllipse2&);
ccEllipse2 ellipse2() const;
```

- `void ellipse2(const ccEllipse2& e);`

  Associates a **ccEllipse2** with this manipulation object.

  Parameters

  e The ellipse to make manipulable.

- `ccEllipse2 ellipse2() const;`

  Returns the **ccEllipse2** associated with this manipulation object

Deprecated Members

The following functions are deprecated and are provided for backwards compatibility only. Use the functions above instead.

ellipse

```
void ellipse(const ccEllipse& e);
ccEllipse ellipse() const;
```

- `void ellipse(const ccEllipse& e);`

  Associates a **ccEllipse** with this manipulation object.

  Parameters

  e The ellipse to make manipulable.

- `ccEllipse ellipse() const;`

  Gets the **ccEllipse** associated with this manipulation object.

ccUIEllipse

ccUIEllipseAnnulusSection

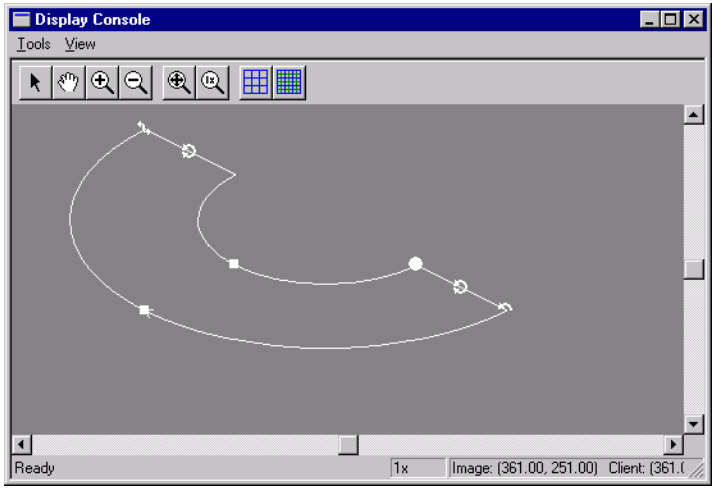
```
#include <ch_cvl/uishapes.h>

class ccUIEllipseAnnulusSection : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an elliptical annulus section (**ccEllipseAnnulusSection**) that you can manipulate. When you add a **ccUIEllipseAnnulusSection** to a **ccDisplay** window an elliptical annulus section is displayed that can be moved about, reshaped, resized, and rotated using your mouse. The following is an example of an elliptical annulus section that has been added to a **ccDisplayConsole** window:



ccUIEllipseAnnulusSection is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window

changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIEllipseAnnulusSection** uses the following handles:

Handle	Description
 Resizing handle	Left-click on a resize handle holding the button down and drag the handle to resize the ellipse radii. **ccUIEllipseAnnulusSection** has two resizing handles, one for the inner ellipse and one for the outer ellipse. When you resize an ellipse, its shape does not change.
 Subtended angle handle	Left-click on the subtended angle handle holding the button down and drag the handle to change the angle that defines the ellipse annulus section end points. **ccUIEllipseAnnulusSection** has two subtended angle handles, one for each end of the ellipse annulus section.
 Orientation handle	Left-click on the orientation handle holding the button down and drag the handle to rotate the ellipse annulus section about the common ellipse center. Note that this moves the section definition around the annulus so that when you stop at a different place, you will see a different annulus section with possibly a different shape.
 Spin handle	Left-click on a spin handle holding the button down and drag the handle to rotate the ellipse annulus section about its own center. Note that you are spinning the defined section and while it changes orientation, it does not change shape.
 Warp handle	Left-click on the warp handle holding the button down and drag the handle to warp the ellipse annulus section.

After manipulating an ellipse annulus section in a **ccDisplay** window, you will generally want to retrieve the final section state and use it in some way. You can use code similar to the following to retrieve the manipulated ellipse.

```
ccEllipseAnnulusSection new_ellipseAnnulusSection;
new_ellipseAnnulusSection =
             ui_ellipseAnnulusSection ->ellipseAnnulusSection();
```

Where **ui_ellipseAnnulusSection** is the manipulated **ccUIEllipseAnnulusSection** object.

Notes

ccUIEllipseAnnulusSection and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIEllipseAnnulusSection

```
ccUIEllipseAnnulusSection (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccEllipseAnnulusSection**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The section's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eLock

This enumeration lets you specify which handles are not visible when the object is selected. By using these locks, you can prevent a section from being modified along different degrees of freedom. These values can be ORed together to form a single bit field argument to **locks()**, **setlocks()**, and **clrlocks()**.

Value	Meaning
eNoLocks = 0	No locks. All manipulations are allowed.
eRadiiLock = 0x1	The section's radii cannot be resized.
eSubtendedAngleLock = 0x2	The angle from the center of the ellipses, subtended by the section's starting and ending angles, cannot be resized.
eOrientationLock = 0x4	Disables the handle that allows rotation of the annulus section around the center of its defining ellipses.

Value	Meaning
eSpinLock = 0x8	Disables the handle that allows rotation of the annulus section around its own center.
eWarpLock = 0x10	Disables the handle that allows warping of the annulus section. Warping keeps the section approximately the same area and with approximately the same center, but changes its curvature.

Public Member Functions

ellipseAnnulusSection

```
void ellipseAnnulusSection (const ccEllipseAnnulusSection
  &e);

const ccEllipseAnnulusSection ellipseAnnulusSection()
  const;
```

- ```
  void ellipseAnnulusSection (const ccEllipseAnnulusSection
    &e);
  ```

  Associates a **ccEllipseAnnulusSection** with this manipulation object.

  Parameters

  e The ellipse annulus section to make manipulable.

  Notes

  The two ellipses used to define an ellipse annulus section must be concentric. You can define an ellipse annulus section where the two ellipses are not concentric and the code will compile with no errors. However, at run time you will get a *ccShapesError::BadGeom* error.

- ```
  const ccEllipseAnnulusSection ellipseAnnulusSection()
    const;
  ```

  Gets the **ccEllipseAnnulusSection** associated with this manipulation object.

updateHandles

```
virtual void updateHandles();
```

Calls base class method and **update()** on the rotate handle.

showHandles

```
virtual void showHandles (bool b);
```

Creates handles if they weren't already created. Calls base class method and makes handles visible or invisible depending on the flag passed in.

Parameters

b True makes handles visible. False makes handles invisible.

freeHandles

```
virtual void freeHandles();
```

Deletes the handles so that the object can not be manipulated.

locks

```
c_UInt32 locks() const;
void locks(c_UInt32 b);
```

- `c_UInt32 locks() const;`

  Returns the lock bits that indicate which resizing operations are not allowed for this object.

- `void locks(c_UInt32 b);`

  Sets the lock bits that indicate the resizing operations that are disallowed for this object.

  Parameters

  b The lock bits. May be any of the members of the **ccEllipseAnnulusSection::eLock** enumeration, ORed together

setLocks

```
void setLocks (c_UInt32 b);
```

ORs the specified locks to the current locks.

Parameters

b The lock bits to OR with the current lock bits. May be any of the members of the **ccEllipseAnnulusSection::eLock** enumeration, ORed together

clrLocks

```
void clrLocks (c_UInt32 b);
```

Clears the locks specified in *b*. (ANDs the current locks with the complement of *b*)

Set/clear lock bits.

Parameters

b The lock bits to clear. May be any of the members of the **ccEllipseAnnulusSection::eLock** enumeration, ORed together

maxRadius

```
double maxRadius() const;
void maxRadius (double maxRadius);
```

- `double maxRadius() const;`

  Returns the current maximum radius setting.

- `void maxRadius (double maxRadius);`

  Sets a value for the largest radius to which an ellipse annulus section can be resized.

  maxRadius The maximum radius size to allow.

isTouched

```
virtual bool isTouched (const cc2Vect& pt, double scale);
```

Parameters

pt The position to test in the coordinate system used to draw the shape.

scale The scale to convert *pt* to pixels.

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call this function yourself.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;
virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the position of the UI shape relative to its parent, in tablet coordinates. The position is the center of the ellipse annulus section.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the position of the UI shape relative to its parent, in tablet coordinates.

  Parameters

pos	The new position.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

Static Functions

touchDist

```
static float touchDist();

static void touchDist (float d);
```

- `static float touchDist();`

  Gets the distance from all instances of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instances of this object that is still considered a click on the object. The distance is specified in display coordinates.

  Parameters

d	The distance from the objects.

ccUIEllipseAnnulusSection

ccUIEventProcessor

```
#include <ch_cvl/uievent.h>

class ccUIEventProcessor;
```

Class Properties

Copyable	No
Derivable	Not intended
Archiveable	Complex

This class provides the interface between keyboard and mouse events, and **ccUIObject** objects. There is one instance of this class for each **ccUIRootObject**.

Constructors/Destructors

ccUIEventProcessor

```
ccUIEventProcessor (ccUIRootObject* root);
```

Parameters

root Root must not be NULL.

Public Member Functions

processEvent

```
void processEvent(const ccMouseEvent& event);

void processEvent(const ccKeyboardEvent& event);
```

- ```
  void processEvent(const ccMouseEvent& event);
  ```

  Process mouse events by calling the appropriate **ccUIObject** virtual methods to implement the GUI behavior.

  Parameters

  event A mouse event.

- ```
  void processEvent(const ccKeyboardEvent& event);
  ```

  Process keyboard events by calling appropriate **ccUIObject** virtual method to implement the GUI behavior.

Parameters

event A keyboard event.

root

```
ccUIRootObject* root();
```

Returns the root UI object associated with this event processor.

owner

```
ccUIObject* owner ();
```

Returns the mouse owner. For example, which **ccUIObject** was the mouse pointing to when the mouse button was clicked.

owner() returns NULL if the **ccUIObject** mouse owner object is deleted.

anchor

```
const ccIPair& anchor () const;
```

Returns the point in screen coordinates where the mouse button down-click (not double-click) occurred. For example, a **click_()** override could call this function to determine where the click occurred, if your application needs to know.

button

```
c_UInt32 button ();
```

Returns which button owns the mouse. See **ccMouseEvent::Button** for enums.

dblClk

```
bool dblClk ();
```

Returns true if the last event was a double-click. This method is generally used in processing an up-click to distinguish those following down-clicks from those following double-clicks.

dwellCount

```
c_Int32 dwellCount ();
```

Returns the number of dwell events that have occurred since the down-click that started it.

invalidateObject

```
void invalidateObject (ccUIObject* obj);
```

Called when an object is deleted or when its root is changed so we can clean up any pointers to it or its ancestors. This is how we make sure, for example, that death does not result when someone double-clicks an object whose response to single-click is to delete itself.

Parameters

obj The object to invalidate.

mouseCapture

```
ccUIObject* mouseCapture ();
void mouseCapture (ccUIObject* obj);
```

The mouse can be associated with (captured) only one object at a time. If the root captures the mouse, the behavior will be the same as if no object has captured the mouse, and **mouseCapture()** will return the root instead of NULL.

- `ccUIObject* mouseCapture ();`

  Returns the object that has captured the mouse, or NULL if there is none.

- `void mouseCapture (ccUIObject* obj);`

  The specified object captures the mouse. NULL means release a captured mouse.

  Parameters

  obj The specified object.

lastMousePos

```
const ccIPair& lastMousePos() const;
```

Returns the last mouse position. Initially set to (0,0).

dragUpdating

```
void dragUpdating(bool b);
bool dragUpdating() const;
```

When set true, **ccUIRootObject::globalUpdate()** is called while dragging objects to update the display. When set false, the call is not made.

- `void dragUpdating(bool b);`

  Sets the update flag, true or false.

  Parameters

  b The new update flag.

- `bool dragUpdating() const;`

  Returns the current update flag.

multiSelectKey

```
void multiSelectKey(ccKeyboardEvent::VirtualKey k);

ccKeyboardEvent::VirtualKey multiSelectKey() const;
```

Specifies the keyboard key to use for multiple selections. If the key specified is held down you can make multiple selections with the mouse.

Valid values are *ccKeyboardEvent::eShift*, *ccKeyboardEvent::eControl*, and *ccKeyboardEvent::eNoVKey*. When you specify *ccKeyboardEvent::eNoVKey* multiple selections are disabled.

The default is *ccKeyboardEvent::eShift*.

- `void multiSelectKey(ccKeyboardEvent::VirtualKey k);`

Set a new key.

Parameters

k The new key.

Throws

ccUIError::BadKeyValue
If *k* is invalid.

Notes

Since each key can only have one function assigned to it at a time, the setting for **multiSelectKey()** interacts with the setting for **panKey()**. If **multiSelectKey()** is changed to the same value as **panKey()**, **panKey()** will be set to *ccKeyboardEvent::eNoVKey*.

- `ccKeyboardEvent::VirtualKey multiSelectKey() const;`

Returns the current key.

panKey

```
void panKey(ccKeyboardEvent::VirtualKey k);

ccKeyboardEvent::VirtualKey panKey() const;
```

Specifies the keyboard key to use for panning. If the specified key is held down the mouse pointer changes to a hand. You can then press the left mouse button and drag the image center to a new location.

Valid values are *ccKeyboardEvent::eShift*, *ccKeyboardEvent::eControl*, and *ccKeyboardEvent::eNoVKey*. When you specify *ccKeyboardEvent::eNoVKey* panning is disabled.

The default is *ccKeyboardEvent::eControl*.

- `void panKey(ccKeyboardEvent::VirtualKey k);`

  Set a new key.

  Parameters

  k The new key.

  Throws

  ccUIError::BadKeyValue
  If *k* is invalid.

  Notes

  Since each key can only have one function assigned to it at a time, the setting for **panKey()** interacts with the setting for **multiSelectKey()**. If **panKey()** is changed to the same value as **multiSelectKey()**, **multiSelectKey()** will be set to *ccKeyboardEvent::eNoVKey*.

- `ccKeyboardEvent::VirtualKey panKey() const;`

  Returns the current key.

ccUIEventProcessor

ccUIFormat

```
#include <ch_cvl/uistring.h>

class ccUIFormat;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Simple

This class is describes the font and alignment of string in classes that draw text such as labels.

Constructors/Destructors

ccUIFormat

```
ccUIFormat(c_Int32 fontId = -1,
  Alignment alignment = eTopLeft);
```

Creates a format object with the specified font and alignment.

Parameters

fontId — The font id to use for this format. The value –1 indicates the system font. Other values correspond to entries in the font table set in the platform-dependent display class such as **ccWin32Display::fontTable()**.

alignment — The alignment of the text. Must be one of:

ccUIFormat::eTopLeft
ccUIFormat::eTopCenter
ccUIFormat::eTopRight
ccUIFormat::eCenterLeft
ccUIFormat::eCenter
ccUIFormat::eCenterRight
ccUIFormat::eBottomLeft
ccUIFormat::eBottomCenter
ccUIFormat::eBottomRight

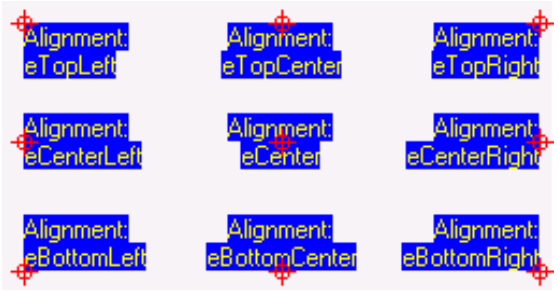
Enumerations

Alignment

```
enum Alignment;
```

These values let you specify how the text is aligned with respect to the drawing point.

Value	Meaning
eTopLeft	The following figure shows how each of the alignment values aligns the text with respect to the drawing point (indicated here by a point icon).
eTopCenter	
eTopRight	
eCenterLeft	
eCenter	
eCenterRight	
eBottomLeft	
eBottomCenter	
eBottomRight	



Public Member Functions

fontId

```
void fontId(c_Int32 id);
c_Int32 fontId() const;
```

- `void fontId(c_Int32 id);`

  Sets the font associated with this format.

  Parameters

  id — The font id to use for this format. The value –1 indicates the system font. Other values correspond to entries in the font table set in the platform-dependent display class such as **ccWin32Display::fontTable()**.

- `c_Int32 fontId() const;`

  Get the font id for this format.

alignment

```
void alignment(Alignment a);
Alignment alignment() const;
```

- `void alignment(Alignment a);`

  Specifies how the text should be aligned with respect to its drawing point.

  Parameters

  a The alignment of the text. Must be one of:

  ccUIFormat::eTopLeft
  ccUIFormat::eTopCenter
  ccUIFormat::eTopRight
  ccUIFormat::eCenterLeft
  ccUIFormat::eCenter
  ccUIFormat::eCenterRight
  ccUIFormat::eBottomLeft
  ccUIFormat::eBottomCenter
  ccUIFormat::eBottomRight

- `Alignment alignment() const;`

  Gets the alignment associated with this format.

ccUIFormat

ccUIGDShape

```
#include <uigdbase.h>

class ccUIGDShape : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This is an abstract base class that provides common support for all manipulable geometrical description shapes. These shapes have the following properties:

- They implement geometric descriptions of objects in shape coordinate space. The shape coordinate frame is attached to the shape and does not change when the shape is dragged.
- They embody a linear transformation that maps shape coordinates to model coordinates. Such linear transformation is automatically updated as the shape is dragged.
- The drawing is with respect to model coordinate space.
- They provide base class support for copying.
- The changes to a shape can be undone.
- Dragging can cause rotation, scaling or translation depending on the selected dragging mode.

Constructors/Destructors

ccUIGDShape

```
ccUIGDShape (ccUIObject* parent = NULL);
```

Constructs this **ccUIGDShape** with parent frame *parent*.

Parameters

parent — The parent frame of this **ccUIGDShape**. Typically, the display system will set up the parent for you when you add the shape to the display. In this case, the default (NULL) should be used.

Enumerations

ceDragMode `enum ceDragMode`

This enumeration defines the dragging modes of this **ccUIGDShape**.

Value	Meaning
eTranslate	Dragging translates this **ccUIGDShape**
eRotate	Dragging rotates this **ccUIGDShape**
eScale	Dragging scales this **ccUIGDShape**

Public Member Functions

clone

```
virtual ccUIGDShape* clone() const = 0;
```

Returns a pointer to a copy of this **ccUIGDShape** shape.

modelFromShape

```
virtual cc2Rigid modelFromShape() const = 0;
virtual void modelFromShape(const cc2Rigid& mFp) = 0;
```

- `virtual cc2Rigid modelFromShape() const = 0;`

  Returns the transformation that maps shape coordinates to model coordinates (typically, the model coordinates are the client coordinates of your application).

- `virtual void modelFromShape(const cc2Rigid& mFp) = 0;`

  Sets the transformation that maps shape coordinates to model coordinate to *mFp*.

  Parameters

  mFp — The transformation that maps shape coordinates to model coordinates.

undo

```
virtual void undo() = 0;
```

Undoes the last action that changed this **ccUIGDShape**.

condChanged

```
virtual bool condChanged() = 0;
```

Returns true if this **ccUIGDShape** has changed since the last time this function was called. Returns false otherwise.

Notes

The function will return false if this **ccUIGDShape** is in the default constructed state.

changed

```
virtual bool changed() const = 0;
```

Returns true if this **ccUIGDShape** shape has changed since the last time **ccUIGenPoly::condChanged** was called. Returns false otherwise.

Notes

The function will return false if this **ccUIGDShape** is in the default constructed state.

dragMode

```
void dragMode(ceDragMode mode);
ceDragMode dragMode() const;
```

- `void dragMode(ceDragMode mode);`

  Sets the dragging mode of this **ccUIGDShape** to *mode*.

  Parameters

  mode The dragging mode this **ccUIGDShape** is set to.

- `ceDragMode dragMode() const;`

  Gets the current dragging mode of this **ccUIGDShape**.

dragOrigin

```
void dragOrigin(const cc2Vect& origin);
const cc2Vect& dragOrigin() const;
```

- `void dragOrigin(const cc2Vect& origin);`

  Sets the origin in model coordinates about which this **ccUIGDShape** is rotated or scaled when **useDragOrigin()** is true.

  Parameters

  origin The origin about which this **ccUIGDShape** is rotated or scaled.

  Notes

  The origin remains unchanged after dragging.

- `const cc2Vect& dragOrigin() const;`

  Gets the current origin in model coordinate space about which this shape will rotate or scale when **useDragOrigin()** is true.

  Notes

  When **useDragOrigin()** is false, dragging is about the bounding box of this **ccUIGDShape** computed in model coordinates.

useDragOrigin

```
bool useDragOrigin() const;

void useDragOrigin(bool use);
```

- `bool useDragOrigin() const;`

  Returns true if this **ccUIGDShape** is in drag origin mode.

- `void useDragOrigin(bool use);`

  When *use* is true, **ccUIGDShape** is in drag origin mode. The rotation and scale dragging is about the origin set by **ccUIGDShape::dragOrigin()**.

  Parameters

use	The boolean variable that controls whether this **ccUIGDShape** is in drag origin mode.

drawWithXform

```
virtual void drawWithXform (ccUITablet& t,
  const ccColor& c,
  const cc2Xform& tabletFromModel,
  ccUIShapes::DrawMode m = drawNormal) = 0;
```

Draws this **ccUIGDShape** using the tablet *t* in the color specified by *c*. Before drawing, the shape is mapped to tablet coordinates by using *tabletFromModel*.

Parameters

t	The tablet used to draw this **ccUIGDShape**.
c	The color used to draw this **ccUIGDShape**.
tabletFromModel	The transformation that maps model coordinates to tablet coordinates.
m	The drawing mode.

snapAngle

```
void snapAngle(const ccDegree& angle);

const ccDegree& snapAngle() const;
```

- `void snapAngle(const ccDegree& angle);`

  Sets the angular step of the rotational dragging of this **ccUIGDShape** to *angle*. After setting this value, this **ccUIGDShape** can be rotated only in steps of *angle* degrees. During dragging this **ccUIGDShape** is snapped to the closest angle compatibile with this constraint.

  Parameters

  angle The smallest angle the shape can be rotated.

- `const ccDegree& snapAngle() const;`

  Returns the angular step used for the rotational dragging of this **ccUIGDShape**.

boundingBox

```
virtual ccRect boundingBox(
  const cc2Xform& clientFromShape) const = 0;

virtual ccRect boundingBox(
  const cc2Rigid& clientFromShape) const;

virtual ccRect boundingBox() const;
```

- ```
  virtual ccRect boundingBox(
    const cc2Xform& clientFromShape) const = 0;
  ```

  Returns the bounding rectangle of this **ccUIGDShape** in the client coordinates specified by *clientfromShape*.

  Parameters

  clientFromShape The transformation that maps shape coordinates to client coordinates.

- ```
  virtual ccRect boundingBox(
    const cc2Rigid& clientFromShape) const;
  ```

  Returns the bounding rectangle of this **ccUIGDShape** in the client coordinates specified by the rigid transformation *clientFromShape*.

  Parameters

  clientFromShape The rigid transformation that maps shape coordinates to client coordinates.

Notes

The client coordinates are defined by a rigid transformation. This type of transformation does not allow you to model scale changes between shape and client coordinates (see *Math Foundations of Transformations* in the *CVL User's Guide*).

- `virtual ccRect boundingBox() const;`

Returns the bounding rectangle of this **ccUIGDShape** in model coordinates.

snappedRigid

```
static cc2Rigid snappedRigid (const cc2Rigid& r,
  const ccDegree& angle);
```

Returns the closest rigid transformation to *r* that is compatibile with the angular step *angle*.

Parameters

r	The rigid transformation.
angle	The angular step.

snappedAngle

```
static ccDegree snappedAngle (const ccDegree& a,
  const ccDegree& angle);
```

Returns the closest angle to *a* that is compatibile with the angular step *angle*.

Parameters

a	The angle.
angle	The angular step.

axesColor

```
void axesColor(const ccColor &c);

const ccColor& axesColor() const;
```

Determines the displayed coordinate axes color.

The default color is yellow.

- `void axesColor(const ccColor &c);`

Sets the axes color. The axes color changes immediately.

Parameters

c	The new color.

- `const ccColor& axesColor() const;`

  Returns the current axes color.

axesVisible

```
void axesVisible(bool bVal);
bool axesVisible();
```

Determines if the coordinate axes are visible on the display. When set to true, the axes are visible. When set to false, the axes are not visible.

The default setting is true.

- `void axesVisible(bool bVal);`

  Set the visible flag, true or false. The axes are erased or drawn immediately.

  Parameters

  bVal The new flag value.

- `bool axesVisible();`

  Returns the current visible flag.

ccUIGenAnnulus

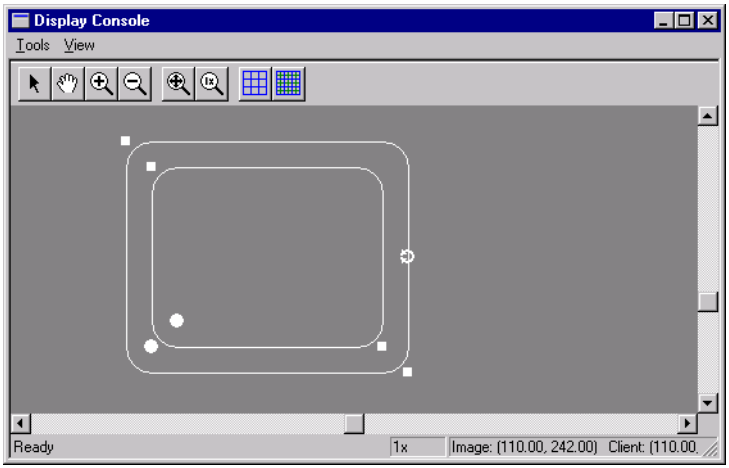
```
#include <ch_cvl/uishapes.h>

class ccUIGenAnnulus : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a generalized annulus (**ccGenAnnulus**) that you can manipulate. When you add a **ccUIGenAnnulus** object to a **ccDisplay** window a generalized annulus is displayed that can be moved about, resized, and rotated using your mouse. The following is an example of a generalized annulus that has been added to a **ccDisplayConsole** window.



ccUIGenAnnulus is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIGenAnnulus** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIGenAnnulus** has two resizing handles each, for both the inner rectangle and the outer rectangle.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the annulus. The rotation handle is on the annulus right-hand edge.
 Rounded corner handle	Left-click on the rounded corner handle holding the button down, and drag the handle to the object interior to round the corners. Dragging the handle to the object exterior squares the corners. Corner rounding handles are at the lower left-hand corner of each rectangle. One handle controls corner rounding for all four rectangle corners. Corner rounding for each rectangle is performed independently.

After manipulating a generalized annulus in a **ccDisplay** window, you will generally want to retrieve the final annulus state and use it in some way. You can use code similar to the following to retrieve the manipulated annulus.

```
ccGenAnnulus new_Annulus;
new_Annulus = ui_genAnnulus->annulus();
```

Where **ui_genAnnulus** is the manipulated **ccUIGenAnnulus** object.

Notes

ccUIGenAnnulus and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIGenAnnulus

```
ccUIGenAnnulus (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccGenAnnulus**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The annulus's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eSide

The following enumerations let you specify the boundary of the annulus object.

Value	Meaning
eInner	Inner boundary of annulus
eOuter	Outer boundary of annulus

Public Member Functions

annulus

```
void annulus(const ccGenAnnulus& a);
const ccGenAnnulus& annulus() const;
```

- `void annulus (const ccGenAnnulus& a);`

  Associates a **ccGenAnnulus** with this manipulation object.

  Parameters

  a The generalized annulus to make manipulable.

- `const ccGenAnnulus& annulus() const;`

  Gets the **ccGenAnnulus** associated with this manipulation object.

isTouched

```
virtual bool isTouched (const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt The position to test in the coordinate system used to draw the shape.

scale The scale to convert *pt* to pixels.

updateHandles

```
virtual void updateHandles ();
```

Calls base class method and **update()** on the rotate handle.

showHandles

```
virtual void showHandles (bool b);
```

Creates handles if they weren't already created. Calls base class method and makes handles visible or invisible depending on the flag passed in.

Parameters

b	True makes handles visible. False makes handles invisible

freeHandles

```
virtual void freeHandles ();
```

Deletes the handles so that the object can not be manipulated.

setHandle

```
void setHandle (ccUIGenAnnulusRotHandle* rh);
```

If the passed handle is non NULL, this function replaces the rotate handle.

Parameters

rh	The rotation handle object

Notes

This function is very useful for implementing constraint behavior. To implement your own constraint behavior, make a handle which derives from the appropriate handle type and implement your own constraint checking in the handle's **dragAnimate_** and **dragStop_** routines.

updateFromUIGR

```
void updateFromUIGR();
```

Updates the **ccGenAnnulus** object based on the **ccGenRect** objects of the contained **ccUIGenRect** objects. This function is called after the **ccGenRect** objects have stopped moving, which is called from the **dragStop()** routines of the handles and of this shape.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

- `virtual ccPoint pos_ () const;`

  Returns the position of the **ccUIGenAnnulus** relative to its parent, in tablet coordinates.

  This function always returns (0,0). This is necessary because the two **ccUIGenRect** objects that makeup the annulus must be children of the **ccUIGenAnnulus**, and since **absPos()** traverses the ancestor tree to find screen coordinates of the current object, the **ccUIGenRect** coordinates are offset by the position of the **ccUIGenAnnulus**. Since we want the position to be the same as if they were just regular **ccUIGenRect** objects, we need to make the returned position of the **ccUIGenAnnulus** be (0, 0).

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the position of the **ccUIGenAnnulus** relative to its parent, in tablet coordinates.

  Parameters

pos	The new position.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal;* draws a full **ccUIGenAnnulus** *ccUIShapes::drawAbridged;* draws a full **ccUIGenAnnulus** *ccUIShapes::drawDrag;* draws a **ccUIGenAnnulus** without rounding

dragStop_

```
virtual void dragStop_ (
  const ccIPair& start,
  const ccIPair& stop);
```

An override.

Calls **dragStop_()** of the inner **ccUIGenRect**. This is needed when the annulus is being dragged, instead of the inner or outer **ccUIGenRect**s.

Parameters

start	Starting drag position in screen coordinates.
stop	Ending drag position of the drag in screen coordinates.

Static Functions

touchDist

```
static float touchDist ();
static void touchDist (float d);
```

- `static float touchDist();`

Gets the distance from all instances of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

Sets the distance from all instances of this object that is still considered a click on the object. The distance is specified in display coordinates.

Parameters

d	The distance from the objects.

checkValid

```
static bool checkValid(const ccGenRect& inner,
          const ccGenRect& outer, eSide = type);
```

Returns true if *inner* is contained in *outer* such that a flood fill starting one pixel in towards the center from any point on the outer boundary will completely color the annulus.

Parameters

inner	The rectangle comprising inner boundary of annulus.
outer	The rectangle comprising outer boundary of annulus.
type	The type of boundary. Must be one of the following:

ccUIGenAnnulus::eInner
ccUIGenAnnulus::eOuter

These values are described in Enumerations on page 3213.

ccUIGenAnnulus

ccUIGenPoly

```
#include <uignpoly.h>

class ccUIGenPoly : public virtual ccUIGDShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class is used to make a **cc2Wireframe** object manipulable from within a **ccDisplay** object. You can scale, rotate, and translate a **ccUIGenPoly** shape by using the functions provided by the base **ccUIGDShape** class. **cUIGenPoly** includes editing modes for changing shape attributes that are specific to wireframes and provides mutually exclusive drawing modes for drawing rectangles, triangles, circles and polygons.

Constructors/Destructors

ccUIGenPoly

```
ccUIGenPoly (ccUIObject* parent = NULL);
```

Constructs this **ccUIGenPoly** shape in no-edit and no-draw mode.

Parameters

parent — The parent frame of this **ccUIGenPoly** shape. Typically, the display system will set up the parent for you when you add the shape to the display. In this case, the default (NULL) should be used.

Enumerations

ceEditMode `enum ceEditMode`

This enumeration defines the editing modes of this **ccUIGenPoly** shape.

Value	Meaning
eNoEditMode	No-edit mode (default value). Only normal dragging modes are supported.
eVertexMode	Editing vertex mode. It displays and enable handles at the vertices of a polygon. You can drag the handles to change the position of the vertices.
eNewVerticesMode	Create new vertices mode. It displays and enables handles at the midpoint of each segment and at the first and last vertex if the polygon is open. You can drag these handles to insert and change the position of vertices.
eRoundingMode	Rounding vertices mode. It displays and enables handles at the midpoint of each segment and at all but the end vertices of the closed polygon. You can drag a segment handle to change its angle span. You can drag a vertex handle to change its rounding.
eVertDelMode	Vertex-deletion mode. Normal dragging is disabled and no handles are visible. You can click on vertices to delete them. If the deleted vertex is not an end vertex, the vertices on either side are directly connected by a new segment.
eSegDelMode	Segment-deletion mode. Normal dragging is disabled and no handles are visible. You can click on segments to delete them.

Notes

The **ccUIGenPoly::isRectilinear(bool r)** member function allows you to constrain this **ccUIGenPoly** shape to be rectilinear. In this case *eNewVerticesMode*, *eRoundingMode* and *eVertDelMode* are not available.

ceDrawMode `enum ceDrawMode`

This enumeration defines the drawing modes of this **ccUIGenPoly** shape.

Value	Meaning
eNoDrawMode	No-draw mode (default value). Normal editing and dragging mode
eDrawPolygonMode	Draw polygon mode. The display enters a mode in which the first mouse click action will place the first vertex, the second mouse click the second vertex, and so on, thereby creating a polygon. A right mouse click will place the last vertex of the polygon, while a double-click or a click on the first vertex will close the polygon. In either case, the object and display are returned to no-draw mode.
eDrawCircleMode	Draw circle mode. The display enters a mode in which the first mouse down action places the center of the circle, and a subsequent dragging determines the radius of the circle by the current distance of the mouse from the center. The circle is finished and the object and display are returned to no-draw mode after a mouse up action.
eDrawRectMode	Draw rectangle mode. The display enters a mode in which the first mouse down action places a corner of the rectangle, and a subsequent dragging determines the diagonal of the rectangle (the line segment between the mouse and the first corner). The rectangle is finished and the object and display are returned to no-draw mode after a mouse up action.

Value	Meaning
eDrawCornerMode	Draw corner mode. The display enters a mode in which the first mouse down action places the vertex of the 90° corner, and a subsequent dragging determines one side of the corner by the line segment between the mouse and the vertex (the other side has the same length). The corner is finished and the object and display are returned to no-draw mode after a mouse up action.
eDrawTriangleMode	Draw triangle mode. The display enters a mode in which the first mouse down action places the center of the triangle, and a subsequent dragging determines one of the base vertices of an isosceles triangle, the vertex with height of the odd vertex being determined by the distance from the base to the center. The triangle is finished and the object and display are returned to no-draw mode after a mouse up action.

Notes

The **ccUIGenPoly::isRectilinear(bool r)** member function allows you to constrain this **ccUIGenPoly** shape to be rectilinear. In this case *eDrawCircleMode* and *eDrawTriangleMode* are not available, and the vertices of polygons drawn in e*DrawPolygonMode* have angles equal to 90°.

Public Member Functions

wireframe

```
cc2Wireframe wireframe() const;
```

Returns the wireframe corresponding to this **ccUIGenPoly** shape in model coordinates (typically, the client coordinates of your application).

shape

```
void shape (const cc2Wireframe& wrfrm);
const cc2Wireframe& shape() const;
```

- `void shape (const cc2Wireframe& wrfrm);`

  Sets this **ccUIGenPoly** shape to *wrfrm*. Calling this function causes handles to be drawn.

  Parameters

  wrfrm The wireframe object this **ccUIGenPoly** shape is set to.

  Throws

  ccShapesError::BadGeom
  wrfrm is immutable.

- `const cc2Wireframe& shape() const;`

  Returns the **cc2Wireframe** object from this **ccUIGenPoly** shape.

shapeAndModelPos

```
void shapeAndModelPos (const cc2Wireframe& wrfrm,
  const cc2Rigid& mFp);
```

Sets this **ccUIGenPoly** shape to *wrfrm* and the transformation that maps shape coordinates to model coordinates to *mFp*.

Parameters

wrfrm The wireframe this **ccUIGenPoly** is set to.

mFp The **cc2Rigid** transformation that maps shape coordinates to model coordinates.

Throws

ccShapesError::BadGeom
wrfrm is immutable.

Notes

Calling **ccUIGenPoly::Undo()** after this function reverts both the wireframe and the transform.

editMode

```
ceEditMode editMode();

void editMode(ceEditMode editMode);
```

- `ceEditMode editMode();`

  Returns the editing mode of this **ccUIGenPoly** shape.

- `void editMode(ceEditMode editMode);`

  Sets the editing mode of this **ccUIGenPoly** to *editMode*.

  Parameters

  editMode The editing mode this **ccUIGenPoly** shape is set to.

  Throws

  ccShapesError::BadGeom
  This **ccUIGenPoly** shape is rectilinear and one of the following modes is selected*: ceEditMode::eNewVerticesMode, ceEditMode::eRoundingMode*, or *ceEditMode::eVertDelMode.*

  Notes

  The shape will remain the in the supplied edit mode until the mode is changed by a call to **ccUIGenPoly::editMode()**. The function has no effect if **ccUIGenPoly::isDrawing()** is true. *ceEditMode::eVertDelMode* and *ccEditMode::eSegDelMode* disable normal dragging for this **ccUIGenPoly** shape.

drawMode

```
ceDrawMode drawMode();

void drawMode(ceDrawMode drawMode,
  const ccDimTol& tol = ccDimTol());
```

- `ceDrawMode drawMode();`

  Returns the drawing mode of this **ccUIGenPoly** shape.

- `void drawMode(ceDrawMode drawMode, const ccDimTol& tol = ccDimTol());`

  Sets the drawing mode of this **ccUIGenPoly** shape to *drawMode* and sets the tolerances of the shape to *tol*. This **ccUIGenPoly** is deleted in preparation for drawing.

  Parameters

  drawMode The drawing mode of this **ccUIGenPoly** shape.

tol The tolerances to be used for each segment of this **ccUIGenPoly** shape (nominal value is ignored).

Throws

ccShapesError::BadGeom
This **ccUIGenPoly** shape is rectilinear and *ceDrawMode::eDrawCircleMode* or *ceDrawMode::eDrawTriangleMode* is selected.

Notes

The drawing mode will return to *ceDrawMode:: eNoDrawMode* after drawing has finished. Normal dragging is disabled for all but *ceDrawMode:: eNoDrawMode*.

isDrawing

```
bool isDrawing();
```

Returns true if the drawing mode of this **ccUIGenPoly** shape is different from *ceDrawMode:: eNoDrawMode*.

isRectilinear

```
void isRectilinear(bool r);
bool isRectilinear() const;
```

- `void isRectilinear(bool r);`

If *r* is true, it constrains this **ccUIGenPoly** shape to be rectilinear and snaps it to the closest rectilinear shape that has the same number of vertices. If *r* is false, it removes any rectilinear constraints. The vertices of a rectilinear **ccUIGenPoly** shape have 90° angles.

Parameters

r If *true* it forces this **ccUIGenPoly** shape to be rectilinear. If *false* it removes any rectilinear constrain.

- `bool isRectilinear() const;`

Returns true if this **ccUIGenPoly** shape is constrained to be rectilinear, false otherwise.

undo

```
virtual void undo();
```

Undoes the last action that changed this **ccUIGenPoly** shape.

modelFromShape

```
virtual cc2Rigid modelFromShape();
virtual void modelFromShape(const cc2Rigid& mFp);
```

- `virtual cc2Rigid modelFromShape();`

  Returns the transformation that maps shape coordinates to model coordinates (typically, the model coordinates are the client coordinates of your application).

- `virtual void modelFromShape(const cc2Rigid& mFp);`

  Sets the transformation that maps shape coordinates to model coordinate to *mFp*.

  Parameters

mFp	The transformation that maps shape coordinates to model coordinates.

condChanged `virtual bool condChanged();`

Returns true if this **ccUIGenPoly** shape has changed since the last time this function was called. Returns false otherwise.

Notes

The function will return false if this **ccUIGenPoly** shape is in the default constructed state.

changed `virtual bool changed() const;`

Returns true if this **ccUIGenPoly** shape has changed since the last time **ccUIGenPoly::condChanged** was called. Returns false otherwise.

Notes

The function will return false if this **ccUIGenPoly** shape is in the default constructed state.

boundingBox

```
virtual ccRect boundingBox() const;

virtual ccRect boundingBox(
  const cc2Xform& clientFromShape) const;

virtual ccRect boundingBox(
  const cc2Rigid& clientFromShape) const;
```

- `virtual ccRect boundingBox() const;`

  Returns the bounding rectangle of this **ccUIGenPoly** shape in model coordinates.

- `virtual ccRect boundingBox(`
  `const cc2Xform& clientFromShape) const;`

  Returns the bounding rectangle of this **ccUIGenPoly** shape in the client coordinates specified by *clientfromShape*.

  Parameters

  clientfromShape The transformation that maps shape coordinates to client coordinates

- `virtual ccRect boundingBox(`
  `const cc2Rigid& clientFromShape) const;`

  Returns the bounding rectangle of this **ccUIGenPoly** shape in the client coordinates specified by the rigid transformation *clientfromShape*.

  Parameters

  clientFromShape The rigid transformation that maps shape coordinates to client coordinates

  Notes

  The client coordinates are defined by a rigid transformation. This type of transformation does not allow you to model scale changes between shape and client coordinates (see *Math Foundations of Transformations* in the *CVL User's Guide*).

clone

```
virtual ccUIGDShape* clone() const;
```

Returns a pointer to a copy of this **ccUIGenPoly** shape.

drawWithXform

```
virtual void drawWithXform (ccUITablet& tablet,
  const ccColor& color, const cc2Xform& xform,
  ccUIShapes::DrawMode m = drawNormal);
```

Draws this **ccUIGenPoly** shape using *tablet* in the color specified by *color.* Before drawing, the shape is mapped to tablet coordinates by using *xform.*

Parameters

tablet	The tablet used to draw this **ccUIGenPoly** shape.
color	The color used to draw this **ccUIGenPoly** shape.
xform	The transformation that maps model coordinates to tablet coordinates.
m	The drawing mode.

updateHandles

```
virtual void updateHandles();
```

Causes all the handles of this **ccUIGenPoly** shape to update themselves.

Notes

Typically, you do not need to call this function since handles are automatically updated by the parent display.

showHandles

```
virtual void showHandles(bool show);
```

If *show* is true, it makes all the handles of this **ccUIGenPoly** shape visible. If false, it makes all the handles of this **ccUIGenPoly** shape invisible.

Parameters

show	Controls whether the handles of this **ccUIGenPoly** shape are visible. If *true* the handles are visible, if *false* they are not.

Notes

Typically, you do not need to call this function since handles are automatically updated by the parent display.

freeHandles

```
virtual void freeHandles();
```

Deletes all the handles of this **ccUIGenPoly** shape.

Notes

Typically, you do not need to call this function since handles are automatically updated by the parent display.

isTouched

```
virtual bool isTouched (const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this **ccUIGenPoly** shape. This function is called automatically for you when you click the mouse on this **ccUIGenPoly** shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw this **ccUIGenPoly** shape
scale	The scale to convert *pt* to pixels

touchDist

```
static float touchDist ();
static void touchDist (float d);
```

- `static float touchDist();`

  Gets the distance from all instances of this object that are still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instances of this object that are still considered a click on the object. The distance is specified in display coordinates.

  Parameters

d	The distance from the object.

ccUIGenPoly

ccUIGenRect

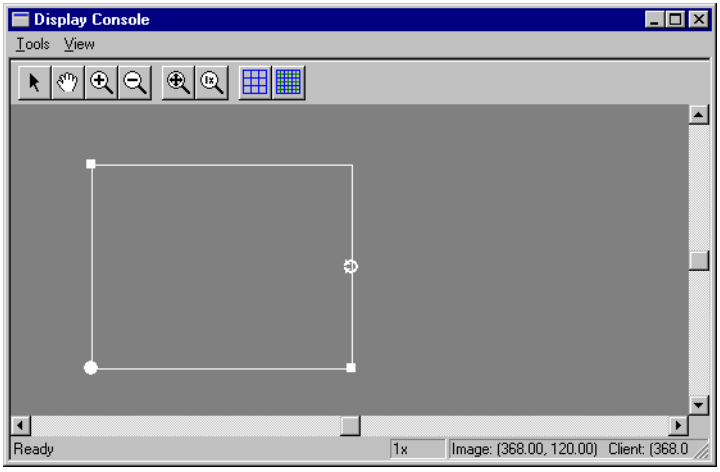
```
#include <ch_cvl/uishapes.h>

class ccUIGenRect : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a generalized rectangle (**ccGenRect**) that you can manipulate. When you add a **ccUIGenRect** object to a **ccDisplay** window a rectangle is displayed that can be moved about, resized, and rotated using your mouse. The following is an example of a generalized rectangle that has been added to a **ccDisplayConsole** window.



ccUIGenRect is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIGenRect** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIGenRect** has two resizing handles which both operate in the same way.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the object. The rotation handle is on the right-hand edge of the rectangle.
 Rounded corner handle	Left-click on the rounded corner handle holding the button down, and drag the handle to the object interior to round the corners. Dragging the handle to the object exterior squares the corners. The corner rounding handle is at the lower left-hand corner of the rectangle. This one handle controls corner rounding for all four rectangle corners.

After manipulating a generalized rectangle in a **ccDisplay** window, you will generally want to retrieve the final rectangle state and use it in some way. You can use code similar to the following to retrieve the manipulated rectangle.

```
ccGenRect new_genRect;
new_genRect = ui_genRect->genRect();
```

Where **ui_genRect** is the manipulated **ccUIGenRect** object.

Notes

ccUIGenRect and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIGenRect

```
ccUIGenRect(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccGenRect**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The rectangle's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eLock

This enumeration lets you specify which handles are not visible when the object is selected. By using these locks, you can prevent a rectangle from being modified along different degrees of freedom.

Value	Meaning
eNoLocks = 0	No locks. All manipulations allowed.
eSizeLock = 0x1	The object cannot be resized.
eRotLock = 0x2	The object cannot be rotated.
eRoundLock = 0x4	The corner radii cannot be changed.
eAspectLock = 0x8	The object keeps the same aspect ratio when resized.
eCenterLock = 0x10	Resizing takes place with respect to the center of the object.
eEllipticLock = 0x20	When changing the size using sizing handles, flat edges are not allowed.

Public Member Functions

genRect

```
void genRect(const ccGenRect& r);

const ccGenRect& genRect() const;
```

- `void genRect(const ccGenRect& r);`

Associates a **ccGenRect** with this manipulation object.

Parameters

r The generalized rectangle to make manipulable.

- `const ccGenRect& genRect() const;`

  Gets the **ccGenRect** associated with this manipulation object.

updateHandles `virtual void updateHandles ();`

Update all of my handles. Called when handles have been repositioned in the display.

showHandles `virtual void showHandles (bool show);`

Make my handles visible/invisible depending on *show*, and the DOF locks. If the handles aren't created yet, create them.

Parameters

show True = show handles. False = do not show handles.

freeHandles `virtual void freeHandles ();`

Deletes all handles.

locks

`c_UInt32 locks() const;`

`void locks(c_UInt32 b);`

- `c_UInt32 locks() const;`

  Returns the lock bits that indicate which resizing operations are not allowed for this object.

- `void locks(c_UInt32 b);`

  Sets the lock bits that indicate the resizing operations that are not allowed for this object.

  Parameters

  b The lock bits. May be any of the following ORed together:

  ccUIGenRect::eNoLocks
  ccUIGenRect::eSizeLock
  ccUIGenRect::eRotLock
  ccUIGenRect::eRoundLock
  ccUIGenRect::eAspectLock
  ccUIGenRect::eCenterLock
  ccUIGenRect::eEllipticLock

  These lock values are described in *Enumerations* on page 3233.

setLocks `void setLocks (c_UInt32 b);`

ORs the specified locks to the current locks.

Parameters

b The locks to OR with the current locks. May be any of the following ORed together:

ccUIGenRect::eNoLocks
ccUIGenRect::eSizeLock
ccUIGenRect::eRotLock
ccUIGenRect::eRoundLock
ccUIGenRect::eAspectLock
ccUIGenRect::eCenterLock
ccUIGenRect::eEllipticLock

These lock values are described in *Enumerations* on page 3233.

clrLocks `void clrLocks (c_UInt32 b);`

Clears the locks specified in *b*. (ANDs the current locks with the complement of *b*)

Parameters

b The locks to clear. May be any of the following ORed together:

ccUIGenRect::eNoLocks
ccUIGenRect::eSizeLock
ccUIGenRect::eRotLock
ccUIGenRect::eRoundLock
ccUIGenRect::eAspectLock
ccUIGenRect::eCenterLock
ccUIGenRect::eEllipticLock

These lock values are described in *Enumerations* on page 3233.

isTouched `virtual bool isTouched (const cc2Vect& pt, double scale);`

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt The position to test in the coordinate system used to draw the shape.

scale The scale to convert *pt* to pixels.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the center position of the UI shape relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center position of the UI shape relative to its parent, in tablet coordinates.

  Parameters

pos	The new center position.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal;* draws full genRect *ccUIShapes::drawAbridged;* draws full genRect *ccUIShapes::drawDrag;* draws genRect without rounding

Static Functions

touchDist

```
static float touchDist();
static void touchDist(float d);
```

- `static float touchDist();`

  Gets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

  Parameters

  d The distance from the object.

ccUIGenRect

ccUIIcon

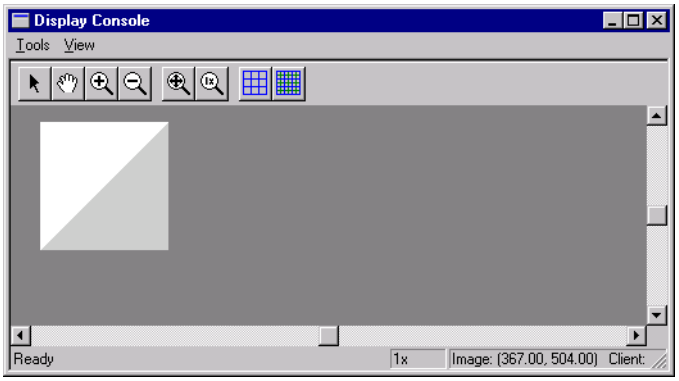
```
#include <ch_cvl/uishapes.h>

class ccUIIcon : public ccUIRLEBuffer;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an icon from a **ccRLEBuffer** object. The icon size cannot be changed and it cannot be rotated. However, you can reposition the icon using your mouse. The displayed icon contains no handles for manipulation. The following is an example of a simple icon that has been added to a **ccDisplayConsole** window.



ccUIIcon is similar to **ccUIRLEBuffer** except **ccUIIcon** does not scale (when you zoom in on a **ccDisplay** window, the icon does not change size) and **ccUIRLEBuffer** does scale. See the **ccUIRLEBuffer** reference page.

ccUIIcon is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

You can left-click on the icon holding the button down to reposition it in a **ccDisplay** window. Icons cannot be resized and have no manipulation handles.

After repositioning an icon you will generally want to retrieve the final icon state and use it in some way. You can use code similar to the following to retrieve the moved icon.

```
ccRLEBuffer new_rleBuf;
new_rleBuf = ui_icon->icon();
```

Where **ui_icon** is the moved **ccRLEBuffer** object.

Notes

ccUIIcon and any UI shape derived from **ccUIPointShapeBase** uses a coordinate space relative to its parent. When you add an object to a display window its parent is automatically set to one of the coordinate frame objects internal to the display.

Constructors/Destructors

ccUIIcon

```
ccUIIcon (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccRLEBuffer** used as an icon.

Parameters

parent	The run-length encoded buffer's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

icon

```
void icon(const ccRLEBuffer& buf);

const ccRLEBuffer& icon();
```

- `void icon(const ccRLEBuffer& buf);`

Associates a **ccRLEBuffer** with this manipulation object.

Parameters

buf	The run-length encoded buffer to make manipulable.

Notes

Pixels whose value is **ccColor::passColor()** are not drawn.

- `const ccRLEBuffer& icon();`

  Gets the **ccRLEBuffer** associated with this manipulation object.

touchMap `void touchMap (const TCHAR* map, const ccIPair& org);`

Installs a touch map associated with this icon. The touch map specifies whether a pixel is considered touched when the icon is clicked on. You can use the same patter that you pass to **ccUITablet::makeIcon()** to create the touch map. The plus signs (+) indicate which background areas are considered touched.

Parameters

map	The touch map.
org	The origin relative to the upper left corner of the icon.

isTouched `virtual bool isTouched (const cc2Vect& pt, double scale);`

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

ccUIIcon

ccUILabel

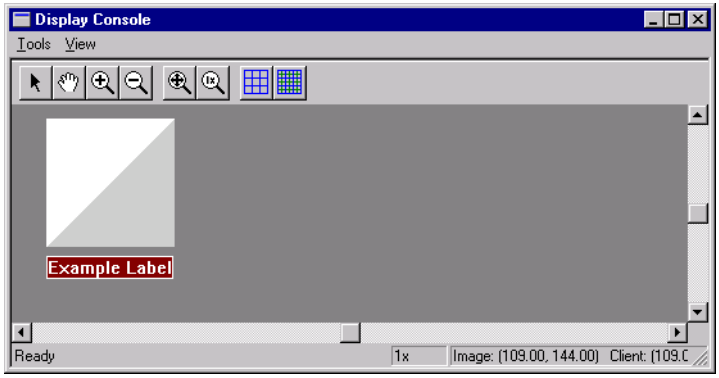
```
#include <ch_cvl/uishapes.h>

class ccUILabel : public ccUIPointShapeBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a label you can use to identify other objects in a display. The label size cannot be changed and it cannot be rotated. However, you can reposition the label using your mouse. The displayed label contains no handles for manipulation. The following is an example of a label that has been added to a **ccDisplayConsole** window. The label is positioned under an icon object to identify it.



ccUILabel is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

You can left-click on the label holding the button down to reposition it in a **ccDisplay** window. Labels cannot be resized and have no manipulation handles.

After repositioning a label in a **ccDisplay** window, you will generally want to retrieve the final label state and use it in some way. You can use code similar to the following to retrieve the moved icon.

```
ccCvlString char_string = ui_label->label();
```

Where **ui_label** is the moved **ccRLEBuffer** object.

Notes

ccUILabel and any UI shape derived from **ccUIPointShapeBase** uses a coordinate space relative to its parent. When you add an object to a display window its parent is automatically set to one of the coordinate frame objects internal to the display.

Constructors/Destructors

ccUILabel

```
ccUILabel(ccUIObject* parent = NULL);
```

Creates a new manipulable object.

Parameters

parent	The label's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

label

```
void label(const ccCvlString& str);
const ccCvlString& label() const;
```

- ```
  void label(const ccCvlString& str);
  ```

  Sets the text of the label.

  Parameters

str	The text of the label.

- ```
  const ccCvlString& label() const;
  ```

  Gets the text of the label.

backColor

```
void backColor(const ccColor& c);
const ccColor& backColor() const;
```

- `void backColor(const ccColor& c);`

  Sets the background color of the label.

  Parameters

  c The color.

- `const ccColor& backColor() const;`

  Gets the background color of the label.

foreColor

```
void foreColor(const ccColor& c);
const ccColor& foreColor() const;
```

- `void foreColor(const ccColor& c);`

  Sets the foreground color (the color of the text) of the label.

  Parameters

  c The color.

  Notes

  The color set via **ccUIShapes::color** is not used during drawing of the label.

- `const ccColor& foreColor() const;`

  Gets the foreground color of the label.

borderColor

```
void borderColor(const ccColor& c);
const ccColor& borderColor() const;
```

- `void borderColor(const ccColor& c);`

  Sets the color of the label border.

  Parameters

  c The label.

- `const ccColor& borderColor() const;`

  Gets the color of the border.

borderWidth

```
void borderWidth(c_Int32 width);
c_UInt32 borderWidth() const;
```

- `void borderWidth(c_Int32 width);`

  Sets the width of the border.

  Parameters

  width The width of the border in pixels.

- `c_UInt32 borderWidth() const;`

  Gets the width of the border.

format

```
void format(const ccUIFormat& f);
const ccUIFormat format() const;
```

- `void format(const ccUIFormat& f);`

  Sets the text format of the label.

  Parameters

  f The format.

- `const ccUIFormat format() const;`

  Gets the label's text format.

isClipped

```
bool isClipped() const;
```

Returns true if some part of the label is clipped in its current position.

isTouched

```
virtual bool isTouched(const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

Protected Member Functions

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the center position of the UI shape relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center position of the UI shape relative to its parent, in tablet coordinates.

  Parameters

pos	The new center position.

ccUILabel

ccUILine

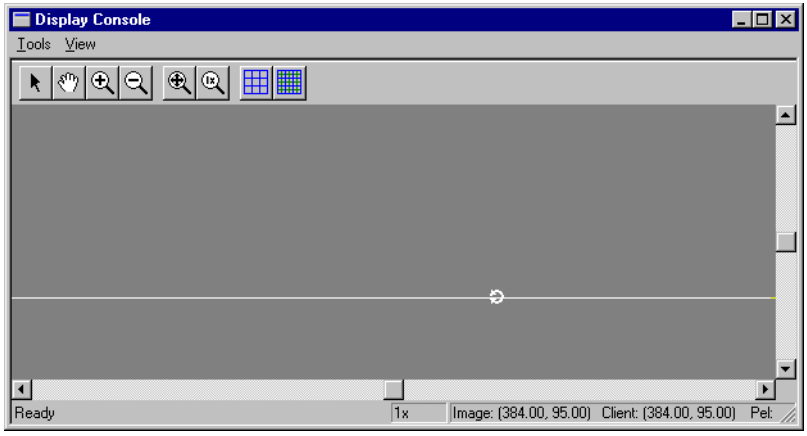
```
#include <ch_cvl/uishapes.h>

class ccUILine : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an infinite-length line (**ccLine**) that you can manipulate. When you add a **ccUILine** object to a **ccDisplay** window the line is displayed and can be moved about and rotated using your mouse. The following is an example of a **ccLine** object that has been added to a **ccDisplayConsole** window.



ccUILine is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUILine** uses the following handles:

Handle	Description
 Rotation handle	The line rotation handle is a fulcrum around which the line can be rotated. Place your mouse pointer on the rotation handle and hold the left mouse button down. Slide the pointer along the line in either direction and the pull the line up or down to rotate it.

After manipulating a **ccUILine** object in a **ccDisplay** window, you will generally want to retrieve the final line state and use it in some way. You can use code similar to the following to retrieve the manipulated line.

```
ccLine new_line;
new_line = ui_line->line();
```

Where **ui_line** is the manipulated **ccUILine** object.

Notes

ccUILine and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUILine

```
ccUILine(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccLine**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent	The line's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

line

```
void line(const ccLine& l);
const ccLine& line() const;
```

- `void line(const ccLine& l);`

  Associates a **ccLine** with this manipulation object.

  Parameters

l	The line to make manipulable.

- `const ccLine& line() const;`

  Gets the **ccLine** associated with this manipulation object.

updateHandles

```
virtual void updateHandles ();
```

Update my handles (if created). Called when handles have been repositioned in the display.

showHandles

```
virtual void showHandles (bool show);
```

Make my handles visible/invisible. If the handles aren't created yet, create them.

Parameters

show	True = show handles. False = do not show handles.

freeHandles

```
virtual void freeHandles ();
```

Deletes my handles.

isTouched

```
virtual bool isTouched(const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns a point through which this line passes, relative to its parent, in tablet coordinates.

  Notes

  pos_() is any point on the line. The **ccVLine** representation has one redundant DOF.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the point through which this line passes, relative to its parent, in tablet coordinates.

  Parameters

  pos The new point.

  Notes

  The new line is parallel to the old line, and passes through the new point *pos*. The rotation handle is placed at *pos*.

dragStop_

```
virtual void dragStop_ (
  const ccIPair& start,
  const ccIPair& stop);
```

An override.

Moves the rotation handle to the ending drag point (*stop*).

Parameters

start Starting drag position in screen coordinates.

stop Ending drag position of the drag in screen coordinates.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag* The draw mode argument is ignored.

Static Functions

touchDist

```
static float touchDist () {return touchDist_;}

static void touchDist (float d) {touchDist_ = d;}
```

- `static float touchDist();`

  Gets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

  Parameters

d	The distance from the object.

ccUILine

ccUILineSeg

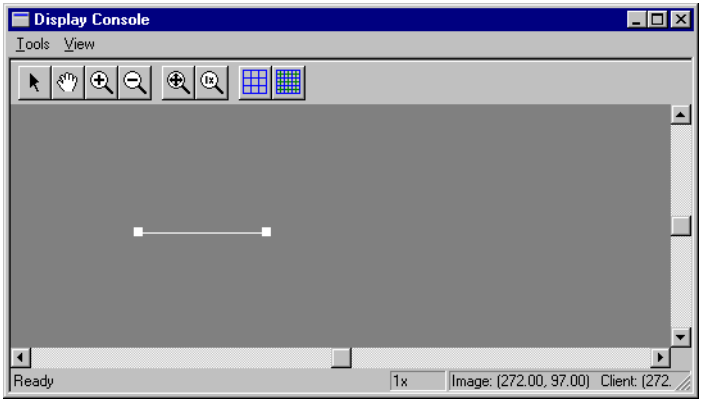
```
#include <ch_cvl/uishapes.h>

class ccUILineSeg : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a line segment (**ccLineSeg**) that you can manipulate. When you add a **ccUILineSeg** object to a **ccDisplay** window the line segment is displayed and can be moved about, resized, and rotated using your mouse. The following is an example of a line segment that has been added to a **ccDisplayConsole** window:



ccUILineSeg is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUILineSeg** uses the following handles:

Handle	Description
 Resize/rotation handle	Left-click on this handle holding the button down and drag the handle to resize the line segment and/or to change its angle. **ccUILineSeg** has two resize/rotation handles which both operate the same way.

After manipulating a **ccUILineSeg** object in a **ccDisplay** window, you will generally want to retrieve the final line segment state and use it in some way. You can use code similar to the following to retrieve the manipulated line segment.

```
ccLineSeg new_lineSeg;
new_lineSeg = ui_lineSeg->lineSeg();
```

Where **ui_lineSeg** is the manipulated **ccUILineSeg** object.

Notes

ccUILineSeg and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUILineSeg

```
ccUILineSeg (ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccLineSeg**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The line segment's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

lineSeg

```
void lineSeg(const ccLineSeg& l);
const ccLineSeg& lineSeg() const;
```

- `void lineSeg (const ccLineSeg&);`

  Associates a **ccLineSeg** with this manipulation object.

  Parameters

l	The line segment to make manipulable.

- `const ccLineSeg& lineSeg() const;`

  Gets the **ccLineSeg** associated with this manipulation object.

updateHandles

```
virtual void updateHandles ();
```

Update my handles (if created). Called when handles have been repositioned in the display.

showHandles

```
virtual void showHandles (bool show);
```

Make my handles visible/invisible. If the handles aren't created yet, create them.

Parameters

show	True = show handles. False = do not show handles.

freeHandles

```
virtual void freeHandles ();
```

Deletes the handles.

isTouched

```
virtual bool isTouched(const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;

virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the position of the line segment relative to its parent, in tablet coordinates. The position is the line segment center.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center position of the line segment relative to its parent, in tablet coordinates.

  Parameters

pos	The new center position.

  Notes

  The new line segment passes through *pos* and is parallel to the old line segment. *pos* is the new line segment center.

dragStop_

```
virtual void dragStop_ (
  const ccIPair& start,
  const ccIPair& stop);
```

An override.

Moves the line segment to the ending drag point (*stop*).

Parameters

start	Starting drag position in screen coordinates.
stop	Ending drag position of the drag in screen coordinates.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the line segment in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag* The draw mode argument is ignored.

Static Functions

touchDist

```
static float touchDist();
static void touchDist(float d);
```

- `static float touchDist();`

  Gets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

  Sets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

  Parameters

d	The distance from the object.

ccUILineSeg

ccUIManShape

```
#include <ch_cvl/uishapes.h>

class ccUIManShape : public ccUIShapes;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This is an abstract class that is used as the base class for all the manipulable shape classes. This class provides the functions for making a shape's handles visible or invisible and whether the handles should be visible when the shape is selected.

Constructors/Destructors

Since this is a pure virtual class, you cannot create an instance of it.

Public Member Functions

manipulable

```
void manipulable(bool m);

bool manipulable() const;
```

- `void manipulable(bool m);`

  Sets whether this shape is manipulable.

  Parameters

m	True if this shape's handles should be visible when the shape is selected, false otherwise.

- `bool manipulable() const;`

  Gets whether this shape is manipulable.

updateHandles

```
virtual void updateHandles () = 0;
```

Update all of my handles. Called when handles have been repositioned in the display.

showHandles `virtual void showHandles (bool show) = 0;`

Make my handles visible/invisible. If the handles aren't created yet, create them.

Parameters

show	True = show handles. False = do not show handles.

freeHandles `virtual void freeHandles () = 0;`

Deletes all handles.

Protected Member Functions

select `virtual void select (States s, bool parentChanged);`

An override.

The UI Framework calls **ccUIObject::select()** when the object's state changes to *selectedState* (the object becomes selected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This override function calls **showHandles()** to make the handles visible.

Parameters

s	The state change that caused the object to become selected. Must be one of the **ccUIObject::States** enums.
parentChanged	True if the select was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

deselect `virtual void deselect (States s, bool parentChanged);`

An override.

The UI Framework calls **ccUIObject::deselect()** when the object's state changes from *selectedState* (the object becomes deselected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This override function calls **showHandles()** to make the handles invisible.

Parameters

s	The state change that caused the object to become selected. Must be one of the **ccUIObject::States** enums.
parentChanged	True if the select was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

ccUIManShape

ccUIObject

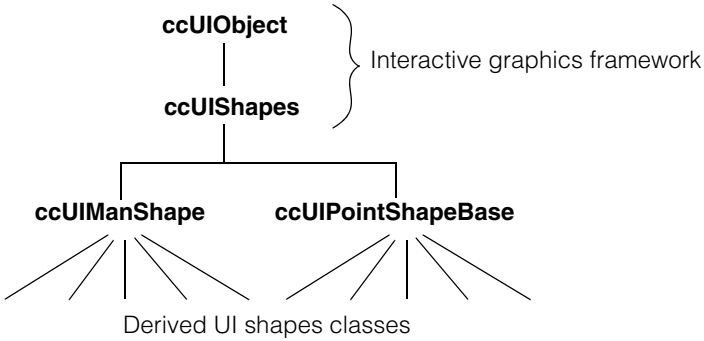
```
#include <ch_cvl/uifrmwrk.h>

class cmImport_cogdisp ccUIObject;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

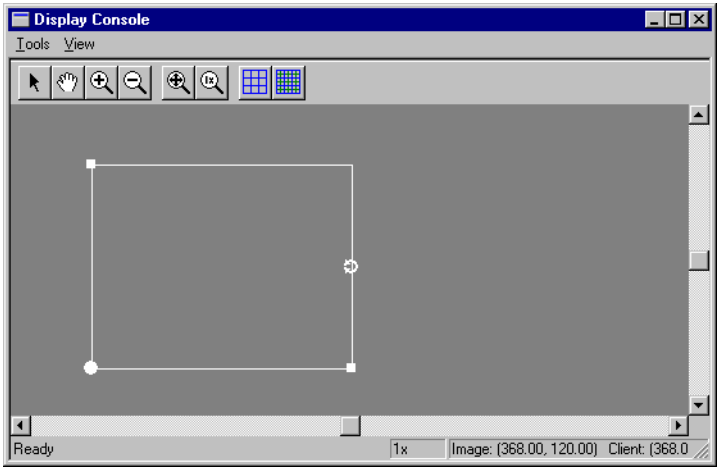
ccUIObject and **ccUIShapes** are base classes for the interactive graphics classes, also called UI shapes classes. These base classes make up the interactive graphics framework. See the following class derivation hierarchy.



Interactive graphics classes use the graphics classes defined in *shapes.h* and include fundamental shapes such as the line, rectangle, circle, ellipse, and others. These interactive classes provide an environment where shapes can be manipulated either graphically using a mouse and a **ccDisplay** window, or with your program using member functions from the framework base classes.

For example, an interactive generalized rectangle (**ccUIGenRect**) class derived from **ccUIObject** and **ccUIShapes** creates a generalized rectangle (**ccGenRect**) that you can manipulate. When you add a **ccUIGenRect** object to a **ccDisplay** window a

rectangle is displayed that can be moved about, resized, and rotated using your mouse or through program control. The following is an example of a generalized rectangle that has been added to a **ccDisplayConsole** window.



Interactive graphic objects displayed in a **ccDisplay** window have the following common graphic features:

Feature	Description
Selecting an object	To manipulate an object you must first select it by left-clicking your mouse pointer on the object outline. Your mouse pointer changes to a cross when you are close enough to select the object. Once selected the object changes to the color set by the last call to **selectColor()**. The default color is yellow. Selected objects are displayed with handles you use to manipulate the object. The handles available with UI shapes objects are described below.
Deselecting an object	You deselect an object by selecting another object or by left-clicking your mouse in free space anywhere in the window. Deselected objects return to their original color which you can set by calling **ccUIShapes::props()**. The default color is cyan.
Moving a selected object	To move a selected object, left-click on the object outline holding the mouse button down, and drag the object to the new location.

Feature	Description
Handles	Handles appear as magenta icons on selected objects. You cannot change the handle color. The following handles are used, although every handle is not available on all shapes.
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the object.
 Rounded corner handle	Left-click on the rounded corner handle holding the button down, and drag the handle to the object interior to round the corners. Dragging the handle to the object exterior squares the corners.
 Skew handle	Left-click on the skew handle holding the button down, and drag the handle to change the object's skew.

Member Function Summary

ccUIObject is a large and complex class. Use the following summaries as a guide to the class capabilities, and as a learning tool. The class member functions can be divided into the following functional groups:

Framework-only	Relationships	States	Information
shapes()^{V}	**parent()^{V}**	**condVisible()**	**wholsTouched()^{V}**
frame()	**frontSib()**	**visible()**	**opNew()**
shapesFrame()	**backSib()**	**condEnabled()**	**root()**
rootObject()	**closerSib()^{V}**	**enabled()**	**rootMutex()**
tablet()^{V}	**fartherSib()^{V}**	**condSelected()**	**orphanMutex()**
	frontKid()^{V}	**selected()**	**uiMutex()**
	backKid()^{V}	**condVisAndEnab()**	**key()**
	numKids()^{V}	**condVisEnabAndSel()**	**isValid()**

(**V**) Virtual function.

You should not call Framework-only classes in your program. *Relationships*, *States*, and *Information* refer to the object from which they are called.

Attributes	Graphics commands	Protected virtual functions
clickable()		**show()**
draggable()		**hide()**
dragging()		**enable()**
dontMove()		**disable()**
keepSel()		**select()**
dwell()		**deselect()**
multiSelectable()	**mouseDown()**	**mouseDown_()**
multiSelected()	**mouseUp()**	**mouseUp_()**
multiDraggable()	**mouseEnter()**	**mouseEnter_()**
userSelect()	**idleMouseEnter()**	**idleMouseEnter_()**
rightButtonMode()	**mouseLeave()**	**mouseLeave_()**
autoDelete()	**mouseMove()**	**mouseMove_()**
mark()	**click()**	**click_()**
selectColor()	**dblClick()**	**dblClick_()**
deselColor()	**dragStart()**	**dragStart_()**
dragColor()	**dragStop()**	**dragStop_()**
curSelColor()	**dragAnimate()**	**dragAnimate_()**
lightColor()	**mouseMiddle()**	**mouseMiddle_()**
shadowColor()	**mouseRight()**	**mouseRight_()**
testColor()	**front()**	**front_()**
faceColor()	**back()**	**back_()**
drawLayer()	**keyboard()**	**keyboard_()**

Attributes allow you to tailor objects for your application. *Graphics commands* are functions called by the UI framework in response to mouse and keyboard events, and can be also be called in your programs to simulate these events. *Protected virtual functions* perform no operations here, but are place holders for derived class overrides. Most of these virtual functions are called by a corresponding graphics command. For example, **click()** calls **click_()** which performs no operation unless overridden in a derived class.

For additional information about interactive graphics classes, see the *Displaying Graphics* chapter of the *CVL User's Guide*.

Constructors/Destructors

This is an abstract class. Only classes derived from this class use the constructors and destructors.

ccUIObject `protected: ccUIObject();`

Default constructor. **opNew()** and **autoDelete()** are true if created with the new operator. All other properties are set false.

~ccUIObject `virtual ~ccUIObject();`

Destructor. Tells the event processor that the UI object is being deleted and removes it from the registry of all objects.

Notes

Other obvious actions, such as notifying parents/kids and making the UI object invisible, must be done by derived objects, as the UI object has now been destroyed to the point where it can no longer find its parents, kids, or tablet.

Enumerations

RightButtonModes

This enumeration defines the actions to be taken when the user clicks the right mouse button on a UI object.

Value	Meaning
eIgnoreRB	Ignore right-mouse clicks.
eClientRB	Call **mouseRight()** so a user-derived class can handle right-mouse click events.
eBackRB	Move the UI object in back of other objects.
eShiftRB	Simulate Shift + left-mouse click behavior.

States

This enumeration specifies the three possible states of a **ccUIObject**.

Value	Meaning
visibleState	The object is displayed on the screen and is visible unless covered by another object. The following conditions specify this state: **visible()** = true **condVisible()** = true Parent **visible()** = true
enabledState	The object is enabled and responds to mouse clicks. The following conditions specify this state: **enabled()** = true **condVisible()** = true **condEnabled()** = true Parent **enabled()** = true
selectedState	The object is displayed using its selected color, showing handles (if any). The following conditions specify this state: **selected()** = true **condVisible()** = true **condEnabled()** = true **condSelected()** = true Parent **selected()** = true

Public Member Functions

shapes

```
virtual ccUIShapes* shapes(bool canFail = false);
```

RTTI framework operation providing base-to-derived type conversion for framework classes. Returns the *this* pointer if the object is one of the **ccUIShapes**, otherwise 0. Relatively lightweight as compared to *dynamic_cast<>*.

Parameters

canFail — Specifies whether or not the operation can fail. False asserts that the conversion can be done and causes a valid pointer always to be returned. A non-zero value causes NULL to be returned if the conversion cannot be done.

Notes

This function is for Cognex internal use only.

frame `virtual ccUIFrame* frame(bool canFail = false);`

RTTI framework operation providing base-to-derived type conversion for framework classes. Returns the *this* pointer if the object is a **ccUIFrame**, otherwise 0. Relatively lightweight as compared to *dynamic_cast<>*.

Parameters

canFail — False means the conversion cannot fail and a valid pointer is always returned. True means the operation can fail and NULL is returned if the conversion cannot be done.

Notes

This function is for Cognex internal use only.

shapesFrame `virtual ccUIShapesFrame* shapesFrame(bool canFail = false);`

RTTI framework operation providing base-to-derived type conversion for framework classes. Returns the *this* pointer if the object is a **ccUIShapesFrame**, otherwise 0. Relatively lightweight as compared to *dynamic_cast<>*.

Parameters

canFail — Specifies whether or not the operation can fail. False asserts that the conversion can be done and causes a valid pointer always to be returned. A non-zero value causes NULL to be returned if the conversion cannot be done.

Notes

This function is for Cognex internal use only.

rootObject `virtual ccUIRootObject* rootObject(bool canFail = false);`

RTTI framework operation providing base-to-derived type conversion for framework classes. Returns the *this* pointer if the object is a **ccUIRootObject,** otherwise 0. Relatively lightweight as compared to *dynamic_cast<>*.

Parameters

canFail — Specifies whether or not the operation can fail. False asserts that the conversion can be done and causes a valid pointer always to be returned. A non-zero value causes NULL to be returned if the conversion cannot be done.

Notes

This function is for Cognex internal use only.

parent

```
virtual ccUIObject* parent() = 0;
```

Gets the parent (runtime owner) of the UI object. This pure virtual function is implemented in the derived class **ccUIShapes**.

closerSib

```
virtual ccUIObject* closerSib() = 0;
```

Returns the sibling object added to the parent object just after this object. If there is none, it returns 0.

This pure virtual function is implemented in the derived class **ccUIShapes**.

The following is an example of code that uses this function to navigate the runtime hierarchy of a UI object:

```
void dumpObjects(ccUIObject* obj, int level = 0) {
  cogOut << ccCvlString(level*3, ' ') << typeid(*obj.name() <<
    cmStd endl;
  for(ccUIObject* p = obj->backKid(); p; p = p->closerSib())
    dumpObjects(p, level + 1);
}
```

Calling:

```
  dumpObject(d.root());
```

on a display console that was created with:

```
  ccDisplayConsole d(...);
```

will yield the following output, showing the runtime object hierarchy of the display console:

```
class ccUIWin32Root
  class ccDisplayConsole
    class ccUINestedCoordFrame
    class ccUINestedCoordFrame
    class ccUIShapesFrame
  class UIFrameSizer
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
    class ccUIFrameSizeHandle
```

fartherSib

```
virtual ccUIObject* fartherSib() = 0;
```

Returns the sibling object added to the parent object just before this object. If there is none, it returns 0.

This pure virtual function is implemented in the derived class **ccUIShapes**.

frontKid

```
virtual ccUIObject* frontKid() = 0;
```

Returns the child object of this shape that was last added. If there is none, it returns 0.

This pure virtual operation is implemented in the derived class **ccUIShapes**.

backKid

```
virtual ccUIObject* backKid() = 0;
```

Returns the child object of this shape that was first added. If there is none, it returns 0.

This pure virtual operation is implemented in the derived class **ccUIShapes**. See **closerSib** for sample code that uses this function to navigate the runtime object hierarchy of a UI object.

frontSib

```
ccUIObject* frontSib();
```

Returns this object's parent's last added child. If this object was the last added, it returns itself.

backSib

```
ccUIObject* backSib();
```

Returns this object's parent's first added child. If this object was the first added, it returns itself.

numKids

```
virtual c_UInt32 numKids() = 0;
```

Gets the number of kids of the UI object. This pure virtual operation is implemented in the derived class **ccUIShapes**.

tablet

```
virtual ccUITablet& tablet() = 0;
```

Gets the tablet in which the UI object is to be drawn. The **draw()** method in a derived UI shape class draws into this tablet.

This pure virtual function is implemented in the derived class **ccUIShapes**.

Notes

The tablet and scope coordinates of the returned tablet are often referred to as the tablet/scope coordinates of this **ccUIObject**. You can use them for the mouse interface methods.

root

```
ccUIRootObject* root();
const ccUIRootObject* root() const;
```

- `ccUIRootObject* root();`

  Gets the root object of the UI object, if it has one.

- `const ccUIRootObject* root() const;`

  Gets a const pointer to the root object of the UI object, if it has one.

rootMutex

```
ccMutex& rootMutex();
```

Gets the root mutex of the UI object, if it has one. If the UI object does not have a root mutex, the orphan mutex is returned. If the UI object is itself a root, then its own mutex is returned.

Root mutex is useful for thread synchronization.

drawLayer

```
void drawLayer(ccUITablet::Layers lyr);
ccUITablet::Layers drawLayer() const;
```

- `void drawLayer(ccUITablet::Layers lyr);`

  Specifies the layer into which this object should be drawn. The derived classes, which do the actual drawing, may choose to ignore this value.

  The default is **ccUITablet::eImageLayer**. The draw layer for a **ccUIObject** must be specified before calling **ccDisplay::addShape()**.

  Parameters

  lyr — Layer into which the UI object should be drawn. Must be one of:

  ccUITablet::eImageLayer (default)
  ccUITablet::eOverlayLayer

Notes

Not all layers are supported on all platforms. You can use the static member function **ccUITablet::overlaySupported()** to determine whether your platform supports overlays.

All interactive shapes are drawn to the image layer by default. If you want to draw the shape on a different layer (for example, the overlay layer), you can set the drawing layer using **ccUIObject::drawLayer(lyr)**. Cognex recommends changing the drawing layer before adding the shape to the display. Changing the drawing layer once a shape has been added to the display will result in lower performance when the graphics are re-rendered.

When assigning a parent to interactive shapes using **ccUIShapes::parent(newParent)**, all children must be on the same drawing layer as the parent. Cognex recommends setting the parent of an interactive shape before adding the shape to the display. Changing a shape's parent once the shape has been added to the display will result in lower performance when the graphics are re-rendered.

For optimal rendering performance, do not change the drawing layer or parent of an interactive shape after adding the shape to the display console.

- `ccUITablet::Layers drawLayer() const;`

Returns the layer into which the UI object should be drawn.

key `c_UInt32 key() const;`

Returns a key that uniquely identifies this object.

Notes

Do not use the address of the UI object (the *this* pointer) as an identifier because it can become non-unique over time. An object could be deleted and a new one constructed at the same address.

curSelColor `ccColor curSelColor() const;`

Returns **selectColor()** if the object is selected. Returns **deselColor()** if the object is deselected.

deselColor `ccColor deselColor() const;`

Returns the color used to indicate that an object is deselected. This color is set in the derived class function **ccUIShapes::props()**.

lightColor `ccColor lightColor() const;`

Returns a light gray color.

Notes

Use **lightColor()**, **shadowColor()**, **testColor()**, and **faceColor()** instead of coding the actual color. Then, if these colors are changed in the future, you will not have to change your application code.

shadowColor

```
ccColor shadowColor() const;
```

Returns a dark gray color, generally used for shadows.

textColor

```
ccColor textColor() const;
```

Returns the color black, generally used for text.

faceColor

```
ccColor faceColor() const;
```

Returns a medium gray color, generally used for faces.

---

condVisible

```
bool condVisible() const;
bool condVisible(bool vis);
```

- `bool condVisible() const;`

  Returns true if the UI object itself is visible, false otherwise. If the UI object's parent is not visible, you will not see the UI object on the screen even if **condVisible()** is true. The parent of a shape is usually the **ccDisplay** window in which it is drawn and is usually visible.

- `bool condVisible(bool vis);`

  Sets whether the UI object itself is visible. If the UI object's parent is not visible, you will not see the UI object on the screen even if **condVisible()** is true.

  Parameters

vis	If true, the UI object is visible when the parent is visible. In CVL, the parent of a shape is usually the **ccDisplay** window in which it is drawn and is usually visible. So, setting *vis* to true normally makes a shape visible.

visible

```
bool visible();
```

Returns true if the UI object is visible, false otherwise. The UI object is visible if **condVisible()** returns true and its parent's **condVisible()** also returns true.

condEnabled

```
bool condEnabled() const;
bool condEnabled(bool enab);
```

- `bool condEnabled() const;`

  Returns true if the UI object itself is enabled, false otherwise. If the UI object's parent is not enabled, the UI object will not be able to respond to mouse events even if **condEnabled()** is true. The parent of a shape is usually the **ccDisplay** window in which it is drawn and is usually enabled.

  Notes

  A conditionally enabled object does not necessarily respond to mouse-click events. See **clickable()** on page 3283.

- `bool condEnabled (bool enab);`

  Sets whether the UI object itself is enabled. If the UI object's parent is not enabled, the UI object will not be able to respond to mouse events, even if **condEnabled()** is true.

  Parameters

enab	If true, the UI object can receive mouse events.

  Notes

  A conditionally enabled object does not necessarily respond to mouse-click events. See **clickable()** on page 3283.

enabled

```
bool enabled();
```

Returns true if the UI object is enabled (can receive mouse events), false otherwise. The UI object is enabled if **condEnabled()** returns true and its parent's **condEnabled()** also returns true.

condSelected

```
bool condSelected() const;
bool condSelected (bool sel, bool kidsToo = false);
```

- `bool condSelected() const;`

  Returns true if the UI object itself is selected, false otherwise. If the UI object's parent is not selected, the UI object will not appear selected in the display even if **condSelected()** is true. The parent of a shape is usually the **ccDisplay** window in which it is drawn unless the shape is part of a parent/child relationship.

- `bool condSelected(bool sel, bool kidsToo=false);`

  Sets whether the UI object itself is selected. If the UI object's parent is not selected, the UI object will not appear selected in the display even if **condSelected()** is true.

  If **keepSel()** is true, the *sel* parameter is ignored in this call. This means you cannot deselect an object when **keepSel()** is true.

  Parameters

sel	If true, the UI object is selected when its parent is selected.
kidsToo	If true, the UI object's children are also selected.

selected

```
bool selected();
```

Returns true if the UI object is selected, false otherwise. The UI object is selected if **condSelected()** returns true and its parent's **condSelected()** also returns true.

condVisAndEnab

```
bool condVisAndEnab() const;
```

Returns true if the UI object is both visible and enabled (**visible()** = true, **enabled()** = true). Returns false otherwise.

condVisEnabAndSel

```
bool condVisEnabAndSel();
```

Returns true if the UI object is visible, enabled, and selected (**visible()** = true, **enabled()** = true, **selected()** = true). Returns false otherwise.

multiSelectable

```
bool multiSelectable() const;

void multiSelectable(bool sel);
```

Specifies whether this object can be simultaneously selected along with one or more other objects. Multi-selected objects can be dragged around together retaining their distance and orientation relative to one another. You multi-select by left-clicking each object while holding down the shift key.

You can prevent an object from being multi-selected by setting this flag false.

Notes

Multi-selection only works on objects that are siblings of one another. In complex parent/child applications check carefully for this condition.

- `bool multiSelectable() const;`

  Returns true if the UI object is set to be multi-selectable. Returns false otherwise.

  Example

  To determine whether the UI object and another are simultaneously selected, use the following code:

```
  // other is a pointer to the other object
if (selected() && multiSelectable()
     && other->selected() && other->multiSelectable()) {
   ...
}
```

- `void multiSelectable(bool sel);`

  Sets the UI object's multi-select flag.

  Parameters

  sel — The new multi-select flag, true of false.

multiSelected `bool multiSelected(const ccUIObject* sib) const;`

Returns true if the specified sibling's multi-select flag is true, meaning it can be multi-selected. Returns false otherwise.

Parameters

sib — The sibling UI object you wish to test. Can be either a sibling or the UI object itself. This method always returns true if *sib* is the UI object itself.

Notes

We do not recommended that you use the **multiSelected()** method in your own programs because its name is not entirely consistent with its implementation. Instead use **multiSelectable()** (see the example code provided with that method).

multiDragable `bool multiDragable();`

Returns true if the UI object and all of its multi-selected siblings can be dragged. Returns false otherwise.

Notes

The **multiDragable()** method is the preferred way to determine if an object can be dragged. The **draggable()** method, on the other hand, determines whether an object is conditionally draggable (that is, draggable if other conditions also hold).

userSelect `void userSelect(c_Uint32 shift);`

Specifies how to implement click-select behavior in combination with the Shift key.

Parameters

shift Specifies the meaning of the Shift key in combination with a mouse button click.

Value	Effect
shift = -1	If **enabled()** == true (requires **condEnabled()** == true and **condVisible()** == true) do the following: • Deselect all sibling objects (using **condSelected(**false**)**). • Select me (using **condSelected(**true**)**. • If **dontMove()** == false, call **front()**. • Recurse up the object hierarchy using **parent()** as the next object. -or- If **enabled()** == false, do nothing on this object but still recurse up the object hierarchy using **parent()** as the next object.

Value	Effect
shift = 0	If **enabled()** == true (requires **condEnabled()** == true and **condVisible()** == true) do the following: • If I am not currently selected, deselect all sibling objects (using **condSelected(**false**)**). • Select me (using **condSelected(**true**)**. • If **dontMove()** == false, call **front()**. • Recurse up the object hierarchy using **parent()** as the next object. -or- If **enabled()** == false, do nothing on this object but still recurse up the object hierarchy using **parent()** as the next object.

shift = 1	if **enabled()** == true and **multiSelectable()** = true, do the following:
	• If I am about to become selected, deselect all my non-multiSelectable siblings.
	• Toggle my conditional-selected state.
	• Recurse up the object hierarchy using **parent()** as the next object.
	-or-
	if **enabled()** == true and **multiSelectable()** = false, do the following:
	• If I am not currently selected, deselect all my non-multiSelectable siblings.
	• Select me (using **condSelected(**true**)**.
	• If **dontMove()** == false, call **front()**.
	• Recurse up the object hierarchy using **parent()** as the next object.

Notes

1. The difference between using a *shift* value of 0 or -1 affects the deselection of other objects. A shift value of 0 will only deselect other objects if the current object is not selected. This choice can be used to mimic the behavior caused by clicking an object with the mouse, or to mimic shift_key-click multi-selectability with the mouse. To mimic a single action mouse-click on this object, call **userSelect(**0**)**. To mimic shift_key-click multi-selectability action, call **userSelect(**1**)**.
2. This function differs from **condSelected(**bool, bool**)** in that it changes the **condSelected()** state of many more objects, including sibling and parent objects. If you wish to modify only the conditional state of this object, use **condSelected(**bool, bool**)**.
3. For this object or any parent object above in the object hierarchy that is visited from this function, **enabled()** must be true for any action to occur. For this object or any parent object above in the object hierarchy with **enabled()** == false, no action is taken. Sibling objects and children objects of this object do not consider the **enabled()** state when changing the selected state.
4. The value of **keepSel()** controls whether an object can be deselected. If **keepSel()** == true then that object will not be deselected by this function call. This function may change the selected state of an object and as such may call **select_()**, **deselect_()**, and/or **front_()**.

whoIsTouched

```
virtual ccUIObject* whoIsTouched(const ccIPair& p);
```

Returns a pointer to the front-most, visible UI object touched by the point *p* that is either this object or one of its descendants. Returns NULL if the point touches neither this UI object nor any of its descendants.

Parameters

p	Position to be checked for proximity to UI objects.

Notes

The point is specified in the scope coordinates of the UI object's parent. For the root object, these are screen coordinates. For shapes, they are the same as the UI object's tablet coordinates.

Notes

Only framework classes should override this method. Override **ccUIFrame::isTouched()** and **ccUIShapes::isTouched()** in classes you derive to specify how particular objects are touched.

front

```
void front();
```

Called by the UI framework when the object is moved to the front. (For example, when it is selected). This function calls **front_()** which can be overridden in a user-derived class.

back

```
void back();
```

Called by the UI framework when the object is moved to the back. This function calls **back_()** which can be overridden in a user-derived class.

clickable

```
bool clickable() const;
void clickable(bool click);
```

- `bool clickable() const;`

  Returns true if the UI object can accept mouse clicks. Returns false otherwise.

- `void clickable(bool click);`

  Sets the UI object's clickable flag, which determines whether or not the UI object can accept mouse clicks.

  Parameters

  click — If true, the UI object is clickable.

draggable

```
bool draggable() const;
void draggable(bool drag);
```

- `bool draggable() const;`

  Returns true if the UI object can be dragged with the mouse. Returns false otherwise. See also **multiDragable()**.

- `void draggable(bool drag);`

  Sets the UI object's draggable flag, which determines whether or not the UI object can be dragged with the mouse.

  Parameters

  drag — If true, the UI object is draggable.

dragging

```
bool dragging() const;
void dragging(bool);
```

- `bool dragging() const;`

  Returns true if the UI object is currently being dragged with the mouse. Returns false otherwise.

- `void dragging(bool drag);`

  Sets the UI object's dragging flag. This is an internal UI framework function. Do not call this function from your program.

  Parameters

  drag — If true, the UI object is currently being dragged.

  Notes

  In your program you can test, but should not set, whether the UI object is being dragged.

dontMove

```
bool dontMove() const;
void dontMove(bool move);
```

- `bool dontMove() const;`

  Returns true if the UI object should not move in front of other objects when it is selected. Returns false otherwise.

- `void dontMove(bool noMove);`

  Sets the UI object's dontMove flag, which determines whether or not the UI object should move to the front when it is selected. Set this flag to true for UI objects that should maintain a fixed screen order that is independent of user mouse clicks.

  Parameters

  noMove — If true, the UI object will not move in front of other objects when selected.

opNew

```
bool opNew() const;
```

Returns true if the UI object was created with **new()** and therefore requires a separate **delete()** to destroy it.

Notes

The **opNew()** method indicates whether the UI object was created with the operator **new()**, but not whether it is currently on the heap. An object can also be on the heap if it was created not directly with the operator **new()** but as a member of another object that was. Such a component object is destroyed when the composite object that contains it is destroyed, and does not require a separate **delete()**.

autoDelete

```
bool autoDelete() const;

void autoDelete(bool autoDel);
```

UI objects record whether they have been created on the heap or the stack so they can be automatically deleted. A **ccUIObject** can do this because it overrides the operator **new()**. This allows you to add a number of shapes to the display without having to remember to clean up after them. Some objects never use **autoDelete()**. For example, **ccWin32Display** disables **autoDelete()** in its constructor.

Notes

Since **ccDisplay** automatically manages UI shapes when added, you should not create UI shapes on the heap. Use stack objects only if you call **autoDelete(***false***)**.

- `bool autoDelete() const;`

  Returns true if the UI object should be deleted when its parent is deleted. Returns false otherwise.

- `void autoDelete(bool autoDel);`

  Sets the UI object's autoDelete flag.

  Parameters

  autoDel If true, the UI object is deleted when its parent is deleted.

  Notes

  The UI object's **opNew()** flag must be set to true before the autoDelete flag can be set to true. The autoDelete flag is set to true by default if the object is created with **new()**, otherwise the flag is set to false.

  Notes

  Calling *display->autoDelete(true)* can crash the display system even if the display was allocated on heap. This is true because the **ccWin32Display** constructor deletes the root **ccUIObject**, which in turn deletes all of its children. Since **ccWin32Display** is a child of **ccUIObject**, if **autoDelete()** is true the display will be deleted twice.

mark

```
bool mark() const;
void mark(bool mflag);
```

- `bool mark() const;`

  Returns true if the UI object is marked. Returns false otherwise.

- `void mark(bool);`

  Sets the UI object's *marked* flag.

  Parameters

  mflag True marks the UI object, false unmarks it.

  Notes

  Clients can mark a UI object for any purpose useful in their application.

keepSel

```
bool keepSel() const;
void keepSel(bool keep);
```

This function is useful when treating multiple UI shapes as a single entity. For example, each shape can be set to remain selected so that all the shapes can be dragged together.

When set to true, **condSelected(false)** calls are ignored.

If the parent becomes deselected **keepSel()** is set to false and **condSelected()** is set to false.

- `bool keepSel() const;`

  Returns true if the UI object cannot be deselected. Returns false otherwise.

- `void keepSel(bool keep);`

  Sets the UI object's keepSel flag, which determines whether or not the object can be deselected. If true, the UI object cannot be deselected and its **condSelected()** flag is also set to true.

  Parameters

  keep If true the UI object cannot be deselected.

dwell

```
bool dwell() const;

void dwell(bool dflag);
```

When **dwell()** is false, each **mouseDown()** - **mouseUp()** pair generates a **click()** event. In addition, when **dwell()** is true, multiple **click()** events are generated at a fixed rate as long as the left mouse button is held down.

- `bool dwell() const;`

  Returns true if the UI object can generate multiple click events while the user holds the left mouse button down.

- `void dwell(bool dflag);`

  Sets the UI object's dwell flag, which determines whether or not it can generate multiple click events while the user holds down the left mouse button.

  Parameters

  dflag — New dwell flag, true or false.

rightButtonMode

```
RightButtonModes rightButtonMode();

void rightButtonMode(RightButtonModes m);
```

- `RightButtonModes rightButtonMode();`

  Returns the UI object's right button mode, which specifies how the object handles right mouse button click events.

- `void rightButtonMode(RightButtonModes m);`

  Sets the UI object's right button mode.

  Parameters

  m — Right mouse button mode. Must be one of the **RightButtonModes** enums (*eIgnoreRB, eClientRB, eBackRB, eShiftRB*).

  See the **RightButtonModes** enum on page 3269.

mouseMiddle

```
void mouseMiddle(const ccIPair& p, MouseAction event,
                 c_UInt32 keys);
```

This method is invoked by the UI framework for a mouse middle button event when the mouse is pointing to this object. **mouseMiddle()** calls **mouseMiddle_()**, a function you must override in your own derived UI class if you wish to implement a mouse middle button response.

Parameters

p	Last position of the mouse in screen coordinates.
event	Type of mouse event that caused this call. Must be one of the **ccMouseEvent::Event** enums (*eNone, eMovement, eDownClick, eDoubleClick, eUpClick, eDwell*).
keys	Modifier keys depressed when the mouse action occurred. Must be one of the **ccMouseEvent::Key** enums (*eNoKey*, *eAlt*, *eControl*, *eShift*).

mouseRight

```
void mouseRight(const ccIPair& p, MouseAction event,
                c_UInt32 keys);
```

This method is invoked by the UI framework for a mouse right button event when the UI object is in the *eClientRB* mode (**rightButtonMode()** = *eClientRB*), and the mouse is pointing to this object. **mouseRight()** calls **mouseRight_()**, a function you must override in your own derived UI class if you wish to implement a mouse right button response.

Parameters

p	Last position of the mouse in screen coordinates.
event	Type of mouse event that caused this call. Must be one of the **ccMouseEvent::Event** enums (*eNone, eMovement, eDownClick, eDoubleClick, eUpClick, eDwell*).
keys	Modifier keys depressed when the mouse action occurred. Must be one of the **ccMouseEvent::Key** enums (*eNoKey*, *eAlt*, *eControl*, *eShift*).

mouseDown

```
void mouseDown();
```

The UI Framework calls **mouseDown()** when the left mouse button is pressed down while pointing to this object (the object must be **clickable()**). **mouseDown()** then calls the protected function **mouseDown_()**. If **mouseDown_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseDown_()** is overridden in a user-derived class, the override function is executed.

mouseUp `void mouseUp();`

The UI Framework calls **mouseUp()** following a mouseDown when the left mouse button is released, or when the mouse pointer is moved off the object. **mouseUp()** then calls the protected function **mouseUp_()**. If **mouseUp_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseUp_()** is overridden in a user-derived class, the override function is executed.

mouseEnter `void mouseEnter();`

The UI Framework calls **mouseEnter()** when the mouse enters the UI object's screen space with a left mouse button held down. **mouseEnter()** then calls the protected virtual function **mouseEnter_()** which is overridden in **ccUIShapes::mouseEnter_()** where the actual implementation is done.

idleMouseEnter `void idleMouseEnter();`

The UI Framework calls **idleMouseEnter()** when the mouse enters the UI object's screen space with the left mouse button up. **idleMouseEnter()** then calls the protected function **idleMouseEnter_()** which is overridden in **ccUIShapes::idleMouseEnter_()** where the actual implementation is done

mouseLeave `void mouseLeave();`

The UI Framework calls **mouseLeave()** when the mouse is moved off the UI object, or also, if an enabled object was entered and it then becomes disabled. **mouseLeave()** then calls the protected function **mouseLeave_()** which is overridden in **ccUIShapes::mouseLeave_()** where the actual implementation is done

mouseMove `void mouseMove(const ccIPair& screenPos);`

The UI Framework calls **mouseMove()** repeatedly when the mouse is moving while pointing to this object. (For example, while resizing the object). Each call includes the current mouse position in screen coordinates. **mouseMove()** then calls the protected function **mouseMove_()**. If **mouseMove_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseMove_()** is overridden in a user-derived class, the override function is executed.

Parameters

screenPos	The current mouse position in screen coordinates.

click

```
void click();
```

The UI Framework calls **click()** following a **mouseDown()** - **mouseUp()** sequence. Also, following a **mouseDown()**, if **dwell()** = true, **click()** is called repeatedly until **mouseUp()**.

click() calls the protected function **click_()**. If **click_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **click_()** is overridden in a user-derived class, the override function is executed.

dblClick

```
void dblClick();
```

The UI Framework calls **dblClick()** following a double click mouse event when the mouse is pointing to this object. **dblClick()** calls the protected function **dblClick_()**. If **dblClick_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **dblClick_()** is overridden in a user-derived class, the override function is executed.

dragStart

```
void dragStart(const ccIPair& startPos);
```

Called by the UI framework at the start of a dragging operation. *startPos* is the mouse starting position. **dragStart()** calls **dragStart_()** which can be overridden in a user-derived class to perform additional custom operations.

Parameters

startPos	Starting position of the mouse in screen coordinates.

dragStop

```
void dragStop(const ccIPair& startPos,
              const ccIPair& stopPos);
```

Called by the UI framework when a dragging operation stops. **dragStop()** calls **dragStop_()** which is overridden in **ccUIShapes::dragStop_()** where drag stop implementation is done.

Parameters

startPos	Starting position of the mouse in screen coordinates.
stopPos	Ending position of the mouse in screen coordinates.

dragAnimate

```
void dragAnimate(const ccIPair& startPos,
  const ccIPair& stopPos);
```

Called by the UI framework to display an outline of the dragged object(s) during the dragging operation. This allows the operator to more accurately choose the final position of the drag. **dragAnimate()** is called repeatedly during the drag so that the dragged object(s) appear to move in real time.

dragAnimate() calls **dragAnimate_()** which is overridden in **ccUIShapes::dragAnimate_()** where the dragging implementation is done.

Parameters

startPos	Starting mouse position of the drag in screen coordinates. For multiple calls to **dragAnimate()** during a dragging operation, *startPos* is always the same.
stopPos	The current mouse position of the drag in screen coordinates. Note that the dragging operation may not be finished, in which case this is an intermediate stopping position.

keyboard

```
void keyboard(const ccKeyboardEvent& ev);
```

Called by the UI framework in response to a keyboard event when the mouse is pointing to this object. For example, the user typing a keyboard key. **keyboard()** calls **keyboard_()** which can be overridden in a user-derived class to perform additional custom operations.

Parameters

ev	The keyboard event that initiated this call. See the **ccKeyboardEvent** reference page.

Protected Member Functions

show

```
virtual void show(bool parentChanged);
```

The UI Framework calls **show()** when the object's state changes to *visibleState (the object becomes visible)*. If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **show()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **show()** is overridden in a user-derived class, the override function is executed.

Parameters

parentChanged True if the state of the UI object's parent (or ancestor) has changed. False if the state of the object itself has changed.

hide

```
virtual void hide(bool parentChanged);
```

The UI Framework calls **hide()** when the object's state changes from *visibleState* (the object becomes not visible). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **hide()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **hide()** is overridden in a user-derived class, the override function is executed.

Parameters

parentChanged True if the state of the UI object's parent (or ancestor) has changed. False if the state of the object itself has changed.

enable

```
virtual void enable(States s, bool parentChanged);
```

The UI Framework calls **enable()** when the object's state changes to *enabledState* (the object becomes enabled). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **enable()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **enable()** is overridden in a user-derived class, the override function is executed.

Parameters

s The state change that caused the object to become enabled. Must be one of the **States** enums.

parentChanged True if the enable was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

disable

```
virtual void enable(States s, bool parentChanged);
```

The UI Framework calls **disable()** when the object's state changes from *enabledState* (the object becomes disabled). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **disable()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **disable()** is overridden in a user-derived class, the override function is executed.

Parameters

s	The state change that caused the object to become disabled. Must be one of the **States** enums.
parentChanged	True if the disable was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

select

```
virtual void select(States s, bool parentChanged);
```

The UI Framework calls **select()** when the object's state changes to *selectedState* (the object becomes selected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **select()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **select()** is overridden in a user-derived class, the override function is executed.

Parameters

s	The state change that caused the object to become selected. Must be one of the **States** enums.
parentChanged	True if the select was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

deselect

```
virtual void deselect(States s, bool parentChanged);
```

The UI Framework calls **deselect()** when the object's state changes from *selectedState* (the object becomes deselected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

If **deselect()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **deselect()** is overridden in a user-derived class, the override function is executed.

Parameters

s	The state change that caused the object to become deselected. Must be one of the **States** enums.
parentChanged	True if the deselect was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

mouseDown_ `virtual void mouseDown_();`

The UI Framework calls **mouseDown()** when the left mouse button is pressed down while pointing to this object (the object must be **clickable()**). **mouseDown()** then calls the protected function **mouseDown_()**. If **mouseDown_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseDown_()** is overridden in a user-derived class, the override function is executed.

mouseUp_ `virtual void mouseUp_();`

The UI Framework calls **mouseUp()** following a mouseDown when the left mouse button is released, or when the mouse pointer is moved off the object. **mouseUp()** then calls the protected function **mouseUp_()**. If **mouseUp_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseUp_()** is overridden in a user-derived class, the override function is executed.

mouseEnter_ `virtual void mouseEnter_();`

The UI Framework calls **mouseEnter()** when the mouse enters the UI object's screen space with a left mouse button up. **mouseEnter()** then calls **mouseEnter_()**. If **mouseEnter_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseEnter_()** is overridden in a user-derived class, the override function is executed.

idleMouseEnter_ `virtual void idleMouseEnter_();`

The UI Framework calls **idleMouseEnter()** when the mouse enters the UI object's screen space with a left mouse button up. **idleMouseEnter()** then calls **idleMouseEnter_()**. If **idleMouseEnter_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **idleMouseEnter_()** is overridden in a user-derived class, the override function is executed.

mouseLeave_ `virtual void mouseLeave_();`

The UI Framework calls **mouseLeave()** when the mouse is moved off the UI object or also if an enabled object was entered and it then becomes disabled. **mouseLeave()** then calls **mouseLeave_()**. If **mouseLeave_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseLeave_()** is overridden in a user-derived class, the override function is executed.

mouseMove_ `virtual void mouseMove_(const ccIPair& screenPos);`

The UI Framework calls **mouseMove()** repeatedly when the mouse is moving while pointing to this object. (For example, while resizing the object). Each call includes the current mouse position in screen coordinates. **mouseMove()** then calls the protected function **mouseMove_()**. If **mouseMove_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **mouseMove_()** is overridden in a user-derived class, the override function is executed.

Parameters

screenPos The current mouse position in screen coordinates.

click_ `virtual void click_();`

The UI Framework calls **click()** following a **mouseDown()** - **mouseUp()** sequence. Also, following a **mouseDown()**, if **dwell()** = true, **click()** is called repeatedly until **mouseUp()**.

click() calls the protected function **click_()**. If **click_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **click_()** is overridden in a user-derived class, the override function is executed.

dblClick_ `virtual void dblClick_();`

The UI Framework calls **dblClick()** following a double click mouse event when the mouse is pointing to this object. **dblClick()** calls the protected function **dblClick_()**. If **dblClick_()** is not overridden in a user-derived class, it does nothing and returns. No additional action is taken. If **dblClick_()** is overridden in a user-derived class, the override function is executed.

dragStart_ `virtual void dragStart_(const ccIPair& startPos);`

Called by **dragStart()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations at the start of a dragging operation.

See **dragStart()**.

Parameters

startPos Starting position of the drag in screen coordinates.

dragStop_

```
virtual void dragStop_(const ccIPair& startPos,
                       const ccIPair& stopPos);
```

Called by **dragStop()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations at the end of a dragging operation.

See **dragStop()**.

Parameters

startPos Starting position of the mouse in screen coordinates.

stopPos Ending position of the mouse in screen coordinates.

dragAnimate_

```
virtual void dragAnimate_(const ccIPair& startPos,
                          const ccIPair& curPos);
```

Called by **dragAnimate()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations during a dragging operation.

See **dragAnimate()**.

Parameters

startPos Starting mouse position of the drag in screen coordinates. For multiple calls to **dragAnimate()** during a dragging operation, *startPos* is always the same.

stopPos The current mouse position of the drag in screen coordinates. Note that the dragging operation may not be finished, in which case this is an intermediate stopping position.

mouseMiddle_

```
virtual void mouseMiddle_(const ccIPair& p,
                          MouseAction event, c_UInt32 keys);
```

Called by **mouseMiddle()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations during a dragging operation.

See **mouseMiddle()**.

Parameters

p Last position of the mouse in screen coordinates.

event Type of mouse event that caused this call. Must be one of the **ccMouseEvent::Event** enums (*eNone, eMovement, eDownClick, eDoubleClick, eUpClick, eDwell*).

keys Modifier keys depressed when the mouse action occurred. Must be one of the **ccMouseEvent::Key** enums (*eNoKey*, *eAlt*, *eControl*, *eShift*).

mouseRight_

```
virtual void mouseRight_(const ccIPair& p,
                         MouseAction event, c_UInt32 keys);
```

Called by **mouseRight()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations during a dragging operation.

See **mouseRight()**.

Parameters

p Last position of the mouse in screen coordinates.

event Type of mouse event that caused this call. Must be one of the **ccMouseEvent::Event** enums (*eNone, eMovement, eDownClick, eDoubleClick, eUpClick, eDwell*).

keys Modifier keys depressed when the mouse action occurred. Must be one of the **ccMouseEvent::Key** enums (*eNoKey*, *eAlt*, *eControl*, *eShift*).

keyboard_

```
virtual void keyboard_(const ccKeyBoardEvent& ev);
```

Called by **keyboard()**. Unless overridden in a user-derived class, this function does nothing. Provides a way for a user to perform custom operations in response to keyboard events.

See **keyboard()**.

Parameters

ev The keyboard event that initiated this call. See the **ccKeyboardEvent** reference page.

Notes

Keyboard events are sent directly to the UI object that is capturing mouse events.

front_

```
virtual void front_(ccUIObject* kid) = 0;
```

Called by **front()** when the object is moved to the front. (For example, when it is selected). This function can be overridden in a user-derived class to add custom functionality. If you do override, make sure your override function calls the parent's **front_()**.

Parameters

kid Pointer to the object moved to the front.

back_

```
virtual void back_(ccUIObject* kid) = 0;
```

Called by **back()** when the object is moved to the back. This function can be overridden in a user-derived class to add custom functionality. If you do override, make sure your override function calls the parent's **back_()**.

Parameters

kid Pointer to the object moved to the back.

Static Functions

uiMutex

```
static ccMutex& uiMutex();
```

Returns a reference to the global UI mutex.

Notes

If you need to lock this operation, lock the UI object's root mutex first.

orphanMutex

```
static ccMutex& orphanMutex();
```

Returns a reference to the global orphan mutex (that is, the mutex for objects without a parent).

isValid

```
static bool isValid(ccUIObject*, c_UInt32 key,
  const ccUIRootObject*);
```

Returns true if the UI object specified by the given address and key exists and has the specified root object as a parent.

Notes

A return value of true means that the first argument points to a valid object that has not been deleted or had an ancestor deleted, that has a valid parent, and all of whose ancestors each have a valid parent. The execution time for this function depends on the number of objects that exist at a given instant.

selectColor

```
static void selectColor(const ccColor& c);
static const ccColor& selectColor();
```

Specifies the *select* color for all UI shapes.

- `static void selectColor(const ccColor& c);`

  Sets the color to use when an object is selected. The color is used for all objects.

  Parameters

  c The color.

- `static const ccColor& selectColor();`

  Returns the color to use when an object is selected.

dragColor

```
static void dragColor(const ccColor& c);
static const ccColor& dragColor();
```

Specifies the *drag* color for all UI shapes.

- `static void dragColor(const ccColor& c);`

  Sets the color to use when an object is dragged. The color is used for all objects.

  Parameters

  c The color.

- `static const ccColor& dragColor();`

  Returns the color to use when an object is dragged.

Typedefs

MouseAction

```
typedef ccMouseEvent::Event MouseAction;
```

ccUIObject

ccUIPointIcon

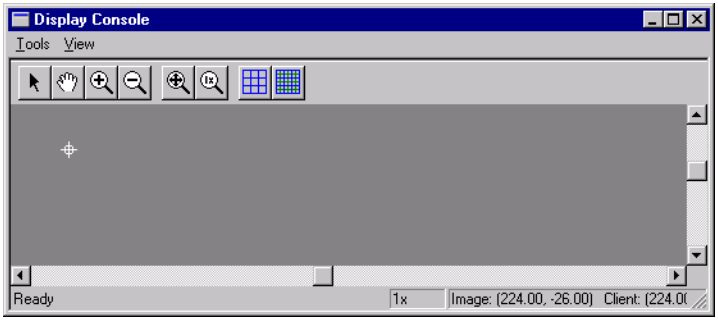
```
#include <ch_cvl/uishapes.h>

class ccUIPointIcon : public ccUIPointShapeBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a point icon you can display in a **ccDisplay** window where you can then position it using your mouse. The point icon size, shape, and orientation cannot be changed. The displayed point icon contains no handles for manipulation. The following is an example of a point icon that has been added to a **ccDisplayConsole** window.



ccUIPointIcon is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

You can left-click on the point icon, holding the button down to reposition it in a **ccDisplay** window. Point icons cannot be resized and have no manipulation handles.

After repositioning an point icon in a **ccDisplay** window, you will generally want to save the final point icon location for later use. Use the **ccUIShapes::pos()** getter function to obtain the final position of the point icon. If you later need to recreate the saved display, create a new default **ccUIPointIcon** and restore it to this saved location with **ccUIShapes::pos(cc2Vect)**.

Notes

ccUIPointIcon and any UI shape derived from **ccUIPointShapeBase** uses a coordinate space relative to its parent. When you add an object to a display window its parent is automatically set to one of the coordinate frame objects internal to the display.

Constructors/Destructors

ccUIPointIcon

```
ccUIPointIcon (ccUIObject* parent = NULL);
```

Creates a new manipulable point icon.

Parameters

parent	The point icon's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Protected Member Functions

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

isTouched `virtual bool isTouched (const cc2Vect& v, double scale);`

An override.

Returns true if the specified position (v) touches this point icon. Returns false otherwise.

Parameters

v	Position to be checked for proximity to the point icon. The position (*v*) is relative to its parent, in tablet coordinates. Multiply (*v*) by *scale* if you want the distance in pixels.
scale	Number by which to multiply (*v*) which is in tablet coordinates, to covert it to pixels.

ccUIPointIcon

ccUIPointSet

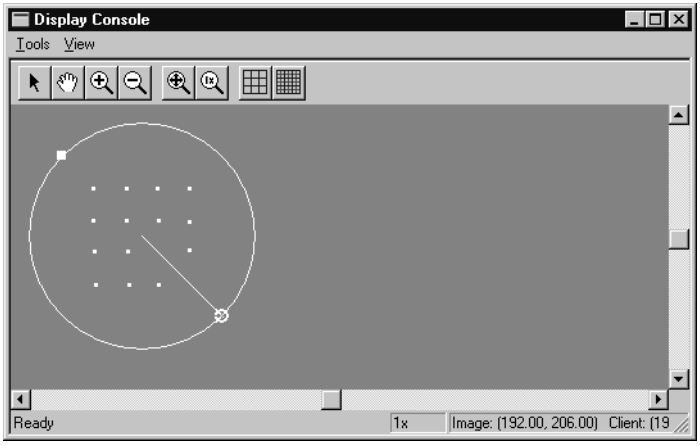
```
#include <ch_cvl/uishapes.h>

class ccUIPointSet : public ccUIManShape;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a point set (**ccPointSet**) that you can manipulate. When you add a **ccUIPointSet** object to a **ccDisplay** window the point set is displayed and can be moved about, resized, and rotated using your mouse. The following is an example of a point set that has been added to a **ccDisplayConsole** window.



The first point you specify in the point set you provide is used as the point set center. The second point you provide specifies the radius (p[0]-p[1]) of the enclosing circle shown in the example above. The display shows the enclosing circle and the radius line from p[0] to p[1]. The remainder of the points you specify make up the point set and are displayed as single pixel points.

ccUIPointSet is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIPointSet** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIPointSet** has one resizing handle which allows you to expand or reduce the size of the enclosing circle. As you change the circle size, all points in the set change position proportionately.
 Rotation handle	Left-click on the rotation handle holding the button down and drag the handle to rotate the point set. The rotation handle is located at p[1].

After manipulating a point set in a **ccDisplay** window, you will generally want to retrieve the final point set state and use it in some way. You can use code similar to the following to retrieve the manipulated point set.

```
ccPointSet new_pointSet;
new_pointSet = ui_pointSet->pointSet();
```

Where **ui_pointSet** is the manipulated **ccUIPointSet** object.

Notes

ccUIPointSet and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIPointSet

```
ccUIPointSet(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccPointSet**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The point set's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Enumerations

eLock

This enumeration lets you specify which handles are not visible when the object is selected. By using these locks, you can prevent a rectangle from being modified along different degrees of freedom.

Value	Meaning
eNoLocks	No locks. All manipulations allowed.
eSizeLock	The object cannot be resized.
eRotLock	The object cannot be rotated.

Public Member Functions

pointSet

```
void pointSet(const ccPointSet& pointSet);
const ccPointSet &pointSet() const;
```

- `void pointSet(const ccPointSet& pointSet);`

  Associated a **ccPointSet** with this manipulation object.

  Parameters

  pointSet The point set to make manipulable.

- `const ccPointSet& pointSet() const;`

  Gets the **ccPointSet** associated with this manipulation object.

updateHandles

```
virtual void updateHandles ();
```

Update all of my handles. Called when handles have been repositioned in the display.

showHandles

```
virtual void showHandles (bool show);
```

Make my handles visible/invisible depending on *show*, and the DOF locks. If the handles aren't created yet, create them.

Parameters

show True = show handles. False = do not show handles.

freeHandles

```
virtual void freeHandles ();
```

Deletes all handles.

locks

```
c_UInt32 locks() const;
void locks(c_UInt32 b);
```

- `c_UInt32 locks() const;`

  Returns the lock bits that indicate which resizing operations are not allowed for this object.

- `void locks(c_UInt32 b);`

  Sets the lock bits that indicate the resizing operations that are not allowed for this object.

  Parameters

  b The lock bits. May be any of the following ORed together:

  ccUIPointSet::eNoLocks
  ccUIPointSet::eSizeLock
  ccUIPointSet::eRotLock

  These lock values are described in *Enumerations* on page 3307.

setLocks

```
void setLocks(c_UInt32 b);
```

ORs the specified locks to the current locks.

Parameters

b The locks to OR with the current locks. May be any of the following ORed together:

ccUIPointSet::eNoLocks
ccUIPointSet::eSizeLock
ccUIPointSet::eRotLock

These lock values are described in *Enumerations* on page 3307.

clrLocks `void clrLocks(c_UInt32 b);`

Clears the locks specified in *b*. (ANDs the current locks with the complement of *b*)

Parameters

b The locks to clear. May be any of the following ORed together:

ccUIPointSet::eNoLocks
ccUIPointSet::eSizeLock
ccUIPointSet::eRotLock

These lock values are described in *Enumerations* on page 3307.

isTouched `virtual bool isTouched(const cc2Vect& pt, double scale);`

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt The position to test in the coordinate system used to draw the shape.

scale The scale to convert *pt* to pixels.

Protected Member Functions

pos_ `virtual ccPoint pos_ () const;`

`virtual void pos_ (const cc2Vect& pos);`

An override.

- `virtual ccPoint pos_ () const;`

  Returns the center position of the point set relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center position of the point set relative to its parent, in tablet coordinates.

  Parameters

  pos The new center position.

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal;* draws full point set *ccUIShapes::drawAbridged;* draws full point set *ccUIShapes::drawDrag;* draws full point set

Static Functions

touchDist

```
static float touchDist();

static void touchDist(float d);
```

- `static float touchDist();`

Gets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

- `static void touchDist (float d);`

Sets the distance from all instance of this object that is still considered a click on the object. The distance is specified in display coordinates.

Parameters

d	The distance from the object.

ccUIPointShapeBase

```
#include <ch_cvl/uishapes.h>

class ccUIPointShapeBase : public virtual ccUIShapes;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class is used as a base class for manipulable shapes that have icon-like behavior such as **ccUIRLEBuffer**, **ccUIIcon**, **ccUIPointIcon**, and **ccUILabel**.

Constructors/Destructors

ccUIPointShapeBase

```
ccUIPointShapeBase();
```

Creates a default manipulable object. You should never need to create an object of this class.

Public Member Functions

isTouched

```
virtual bool isTouched (const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

touchDist

```
float touchDist();
void touchDist(float d);
```

- `float touchDist();`

  Gets the distance from all instance of this object that is still considered a click on the object. The distance is specified in the coordinate system that the object is drawn in.

- `void touchDist(float d);`

  Sets the distance from all instance of this object that is still considered a click on the object. The distance is specified in the coordinate system that the object is drawn in.

  Parameters

  d The distance from the object.

Protected Member Functions

pos_

```
virtual ccPoint pos_ () const;
virtual void pos_ (const cc2Vect& pos);
```

An override.

- `virtual ccPoint pos_ () const;`

  Returns the center position of the UI shape relative to its parent, in tablet coordinates.

- `virtual void pos_ (const cc2Vect& pos);`

  Sets the center position of the UI shape relative to its parent, in tablet coordinates.

  Parameters

  pos The new center position.

Typedefs

ccUIInvisibleShape

```
typedef ccUIPointShapeBase ccUIInvisibleShape;
```

ccUIRectangle

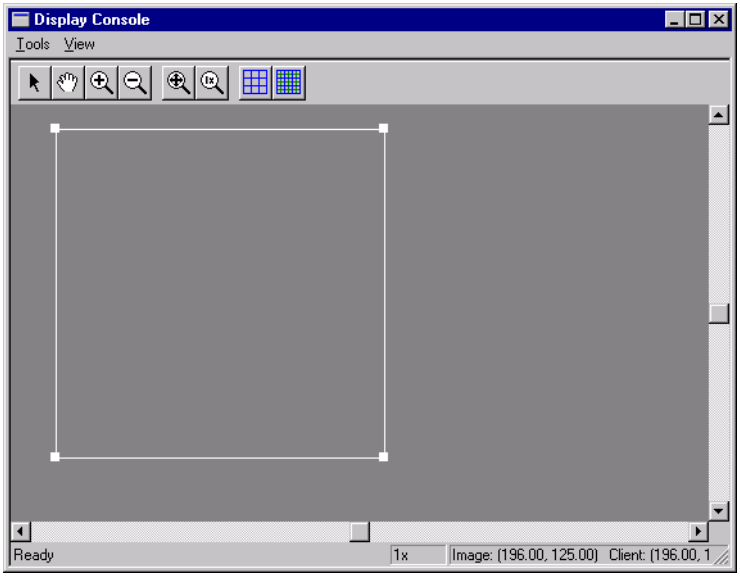
```
#include <ch_cvl/uishapes.h>

class ccUIRectangle : public ccUIGenRect;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates a rectangle (**ccRect**) that you can manipulate. When you add a **ccUIRectangle** object to a **ccDisplay** window a rectangle is displayed that can be moved about and resized using your mouse. The following is an example of a rectangle that has been added to a **ccDisplayConsole** window.



ccUIRectangle is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the **ccUIObject** and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

When you select interactive graphic objects in a **ccDisplay** window, *handles* appear as blue icons on the selected objects. You can grab these handles with the mouse to manipulate the objects. **ccUIRectangle** uses the following handles:

Handle	Description
 Resizing handle	Left-click on the resize handle holding the button down and drag the handle to resize the object. **ccUIRectangle** has four resizing handles which all operate in the same way.

After manipulating a rectangle in a **ccDisplay** window, you will generally want to retrieve the final rectangle state and use it in some way. You can use code similar to the following to retrieve the manipulated rectangle.

```
ccRect new_rect;
new_rect = ui_rect->rect();
```

Where **ui_rect** is the manipulated **ccUIRectangle** object.

Notes

ccUIRectangle and all UI shapes derived from **ccUIManShape** use a coordinate space relative to the tablet into which the shape is drawn.

Constructors/Destructors

ccUIRectangle

```
ccUIRectangle(ccUIObject* parent = NULL);
```

Creates a new manipulation object for a **ccRect**.

Notes

If you specify a parent, it must be derived from **ccUIPointShapeBase**. These include **ccUILabel**, **ccUIPointIcon**, **ccUIRLEBuffer**, and **ccUIIcon**.

Parameters

parent The rectangle's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

rect

```
void rect(const ccRect& r);
ccRect rect() const;
```

- `void rect(const ccRect& r);`

  Associates a **ccRect** with this manipulation object.

  Parameters

  r The rectangle to make manipulable.

  Throws

  ccShapesError::DegenerateShape
  r is degenerate.

  See **ccRect::degen()** for a description of degenerate rectangles.

- `ccRect rect() const;`

  Gets the **ccRect** associated with this manipulation object.

pelRect

```
void pelRect(const ccPelRect& r);
ccPelRect pelRect(bool enclosing = true) const;
```

- `void pelRect(const ccPelRect& r);`

  Sets the rectangle of this rectangle to the specified **ccPelRect**.

  Parameters

  r The pel rect to use to set the manipulable rectangle.

- `ccPelRect pelRect(bool enclosing = true) const;`

  Gets the pel rect that corresponds to this manipulable rectangle.

  Parameters

  enclosing If true, returns the largest **ccPelRect** that encloses this shapes corresponding **ccRect**.

  If false, returns the that largest **ccPelRect** smaller than the shape's **ccRect**.

Protected Member Functions

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

ccUIRLEBuffer

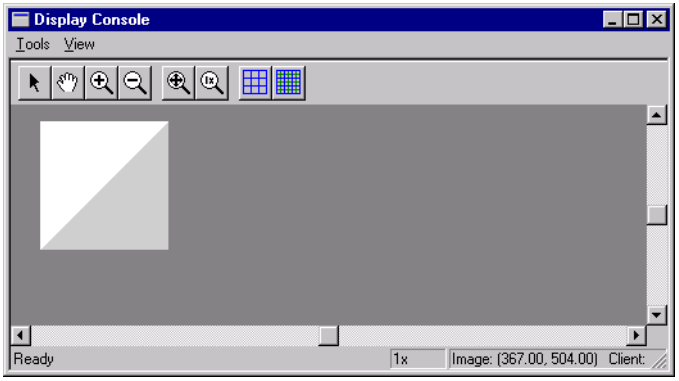
```
#include <ch_cvl/uishapes.h>

class ccUIRLEBuffer : public ccUIPointShapeBase;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	No

This class creates an icon from a **ccRLEBuffer** object. The icon size cannot be changed and it cannot be rotated. However, you can reposition the icon using your mouse. The displayed icon contains no handles for manipulation. The following is an example of a simple icon that has been added to a **ccDisplayConsole** window.



ccUIRLEBuffer is similar to **ccUIIcon** except **ccUIRLEBuffer** scales (when you zoom in on a **ccDisplay** window, the icon changes size) and **ccUIIcon** does scale. See the **ccUIIcon** reference page.

ccUIRLEBuffer is a member of a family of shapes that can be manipulated in a **ccDisplay** window. These classes are generally referred to as *UI shapes* or *interactive graphics* and are all derived from the **ccUIObject** and **ccUIShapes** base classes. Please see these base class reference pages for a discussion of how to manipulate UI shapes in a **ccDisplay** window using your mouse.

The **ccUIObject** and **ccUIShapes** base classes also provide member functions you can program to perform the same graphical manipulations as the mouse. When your program executes these functions, the shape displayed in a **ccDisplay** window changes in the same way it does when manipulated by the mouse. Please see the

ccUIObject and **ccUIShapes** reference pages for descriptions of these member functions. Also see the *Display Graphics* chapter of the *CVL User's Guide* for more information about using and displaying interactive graphics.

You can left-click on the icon holding the button down to reposition it in a **ccDisplay** window. Icons cannot be resized and have no manipulation handles.

After repositioning an icon you will generally want to retrieve the final icon state and use it in some way. You can use code similar to the following to retrieve the moved icon.

```
ccRLEBuffer new_rleBuf;
new_rleBuf = ui_rleBuf->rleBuffer();
```

Where **ui_rleBuf** is the moved **ccRLEBuffer** object.

Notes

ccUIRLEBuffer and any UI shape derived from **ccUIPointShapeBase** uses a coordinate space relative to its parent. When you add an object to a display window its parent is automatically set to one of the coordinate frame objects internal to the display.

Constructors/Destructors

ccUIRLEBuffer `ccUIRLEBuffer (ccUIObject* parent = NULL);`

Creates a new manipulation object for a **ccRLEBuffer**.

Parameters

parent	The run-length encoded buffer's parent frame. Typically, the display system will set up the parent for you when you add the shape to a display.

Public Member Functions

rleBuffer

```
void rleBuffer(const ccRLEBuffer& buf);

const ccRLEBuffer& rleBuffer() const;
```

- `void rleBuffer (const ccRLEBuffer& buf);`

Associates a **ccRLEBuffer** with this manipulation object.

Parameters

buf	The run-length encoded buffer to make manipulable.

Notes

Pixels whose value is **ccColor::passColor()** are not drawn.

- `const ccRLEBuffer& rleBuffer() const;`

  Gets the **ccRLEBuffer** associated with this manipulation object.

origin

```
void origin(const ccPoint& pt);
const ccPoint& origin() const;
```

- `void origin(const ccPoint& pt);`

  Specifies the origin within this image. The default is (0,0). The image is displayed at **absPos() – origin()**.

  Parameters

  pt The point

- `const ccPoint& origin() const;`

  Returns the origin with the point.

colorMap

```
void colorMap(cmStd vector<c_UInt8>& map);
const cmStd vector<c_UInt8>& colorMap() const;
```

- `void colorMap(cmStd vector<c_UInt8>& map);`

  Sets the color map to be associated with this run-length encoded image. The length of the map can range from zero to 256 elements.

  Parameters

  map The color map.

- `const cmStd vector<c_UInt8>& colorMap() const;`

  Gets the color map associated with this run-length encoded image.

useClientColor

```
void useClientColor(bool b);
bool useClientColor() const;
```

- `void useClientColor(bool b);`

  Specifies whether the run-length encoded image should use the color passed to the appropriate drawing routine for all instances of the client color set by **clientColor()** when the image is selected.

  Parameters

  b — If true, substitute the client color for all instances of the specified drawing color when the image is selected.

- `bool useClientColor() const;`

  Returns whether this image uses the client color when it is selected.

clientColor

```
void clientColor(c_UInt8 color);
c_UInt8 clientColor() const;
```

- `void clientColor(c_UInt8 color);`

  Specifies the pixel value (color) that should be replaced by the color passed to the appropriate drawing routine when the image is selected.

  Parameters

  color — The client color.

  Notes

  ccColor::isIndex() should be true for *color*.

- `c_UInt8 clientColor() const;`

  Returns the pixel value (color) that should be replaced by the color passed to the appropriate drawing routine when the image is selected.

passThrough

```
void passThrough(bool b);
bool passThrough() const;
```

- `void passThrough(bool b);`

  Sets whether the color specified by **passColor()** should not be drawn when drawing the run-length encoded buffer.

  Parameters

b	If true, the color specified by **passColor()** is not drawn.

- `bool passThrough() const;`

  Returns whether the color specified by **passColor()** should not be drawn when drawing the run-length encoded buffer.

passColor

```
void passColor(c_UInt8 color);
c_UInt8 passColor();
```

- `void passColor(c_UInt8 color);`

  Specifies the color in the image that should not be drawn when **passThrough()** returns true.

  Parameters

color	The passthrough color.

- `c_UInt8 passColor() const;`

  Returns the passthrough color.

dontScale

```
void dontScale(bool b);
bool dontScale() const;
```

- `void dontScale(bool b);`

  Specifies whether the run-length encoded image should be scaled to match the coordinate system in which it is drawn.

  Parameters

b	True if the image should not be scaled.

- `bool dontScale() const;`

  Returns whether the image should be scaled.

isTouched

```
virtual bool isTouched(const cc2Vect& pt, double scale);
```

Returns true if *pt* is within **touchDist()** of this object. This function is called automatically for you when you click the mouse on a shape. You should not need to call it yourself.

Parameters

pt	The position to test in the coordinate system used to draw the shape.
scale	The scale to convert *pt* to pixels.

Protected Member Functions

draw_

```
virtual void draw_ (
  ccUITablet& t,
  const ccColor& c,
  DrawMode m = drawNormal);
```

An override.

Called by **ccUIShapes::draw()** to draw the UI shape in a specified tablet.

Parameters

t	Tablet in which to draw the UI shape.
c	Color of the UI shape.
m	The drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

ccUIShapes

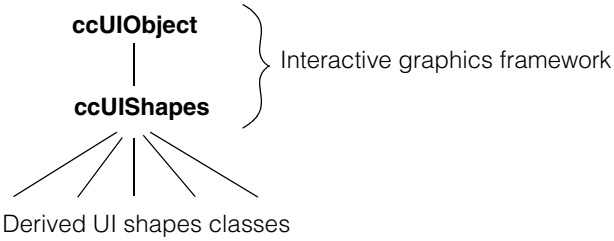
```
#include <ch_cvl/uifrmwrk.h>

class cmImport_cogdisp ccUIShapes : public ccUIObject;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccUIObject and **ccUIShapes** are base classes for the interactive graphics classes, also called UI shapes classes. These base classes make up the interactive graphics framework. See the following class derivation hierarchy.



Interactive graphics classes use the graphics classes defined in *shapes.h* and include fundamental shapes such as the line, rectangle, circle, ellipse, and others. These interactive classes provide an environment where shapes can be manipulated either graphically using a mouse and a **ccDisplay** window, or with your program using member functions from the framework base classes. Please see the **ccUIObject** reference page for additional functions that comprise the interactive graphics framework.

Member Function Summary

Use the following summaries as a guide to the **ccUIShapes** classes, and as a learning tool. The class member functions can be divided into the following functional groups:

Framework-only (these are overrides)	Relationships	Information
shapes() **tablet()**	**parent()** **closerSib()** **fartherSib()** **frontKid()** **backKid()** **numKids()**	**whoIsTouched()**^{v} (an override) **getGraphicProps()**^{v} **isTouched()**^{v} **pos()** **absPos()**

(**v**) = Virtual function

You should not call *Framework-only* classes in your program. *Relationships* and *Information* refer to the object from which they are called.

Attributes	Commands	Protected virtual functions	Protected virtual function overrides
props()	**draw()** **move()** **update()**	**draw_()** **move_()** **pos_()** **redim_()**	**show()** **hide()** **select()** **deselect()** **mouseEnter_()** **idleMouseEnter_()** **mouseLeave_()** **dragStop_()** **dragAnimate_()** **front_()** **back_()**

Attributes allow you to tailor objects for your application. *Commands* are functions you can call when you are manipulating graphics under program control. *Virtual functions* are place holders for overrides in derived classes. *Virtual function overrides* are functions implemented in this class that override place holders in **ccUIObject**. These functions can be overridden again in other derived classes to add additional functionality. However, these downstream overrides should include a call to the base class function being overridden since required functionality is implemented here.

For additional information about interactive graphics classes, see the *Displaying Graphics* chapter of the *CVL User's Guide*.

Constructors/Destructors

This is a pure virtual class. Only classes derived from this class use the constructors and destructors.

~ccUIShapes

```
virtual ~ccUIShapes();
```

Destructor. Destroys the UI shape and removes it from its parent's list of kids. Scans the UI shape's list of kids, deletes those whose autoDelete flag is set, and sets the parent of the remaining kids to NULL.

Enumerations

DrawMode

This enumeration specifies the drawing mode for shapes. It is used to specify the appearance of a shape during various drawing operations.

Value	Meaning
drawNormal	Normal shape appearance
drawAbridged	Abridged appearance for faster drawing
drawDrag	Appearance during a drag operation

Public Member Functions

shapes

```
virtual ccUIShapes* shapes(bool canFail);
```

RTTI framework operation providing base-to-derived type conversion for framework classes. Returns the *this* pointer if the object is an instance of **ccUIShapes**, otherwise 0. Relatively lightweight as compared to *dynamic_cast<>*.

Parameters

canFail — Specifies whether or not the operation can fail. False asserts that the conversion can be done and causes a valid pointer always to be returned. A non-zero value causes NULL to be returned if the conversion cannot be done.

closerSib

```
virtual ccUIObject* closerSib();
```

Returns the sibling object added to the parent object just after this object. If there is none, it returns 0.

This is an override.

fartherSib

```
virtual ccUIObject* fartherSib();
```

Returns the sibling object added to the parent object just before this object. If there is none, it returns 0.

This is an override.

frontKid

```
virtual ccUIObject* frontKid();
```

Returns the child object of this shape that was last added to the parent object. If there is none, it returns 0.

This is an override.

backKid

```
virtual ccUIObject* backKid();
```

Returns the child object of this shape that was first added to the parent object. If there is none, it returns 0.

This is an override.

See **ccUIObject::closerSib** on page 3272 for an example of code that uses this function.

numKids

```
virtual c_Int32 numKids();
```

Gets the number of kids of the UI object.

This is an override.

tablet

```
virtual ccUITablet& tablet();
```

Gets the tablet in which the UI shape is to be drawn. Shapes do not have their own tablet, rather they are drawn in their parent's tablet. If the UI shape's parent is also a shape, then the UI shape is drawn in the grandparent's tablet, and so on until an ancestor is found that is a frame.

This is an override.

whoIsTouched

```
virtual ccUIObject* whoIsTouched(const ccIPair& p);
```

Returns a pointer to the front-most, visible UI object touching the specified point that is either the UI shape or one of its kids. Returns NULL if the point touches neither the shape nor any of its kids. The point is translated from the parent's scope to the UI shape's tablet coordinates. Calls the private non-virtual **whoIsTouched()** function to do the work.

Parameters

p Position to be checked for proximity to UI objects.

Notes

The point is specified in the scope coordinates of the UI object's parent. For the root object, these are screen coordinates. For shapes, they are the same as the UI object's tablet coordinates.

Notes

Only framework classes should override this method. Override **ccUIFrame::isTouched()** and **ccUIShapes::isTouched()** in classes you derive to specify how particular objects are touched.

---

props

```
void props(const ccGraphicProps &props);

const ccGraphicProps &props() const;
```

- `void props(const ccGraphicProps &props);`

  Sets the graphic properties of the UI shape. Triggers updating, erasing, and redrawing of the UI shape.

  Parameters

  props The new graphics properties.

  Note that **ccGraphicProps::penColor()** specifies the object's deselected color.

- `const ccGraphicProps &props() const;`

  Gets the graphic properties of the UI shape. To get the graphic properties of the current rendering state, depending on whether or not the shape is selected, use **getGraphicProps** instead.

---

color

```
void color(const ccColor& c);

const ccColor& color() const;
```

Note This function is deprecated and is retained for backward compatibility only. All new code should use **props()**.

- `void color(const ccColor& c);`

  Sets the color of the UI shape. You can use this function to override **getColor** to return a different color. This function also allows you to set a shape's color without deriving a new class. This function applies the new color to the UI shape's graphical properties, triggering an update but no erasing or redrawing of the shape.

  Parameters

c	The color.

- `const ccColor& color() const;`

  Gets the color of the UI shape. Used by the **getColor** function.

isTouched

`virtual bool isTouched(const c2Vect& v, double scale);`

Returns false. Derived classes override this function to return true if the specified position (v) touches the UI shape. For example, the touch criteria for a circle may be whether the point falls either inside the circle or on its border, whereas for a line the touch criteria would depend on the positions of its endpoints.

Parameters

v	Position to be checked for proximity to the UI shape. The position (*v*) is relative to the UI shape's parent, in tablet coordinates. Multiply (*v*) by *scale* if you want the distance in pixels.
scale	Number by which to multiply (*v*) which is in tablet coordinates, to covert it to pixels.

getGraphicProps

`virtual ccGraphicProps getGraphicProps() const;`

Gets the current graphic properties of the UI shape. If the shape is not selected, **ccGraphicProps::penColor()** returns its default color or the color you have set. This is the deselected color.

If the shape is selected, **ccGraphicProps::penColor()** returns **ccUIObject::selectColor()**.

Notes

To get the current **ccGraphicProps** object associated with the shape, derived classes overriding the **draw_** function should call this function in their implementations rather than calling **props**. The base implementation sets the color of the shape based on its selected state. If overloading this function, you may want to call this base function first to maintain the selection color behavior.

getColor

```
virtual ccColor getColor() const;
```

Note This function is deprecated and is retained for backward compatibility only. All new code should use **props()**.

If UI the shape is selected, this function returns the color associated with selected shapes (as returned by **selectColor()**), otherwise that associated with deselected shapes (as returned by **color()**). Derived classes can override the function to return the color used for normal drawing.

parent

```
virtual ccUIObject* parent();

void parent(ccUIObject *newParent);
```

Retrieves or sets the parent of the UI shape.

- `virtual ccUIObject* parent();`

  Retrieves the parent (runtime owner) of the UI shape. Implements the pure virtual function of the base class.

- `void parent(ccUIObject *newParent);`

  Sets or changes the parent of the UI shape.

  Parameters

  newParent The new parent. Must be either a NULL pointer or a pointer to a an instance of **ccUIShapes** or **ccUIShapesFrame**.

  Throws

  ccUIError::BadParams

  newParent is pointing to this UI shape. The parent must be a different UI object.

  Notes

  When assigning a parent to interactive shapes using **ccUIShapes::parent(newParent)**, all children must be on the same drawing layer as the parent. Cognex recommends setting the parent of an interactive shape before adding the shape to the display. Changing a shape's parent once the shape has been added to the display will result in lower performance when the graphics are re-rendered.

  For optimal rendering performance, do not change the drawing layer or parent of an interactive shape after adding the shape to the display console.

pos

```
ccPoint pos() const;
void pos(const cc2Vect& v);
```

Returns the center location of the UI shape relative to its parent in tablet coordinates.

pos() calls **pos_()**, a protected virtual function you can override in your own derived class to customize this method.

- `ccPoint pos() const;`

  Returns the center location of the UI shape.

- `void pos(const cc2Vect& v);`

  Sets the center location of the UI shape relative to its parent in tablet coordinates.

  Parameters

  v The position.

absPos

```
ccPoint absPos();
```

Returns the center location of the UI shape in tablet coordinates. This is the same as **pos()** if the object is not grouped.

move

```
void move(const cc2Vect& del);
```

Moves the UI shape by adding **del.x()** and **del.y()** to the current position.

move() calls **move_()**, a protected virtual function you can override in your own derived class to customize this method.

Parameters

del The distance to move.

update

```
void update(
  bool kidsToo = true,
  bool eraseFirst = true,
  const ccUIRect* activeScopes = NULL,
  ccUITablet::Layers l = ccUITablet::eUnspecifiedLayer);
```

Redraws the UI shape.

Parameters

kidsToo If true, update all descendants (default = true).

eraseFirst	If true, erase the UI shape before redrawing. Use false if you know that only the color has changed (default = true).
activeScopes	Set of rectangles defining the active scopes of the UI shape.
l	Tablet layer in which to redraw the UI shape.

draw

```
void draw(ccUITablet& t, const ccColor& c,
  DrawMode m = drawNormal);
```

Draws the UI shape in the specified tablet, using the specified graphic properties, and in the specified drawing style.

draw() calls **draw_()**, a protected virtual function you can override in your own derived class to customize this method.

Parameters

t	Tablet in which to draw the UI shape.
c	Graphic properties used for drawing.
m	Drawing mode. Must be one of: *ccUIShapes::drawNormal* *ccUIShapes::drawAbridged* *ccUIShapes::drawDrag*

Notes

Do not use this function to cause a UI shape to appear on the screen or to reflect changes in state. Use **condVisible** and **update** for those purposes. This function is provided as a public member so that clients can render the UI shape in a tablet other than the shape's own tablet (for example, to make a sketch).

Protected Member Functions

This section describes only the protected member functions of **ccUIShapes** that are also virtual.

front_

```
virtual void front_(ccUIObject* kid);
```

An override.

Called by **ccUIObject::front()** when the object is moved to the front. (For example, when it is selected). If you override this function, make sure your override function calls the parent's **front_()**.

Parameters

kid	Pointer to the object moved to the front.

back_ `virtual void back_(ccUIObject* kid);`

An override.

Called by **ccUIObject::back()** when the object is moved to the back. If you override this function, make sure your override function calls the parent's **back_()**.

Parameters

kid Pointer to the object moved to the back.

show `virtual void show(bool parentChanged);`

The UI Framework calls **ccUIObject::show()** when the object's state changes to *visibleState (the object becomes visible).* If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This is an override function that displays the changed object. If **show()** is overridden in a user-derived class, the override function should call **show()** in the parent class.

Parameters

parentChanged True if the state of the UI object's parent (or ancestor) has changed. False if the state of the object itself has changed.

hide `virtual void hide(bool parentChanged);`

The UI Framework calls **ccUIObject::hide()** when the object's state changes from *visibleState* (the object becomes not visible). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This is an override function that displays the changed object. If **hide()** is overridden in a user-derived class, the override function should call **hide()** in the parent class.

Parameters

parentChanged True if the state of the UI object's parent (or ancestor) has changed. False if the state of the object itself has changed.

select

```
virtual void select(States s, bool parentChanged);
```

The UI Framework calls **ccUIObject::select()** when the object's state changes to *selectedState* (the object becomes selected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This is an override function that implements the *select* procedure and calls **update** in the case of display color or other appearance changes. If **select()** is overridden in a user-derived class, the override function should call **select()** in the parent class.

Parameters

s	The state change that caused the object to become selected. Must be one of the **ccUIObject::States** enums.
parentChanged	True if the select was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

deselect

```
virtual void deselect(States s, bool parentChanged);
```

The UI Framework calls **ccUIObject::deselect()** when the object's state changes from *selectedState* (the object becomes deselected). If the change was caused by the parent object, *parentChanged* = true. If the change was caused by the object itself, *parentChanged* = false.

This is an override function that implements the *deselect* procedure and calls **update** in the case of display color or other appearance changes. If **deselect()** is overridden in a user-derived class, the override function should call **deselect()** in the parent class.

Parameters

s	The state change that caused the object to become selected. Must be one of the **ccUIObject::States** enums.
parentChanged	True if the select was caused by a parent (or ancestor) state change. False if the state of the object itself has changed.

dragAnimate_

```
virtual void dragAnimate_(const ccIPair& p1,
  const ccIPair& p2);
```

An override that implements the drag display for all shapes.

Draws the drag animator, the graphical representation of a UI shape while it is being dragged, at the current position. Implements the protected virtual function of the base class to handle generic dragging for all shapes. The drag animator is the *drawDrag* version of the shape itself, drawn in the *dragColor*.

Parameters

p1	Starting position in screen coordinates.

p2 Current position of the drag in screen coordinates.

Notes

If the current position is the Cancel position, the drag animator is drawn at the starting position. Do not use this function to implement non-generic dragging. This function requires derived classes to fully support the **pos()** and **pos(ccVect)** functions.

dragStop_

```
virtual void dragStop_(const ccIPair& p1,
  const ccIPair& p2);
```

An override.

Updates the state of the UI shape based on its final drag position. Implements the protected virtual function of the base class to handle generic dragging for all shapes. The drag animator is the *drawDrag* version of the shape itself, drawn in the *dragColor*.

Parameters

p1 Starting position in screen coordinates.

p2 Ending position of the drag in screen coordinates.

Notes

It is good practice to define certain drag positions to mean Cancel, so that **dragStop_** can do nothing in those cases. Do not use this function to implement non-generic dragging. This function requires derived classes to fully support the **pos()** and **pos(ccVect)** functions.

mouseEnter_

```
virtual void mouseEnter_();
```

An override. See **ccUIObject::mouseEnter()**.

Implements mouse enter when the mouse enters the UI object's screen space with a left mouse button held down. Switches the mouse cursor between the shape used for the UI object and a default cursor shape.

mouseLeave_

```
virtual void mouseLeave_();
```

An override. See **ccUIObject::mouseLeave()**.

Implements mouse leave when the mouse is moved off the UI object, or also, if an enabled object was entered and it then becomes disabled. Switches the mouse cursor between the shape used for the UI object and a default cursor shape.

idleMouseEnter_

```
virtual void idleMouseEnter_();
```

An override. See **ccUIObject::idleMouseEnter()**.

Implements idle mouse enter when the mouse enters the UI object's screen space with the left mouse button up. Switches the mouse cursor between the shape used for the UI object and a default cursor shape.

pos_

```
virtual ccPoint pos_() const = 0;

virtual void pos_(const cc2Vect& v) = 0;
```

Called by **pos()** to get/set the object's center location. These virtual functions are implemented in a derived class.

- `virtual ccPoint pos_() const = 0;`

  Gets the center location of the UI shape relative to its parent in tablet coordinates. Derived classes implement this pure virtual function. Call the like-named public member function in your own programs.

- `virtual void pos_(const cc2Vect& v) = 0;`

  Sets the center location of the UI shape relative to its parent in tablet coordinates. Derived classes implement this pure virtual function. Call the like-named public member function in your own programs.

  Parameters

v	Center location of the UI shape relative to its parent in tablet coordinates.

  Notes

  Derived classes should override this function only if standard dragging support is required.

draw_

```
virtual void draw_(ccUITablet& t, const ccColor& c,
  DrawMode m = drawNormal);
```

Called by **draw()** to draw the UI shape in a specified tablet. This function should be overridden and implemented in derived classes. You should call **draw()** in your programs.

Parameters

t	Tablet in which to draw the UI shape.

c Color of the UI shape.

m The drawing mode. Must be one of:
ccUIShapes::drawNormal
ccUIShapes::drawAbridged
ccUIShapes::drawDrag

Notes

The color is based on the value returned by **getColor**. Derived classes that override this function and want to use the graphic properties should call **getGraphicProps** in their implementations.

move_ `virtual void move_(const cc2Vect& v);`

Called by **move()** to move the UI shape. This function should be overridden and implemented in derived classes. You should call **move()** in your programs.

Parameters

v Ending position of the move.

Notes

This function is called just before the UI shape moves to a new position. The **pos** function supplies the current position, the argument the ending position. This function is called if the position is changed via the **pos(const cc2Vect&)** overload and the ending position is different from the current position.

redim_ `virtual void redim_();`

This virtual function has no effect. Derived classes override the function to take some action when any of the UI shape's dimensions (for example, size, orientation, or position) changes.

Notes

This function is called just after the shape's dimensions change via a call to **pos**, **move**, or any shape-specific geometry setter.

ccUISketch

```
#include <ch_cvl/uisketch.h>

class ccUISketch;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A sketch is a list of zero or more drawing commands used to draw shapes into a tablet. You typically draw shapes into a tablet using the **ccUITablet::draw()** functions. When you draw shapes into a tablet, the shapes are actually accumulated in the tablet's sketch. When you create a tablet, a sketch is automatically created, so in most cases you do not need to create a sketch object yourself.

After you have drawn the shapes into a tablet, you use **ccUITablet::sketch()** to obtain the sketch, and then call **ccDisplay::drawSketch()** to draw the shapes accumulated in the sketch onto the display.

You can use sketch marks (see **ccUISketchMark** on page 3341) to delimit subsketches, or components of sketches.

Note It is not possible to archive a **ccUISketch** within another **ccUISketch**.

Constructors/Destructors

ccUISketch

```
ccUISketch();

ccUISketch(const ccUISketch&);

~ccUISketch();
```

- `ccUISketch();`

  Creates an empty sketch.

- `ccUISketch(const ccUISketch& s);`

  Copy constructor.

  Parameters

s	The **ccUISketch** to copy.

- `~ccUISketch();`

  Destructor.

Operators

operator+= `ccUISketch& operator+=(const ccUISketch& s);`

Adds the sketch *s* to the end of this sketch.

Parameters

s	The sketch to add to the end of this sketch.

operator= `ccUISketch& operator=(const ccUISketch& s);`

Assignment operator. Assignment the value of *sketch* to this object.

Parameters

s	The sketch to assign to this one.

operator+ `ccUISketch operator+(const ccUISketch& s) const;`

Returns the concatenation of this object and the supplied sketch.

Parameters

s	The sketch to add to this one.

Public Member Functions

isNull `bool isNull() const;`

Returns true if this sketch is empty, false otherwise.

mark `ccUISketchMark mark() const;`

Returns the sketch mark at the end of this sketch.

subSketch

```
ccUISketch subSketch(ccUISketchMark start,
  ccUISketchMark end) const;
```

Returns a new sketch from *start* up to (but not including) *end*.

Parameters

start	The beginning of the subsketch.
end	The end of the subsketch.

Notes

If *start* is greater than or equal to *end*, this method returns an empty sketch.

remove

```
ccUISketch& remove(ccUISketchMark start,
  ccUISketchMark end);
```

Removes a portion of the sketch from *start* up to (but not including) *end*. Returns this sketch minus the specified portion.

Parameters

start	The beginning of the portion to remove.
end	The end of the portion to remove.

Notes

If *start* is greater than or equal to *end*, this sketch is returned unchanged.

insert

```
ccUISketch& insert(const ccUISketch& s,
  ccUISketchMark beforeHere);
```

Inserts the sketch *s* into this sketch before the specified position.

Parameters

s	The sketch to insert.
beforeHere	The place before which to insert the sketch.

erase

```
ccUISketch& erase();
```

Erases this sketch and returns an empty sketch.

Notes

This method also resets the graphical properties back to the default.

eraseAndDelete

```
ccUISketch& eraseAndDelete();
```

Erases this sketch, releases any accumulated storage, and returns an empty sketch.

Notes

This method also resets the graphical properties back to the default.

ccUISketchMark

```
#include <ch_cvl/uisketch.h>

class ccUISketchMark;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

You can use sketch marks to identify parts of sketches. A sketch mark is a value that identifies the beginning or end of a component in a sketch.

See **subSketch()**, **insert()**, and **remove()** in **ccUISketch** on page 3337 for information on methods you can use to access and manipulate components of sketches.

Constructors/Destructors

ccUISketchMark `ccUISketchMark();`

Creates a new mark.

Operators

operator== `bool operator==(ccUISketchMark &m) const;`

Returns true if this mark and the mark *m* are the same mark.

Parameters

m	The other mark.

operator!= `bool operator!= (ccUISketchMark &m) const;`

Returns true if this mark and the mark *m* are not the same mark.

Parameters

m	The other mark.

ccUISketchMark

ccUITablet

```
#include <ch_cvl/uitablet.h>

class cmImport_cogdisp ccUITablet;
```

Class Properties

Copyable	Yes
Derivable	Not intended
Archiveable	No

The **ccUITablet** class can be used in two distinct ways:

1. It is used as a base class for the **ccDisplay** class hierarchy:
   - To provide the interface for rendering non manipulable graphics (for example, static graphics) into the display.
   - Provides helper functions to manage the display content and to refresh the display of interactive graphics.
2. It can be instantiated directly and used for recording, a procedure where graphics operations are recorded into a tablet. No display-derived class is necessary for recording, meaning you can construct a **ccUITablet** for just recording with no display. Recordings can later be passed to a **ccDisplay** via **ccUISketch** for playback where the recordings are rendered into the display.

Because **ccUITablet** has this dual role, some of its member functions apply to only one particular use. Where this is the case, member functions contain comments to help clarify the intended use. For more about using this class see the discussion on page 3356.

Notes

ccUITablet is not multi-thread safe. If your application is multi-threaded you are responsible for controlling proper access to this class.

Scopes are a **ccUITablet** internal property used by Cognex developers when creating **ccUITablet**-derived display classes. You may see scopes mentioned in this reference material, but you do not have to be concerned about scopes.

Coordinate Spaces

When you record graphics into a tablet the graphics are specified in tablet space, a left-handed coordinate system. Later when you display a tablet you specify the display coordinate space; *eDisplayCoords*, *eImageCoords*, or *eClientCoords*. If you display in client coordinates, tablet (0,0) equals client (0,0). If you display in image coordinates, tablet (0,0) equals image (0,0), and so on.

See the **ccDisplay** reference page for more information regarding coordinate spaces for display windows.

Z-Order

When recording graphics and other components into a tablet's sketch list, new graphics are appended to the list end. Playback starts at the list beginning. Therefore, operations added first are rendered in the display first.

Using ccUITablet

ccUITablet describes a drawing environment for drawing shapes such as the ones described in the file *shapes.h*. In typical use, you draw shapes using **ccUITablet::draw()** or one of the specific shape-drawing functions, such as **ccUITablet::drawCircle()**. These shapes are accumulated into a sketch (see **ccUISketch** on page 3337) which is then drawn into a display derived from **ccDisplay** such as **ccDisplayConsole** using **ccDisplay::drawSketch()**.

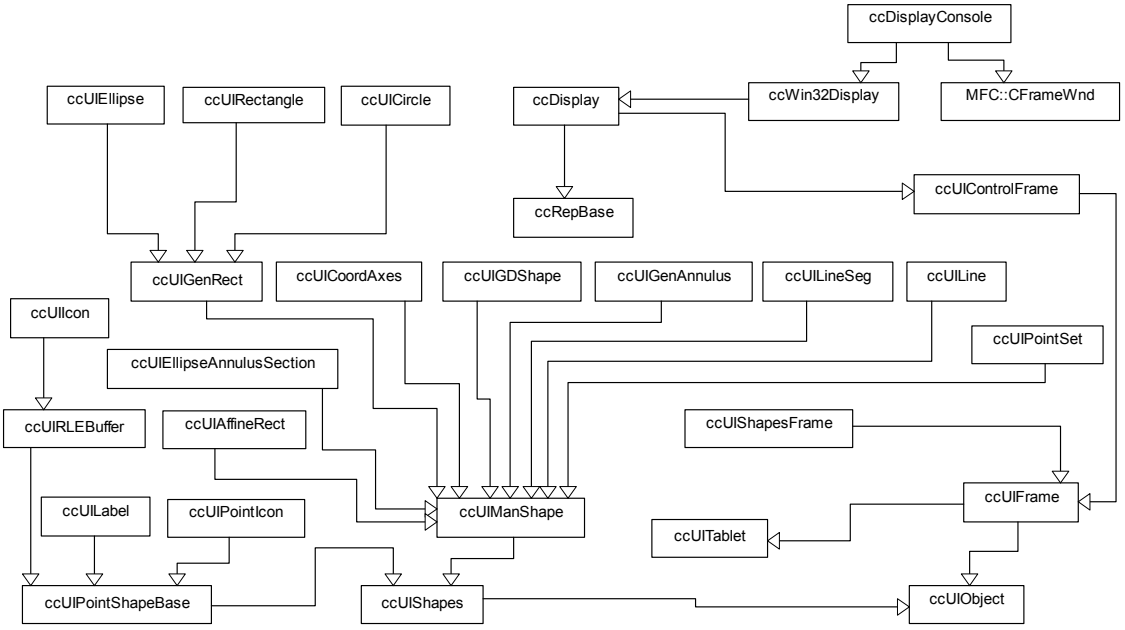
You can draw either into the overlay layer or the image layer. Whenever you draw into the image layer the display must be rerendered, adding time to the application. Drawing into the overlay layer, on the other hand, does not require the image layer to be rerendered, enabling your application to run faster.

By default, graphics are placed in the image layer. On some display systems the overlay layer must be explicitly enabled, and may not be enabled by default. Graphics added to an overlay layer that has not been enabled are not displayed

Display type	Overlay default	Description
ccWin32Display	Disabled	Call **ccWin32Display::enableOverlay()** to enable.
ccDisplayConsole	Disabled	

All of the shape classes in *shapes.h* and many of the drawing functions in **ccUITablet** require you to specify locations. These locations do not refer to any particular coordinate system. Rather, you specify the coordinate system to use with a tablet's sketch when you call **drawSketch()**. To draw different shapes in different coordinate systems, use different drawing tablets.

The following figure shows the interactive graphics class derivation hierarchy:



Constructors/Destructors

ccUITablet

```
ccUITablet();

virtual ~ccUITablet();
```

For recording graphical operations use the default constructor. This is the most common use. A **ccUITablet** is used for display when you construct a derived display class from **ccDisplay**. For example, a **ccWin32Display** or **ccDisplayConsole**. Scopes are not required to record into a tablet.

Direct derivation from this class is not supported. Only derivation through the **ccDisplay** class hierarchy is supported.

- `ccUITablet();`

  Default constructor. Creates a tablet for recording drawing commands. The scope is NULL, recording is enabled, drawing is disabled, the tablet does not have a parent, and an empty sketch is automatically created.

Notes

Except for the initial drawing and recording states, this is equivalent to **ccUITablet(0,0)**. You can use a default-constructed tablet for drawing after setting the scope and enabling drawing.

Use this constructor to create a tablet for recording graphics into a sketch. This sketch can then be passed to a display for rendering.

~ccUITablet

```
virtual ~ccUITablet();
```

Destructor. Erases the tablet from the screen and removes the tablet from the parent's list of kids. Sets all of its kids' parent to NULL.

Enumerations

Layers

```
enum Layers;
```

An enumeration of supported layers used for recording into a sketch or drawing into a display.

Notes

The **overlaySupported()** static function can be used to determine if your display supports the overlay layer.

Some platforms require you to enable the overlay layer for graphics to appear. See the derived class reference documentation for information about enabling overlay layers.

Value	Meaning
eImageLayer = 0	Draw shapes into the image layer.
eOverlayLayer = 1	Draw shapes into the overlay layer. For Cognex frame grabbers which use Windows 2000 as the host OS, you must explicitly enable the overlay layer via **ccWin32Display::enableOverlay(ccWin32Display::eOverlayPlane)**.
eNumLayers = 2	Number of layers used.
eUnspecifiedLayer = *eNumLayers*	The layer is not specified. Typically, this pseudo-layer is used in recording and playback. It is also used for sub-sketches. When you call **draw()** to draw a subsketch, you specify the layer into which otherwise unspecified shapes are drawn.

FillType

```
enum FillType;
```

This enumeration lets you specify how **fill()** fills an area with color.

Value	Meaning
eFillBorder	Fills the area until it reaches a specified stop color.
eFillSurface	Fills the area until it reaches a color other than the stop color.

InterpolationModes

```
enum InterpolationModes
```

This enumeration defines the type of display interpolation. It affects how the image is rendered when magnification is applied.

Notes

This functionality is only supported for **ccPelBuffer<c_UInt8>** images.

Value	Meaning
eNone	No display interpolation is performed. This option provides the fastest display, but the display can appear blocky or jagged when used to display zoomed images.
eBilinear	Uses bilinear interpolation to compute the value of each display pixel. This option produces a blurry-appearing display but requires only a modest additional amount of time for display. If you specify *eBilinear*, the displayed image is reduced in size by 2 pixels on each side.
eHighPrecision	Uses a high-precision interpolation method that considers additional pixel values. This option produces a smoothed image that does not appear blurry, but requires the most additional time for display. If you specify *eHighPrecision*, the displayed image is reduced in size by 3 pixels on each side.

Public Member Functions

interpolation

```
void interpolation(InterpolationModes interpolationMode);
InterpolationModes interpolation()const;
```

Interpolation mode is intended for use by derived classes (for example, **ccDisplay**) when a **ccUITablet** is being used as a base class for display.

Interpolation mode is not intended to be used when recording into a **ccUITablet**.

- `void interpolation(InterpolationModes interpolationMode);`

Sets the display interpolation mode for this display object. If you specify a value of *ccUITablet::eNone*, no interpolation is performed. If you specify one of the other interpolation modes and the image is displayed at a scale greater than 1.0, the specified interpolation mode is used to compute the value for each display pixel.

In all cases, nearest-neighbor sampling is used to compute the value of each display pixel when the scale is less than or equal to 1.0.

When you change the interpolation mode, the display is updated.

Parameters

interpolationMode

The interpolation method to use. Must be one of the following values:

ccUITablet::eNone
ccUITablet::eBilinear
ccUITablet::eHighPrecision

Notes

Display interpolation is not performed on images smaller than 8x8 pixels.

- `InterpolationModes interpolation() const;`

Returns the display interpolation mode for this tablet. This function returns one of the following values:

ccUITablet::eNone (default)
ccUITablet::eBilinear
ccUITablet::eHighPrecision

sketch

```
const ccUISketch& sketch() const;

ccUISketch& sketch();
```

Returns a display list of static graphics and other graphical elements (for example, filling areas) created by recording. Typically, you pass the sketch to **ccDisplay::drawSketch()** to draw the contents of a sketch.

When using a default constructed **ccUITablet**, recorded components are placed into this sketch. When this **ccUITablet** is being used as part of a display system and recording is on, graphical components are recorded into this sketch.

- `const ccUISketch& sketch() const;`

  Returns a read-only sketch.

- `ccUISketch& sketch();`

  Returns a read-write sketch. This version allows you to assign a sketch.

encloseRect

```
ccUIRect encloseRect(
  const ccUISketch& sketch,
  const ccPoint& point,
  Layers layer = eImageLayer) const;
```

Returns the enclosing rectangle of the sketch if drawn in the specified layer at the specified point, of this tablet. The returned rectangle is in scope coordinates, without regard to clipping by the current scope boundaries.

Parameters

sketch	The sketch enclosed by the returned rectangle.
point	The point in this tablet where the sketch is located.
layer	The layer in this tablet where the sketch is located.

Notes

Any components of *sketch* that explicitly use a layer other than that specified in *layer* are ignored. Components of a sketch generally use *eUnspecifiedLayer*.

The enclosing rectangle of all changes made to a tablet by drawing functions can be recorded. The enclosing rectangle is computed assuming that the scope is infinite, for example, without regard to the current actual boundaries of the scope's window. Some drawing functions, notably **set (ccColor)** and **setComplement()**, have an infinite enclosing rectangle. One exception is **draw (ccLine**, ...**)** which theoretically has an infinite enclosing rectangle, but is drawn as a line segment clipped to the active area of the display.

scopeCoords `ccIPair scopeCoords(const ccPoint &tabletP) const;`

Returns a point in scope coordinates for a tablet point you provide. This conversion is useful in drag animation.

Parameters

tabletP A tablet point you provide.

screenCoords `ccIPair screenCoords(const ccPoint &tabletP) const;`

Returns a point in screen coordinates for a tablet point you provide. This conversion is useful in drag animation.

Parameters

tabletP A tablet point you provide.

tabletCoords `ccPoint tabletCoords(const ccIPair &scopeP) const;`

Returns a point in tablet coordinates for a scope point you provide. This conversion is useful in drag animation.

Parameters

scopeP A scope point you provide.

visible

```
bool visible() const;
bool visible(bool vis);
```

- `bool visible() const;`

  Returns true if this tablet is visible. Returns false if it is not visible.

- `bool visible(bool vis);`

  When *vis* is set true this tablet is made visible. When *vis* is set false, this tablet is made invisible.

  Returns true if the visible state changed as a result of this call.

  Parameters

  vis The new visible flag, true or false.

Notes

Calling this function may cause a full screen refresh or a display erase.

This function should not be called on a default-constructed tablet used for recording.

lockScreenUpdatesPush

```
void lockScreenUpdatesPush(
  bool lock,
  Layers layer = eUnspecifiedLayer);
```

Increments or decrements the lock level to lock or unlock screen layer updates. When a layer is locked you can change its contents and the screen is not updated (refreshed). When the layer is unlocked the screen is updated each time you write into the layer. Locking updates while you are making layer changes can save time in your application by eliminating unnecessary screen updates.

Initially the lock level is 1 and screen updates are enabled. Calling **lockScreenUpdatesPush(***true***)** increments the lock level and **lockScreenUpdatesPop()** decrements the lock level. When the lock level is greater than 1, screen updates are disabled. When the lock level is decremented from 2 to 1 the screen is updated. Decrementing the lock level to less than 1 causes an error.

Parameters

lock	Lock the layer (true), or unlock the layer (false).
layer	The specified layer. *eUnspecifiedLayer* = all layers.

Throws

ccUIError::FlagStackUnderflow
: If the lock level is decremented below 1. The lock level is implemented using a flag stack. (See *flagstck.h*).

ccUIError::FlagStackOverflow
: If the lock level exceeds the upper limit (32). The lock level is implemented using a flag stack. (See *flagstck.h*).

ccUIError::BadLayer
: If *layer* is invalid.

You typically use **lockScreenUpdatesPush()** to lock screen updates and then use **lockScreenUpdatesPop()** to unlock screen updates and to refresh the screen. For example:

```
lockScreenUpdatesPush(true, ccUITablet::eUnspecifiedLayer);
```

```
// Do work here that would cause the display
// content to change (for example, drawing graphics)
// ...
// The display screen won't actually be updated until
// the following function call.

lockScreenUpdatesPop();
```

Notes

lockScreenUpdatesPush(*false***)** also decrements the lock level, however this is seldom used.

The lock level is implemented using a flag stack. (See *flagstck.h*).

lockScreenUpdatesPop

```
void lockScreenUpdatesPop(
  Layers layer = eUnspecifiedLayer);
```

Decrements the lock level to unlock screen layer updates. You typically use **lockScreenUpdatesPush(***true***)** to lock screen updates and then use **lockScreenUpdatesPop()** to unlock screen updates and to refresh the screen. See **lockScreenUpdatesPush()** above for more information.

Parameters

layer The specified layer. *eUnspecifiedLayer* = all layers.

Throws

ccUIError::FlagStackUnderflow
If the lock level is decremented below 1. The lock level is implemented using a flag stack. (See *flagstck.h*).

ccUIError::BadLayer
If *layer* is invalid.

screenUpdatesLocked

```
bool screenUpdatesLocked(Layers layer) const;
```

Returns true if the specified layer is locked. Returns false if it is not locked. If *layer* = *eUnspecifiedLayer*, all layers are specified.

See **lockScreenUpdatesPush()** and **lockScreenUpdatesPop()** above for information about locking screen updates.

Parameters

layer The specified layer. *eUnspecifiedLayer* = all layers.

Throws

ccUIError::BadLayer
If *layer* is invalid.

draw

```
void draw(const ccShape & s, const ccGraphicProps & props,
 Layers layer = eImageLayer);

void draw(const ccPoint& p, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const cc2Point& p, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccLineSeg& l, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccLine& l, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccCross& c, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccRect& r, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccCircle& c, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccAnnulus& a, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccEllipse2& e, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccEllipseArc2& e,
 const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccGenRect& r, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccGenAnnulus& a,
 const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccCoordAxes& a,
 const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccPointSet& p, const ccGraphicProps& props,
 Layers layer = eImageLayer);

void draw(const ccAffineRectangle& r,
 const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccPolyline & p,
 const ccGraphicProps & props, Layers layer = eImageLayer);

void draw(const ccBezierCurve & b,
```

```
  const ccGraphicProps & props, Layers layer = eImageLayer);

void draw(const ccCubicSpline & s,
  const ccGraphicProps & props, Layers layer = eImageLayer);

void draw(const ccEllipseAnnulusSection& eas,
  const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccGenPoly& gp, const ccGraphicProps& props,
  Layers layer = eImageLayer);

void draw(const cc2Wireframe& wf,
  const ccGraphicProps& props, Layers layer = eImageLayer);

void draw(const ccCvlString& s, const ccPoint& p,
  const ccColor& ink, const ccColor& backgr,
  const ccUIFormat& fmt, Layers layer = eImageLayer);

void draw(const ccPelBuffer_const<c_UInt8> &pb,
  const ccPoint& p, bool passThrough = false,
  c_UInt8 passColor = 0, bool displayRaw = true,
  Layers layer = eImageLayer);

void draw(const ccPelBuffer_const<c_UInt16> &pb,
  const ccPoint& p, bool passThrough = false,
  c_UInt16 passColor = 0, Layers layer = eImageLayer);
```

Note: This method is not supported.

```
void draw (const ccPelBuffer_const<ccPackedRGB16Pel> &pb,
  const ccPoint& p, bool passThrough = false,
  c_UInt16 passColor = 0, Layers layer = eImageLayer);

void draw (const ccPelBuffer_const<ccPackedRGB32Pel> &pb,
  const ccPoint& p, bool passThrough = false,
  c_UInt32 passColor = 0, Layers layer = eImageLayer);

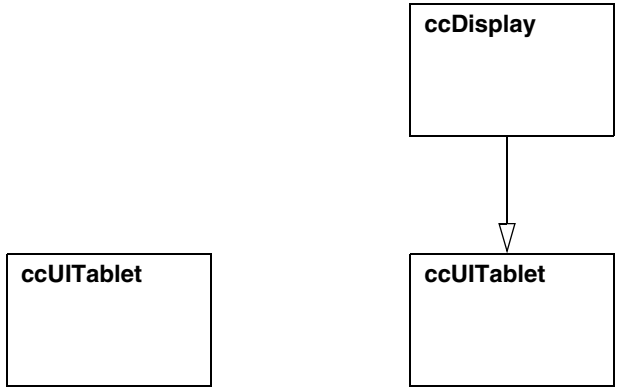
void draw(const ccRLEBuffer &rle, const ccPoint& p,
  const cmStd vector<c_UInt8>& colorMap,
  bool passThrough = true, c_UInt8 passColor = 0,
  bool ignoreScale = false, Layers layer = eImageLayer);

void draw (const ccUISketch& s, const ccPoint& p,
  Layers layer = eImageLayer);
```

The following notes apply to the draw graphics overloads, the first 22 **draw()** overloads described below. These overloads are the drawing functions for geometric shapes. They can record a static graphic into the tablet and/or render the graphic to a display

when called from a derived display class. Graphics must not contain degenerate geometry. For example, a rectangle cannot have a height or width of 0. The **ccPointSet** size must be greater than one.

It is important to understand the two ways these draw functions are used. See the following diagram:



Tablet
(For recording only)

Tablet + display
(For display and/or recording)

When you create a **ccUITablet** object and call its draw functions you can only record the drawings into its internal sketch list. There is no display support. When you program a **ccUITablet** object in this way you typically do the following:

1. Call the draw functions to record graphics into the tablet sketch list.
2. Call **ccUITablet::sketch()** to retrieve the sketch list.
3. Pass the retrieved sketch list to **ccDisplay::drawSketch()** to display the graphics.

Recording graphics into a tablet does not use the tablet's scaled map or base map. Recording occurs without regard to any offset or scale, it simply records the geometry given. When you program a display class such as **ccDisplay** that derives from **ccUITablet**, you typically call the draw functions to display graphics directly.

Notes

If you want static graphics to be a permanent part of the display, and to be automatically re-rendered when the viewport changes or a new image is inserted into the display, you should use **ccUITablet** derived classes that implement and support this functionality. (For example, **ccDisplay::drawSketch()**).

There is an implicit conversion from a **ccColor** object to a **ccGraphicProps** object, but the converse is not true.

There are some implicit conversions between some of the graphic types listed in ch_cvl/shapes.h. As such, there may not be a corresponding draw function for every shape (For example, **ccAnnulus** is implicitly converted to a **ccGenAnnulus**).

Not all graphical properties are supported for all graphical shapes. See the shape class documentation for which graphical properties are supported. For example, closed shape filling may not be fully supported for all shapes.

- ```
  void draw(const ccShape & s, const ccGraphicProps & props,
    Layers layer = eImageLayer);
  ```

  Draws a shape in the specified layer using the specified graphic properties.

  Parameters

s	The shape.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- ```
  void draw(const ccPoint& p, const ccGraphicProps& props,
    Layers layer = eImageLayer);
  ```

  Draws a point in the specified layer using the specified graphic properties.

  Parameters

p	The point.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void draw(const cc2Point& p, const ccGraphicProps& props, Layers layer = eImageLayer);`

Draws a point in the specified layer using the specified graphic properties. This method draws a **cc2Point** which derives from **ccShape**. To draw a **ccPoint** use the draw method above.

Parameters

p The point.

props The graphic properties of the shape.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void draw(const ccLineSeg& l, const ccGraphicProps& props, Layers layer = eImageLayer);`

Draws a line segment in the specified layer using the specified graphic properties.

Parameters

l The line segment.

props The graphic properties of the shape.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void draw(const ccLine& l, const ccGraphicProps& props, Layers layer = eImageLayer);`

Draws a line in the specified layer using the specified graphic properties.

Parameters

l	The line segment.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccCross& c, const ccGraphicProps& props, Layers layer = eImageLayer);`

Draws a cross in the specified layer using the specified graphic properties.

Parameters

c	The cross.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccRect& r, const ccGraphicProps& props, Layers layer = eImageLayer);`

Draws a rectangle in the specified layer using the specified graphic properties.

Parameters

r	The rectangle.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccCircle& c, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws a circle in the specified layer using the specified graphic properties.

  Parameters

c	The circle.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccAnnulus& a, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws an annulus in the specified layer using the specified graphic properties.

  Parameters

a	The annulus.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccEllipse2& e, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws an ellipse in the specified layer using the specified graphic properties.

  Parameters

e	The ellipse.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- ```
  void draw(const ccEllipseArc2& e,
    const ccGraphicProps& props, Layers layer = eImageLayer);
  ```

  Draws an ellipse arc in the specified layer using the specified graphic properties.

  Parameters

  e The ellipse arc.

  props The graphic properties of the shape.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

- ```
  void draw(const ccGenRect& r, const ccGraphicProps& props,
    Layers layer = eImageLayer);
  ```

  Draws a generalized rectangle in the specified layer using the specified graphic properties.

  Parameters

  r The generalized rectangle.

  props The graphic properties of the shape.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

- ```
  void draw(const ccGenAnnulus& a,
    const ccGraphicProps& props, Layers layer = eImageLayer);
  ```

  Draws a generalized annulus in the specified layer using the specified graphic properties.
  ```

Parameters

a	The generalized annulus.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- ```
  void draw(const ccCoordAxes& a,
    const ccGraphicProps& props, Layers layer = eImageLayer);
  ```

  Draws a set of coordinate axes in the specified layer using the specified graphic properties.

  Parameters

a	The coordinate axes.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- ```
  void draw(const ccPointSet& p, const ccGraphicProps& props,
    Layers layer = eImageLayer);
  ```

  Draws a point set in the specified layer using the specified graphic properties.

  Parameters

p	The point set. A point set size must be greater than 1.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccAffineRectangle& r, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws an affine rectangle in the specified layer using the specified graphic properties.

  Parameters

r	The affine rectangle.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccPolyline & p, const ccGraphicProps & props, Layers layer = eImageLayer);`

  Draws a polyline in the specified layer using the specified graphic properties.

  Parameters

p	The polyline.
props	The graphic properties of the polyline.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void draw(const ccBezierCurve & b, const ccGraphicProps & props, Layers layer = eImageLayer);`

  Draws a bezier curve in the specified layer using the specified graphic properties.

  Parameters

b	The bezier curve.
props	The graphic properties of the shape.
layer	The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void draw(const ccCubicSpline & s, const ccGraphicProps & props, Layers layer = eImageLayer);`

  Draws a cubic spline in the specified layer using the specified graphic properties.

  Parameters

  s The cubic spline.

  props The graphic properties of the shape.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

- `void draw(const ccEllipseAnnulusSection& eas, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws an ellipse annulus in the specified layer using the specified graphic properties.

  Parameters

  eas The ellipse annulus section.

  props The graphic properties of the shape.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

- `void draw(const ccGenPoly& gp, const ccGraphicProps& props, Layers layer = eImageLayer);`

  Draws a generalized polygon in the specified layer using the specified graphic properties.

Parameters

gp	The generalized polygon.
props	The drawing properties.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

Notes

To show or hide vertices for a generalized polygon, use the **ccGraphicProps::showVertex()** method.

- ```
  void draw(const cc2Wireframe& wf,
    const ccGraphicProps& props, Layers layer = eImageLayer);
  ```

  Draws a two-dimensional shape in the specified layer using the specified graphic properties.

  Parameters

wf	The wireframe shape to draw.
props	The drawing properties.
layer	The layer in which to draw.

  Notes

  The direction (edge polarity) arrows are drawn if and only if the **arrowHead()** field of *props* is true. Sharp vertex corners are superimposed over rounded ones if and only if the **showVertex()** field of *props* is true.

- ```
  void draw(const ccCvlString& s, const ccPoint& p,
    const ccColor& ink, const ccColor& backgr,
    const ccUIFormat& fmt, Layers layer = eImageLayer);
  ```

  Draws a character string starting at the specified point, in the specified color and format, with the specified background, in the specified layer.

  Notes

  This draw string function behaves the same as the draw graphics functions above and follows the same rules for recording and displaying. See the description on page 3356.

Parameters

s	The text string to draw.
p	The location of the upper left corner of the string. *p* is in the coordinate space specified when adding the text to a display using **ccDisplay::drawSketch()**.
ink	The color of the text.
backgr	The background color. This is the area within the bounding rectangle of the text but not including the text itself.
fmt	The text format contains the font and alignment. The alignment location is positioned at point *p*.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- ```
  void draw(const ccPelBuffer_const<c_UInt8> &pb,
    const ccPoint& p, bool passThrough = false,
    c_UInt8 passColor = 0, bool displayRaw = true,
    Layers layer = eImageLayer);
  ```

  Draws a grey-scale pel buffer.

  Parameters

pb	The grey scale image to draw.
p	The point at which to draw the pel buffer. *p* is in the coordinate space specified when adding *pb* to a display using **ccDisplay::drawSketch()**.
passThrough	If true, pixels with the value *passColor* are not drawn.
passColor	The pass-through color. If *passThrough* is true, pixels with value *passColor* are not drawn.
displayRaw	If false, values in the image are mapped to the range *ccUIRootObject::eFirstUserColor* through *ccUIRootObject::eFirstUIReservedColor* - 1 before being displayed.
layer	The layer to draw into. Must be one of:
  ```

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Notes

The pixel map is applied before the *passColor* comparison is performed.

This draw pel buffer function behaves the same as the draw graphics functions above and follows the same rules for recording and displaying. See the description on page 3356.

- ```
  void draw(const ccPelBuffer_const<c_UInt16> &pb,
    const ccPoint& p, bool passThrough = false,
    c_UInt16 passColor = 0, Layers layer = eImageLayer);
  ```

Draws a 16-bit grey-scale pel buffer.

Notes

This method is not supported.

- ```
  void draw(const ccPelBuffer_const<ccPackedRGB16Pel> &pb,
    const ccPoint& p, bool passThrough = false,
    c_UInt16 passColor = 0, Layers layer = eImageLayer);
  ```

Draws a color (RGB 5-6-5) pel buffer to the display. If *passThrough* is true, pixels with value *passColor* are not drawn.

Calling this method with recording on is not supported. You cannot use this method to add a **ccPackedRGB16Pel** pel buffer into a recording tablet. That operation has no effect. For a discussion of the draw function rules for recording and displaying see the description on page 3356.

Parameters

pb	The pel buffer to draw.
p	The point at which to draw the pel buffer. *p* is in the coordinate space specified when adding *pb* to a display using **ccDisplay::drawSketch()**.
passThrough	If true, pixels with the value *passColor* are not drawn.
passColor	The pass-through color. If *passThrough* is true, pixels with value *passColor* are not drawn.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Notes

To permanently display this type of pel buffer, see the **ccDisplay::image()** overload that takes the same argument type.

- ```
  void draw(const ccPelBuffer_const<ccPackedRGB32Pel> &pb,
    const ccPoint& p, bool passThrough = false,
    c_UInt32 passColor = 0, Layers layer = eImageLayer);
  ```

Draws a 32-bit (RGB 0-8-8-8)pel buffer. If *passThrough* is true, pixels with value *passColor* are not drawn.

Calling this method with recording on is not supported. You cannot use this method to add a **ccPackedRGB32Pel** pel buffer into a recording tablet. That operation has no effect. For a discussion of the draw function rules for recording and displaying see the description on page 3356.

Parameters

pb The pel buffer to draw.

p The point at which to draw the pel buffer. *p* is in the coordinate space specified when adding *pb* to a display using **ccDisplay::drawSketch()**.

passThrough If true, pixels with the value *passColor* are not drawn.

passColor The pass-through color. If *passThrough* is true, pixels with value *passColor* are not drawn.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Notes

To permanently display this type of pel buffer, see the **ccDisplay::image()** overload that takes the same argument type.
  ```

- ```
  void draw(const ccRLEBuffer &rle, const ccPoint& p,
    const cmStd vector<c_UInt8>& colorMap,
    bool passThrough = true, c_UInt8 passColor = 0,
    bool ignoreScale = false, Layers layer = eImageLayer);
  ```

  Draws a run-length encoded image using the specified color map.

  Parameters

rle	The run-length encoded image to draw.
p	The point at which to draw the RLE buffer. Specified in the coordinate space used when adding the RLE buffer to a display using **ccDisplay::drawSketch()**.
colorMap	A vector of up to 256 values of type **c_UInt8**, each representing an index into the color map returned by **ccDisplay::colorMap()**. The size of the color map vector depends on the number of grey levels in the RLE buffer to be drawn.
passThrough	If true, pixels with the value *passColor* are not drawn.
passColor	The pass-through color. If *passThrough* is true, pixels with value *passColor* are not drawn.
ignoreScale	If true, the image is not expanded or subsampled. This value is used when drawing icons.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

  Notes

  You typically initialize the color map using predefined instances of **ccColor** and the **ccColor::index()** method. For example, to create a color map with two elements and initialize them to the pass-through color and red, use the following code:

  ```
  cmStd vector<c_UInt8> colorMap(2);
  colorMap[0] = ccColor::passColor().index();
  colorMap[1] = ccColor::redColor().index();
  ```

  The color map is applied before the pass-through comparison is made. The pass-through color used for RLE buffers (index value 0) is different from the pass-through color used for general display (index value 243).

  See the *Color Maps* section of the *Displaying Images* chapter in the *CVL User's Guide* for more information on color maps.
  ```

To permanently add the RLE buffer to a display, this function must be called from a tablet with recording enabled, and then the tablet's sketch must be added to the display. For a description of how to use the draw functions to record and display RLE buffers, see the discussion on page 3356.

- ```
  void draw (const ccUISketch& s, const ccPoint& p,
    Layers layer = eImageLayer);
  ```

Displays the recorded sketch *s*. All coordinates in the sketch are relative to the specified point. The specified layer is used only for sketch components for which no layer is specified. If both *layer* and the recorded sketch specify *eUnspecifiedLayer*, the sketch is not displayed.

For tablet objects with no display, it records the sketch *s* into this tablet's sketch.

Parameters

s	The sketch.
p	The orientation point of the sketch. All coordinates in the sketch are relative to this point.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346. If both the *layer* argument and the sketch component use *eUnspecifiedLayer*, the component is not drawn.

Notes

Do not pass in this tablet's **sketch()** as the first argument. The intent is for other tablets to call this function to record their sketch list and/or display their sketch. The following construct is not allowed: **tablet.draw(tablet.sketch())**.

textRect

```
ccUIRect textRect (const ccCvlString& s, const ccPoint& p,
  const ccUIFormat& fmt, ccUIRect& clippedRect,
  Layers layer=eImageLayer);
```

Returns the rectangle that would enclose the string *s* if it were drawn. If the string is clipped by an area of the display, then the clipped part of the rectangle is returned in *clippedRect*. Otherwise, *clippedRect* is the same as the returned rectangle.

Parameters

s	The text string to be measured.
```

p	The upper left corner of the string. This is the offset in the current tablet coordinate space.
fmt	The text format. Contains alignment and font information.
clippedRect	The clipped rectangle if the string needed to be clipped. Otherwise it is the same as the returned **ccUIRect**.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

Notes

This method is intended to be called from a display class derived from **ccUITablet**. Do not call this function from a default constructed **ccUITablet**.

When calling this function to get the text rectangle of an interactive **ccUILabel** the offset point *p* and returned values are in the coordinate space to which the interactive graphic was added to the display from **ccDisplay::addShape()**. For example:

```
ccUILabel *uiLabel = new ccUILabel;
myDisplay.addShape(uiLabel, ccDisplay::eDisplayCoords);
uiLabel->tablet()->textRect(...).
```

When calling this method on a text string from a display that contains an image, the offset *p* and returned values are in client coordinates.

This function is not intended to be called from a tablet constructed for recording. It returns a NULL rectangle when called on such a tablet.

drawPointIcon

```
void drawPointIcon (
  const ccPoint& p,
  const ccGraphicProps& props,
  Layers layer=eImageLayer);
```

Draws a static point icon centered at the specified location.

Parameters

p	The point at which to draws the point icon.
props	The drawing properties of the point icon.
layer	The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Notes

This function behaves the same as the draw graphics functions above and follows the same rules for recording and displaying. See the description on page 3356.

set

```
void set(const ccColor& color, Layers layer=eImageLayer);

void set(const ccUIRect& rect, const ccColor& color,
  Layers layer=eImageLayer);

void set(const ccRect& rect, const ccColor& color,
  Layers layer=eImageLayer);
```

Set all or part of the specified layer to the specified color.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

The tablet base map transform must not contain rotation or skew when using this method. This method doesn't draw filled or rotated rectangles.

- `void set(const ccColor& color, Layers layer=eImageLayer);`

Set the entire specified layer to the specified color. If recording is enabled, all previously recorded components in the specified layer are erased.

This version of **set()** uses scope coordinates.

Parameters

color The new color of the layer.

layer The layer. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void set(const ccUIRect& rect, const ccColor& color, Layers layer=eImageLayer);`

  Set the area described by *rect* in the specified layer, to the specified color. This version of **set()** uses tablet coordinates.

  Parameters

rect	The area whose color to set.
color	The new color.
layer	The layer to change. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- `void set(const ccRect& rect, const ccColor& color, Layers layer=eImageLayer);`

  Set the area described by *rect* in the specified layer, to the specified color. This version of **set()** uses scope coordinates.

  Parameters

rect	The area whose color to set.
color	The color of the layer.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

setComplement

```
void setComplement (const ccUIRect& rect,
 const ccColor& color, Layers layer=eImageLayer);

void setComplement (const ccRect& rect,
 const ccColor& color, Layers layer=eImageLayer);
```

Sets all of the specified layer to the specified color except for the area enclosed by *rect*. The area enclosed by *rect* is unchanged.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

The tablet **baseMap()** transform must not contain rotation or skew when using this method. This method doesn't draw filled or rotated rectangles.

- ```
  void setComplement (const ccUIRect& rect,
   const ccColor& color, Layers layer=eImageLayer);
  ```

  This version of **setComplement()** uses the scope coordinate system regardless of the coordinate system you use to draw the tablet's sketch.

  Parameters

rect	The area whose color is unchanged.
color	The new color.
layer	The layer to color. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

- ```
  void setComplement (const ccRect& rect,
   const ccColor& color, Layers layer=eImageLayer);
  ```

  This version of **setComplement()** uses the tablet coordinate system regardless of the coordinate system you use to draw the tablet's sketch.

  Parameters

rect	The area whose color is unchanged.

color The new color.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

fill

```
void fill (const ccIPair& pt, const ccColor& fillClr,
  const ccColor& clr, FillType fillType,
  Layers layer=eImageLayer);

void fill (const ccPoint& pt, const ccColor& fillClr,
  const ccColor& clr, FillType fillType,
  Layers layer=eImageLayer);
```

Fills in an area with a specified color.

If *fillType* is *ccUITablet::eFillBorder*, this function starts filling from the point *pt* in all directions until it reaches the border color *clr*. If *fillType* is *ccUITablet::eFillSurface*, filling starts at *pt* and continues in all directions until the color is not *clr*.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

- ```
  void fill (const ccIPair& pt, const ccColor& fillClr,
    const ccColor& clr, FillType fillType,
    Layers layer=eImageLayer);
  ```

  This version of **fill()** always uses the scope coordinate system regardless of the coordinate system you use to draw the tablet's sketch.

  Parameters

  pt The point at which to start filling.

  fillClr The color to use for filling.

  clr The *stop* color.

  fillType *ccUITable::eFillBorder*: fills until the stop color is encountered.
  ```

ccUITable::eFillSurface: fills until a color other than the stop color is encountered.

layer — The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- ```
  void fill (const ccPoint& pt, const ccColor& fillClr,
    const ccColor& clr, FillType fillType,
    Layers layer=eImageLayer);
  ```

This version of **fill()** uses the coordinate system that you use to draw the tablet's sketch.

Parameters

pt — The point at which to start filling.

fillClr — The color to use for filling.

clr — The *stop* color.

fillType — *ccUITable::eFillBorder*: fills until the stop color is encountered.

ccUITable::eFillSurface: fills until a color other than the stop color is encountered.

layer — The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.
  ```

drawStart

```
void drawStart (const ccPoint& pt,
  Layers layer=eImageLayer);
```

Sets the *drawing point* in the specified layer. The drawing point is used as the current pen location by some tablet drawing routines. Drawing routines never change the drawing point, unless otherwise specified.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

Parameters

pt	The initial location of the drawing point.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

drawTo

```
void drawTo(
  const ccPoint& pt,
  const ccGraphicProps& props,
  Layers layer=eImageLayer);
```

Draws a line segment from the current drawing point to a point *pt*. Updates the drawing point to the point *pt* after the line is drawn.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

Parameters

pt	The line segment end point.
props	The graphic properties of the line segment.
layer	The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

moveToRelPels

```
void moveToRelPels (c_Int32 x, c_Int32 y,
  Layers layer=eImageLayer);

void moveToRelPels (const cc2Vect& tabletDir,
  float distPels, Layers layer=eImageLayer);
```

Move the current drawing point and update it. No drawing is performed.

When calling this function on a display class derived from **ccUITablet**, the operation takes effect immediately as long as there is a scope associated with the tablet, but is *temporary* unless this operation is part of a tablet sketch.

Regarding temporary operations, this function behaves the same as the draw graphics functions and follows the same rules for recording and displaying. See the description on page 3356.

- ```
  void moveToRelPels (c_Int32 x, c_Int32 y,
    Layers layer=eImageLayer);
  ```

  Moves the drawing point to a point that is *x* and *y* pixels away from the current drawing point.

  Parameters

x	The number of pixels in the x-direction to add to the current drawing point.
y	The number of pixels in the y-direction to add to the current drawing point.
layer	The specified layer. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.
  ```

- ```
  void moveToRelPels (const cc2Vect& tabletDir,
    float distPels, Layers layer=eImageLayer);
  ```

  Moves the drawing point to a point that is *dist* pixels away frmo the current drawing point, in the direction specified by the vector *tabletDir*. The direction uses the coordinate system used to draw the tablet's sketch.

  Parameters

tabletDir	The direction in which to draw the line.
distPels	The length of the line segment to draw in scope coordinates.
layer	The specified layer. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

  Notes

  The length of the direction vector is ignored.

drawToRelPels

```
void drawToRelPels(
  c_Int32 x,
  c_Int32 y,
  const ccGraphicProps& props,
  Layers layer = eImageLayer);

void drawToRelPels(
  const cc2Vect& tabletDir,
  float distPels,
  const ccGraphicProps& props,
  Layers layer = eImageLayer);
```

- ```
  void drawToRelPels(
    c_Int32 x,
    c_Int32 y,
    const ccGraphicProps& props,
    Layers layer = eImageLayer);
  ```

  Draws a line segment from the current drawing point to a point that is *x* and *y* pixels away from it, and then updates the current drawing point.

  Parameters

x	The number of pixels in the x-direction to add to the current drawing point.

y The number of pixels in the y-direction to add to the current drawing point.

props The drawing properties.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- ```
  void drawToRelPels(
    const cc2Vect& tabletDir,
    float distPels,
    const ccGraphicProps& props,
    Layers layer = eImageLayer);
  ```

  Draws a line segment from the current drawing point to a point *distPels* from the drawing point in the direction specified by the vector *tabletDir*. The direction uses the coordinate system you use to draw the tablet's sketch. Updates the current drawing point.

  Parameters

  tabletDir The direction in which to draw the line.

  distPels The length, in pixels, of the line segment to draw.

  props The drawing properties.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

  Notes

  The length of the direction vector is ignored.

drawingPoint

```
ccPoint drawingPoint(Layers layer=eImageLayer) const;
```

Returns the current drawing point using the coordinate system that you use to draw the tablet's sketch.

Parameters

layer The specified layer. Must be one of:
```

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Throws

ccUIError::BadLayer
If *layer* is invalid.

drawPointArg

```
const ccPoint& drawPointArg () const;
```

Returns a special **ccPoint** that can be used as an argument to any drawing routine to specify the current drawing point.

outline

```
void outline(const ccUIRect& rect, const ccColor& color,
  c_Int32 thickness, Layers layer=eImageLayer);

void outline(const ccRect& rect, const ccColor& color,
  c_Int32 thickness, Layers layer=eImageLayer);
```

Draws a rectangular outline into the specified layer. The tablet **baseMap()** transform must not contain rotation or skew when using these methods. The methods do not draw filled or rotated rectangles.

-
```
void outline(const ccUIRect& rect, const ccColor& color,
  c_Int32 thickness, Layers layer=eImageLayer);
```

Draws an outline of *rect* in the specified color and thickness. This version of **outline()** uses the scope coordinate system regardless of the coordinate system you use to draw the tablet's sketch.

Parameters

rect The rectangle whose outline is to be drawn.

color The color to use for drawing.

thickness The thickness of the outline in pixels.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- `void outline(const ccRect& rect, const ccColor& color, c_Int32 thickness, Layers layer=eImageLayer);`

  Draws an outline of *rect* in the specified color and thickness. This version of **outline()** uses the coordinate system that you use to draw the tablet's sketch.

  Parameters

rect	The rectangle whose outline is to be drawn.
color	The color to use for drawing.
thickness	The thickness of the outline in pixels.
layer	The layer to draw into. Must be one of: *ccUITablet::eImageLayer* *ccUITablet::eOverlayLayer* *ccUITablet::eUnspecifiedLayer* See *Layers* on page 3346.

outline3D

```
void outline3D(const ccUIRect& rect, const ccColor& light,
 const ccColor& shadow, c_Int32 thickness,
 Layers layer=eImageLayer);

void outline3D(const ccRect& rect, const ccColor& light,
 const ccColor& shadow, c_Int32 thickness,
 Layers layer=eImageLayer);
```

Draws a rectangular outline into the specified layer. The rectangle is drawn with highlights and shadows for a 3D effect. The tablet **baseMap()** transform must not contain rotation or skew when using these methods. The methods do not draw filled or rotated rectangles.

- `void outline3D(const ccUIRect& rect, const ccColor& light, const ccColor& shadow, c_Int32 thickness, Layers layer=eImageLayer);`

  Draws an outline of *rect* in the specified thickness using the *light* color for the top and left edges and the *shadow* color for the bottom and right edges. This version of **outline3D()** always uses the scope coordinate system regardless of the coordinate system you use to draw the tablet's sketch.

  Parameters

rect	The rectangle whose outline is to be drawn.
light	The color to use for drawing the left and top edges.

shadow The color to use for drawing the right and bottom edges.

thickness The thickness of the outline in pixels.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- ```
  void outline3D(const ccRect& rect, const ccColor& light,
    const ccColor& shadow, c_Int32 thickness,
    Layers layer=eImageLayer);
  ```

  Draws an outline of *rect* in the specified thickness using the *light* color for the top and left edges and the *shadow* color for the bottom and right edges. This version of **outline()** uses the coordinate system that you use to draw the tablet's sketch.

  Parameters

  rect The rectangle whose outline is to be drawn.

  light The color to use for drawing the left and top edges.

  shadow The color to use for drawing the right and bottom edges.

  thickness The thickness of the outline in pixels.

  layer The layer to draw into. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

arrowHead

```
void arrowHead (const ccPoint& pt, const cc2Vect& dir,
  float armLen, const ccGraphicProps& props,
  Layers layer=eImageLayer);
```

Draws an arrowhead pointing in the direction *dir* with its vertex at the point *pt*. Updates the current drawing point to *pt*.

Parameters

pt The vertex of the arrowhead in the coordinate system that you use to draw the tablet's sketch.

dir The direction that the arrowhead points.
```

armLen The length of the arrowhead's arms in pixels.

props The drawing properties.

layer The layer to draw into. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

Notes

The length of the vector is ignored.

erase

```
void erase(Layers layer = eUnspecifiedLayer);

void erase(
  const ccUIRect& rect,
  Layers layer = eUnspecifiedLayer);
```

Erases all or the selected part (*rect*, in scope coords) of this tablet. The layer you specify causes the following:

Specified layer	Description
eImageLayer	Erases the image layer
eOverlayLayer	Erases the overlay layer
eUnspecifiedLayer	Erases both the image layer and the overlay layer

This function erases but does not redraw the display. You will not see the erase effect until you do a redraw.

- `void erase(Layers layer = eUnspecifiedLayer);`

Erases the entire sketch of this tablet. See the above description.

Parameters

layer The layer to erase. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

- ```
  void erase(
    const ccUIRect& rect,
    Layers layer = eUnspecifiedLayer);
  ```

  Erases the area enclosed by *rect*, of this tablet's sketch. See the above description.

  Parameters

  rect The portion of the sketch to erase in scope coordinates.

  layer The layer to erase. Must be one of:

  ccUITablet::eImageLayer
  ccUITablet::eOverlayLayer
  ccUITablet::eUnspecifiedLayer

  See *Layers* on page 3346.

fullDraw

```
void fullDraw(Layers layer = eUnspecifiedLayer);
```

Redraws this tablet and all other tablets managed by the display system, in back-to-front order.

Parameters

layer The layer to draw. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.

redraw

```
void redraw(Layers = eUnspecifiedLayer);
```

Redraws this tablet. This method temporarily disables recording during the redraw operation.

Parameters

Layers The layer to redraw. Must be one of:

ccUITablet::eImageLayer
ccUITablet::eOverlayLayer
ccUITablet::eUnspecifiedLayer

See *Layers* on page 3346.
```

Static Functions

overlaySupported

```
static bool overlaySupported();
```

Returns true if the overlay layer is supported for your display.

Notes

Some hardware platforms do not support overlay graphics.

makeIcon

```
static ccRLEBuffer makeIcon(const TCHAR* pattern,
  const cmStd vector<c_UInt8>& colorMap);
```

This function creates an icon as a run-length encoded buffer using the specified pattern and color map. *pattern* must be non-NULL and point to a NULL-terminated string that is formed strictly according to the following rules.

The pattern is a string consisting of the digits 0 through 9, dot (.), plus (+), and a terminator (/, or newline). The first character of the string specifies the terminator (typically either "/" or newline). The terminator ends each row and all rows must be the same size. Other characters specify pixel values. The digits are used to lookup values in the *colorMap*. Space, dot, and plus refer to the pass value (**ccColor::passColor()**), Space and dot give you some artistic freedom. Plus is used when the pattern is also used to specify a touchMap (see **ccUIIconShape**).

Parameters

pattern	An icon pattern.
colorMap	The color map to map the values 0 through 9 into the range 0 through 256.

Example

```
const TCHAR* cross =
    "/"
    "...+0+.../"
    "...+0+.../"
    "...+0+.../"
    "++++0++++/"
    "000000000/"
    "++++0++++/"
```

```
    "...+0+.../"
    "...+0+.../"
    "...+0+.../";
```

Throws

ccUIError::BadIconPattern
The icon pattern does not conform to the rules.

iconTouched

```
static bool iconTouched(const TCHAR* touchMap,
  const ccIPair& p, c_Int32 touchMapWidth = -1);
```

Returns true if the icon specified by the pattern *touchMap* is touched at the point *p*. *p* is relative to the upper left corner of the icon. This function returns true if the pixel designated by *p* is a digit or a + in the map.

Parameters

touchMap	An icon pattern.
p	The point.
touchMapWidth	The width of the touch map. If –1, compute the touch map width from the pattern.

Deprecated Members

The following functions are provided for backward compatibility only and should not be used for new development. These functions may be removed and not supported in a future CVL release.

draw

The drawing functions for **ccEllipse** and **ccEllipseArc** have been replaced with functions that use **ccEllipse2** and **ccEllipseArc2**.

```
void draw(const ccEllipse & e, const ccGraphicProps & props,
Layers layer = eImageLayer);

void draw(const ccEllipseArc & e,
 const ccGraphicProps & props, Layers layer = eImageLayer);
```

The drawing function for **ccPolygon** has been replaced with the drawing function that uses **ccPolyline**.

```
void draw(const ccPolygon& p, const ccGraphicProps& props,
 Layers layer = eImageLayer);
```

The following functions that use `const ccColor&` have been replaced with drawing functions that use `const ccGraphicProps&`.

```
void draw(const ccPoint& p, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccLineSeg& l, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccLine& l, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccCross& c, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccRect& r, const ccColor& color,
 Layers layer = eImageLayer, bool fill = false);

void draw(const ccCircle& c, const ccColor& color,
 Layers layer = eImageLayer, bool fill = false);

void draw(const ccAnnulus& c, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccEllipse& e, const ccColor& color,
 Layers layer = eImageLayer, bool fill = false);

void draw(const ccEllipseArc& e, const ccColor& color,
 Layers layer = eImageLayer);

void draw(const ccGenRect& r, const ccColor& color,
 Layers layer = eImageLayer, bool fill = false);

void draw(const ccGenAnnulus& a, const ccColor& color,
 Layers layer = eImageLayer);
```

```
void draw(const ccCoordAxes& a, const ccColor& color,
  Layers layer = eImageLayer);

void draw(const ccPointSet& p, const ccColor& color,
  Layers layer = eImageLayer);

void draw(const ccAffineRectangle& r, const ccColor& color,
  Layers layer = eImageLayer);

void draw(const ccPolygon& p, const ccColor& color,
  Layers layer = eImageLayer);

void draw(const ccEllipseAnnulusSection& eas,
  const ccColor& color, Layers layer = eImageLayer,
  bool drawArrowHead = true,
  bool drawArrowHeadForward = true);

void draw(const ccGenShape& gs, const ccColor& color,
  Layers layer = eImageLayer);

void draw(const ccGenPoly& gp, const ccColor& color,
  Layers layer = eImageLayer, bool showVertex = false);

void draw(const cc2Wireframe& wf,
  const ccColor& c, Layers layer = eImageLayer, bool
showVertex = false);

void draw(const class ccGraphic& g,
  Layers layer = eImageLayer);
```

drawPointIcon

```
void drawPointIcon (const ccPoint& p, const ccColor& color,
  Layers layer=eImageLayer);
```

drawTo

```
void drawTo(const ccPoint& p, const ccColor& color,
  Layers layer = eImageLayer);
```

drawToRelPels

```
void drawToRelPels(c_Int32 x, c_Int32 y,
  const ccColor& color, Layers layer = eImageLayer);

void drawToRelPels(const cc2Vect& tabletDir,
  float distPels, const ccColor& color,
  Layers layer = eImageLayer);
```

drawPixel

```
void drawPixel (const ccDPair& p, const ccColor& color,
  Layers layer=eImageLayer);
```

drawLineSeg

```
void drawLineSeg (const ccDPair& pt1, const ccDPair& pt2,
  const ccColor& color, Layers layer=eImageLayer);
```

drawLine

```
void drawLine (const ccDPair& pt, ccRadian t,
  const ccColor& color, Layers layer=eImageLayer);
```

drawCross

```
void drawCross (const ccDPair& center,
const ccRadian& angle, const ccColor& color,
Layers layer=eImageLayer);
```

drawRect

```
void drawRect (const ccDPair& ul, const ccDPair& lr,
  const ccColor& color, Layers= eImageLayer);
```

drawCircle

```
void drawCircle (const ccDPair& center, double radius,
  const ccColor& color, Layers layer=eImageLayer);
```

drawEllipse

```
void drawEllipse (const ccDPair& center,
  const ccDPair& radii, ccRadian t, const ccColor& color,
  Layers layer=eImageLayer);
```

drawEllipseArc

```
void drawEllipseArc (const ccDPair& center, const ccDPair&
radii, ccRadian t, ccRadian phi1, ccRadian phi2,
  const ccColor& color, Layers layer=eImageLayer);
```

drawGenRect

```
void drawGenRect (const ccDPair& center,
```

```
const ccDPair& radii, ccRadian& t, const ccDPair& round,
const ccColor& color, Layers layer=eImageLayer);
```

drawAffineRect

```
void drawAffineRect(const ccDPair& center, double xLen,
 double yLen, const ccRadian& xRotation,
 const ccRadian& skew, const ccColor& color,
 Layers layer=eImageLayer);
```

drawPolygon

```
void drawPolygon (const cmStd vector<cc2Vect>& pts,
 ccPolygon::PolyFillMode fm, const ccColor& color,
 Layers layer=eImageLayer);
```

scratchPad

```
static ccUITablet scratchPad;
```

A tablet in record mode with a NULL scope to make sketches on. Erase before use.

Notes

This variable has been deprecated. Use the default constructor to create a tablet for recording.

drawOn

```
ccFlagStack& drawOn();
```

recordOn

```
ccFlagStack& recordOn();
```

drawOnOverlay

```
ccFlagStack& drawOnOverlay();
```

ccUITablet

ccVersion

```
#include <ch_cvl/version.h>

class ccVersion;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

Constructors/Destructors

ccVersion

```
ccVersion(c_UInt32 version, c_UInt32 details,
  const ccCvlString& product = cmT("CVL"));
```

Constructs a version object with the given version information.

Parameters

version Hexadecimal number specifying the CVL version. See also **cmCvlVersion** on page 3396.

details Hexadecimal number specifying the version details. See also **cmCvlVersionDetails** on page 3397.

product The product name, set by default to “CVL”.

Enumerations

ReleaseType

```
enum ReleaseType;
```

Specifies the type of release.

Value	Meaning
eRelease = 0	Released software
ePreRelease	Prerelease software

Operators

operator== `bool operator==(const ccVersion& rhs) const;`

Returns true if this version is equal to *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs The other version.

operator!= `bool operator!=(const ccVersion& rhs) const;`

Returns true if this version is not equal to *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs The other version.

operator> `bool operator>(const ccVersion& rhs) const;`

Returns true if this version is greater than the *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs The other version.

operator< `bool operator<(const ccVersion& rhs) const;`

Returns true if this version is less than *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs The other version.

operator>= `bool operator>=(const ccVersion& rhs) const;`

Returns true if this version is greater than or equal to *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs The other version.

operator<= `bool operator<=(const ccVersion& rhs) const;`

Returns true if this version is less than or equal to *rhs*, false otherwise. Use this operator only after verifying that **ccVersion::canCompare(rhs)** is true.

Parameters

rhs	The other version.

Public Member Functions

getAsText `ccCvlString getAsText() const;`

Returns the version information represented by this object as a formatted text string.

product `ccCvlString product() const;`

Returns the product name, for example, “CVL”.

version `c_UInt32 version() const;`

Returns the version as a 32-bit hexadecimal number, for example, 0x06000000 for CVL 6.0.0.

details `c_UInt32 details() const;`

Return the version details as a 32-bit hexadecimal number, for example, 0x05030100 for CVL 5.3.1.

major `int major() const;`

Retrieves the major version number, for example the 6 in CVL 6.0.0.

minor `int minor() const;`

Retrieves the minor version number, for example the 4 in CVL 5.4.0.

point `int point() const;`

Retrieves the point version, for example the 1 in CVL 5.3.1.

type `ReleaseType type() const;`

Retrieves the release type. This will always be 0 for released software.

sr `int sr() const;`

Retrieves the service release number, for example the 1 in CVL 5.5.2 SR1. Returns zero if this is not a service release.

cr `int cr() const;`

Retrieves the customer release number, for example the 17 in CVL 5.4 CR17. Returns zero if this is not a customer release.

pr `int pr() const;`

Retrieves the patch release number, for example the 6 in CVL 5.4 PR6. Returns zero if this is not a patch release.

build `int build() const;`

Retrieves the build number, for example the 38 in CVL 6.0.0 build 38.

canCompare `bool canCompare(const ccVersion& rhs) const;`

Returns true if this version can be compared to *rhs*. Returns false if the versions cannot be compared, for example for two different products.

Parameters

rhs	The other version.

Macros

cmCvlVersion `cmCvlVersion 0xAABBCCDD`

The CVL version is a 32-bit hexadecimal number defined in *ch_cvl/verdefs.h*. The bytes of the version number specify the following information:

Digits	Meaning
AA	Major version number (for example, the 6 in 6.0.0)
BB	Minor version number (for example, the 4 in 5.4.0)
CC	Point release number (for example, the 1 in 5.3.1)
DD	Release type (always 00 for released software)

cmCvlVersionDetails

```
cmCvlVersionDetails     0xAABBCCDD
```

The CVL version details number is a 32-bit hexadecimal number defined in *ch_cvl/verdefs.h*. The bytes of the version details number specify the following information:

Digits	Meaning
AA	Service release number, for example the 1 in CVL 5.5.2 SR1.
BB	Customer release number, for example the 17 in CVL 5.4 CR17.
CC	Patch release number, for example the 6 in CVL 5.4 PR6.
DD	Build number, for example the 38 in CVL 6.0.0 build 38.

cmCvlVersionMajor

```
cmCvlVersionMajor(cmCvlVersion);
```

Extracts the major version number from the supplied version, for example the 6 in CVL 6.0.0.

cmCvlVersionMinor

```
cmCvlVersionMinor(cmCvlVersion);
```

Extracts the minor version number from the supplied version, for example the 4 in CVL 5.4.0.

cmCvlVersionPoint

```
cmCvlVersionPoint(cmCvlVersion);
```

Extracts the point release number from the supplied version, for example the 1 in CVL 5.3.1.

cmCvlVersionType

```
cmCvlVersionType(cmCvlVersion);
```

Extracts the release type from the supplied version. Always 0 for released software.

ccVersion

cmCvlVersionSr

```
cmCvlVersionSr(cmCvlVersionDetails);
```

Extracts the service release from the supplied CVL version details number, for example the 1 in CVL 5.5.2 SR1.

cmCvlVersionCr

```
cmCvlVersionCr(cmCvlVersionDetails);
```

Extracts the customer release from the supplied CVL version details number, for example the 17 in CVL 5.4 CR17.

cmCvlVersionPr

```
cmCvlVersionPr(cmCvlVersionDetails);
```

Extracts the patch release from the supplied CVL version details number, for example the 6 in CVL 5.4 PR6.

cmCvlVersionBuild

```
cmCvlVersionBuild(cmCvlVersionDetails);
```

Extracts the build number from the supplied CVL version details number, for example the 38 in CVL 6.0.0 build 38.

Note To get version information at run time, call **cfGetRunTimeCvlVersion()** (see **cfGetRunTimeCvlVersion()** on page 3689). To get version information at compile time, call **cfGetRunTimeCvlVersion()** (see **cfGetCompileTimeCvlVersion()** on page 3685).

ccVideoFormat

```
#include <ch_cvl/vidfmt.h>

class ccVideoFormat;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

This is an abstract base class that the acquisition software uses to describe operations on video formats. The acquisition software defines a video format as the pairing of a particular camera type with a particular image size.

The acquisition software creates a single object of class **ccStdVideoFormat** (see page 3009) for each camera type and image size. You use these video format objects to create an acquisition FIFO that is appropriate for the camera and frame grabber that your application uses.

To get a video format, you use **ccStdVideoFormat::getFormat()** described on page 3012.

Notes

There is no need for you to use this class directly in your code. Use the **ccStdVideoFormat** class for all of your format programming.

Constructors/Destructors

ccVideoFormat

```
virtual ~ccVideoFormat();
```

Destructor.

The acquisition software creates one object for each supported video format. You do not create video formats yourself.

Operators

operator==

```
bool operator==(const ccVideoFormat& that);
```

Returns true if this video format is the same as *that* video format.

Parameters

that	The other video format.

operator!=

```
bool operator!=(const ccVideoFormat& that);
```

Returns true if this video format and *that* video format are different.

Parameters

that The other video format.

Notes

Since there is only one instance of each video format, testing video formats for equality is very quick and very simple.

Public Member Functions

width

```
c_Int32 width() const;
```

Returns the width of the video format in pixels.

height

```
c_Int32 height() const;
```

Returns the height of the video format in pixels.

Notes

Due to the limitations of some frame grabbers, it may be necessary to acquire images that are slightly larger or slightly smaller than the image that comes from the camera. The format name always reflects the size of the image coming from the camera. For images returned by **ccAcqFifo**, **ccPelBuffer<P>::width()** and **ccPelBuffer<P>::height()** reflect the actual size of the acquired image.

If you are using a GigE Vision camera with a generic GigE video format, both **width()** and **height()** return 1. To determine the actual size of the acquired image, get the region of interest immediately after creating the acquisition FIFO like this:

```
ccPelRect imageSize(fifo->properties().actualRoi());
```

depth

```
c_Int32 depth() const;
```

Return the depth of the video format in bits per pixel.

newAcqFifo

```
ccAcqFifo* newAcqFifo(ccFrameGrabber& fg);
```

Creates and returns a new acquisition FIFO suitable for acquiring images of this format from the frame grabber *fg*.

Parameters

fg The frame grabber to use to acquire images.

Throws

ccVideoFormat::NotSupported
The specified frame grabber does not support this video format.

ccAcqFifo::CouldNotCreate
An error occurred during creation of the acquisition FIFO.

name

```
const TCHAR* name() const;
```

Returns the name of this video format as a printable string. For example, "Sony XC75 640x480".

cameraManufacturer

```
const TCHAR* cameraManufacturer() const;
```

Returns the name of the manufacturer for the camera that this video format describes. For example, “Sony”.

Notes

NULL is returned if this video format is not specific to a particular camera.

This string is provided for information purposes only, and the string returned by a particular video format should not be relied upon to remain constant from release to release.

cameraModel

```
const TCHAR* cameraModel() const;
```

Returns the name of the model for the camera that this video format describes. For example: “XC-55”.

Notes

NULL is returned if this video format is not specific to a particular camera.

This string is provided for information purposes only, and the string returned by a particular video format should not be relied upon to remain constant from release to release.

videoFormatResolution

```
const TCHAR* videoFormatResolution() const;
```

Returns the text string describing the default resolution of the pel buffer returned by this video format. For example: “640x480”.

Notes

NULL may be returned for some formats.

This string is provided for information purposes only, and the string returned by a particular video format should not be relied upon to remain constant from release to release.

videoFormatDriveType

```
const TCHAR* videoFormatDriveType() const;
```

Returns the text string describing the drive type (internal or external) to be used with this camera (if any). For example: “IntDrv”.

Notes

NULL may be returned when syncModel property is used to control the drive type of this video format, or the sync mode is not applicable.

This string is provided for information purposes only, and the string returned by a particular video format should not be relied upon to remain constant from release to release.

videoFormatOptions

```
const TCHAR* videoFormatOptions() const;
```

Returns the text string defining the operation mode of the camera. Some cameras have several operation modes, so this text string defines the mode that should be used with this video format. For example, “rapid-reset, shutter-sw-EDONPISHAII”.

Notes

NULL may be returned when no special option of the camera is used.

This string is provided for information purposes only, and the string returned by a particular video format should not be relied upon to remain constant from release to release.

formatFromCCF `bool formatFromCCF() const;`

Returns true when the video format was created from a CCF file, or false when the video format is built into CVL.

isSupportedForLegacy

```
bool isSupportedForLegacy(ccFrameGrabber&) const;
```

Returns true when this format is only provided for backwards compatibility reasons on the given frame grabber, but is implemented internally by means of an alias to a CCF video format.

Example

This would return true for the **cfXc55_640x480()** format when used on the MVS-8120/CVM1. The frame grabber actually uses the CCF version of this format in order to perform acquisitions.

Static Functions

fullList

```
static const cmStd vector<const ccVideoFormat*>&
  fullList();
```

Returns a vector of pointers to all supported **ccVideoFormat** objects.

Example

To print out a list of the names of all video formats you might use the following code:

```
#include <ch_cvl/vidfmt.h>
#include <ch_cvl/constrea.h>

typedef cmStd vector<const ccVideoFormat*> Vfv;

void printVideoFormats()
{
  Vfv videoFormats;
  videoFormats = ccVideoFormat::fullList();

  cogOut << cmT("The full list contains ") <<
    videoFormats.size() << cmT(" elements.") << cmStd endl;

  for (Vfv::const_iterator i = videoFormats.begin();
       i != videoFormats.end(); i++)
    cogOut << (*i)->name() << cmStd endl;
}
```

filterList

```
static cmStd vector<const ccVideoFormat*>
  filterList(const cmStd vector<const ccVideoFormat*>& vfs,
  ccFrameGrabber& fg);
```

Given a vector of video formats *vfs*, returns a list of those video formats supported by the frame grabber *fg*.

Parameters

vfs	A vector of video formats.
fg	A frame grabber.

Example

To return a list of all the video formats that support the frame grabber *fg*, you would use the following code:

```
cmStd vector<const ccVideoFormat*>myVidFmts =
  ccVideoFormat::filterList(ccVideoFormat::fullList(), fg);
```

Note

The **ccVideoFormat::filterList()** function returns the Sony XC-55 format as being supported on the MVS-8100. This format is supported only on the MVS-8100M but not the MVS-8100.

ccWaferPreAlign

```
#include <ch_cvl/prealign.h>

class ccWaferPreAlign: public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	Yes
Archiveable	Complex

A class that contains a Wafer Pre-Align tool. A **ccWaferPreAlign** contains the expected diameter and type of the wafer. A **ccWaferPreAlign** must be trained before it can find a wafer.

Constructors/Destructors

ccWaferPreAlign

```
ccWaferPreAlign(double diameter = 200,
  ccWaferPreAlignDefs::FeatureType feature =
  ccWaferPreAlignDefs::eNone,
  ccWaferPreAlignDefs::OperatingMode opMode =
  ccWaferPreAlignDefs::eAutoDetect);

virtual ~ccWaferPreAlign();

ccWaferPreAlign(const ccWaferPreAlign& src);
```

- ```
  ccWaferPreAlign(double diameter = 200,
    ccWaferPreAlignDefs::FeatureType feature =
    ccWaferPreAlignDefs::eNone,
    ccWaferPreAlignDefs::OperatingMode opMode =
    ccWaferPreAlignDefs::eAutoDetect);
  ```

  Constructs a tool in an untrained state.

  Parameters

  diameter — The expected diameter of the wafer in client units. The default value of 200 assumes that client coordinates are calibrated in millimeters.

  feature — The expected feature type of the wafer. *feature* must be one of the following values:
  ```

ccWaferPreAlignDefs::eFlat
ccWaferPreAlignDefs::eNotch
ccWaferPreAlignDefs::eNone

opMode The tool operating mode. *opMode* must be one of the following values:

ccWaferPreAlignDefs::eNotchMax
ccWaferPreAlignDefs::eStandard
ccWaferPreAlignDefs::eAutoDetect

- `virtual ~ccWaferPreAlign();`

  The **ccWaferPreAlign** destructor is virtual, indicating that you may create derived classes from this one.

- `ccWaferPreAlign(const ccWaferPreAlign& src);`

  Copy constructor.

  Parameters
  src The source **ccWaferPreAlign**.

Operators

operator= `ccWaferPreAlign& operator=(const ccWaferPreAlign& src);`

Assignment operator.

Parameters
src The source **ccWaferPreAlign**.

Public Member Functions

diameter

```
double diameter() const;
void diameter(double diameter);
```

- `double diameter() const;`

  Returns the expected diameter of the wafer in client units.

- `void diameter(double diameter);`

  Sets the expected diameter of the wafer in client units. If you call this function, the tool is placed in an untrained state.

  Parameters

  diameter The expected wafer diameter in client units.

  Notes

  This parameter can be set by the tool during learning.

clientFromImageXform

```
cc2Xform clientFromImageXform() const;
```

Returns a **cc2Xform** that describes the transformation between image and client units. This transformation is set when you call train and is typically used to account for any aspect ratio changes between the image coordinates and client coordinates.

featureType

```
ccWaferPreAlignDefs::FeatureType featureType() const;

void featureType(
  ccWaferPreAlignDefs::FeatureType feature);
```

- `ccWaferPreAlignDefs::FeatureType featureType() const;`

  Returns the type of wafer that this **ccWaferPreAlign** is configured to find. This function returns one of the following values:

  ccWaferPreAlignDefs::eFlat
  ccWaferPreAlignDefs::eNotch
  ccWaferPreAlignDefs::eNone

- `void featureType(`
  `ccWaferPreAlignDefs::FeatureType feature);`

  Sets the type of wafer that this **ccWaferPreAlign** is configured to find. You can change the feature type without needing to retrain the **ccWaferPreAlign**.

  Parameters

  feature The type of wafer to find. *feature* must be one of the following values:

  ccWaferPreAlignDefs::eFlat
  ccWaferPreAlignDefs::eNotch
  ccWaferPreAlignDefs::eNone

Notes

This parameter can be set by the tool during learning.

operatingMode

```
ccWaferPreAlignDefs::OperatingMode operatingMode() const;
```

Returns the operating mode for this **ccWaferPreAlign**. This function returns one of the following values:

ccWaferPreAlignDefs::eNotchMax
ccWaferPreAlignDefs::eStandard
ccWaferPreAlignDefs::eAutoDetect

train

```
void train(const cc2Xform &clientFromImageXform);
```

Train a synthetic wafer model. The model is trained using the diameter specified during construction or through a call to **diameter**.

Parameters

clientFromImageXform

A **cc2Xform** describing the transformation between image coordinates and client coordinates.

Throws

ccSecurityViolation

The security information on the Cognex hardware device does not correspond to the operating mode specified for this **ccWaferPreAlign** *object.*

Notes

In most cases, *clientFromImageXform* should be the same **cc2Xform** produced when you calibrated your system. The aspect ratio of *clientFromImageXform* must be identical to the aspect ratio of the client coordinate system associated with images used for learning or searching.

isTrained

```
bool isTrained() const;
```

Returns true if this **ccWaferPreAlign** is currently trained, false otherwise.

learn

```
void learn(const ccPelBuffer_const<c_UInt8>& image,
  const ccWaferPreAlignRunParams& runParams,
  c_UInt32 learnFlags, ccWaferPreAlignResult& result);
```

Analyzes the supplied image of a wafer and determines the wafer's diameter, feature type, or both (as you specify)

The tool sets this **ccWaferPreAlign** object's diameter and feature type. The tool then locates the wafer in the image and places its size, location, and orientation in the supplied **ccWaferPreAlignResult** object.

You must call **train()** before you call this function, and the **cc2Xform** that you supply to **train()** must have the same aspect ratio as the client coordinate system of the image that you supply to this function. A simple way of making sure the aspect ratios are the same is to supply use the same image for both **train()** and **learn()**, as shown in the following example:

```
ccPelBuffer_const<c_UInt8> image;
ccWaferPreAlignRunParams params;
ccWaferPreAlignResult results;

...

void train(image.clientFromImageXform());
void learn(image, params, ccWaferPreAlignDefs::eAll, results);
```

Parameters

image An image of the wafer. The wafer should be backlit and it should occupy approximately 90% of *image*'s area.

runParams A **ccWaferPreAlignRunParams** that specifies the parameters used to align the wafer.

learnFlags Which wafer parameters to learn. *learnFlags* must be formed by ORing together one or more of the following values:

ccWaferPreAlignDefs::eDiameter
ccWaferPreAlignDefs::eFeature
ccWaferPreAlignDefs::eAll

result A **ccWaferPreAlignResult** into which the results of the pre-alignment are placed.

Throws

ccWaferPreAlignDefs::BadParams
learnFlags is not formed by ORing together one or more of *ccWaferPreAlignDefs::eDiameter*, *ccWaferPreAlignDefs::eFeature*, or *ccWaferPreAlignDefs::eAll* or *runParams* does not contain valid parameters.

ccWaferPreAlignDefs::BadImage
image is unbound.

ccWaferPreAlignDefs::BadXform
: The aspect ratio specified by *image*'s client coordinates is not the same as the aspect ratio that you supplied to the **train()** function.

ccSecurityViolation
: The security information on the Cognex hardware device does not correspond to the operating mode specified for this **ccWaferPreAlign** *object.*

run

```
void run(const ccPelBuffer_const<c_UInt8>& image,
  const ccWaferPreAlignRunParams& runParams,
  ccWaferPreAlignResult& result) const;
```

Attempts to locate a wafer of the diameter and type specified by this **ccWaferPreAlign** using the supplied **ccWaferPreAlignRunParams**. The results of the alignment operation are placed in the supplied **ccWaferPreAlignResult**.

This function first locates the center of the wafer. Then, if the wafer type is flat or notched, the tool determines the location of the alignment feature on the wafer.

You must call **train()** before you call this function, and the **cc2Xform** that you supply to **train()** must have the same aspect ratio as the client coordinate system of the image that you supply to this function. A simple way of making sure the aspect ratios are the same is to use the same image for both **train()** and **learn()**, as shown in the following example:

```
ccPelBuffer_const<c_UInt8> image;
ccWaferPreAlignRunParams params;
ccWaferPreAlignResult results;
ccWaferPreAlign wpa;

...

wpa.train(image.clientFromImageXform());
wpa.learn(image, params, ccWaferPreAlignDefs::eAll, results);
wpa.run(image, params, results);
```

Parameters

image
: An image of the wafer. The wafer should be backlit and it should occupy approximately 90% of *image*'s area.

runParams
: A **ccWaferPreAlignRunParams** which specifies the parameters for the pre-alignment.

result
: A **ccWaferPreAlignResult** into which the results of the pre-alignment are placed.

Throws

ccSecurityViolation
The security information on the Cognex hardware device does not correspond to the operating mode specified for this **ccWaferPreAlign** *object.*

ccWaferPreAlignDefs::BadParams
runParams contains an invalid combination of run-time parameters.

ccWaferPreAlignDefs::BadImage
image is unbound.

ccWaferPreAlignDefs::BadXform
The aspect ratio specified by *image*'s client coordinates is not the same as the aspect ratio that you supplied to the **train()** function.

update

```
virtual bool update(c_UInt32 currDiameter,
  double currAspectRatio,
  ccWaferPreAlignDefs::FeatureType currFeature,
  c_UInt32 bestDiameter, double bestAspectRatio,
  ccWaferPreAlignDefs::FeatureType bestFeature,
  const ccWaferPreAlignResult &currResult,
  const ccWaferPreAlignResult &bestResult);
```

This function is called during the learning process by the Wafer Pre-Align tool. You can override this function in a class derived from **ccWaferPreAlign** to monitor the progress of the learning operation. You can terminate the learning process by having your override return false. Returning true continues the learning process.

Parameters

currDiameter The most recently evaluated wafer diameter in client units.

currAspectRatio The most recently evaluated aspect ratio.

currFeature The most recently evaluated feature type. *currFeature* is one of the following values:

ccWaferPreAlignDefs::eFlat
ccWaferPreAlignDefs::eNotch
ccWaferPreAlignDefs::eNone

bestDiameter The wafer diameter that has produced the best result so far.

bestAspectRatio The aspect ratio that has produced the best result so far.

bestFeature The feature type that has produced the best result so far. *bestFeature* is one of the following values:

ccWaferPreAlignDefs::eFlat
ccWaferPreAlignDefs::eNotch
ccWaferPreAlignDefs::eNone

Notes

You should not call this function. You use this function by overriding it in a derived class.

ccWaferPreAlignDefs

```
#include <ch_cvl/prealign.h>

class ccWaferPreAlignDefs;
```

A name space that holds enumerations and constants used by the Wafer Pre-Align tool.

Enumerations

FeatureType

```
enum FeatureType;
```

This enumeration defines types of wafers that can be located by the Wafer Pre-Align tool.

Value	Meaning
eFlat	Round wafer with an alignment flat
eNotch	Round wafer with an alignment notch
eNone	Round wafer with no alignment feature

LearnFlags

```
enum LearnFlags;
```

This enumeration defines which wafer parameters will be learned by automatic learning.

Value	Meaning
eDiameter	Learn the diameter of the wafer.
eFeature	Learn the feature type (alignment flat, alignment notch, or no alignment feature)
eAll	Learn both the diameter and the feature type.

OperatingMode `enum OperatingMode;`

This enumeration defines the operating modes supported by the Wafer Pre-Align Tool. Keep in mind that your Cognex hardware must have the security bit enabled that corresponds to the operating mode you request.

Value	Meaning
eNotchMax	Use the NotchMax operating mode. This is a general-purpose operating mode for front-lit wafers.
eStandard	Use the Standard operating mode. This mode requires that the wafer be backlit and that the input image contain a silhouette of the wafer.
eAutoDetect	If the Cognex hardware has NotchMax enabled, the tool uses the NotchMax operating mode regardless of whether Standard mode is enabled. If only Standard mode is enabled, the tool uses Standard operating mode.

ccWaferPreAlignResult

```
#include <ch_cvl/prealign.h>

class ccWaferPreAlignResult : public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains the results produced by the Wafer Pre-Align tool.

Constructors/Destructors

ccWaferPreAlignResult

```
ccWaferPreAlignResult();
```

Constructs a **ccWaferPreAlignResult** with the following default values:

Parameter	Value
waferFoundFlag	False
featureFoundFlag	False
featureType	*eNone*
center	0.0, 0.0
angle	0.0
scale	1.0
score	0.0
time	0.0
imgFromClient	Identity transform
featureLocation	0.0, 0.0
notchDepth	0.0
notchWidth	0.0

Parameter	Value
flatLength	0.0
flatRadius	0.0

Public Member Functions

isWaferFound

```
bool isWaferFound() const;
```

Returns true if a wafer was found, false otherwise. In NotchMax mode, this value is true if the score is 1.0, false if the score is 0.0. In Standard mode, this value is true if the score equals or exceeds the accept threshold you specified.

isFeatureFound

```
bool isFeatureFound() const;
```

Returns true if both the wafer and the feature specified in the **ccWaferPreAlign** that was run are found, false otherwise. If the **ccWaferPreAlign** was configured to find a round wafer, this function returns true if the wafer is found.

featureType

```
ccWaferPreAlignDefs::FeatureType featureType() const;
```

Returns the type of feature specified by the **ccWaferPreAlign** that was run.

center

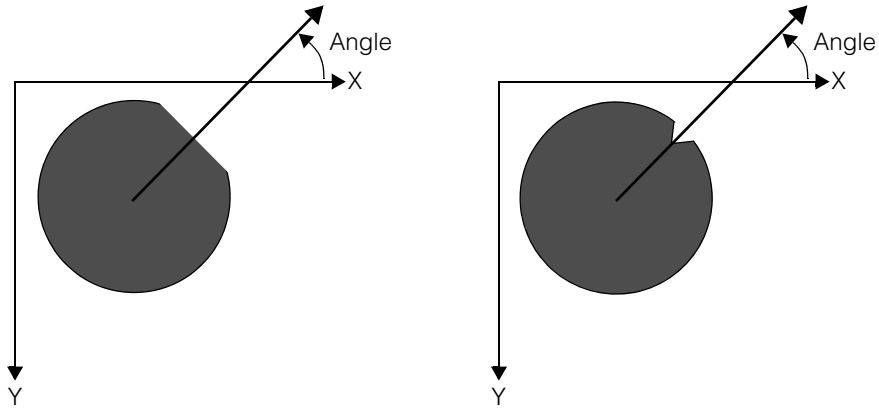
```
cc2Vect center() const;
```

Returns the location of the center of the found wafer. The wafer center is reported in the client coordinate system, offset by the origin specified in the **ccWaferPreAlignRunParams** used for this search.

angle

```
ccRadian angle() const;
```

Returns the angle of the notch or the midpoint of the flat area. The angle is reported as the angle from the client coordinate system x-axis to a line drawn from the wafer center through the center of the notch or flat, as shown in the following diagram:



If this **ccWaferPreAlign** is configured to locate round wafers, then this function returns 0.0.

Throws

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

scale

```
double scale() const;
```

Returns the scale of the found wafer as a multiple of the size of the trained wafer.

score

```
double score() const;
```

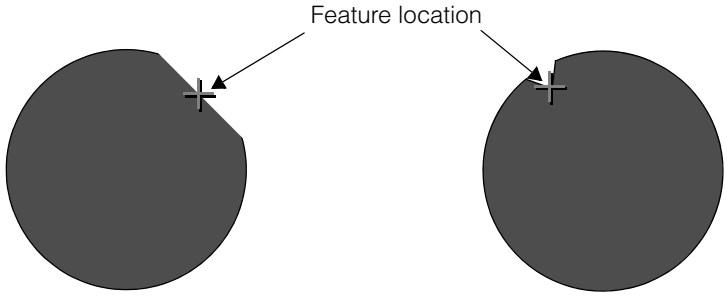
In Standard mode, this function returns the result score, a number between 0.0 and 1.0, where 1.0 represents a perfect match and 0.0 represents a total failure. In NotchMax mode, the score is either 0.0 (failure) or 1.0 (success).

Notes

In Standard mode, if the score is determined to be 0.0 while locating the wafer, the feature locating step is not performed. The Standard mode score considers only the perimeter of the wafer, not the feature. A wafer can have a high score (a good perimeter) even if no feature is found.

featureLocation `cc2Vect featureLocation() const;`

Returns the location of the feature with respect to the origin of the client coordinate system. For notched wafers, the feature location is the deepest point in the notch. For flat wafers, the feature location is the center of the flat. The following diagram shows how the feature location is reported:



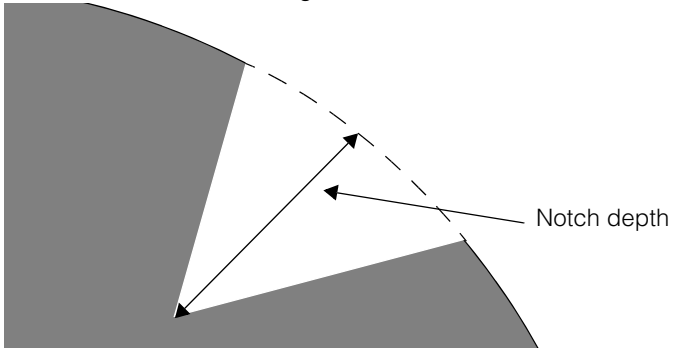
Throws

ccWaferPreAlignDefs::WrongFeatureType
This **ccWaferPreAlign** is configured to locate round wafers

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

notchDepth `double notchDepth() const;`

Returns the distance from the nominal perimeter of the wafer to the deepest point on the found notch measured along the wafer radius, as shown in the following figure:



The distance is returned in client units. This is equal to the difference between the wafer radius and the distance from the wafer center to the deepest point on the found notch.

Throws

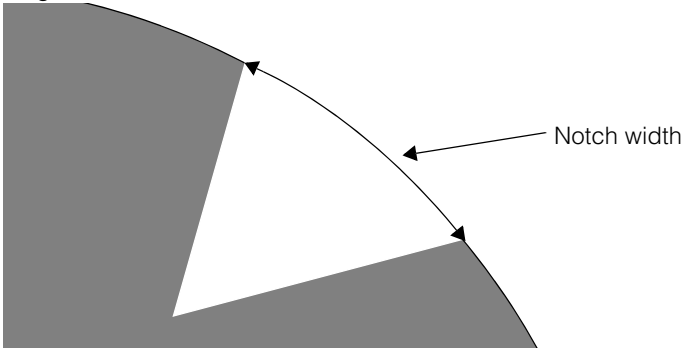
ccWaferPreAlignDefs::WrongFeatureType
This **ccWaferPreAlign** is not configured to find notched wafers.

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

notchWidth

```
double notchWidth() const;
```

Returns the distance from one corner of the found notch to the other measured along the wafer's circumference in the client coordinate system, as shown in the following diagram:



Throws

ccWaferPreAlignDefs::WrongFeatureType
This **ccWaferPreAlign** is not configured to find notched wafers.

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

flatLength

```
double flatLength() const;
```

Returns the length of the found flat area in the client units.

Throws

ccWaferPreAlignDefs::WrongFeatureType
This **ccWaferPreAlign** is not configured to find flat wafers.

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

flatRadius

```
double flatRadius() const;
```

Returns the shortest distance between the wafer center and the wafer's flat section in the client units.

Throws

ccWaferPreAlignDefs::WrongFeatureType
This **ccWaferPreAlign** is not configured to find flat wafers.

ccWaferPreAlignDefs::NotFound
The specified feature type was not found.

time

```
double time() const;
```

Returns the time in seconds required to locate the wafer and the feature.

imageFromClientXform

```
const cc2Xform& imageFromClientXform () const;
```

Returns the **cc2Xform** that converts client coordinate system locations to image coordinate system locations.

updateWaferResults

```
void updateWaferResults(bool waferFound,
  const cc2Vect &center, const ccRadian &angle,
  double scale, double score, const cc2Xform& xform);
```

Sets the following values in this **ccWaferPreAlignResult**:

- Whether a wafer was found
- The wafer location
- The wafer angle
- The wafer scale
- The wafer score
- The image-to-client transformation.

This function is intended to let you manually set the values in a **ccWaferPreAlignResult** for the purposes of testing your application.

Parameters

waferFound If true, the wafer was found, if false it was not.

scale The scale of the found wafer as a multiple of the size of the trained wafer.

center	The location of the center of the wafer in client coordinates.
angle	The angle from the client coordinate system x-axis to a line drawn from the wafer center through the center of the notch or flat.
score	The score received by the wafer. *score* must be in the range of 0.0 through 1.0.
xform	A **cc2Xform** that converts client coordinate system locations to image coordinate system locations.

updateFeatureResults

```
void updateFeatureResults(bool featureFound,
  ccWaferPreAlignDefs::FeatureType feature,
  const cc2Vect &location, const ccRadian &angle,
  double notchDepth, double notchWidth, double flatLength,
  double flatRadius, double time);
```

Sets the following values in this **ccWaferPreAlignResult**:

- Whether the requested feature type was found
- The feature type
- The feature location
- The notch depth and width
- The flat length and radius
- The orientation of the wafer
- The amount of time required to locate the wafer and feature.

This function is intended to let you manually set the values in a **ccWaferPreAlignResult** for the purposes of testing your application.

Parameters

featureFound	If true, the specified feature was found, if false it was not.
feature	The type of feature. *feature* must be one of the following values: *ccWaferPreAlignDefs::eFlat* *ccWaferPreAlignDefs::eNotch* *ccWaferPreAlignDefs::eNone*
location	The location of the feature in the client coordinate system offset.
angle	The angle from the client coordinate system x-axis to a line drawn from the wafer center through the center of the notch or flat.

notchDepth	The depth of the notch in client units, measured from the nominal wafer perimeter to the deepest point of the notch along the radius of the wafer.
notchWidth	The width of the notch in client units, measured along the nominal wafer perimeter.
flatLength	The length of the flat in client units.
flatRadius	The minimum distance from the flat to the center of the wafer in client units.
time	The number of seconds required to find the wafer and feature.

ccWaferPreAlignRunParams

```
#include <ch_cvl/prealign.h>

class ccWaferPreAlignRunParams : public ccPersistent;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Complex

A class that contains the run-time parameters used by the Wafer Pre-Align tool.

Many of the run-time parameters defined in this class apply only to Standard mode; in NotchMax mode, those parameters are ignored. The following table lists which parameters are used in the two modes.

Parameter	Standard Mode	NotchMax Mode
origin	Yes	Yes
accept	Yes	No
scale	Yes	Yes
scaleRange	Yes	Yes
maxEccentricity	Yes	No
minNotchDepth	Yes	No
maxNotchDepth	Yes	No
minNotchWidth	Yes	No
maxNotchWidth	Yes	No
minFlatRadius	Yes	No
maxFlatRadius	Yes	No
minFlatLength	Yes	No
maxFlatLength	Yes	No

Constructors/Destructors

ccWaferPreAlignRunParams

```
ccWaferPreAlignRunParams();
```

Constructs **ccWaferPreAlignRunParams** with the following default values:

Parameter	Default value
origin	0.0, 0,0
accept	0.3
scale	1.0
scaleRange	0.0
maxEccentricity	0.0
minNotchDepth	0.0
maxNotchDepth	0.0
minNotchWidth	0.0
maxNotchWidth	0.0
minFlatRadius	0.0
maxFlatRadius	0.0
minFlatLength	0.0
maxFlatLength	0.0

Public Member Functions

origin

```
cc2Vect origin() const;
void origin(const cc2Vect &origin);
```

- `cc2Vect origin() const;`

  Returns the origin in client coordinates. The wafer position is reported relative to the origin that you specify.

- `void origin(const cc2Vect &origin);`

  Sets the origin in client coordinates. The wafer position is reported relative to the origin that you specify.

  Parameters

  origin The origin in client coordinates

accept

```
double accept() const;
void accept(double accept);
```

- `double accept() const;`

  Returns the accept threshold. Only wafers that receive a score greater than or equal to the accept threshold are returned.

- `void accept(double accept);`

  Sets the accept threshold. Only wafers that receive a score greater than or equal to the accept threshold are returned.

  Parameters

  accept The accept threshold. *accept* must be in the range 0.0 through 1.0.

  Throws

  ccWaferPreAlignDefs::BadParams

  accept is not in the range 0.0 through 1.0.

scale

```
double scale() const;
void scale(double scale);
```

- `double scale() const;`

  Returns the expected scale of the wafer.

- `void scale(double scale);`

  Sets the expected scale of the wafer.

  You specify a tolerance range for the scale using **scaleRange**.

Parameters

scale The expected scale of the wafer, expressed as the scale of the found wafer with respect to the trained wafer. A value of 1.25 specifies that the found wafer will be 25% larger than the trained wafer.

Throws

ccWaferPreAlignDefs::BadParams
scale is less than or equal to 0.0.

---

scaleRange

```
double scaleRange() const;
void scaleRange(double range);
```

- `double scaleRange() const;`

  Returns one half of the total scale tolerance.

- `void scaleRange(double range);`

  Sets the scale tolerance range. You specify the range as the permitted positive or negative scale variation from the expected scale (specified with **scale()**).

  To specify a scale range of 1.0 to 1.5, you would specify a value of 1.25 to **scale()** and a value of 0.25 to **scaleRange()**.

  Parameters

  range The maximum positive or negative scale difference from the expected scale of the wafer.

  Throws

  ccWaferPreAlignDefs::BadParams
  range is less than 0.0.

---

maxEccentricity

```
double maxEccentricity() const;
void maxEccentricity(double maxEccentricity);
```

- `double maxEccentricity() const;`

  Returns the maximum expected deviation of the shape of the wafer from a circle.

- `void maxEccentricity(double maxEccentricity);`

  Sets the maximum expected deviation of the shape of the wafer from a circle.

  When *maxEccentricity* is set to 0.0, the wafer is expected to appear as a perfect circle. As *maxEccentricity* is increased, the wafer is assumed to become progressively more elliptical.

  The Wafer Pre-Align tool uses this value to help determine the wafer boundary. Larger values of *maxEccentricity* may make the tool more sensitive to the effects of video noise.

  maxEccentricity is computed using the following formula:

$$maxEccentricity = \sqrt{1 - \frac{min^2}{max^2}}$$

  where *min* is the length of the minor principal axis and *max* is the length of the major principal axis.

  Parameters

  maxEccentricity The maximum expected eccentricity, as computed above.

  Throws

  ccWaferPreAlignDefs::BadParams
  maxEccentricity is less than 0.0 or greater than 0.25.

minNotchDepth `double minNotchDepth() const;`

Returns the minimum expected depth of the notch feature in client units.

maxNotchDepth `double maxNotchDepth() const;`

Returns the maximum expected depth of the notch feature in client units.

notchDepthRange

`void notchDepthRange(double minimum, double maximum);`

Sets the minimum and maximum expected depth of the notch feature in client units. The notch depth is measured from the point within the notch that is closest to the wafer center to the nominal perimeter of the wafer. This is equal to the difference between the wafer radius and the distance from the wafer center to the deepest point on the notch.

Parameters

minimum The minimum expected notch depth.

maximum The maximum expected notch depth.

Throws

ccWaferPreAlignDefs::BadParams

minimum or *maximum* is less than 0.0 or *minimum* is greater than *maximum*.

Notes

These parameters are only used for wafer notch location and are not considered for the location of other features.

minNotchWidth

```
double minNotchWidth() const;
```

Returns the minimum expected width of the notch feature in client units.

maxNotchWidth

```
double maxNotchWidth() const;
```

Returns the maximum expected width of the notch feature in client units.

notchWidthRange

```
void notchWidthRange(double minimum, double maximum);
```

Sets the minimum and maximum expected width of the notch feature in client units. The notch width is defined as the distance between the two corners of the notch measured along the wafer's circumference.

Parameters

minimum The minimum expected notch width.

maximum The maximum expected notch width.

Throws

ccWaferPreAlignDefs::BadParams

minimum or *maximum* is less than 0.0 or *minimum* is greater than *maximum*.

Notes

These parameters are only used for wafer notch location and are not considered for the location of other features.

minFlatLength

```
double minFlatLength() const;
```

Returns the minimum expected length of the flat feature in client units.

maxFlatLength

```
double maxFlatLength() const;
```

Returns the maximum expected length of the flat feature in client units.

flatLengthRange

```
void flatLengthRange(double minimum, double maximum);
```

Sets the minimum and maximum expected length of the flat feature in client units.

Parameters

minimum The minimum expected flat length.

maximum The maximum expected flat length.

Throws

ccWaferPreAlignDefs::BadParams

minimum or *maximum* is less than 0.0 or *minimum* is greater than *maximum*.

Notes

These parameters are only used for wafer flat location and are not considered for the location of other features.

minFlatRadius

```
double minFlatRadius() const;
```

Returns the minimum expected distance from the wafer center to the center of the flat in client units.

maxFlatRadius

```
double maxFlatRadius() const;
```

Returns the maximum expected distance from the wafer center to the center of the flat in client units.

flatRadiusRange

```
void flatRadiusRange(double minimum, double maximum);
```

Sets the minimum and maximum expected distance from the wafer center to the center of the flat in client units.

Parameters

minimum The minimum expected distance.

maximum The maximum expected distance.

Throws

ccWaferPreAlignDefs::BadParams

minimum or *maximum* is less than 0.0 or *minimum* is greater than *maximum*.

Notes

These parameters are only used for wafer flat location and are not considered for the location of other features.

ccWin32Display

```
#include <ch_cvl/w32disp.h>

class ccWin32Display : public ccDisplay;
```

Class Properties

Copyable	No
Derivable	Yes
Archiveable	No

The **ccWin32Display** class provides a display window for images and graphics you can program using the Microsoft Win32 API for execution on a Windows host computer. **ccWin32Display** is intended for Microsoft Windows applications that do not use MFC, or for any application that requires a simple display window. **ccWin32Display** windows do not include a title bar, menu bar, tool bar, and status bar like those built into **ccDisplayConsole** windows. The class does provide scroll bars and methods you can call for zooming, panning, and other features.

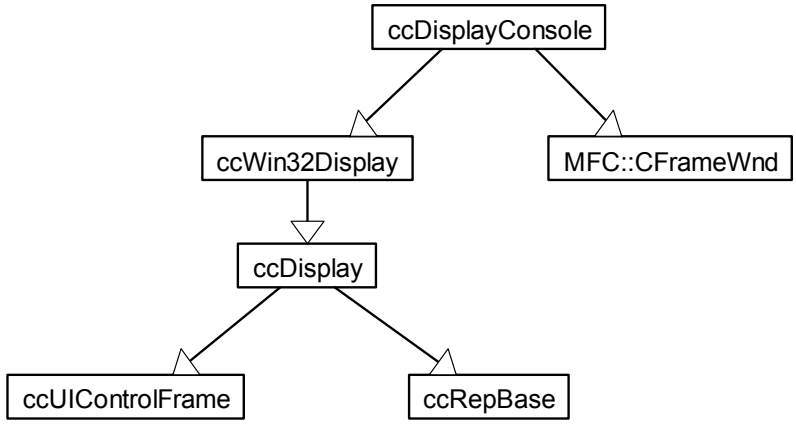


Figure 1. ccWin32Display class inheritance hierarchy

When you build a **ccWin32Display** application, the project's preprocessor settings should define the macro **cmNoMFCDependency** to avoid including MFC header files.

If you are programming under MFC, you may wish to use the **ccDisplayConsole** class which provides a full-featured display and drawing environment and graphical user interface, all through MFC. Tool bars, status bars, and many other GUI features are provided by MFC that may improve your application's user interface.

The **ccWin32Display** class has the following capabilities:

- Displaying images (pel buffers)
- Displaying live images from Cognex frame grabbers
- Adding static graphics to the display
- Adding interactive graphics to the display
- GUI with mouse support

Constructors/Destructors

ccWin32Display

```
ccWin32Display(HWND hWnd = 0);
```

Creates a display object using *hWnd* as the display window. *hWnd* is subclassed so that the display can receive Windows messages such as mouse movements, mouse clicks, and window resizing.

Parameters

hWnd Handle to the window to use for the display.

Notes

hWnd must belong to the current process and must not be subclassed by any other **ccWin32Display** object.

Public Member Functions

window

```
void window(HWND hWnd);

HWND window();
```

- `void window(HWND hWnd);`

Specifies the window where the image and graphics should be displayed. This window is subclassed so that the display can receive Windows messages, such as mouse movements, mouse clicks, and window resizing.

Parameters

hWnd Handle to the window to use for the display.

Notes

hWnd must belong to the current process and must not be subclassed by any other **ccWin32Display** object.

A valid window should be set before attempting to use the display.

- `HWND window();`

Returns the handle of the window that this display appears in.

fontTable

```
void fontTable(const cmStd vector<HFONT>& table);
const cmStd vector<HFONT>& fontTable() const;
```

- `void fontTable(const cmStd vector<HFONT>& table);`

Sets the font table. The **ccUIFormat::fontID()** corresponds to the font table index. If an out-of-range font ID is passed to a drawing routine, the system font is used.

Parameters

table The font table

Notes

You are responsible for ensuring the proper *HFONT* lifetime.

- `const cmStd vector<HFONT>& fontTable() const;`

Retrieves the current font table.

showScrollBar

```
void showScrollBar(bool horiz, bool vert);
```

Specifies whether the scroll bars are visible.

Parameters

horiz If true, makes the horizontal scroll bar visible; if false, makes the horizontal scroll bar invisible.

vert If true, makes the vertical scroll bar visible; if false, makes the vertical scroll bar invisible.

horzScrollbarEnabled

```
bool horzScrollbarEnabled() const;
```

Returns true if the horizontal scroll bar is visible.

vertScrollbarEnabled

```
bool vertScrollbarEnabled() const;
```

Returns true if the vertical scroll bar is visible.

enableOverlay

```
overlayState enableOverlay() const;

void enableOverlay(overlayState val);
```

Notes

These overrides implement the **enableOverlay()** methods, inherited from the **ccDisplay** base class, with behavior specific to **ccWin32Display** objects.

- `overlayState enableOverlay() const;`

  Returns the state of the overlay layer on this **ccWin32Display**.

- `void enableOverlay(overlayState state);`

  Enables or disables the overlay layer on this **ccWin32Display**. For MVS-8500 series frame grabbers, you must explicitly enable the overlay layer by calling this function with *ccDisplay::eOverlayPlane* as the argument.

  Parameters

  state — The state of the host graphics overlay layer. Must be one of:

  ccDisplay::eOverlayPlane
  ccDisplay::eDisableOverlayPlane
  ccDisplay::eNone

  Notes

  Overlay state values cannot be ORed together. *ccDisplay::eNone* should never be passed as an argument to **enableOverlay()**. This value can be returned by **enableOverlay()** when the overlay layer is disabled.

  When the overlay layer is disabled (*ccDisplay::eDisableOverlayPlane*), any sketches and interactive shapes added to the overlay layer disappear from the screen. Before disabling the overlay layer, you must remove any interactive shapes currently on the overlay layer and erase all sketches on all layers.

  If there is not enough video memory to allocate to the overlay layer, system memory is used. Using system memory may slow down overlay performance.

  The overlay layer cannot be enabled unless a valid window handle has been set. See **window(HNWD)** for more information.

  See **ccDisplay::enableOverlay()** for more information.

selectAreaStart

```
virtual c_Int32 selectAreaStart(CoordinateSystem cs,
  const ccPelRect& startLocation, const ccColor& color);
```

Starts an interactive area selection and returns a tag used to specify the end of the selection.

Parameters

cs The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation The initial location of the selection area in the specified coordinate system. If *startLocation* is a null rectangle or if it does not overlap the visible portion of the image, the initial location of the selection area is the location of the most recently selected area. If the most recently selected area is not visible or if there was no previously selected area, the starting location is two-thirds of the visible area.

color The color to use to draw the selection rectangle.

Example

For selecting an area, **selectArea()** is easier to use than **selectAreaStart()** and **selectAreaEnd()**. However, you can use **selectAreaStart()** and **selectAreaEnd()** to implement specialized versions of **selectArea()**. The following example shows how to write an override of **selectArea()** that the user can cancel without making a selection. Assume that **ccMyWin32Display** is derived from this class.

```
ccPelRect ccMyWin32Display::selectArea(CoordinateSystem cs,
             const ccPelRect &rect, const TCHAR* prompt,
             const ccColor& c)
{
  c_Int32 tag = ccWin32Display::selectAreaStart(cs,rect,c);
  c_Int32 v = MessageBox(NULL, prompt, cmT("Select Area"),
                         MB_OKCANCEL);

  if(v == IDOK){
    return ccWin32Display::selectAreaEnd(tag);
  } else if(v == IDCANCEL) {
    return ccPelRect();
```

```
  } else
    return ccPelRect();
}
```

Notes

If the specified coordinate system is *eClientCoords*, then the client coordinates of the last displayed image are used. If there is no such image, then display coordinates are silently used and no error is returned.

The box manipulated during the drag operation is always image aligned. Therefore, if the specified coordinate system is *eClientCoords* and the client coordinate system contains skew, this skew is not reflected in the drawn rectangle.

selectAreaEnd

```
virtual ccPelRect selectAreaEnd(c_Int32 tag);
```

Completes the area selection started by **selectAreaStart()** by hiding the rectangle graphics.

Parameters

tag — The tag that identifies the selection to finish. If tag is not a value returned by **selectAreaStart()**, this function has no effect.

selectArea

```
virtual ccPelRect selectArea(CoordinateSystem cs,
  const ccPelRect& startLocation,
  const TCHAR* prompt, const ccColor& color);
```

Waits for the user to select a rectangular area on the display and returns the rectangle in the coordinate system specified. The prompt is displayed in a message box. This function does not return until the user confirms their selection in the message box.

Parameters

cs — The coordinate system to use for reporting the location of the selected rectangle. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation — The initial location of the selection area in the specified coordinate system. If *startLocation* is a null rectangle or if it does not overlap the visible portion of the image, the initial location of the selection area is the location of the most recently selected area. If the most recently selected area is not visible or if there was no previously selected area, the starting location is two-thirds of the visible area.

prompt — The prompt that appears in the message box.

color The color to use to draw the selection rectangle.

Notes

If the specified coordinate system is *eClientCoords*, then the client coordinates of the last displayed image are used. If there is no such image, then display coordinates are silently used and no error is returned.

The box manipulated during the drag operation is always image aligned. Therefore, if the specified coordinate system is *eClientCoords* and the client coordinate system contains skew, this skew is not reflected in the drawn rectangle.

selectPointStart

```
virtual c_Int32 selectPointStart(CoordinateSystem cs,
  const ccDPair& startLocation, const ccColor& color);
```

Starts a point selection. The start location is specified in image coordinates or display coordinates.If start location is not in the visible part of the image, the initial location of the cross will be the last selected point (or the center of the display if there was no last selection or if the last selected point would not be visible)

Parameters

cs The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation The initial location of the selection cross in the specified coordinate system. If *startLocation* is not in the visible portion of the image, the initial location of the selection cross is the location of the most recently selected point. If the most recently selected point is not visible or if there was no previously selected point, the starting location is the center of the display.

color The color to use to draw the selection cross.

Notes

If the specified coordinate system is *eClientCoords*, then the client coordinates of the last displayed image are used. If there is no such image, then display coordinates are silently used and no error is returned.

selectPointEnd

```
virtual ccDPair selectPointEnd(c_Int32 tag);
```

Completes a point selection started with **selectPointStart()** by hiding the cross graphics.

Parameters

tag — The tag that identifies the selection to finish. If tag is not a value returned by **selectPointStart()**, this function has no effect.

selectPoint

```
virtual ccDPair selectPoint(CoordinateSystem cs,
  const ccDPair& startLocation, const TCHAR* prompt,
  const ccColor& color);
```

Waits for the user to select a point on the display and returns the point in the coordinate system specified. The prompt is displayed in a message box; this function does not return until the user confirms the selection in the message box. The user may cancel the operation instead of selecting.

Parameters

cs — The coordinate system to use. Must be one of:

ccDisplay::eDisplayCoords
ccDisplay::eImageCoords
ccDisplay::eClientCoords

startLocation — The initial location of the selection cross in the specified coordinate system. If *startLocation* is not in the visible portion of the image, the initial location of the selection cross is the location of the most recently selected point. If the most recently selected point is not visible or if there was no previously selected point, the starting location is the center of the display.

prompt — A prompt that appears in a message box.

color — The color to use to draw the selection cross.

Notes

If the specified coordinate system is *eClientCoords*, then the client coordinates of the last displayed image are used. If there is no such image, then display coordinates are silently used and no error is returned.

displayFormat

```
virtual DisplayFormat displayFormat() const;
```

Returns the display format of this display.

startLiveDisplay

```
bool startLiveDisplay(ccGreyAcqFifoPtrh fifo);
bool startLiveDisplay(ccRGB16AcqFifoPtrh fifo);
bool startLiveDisplay(ccRGB32AcqFifoPtrh fifo);
```

Notes

While live display is in progress, **startLiveDisplay()** owns the FIFO. Your application should not make changes to *fifo* until you stop live display.

- `bool startLiveDisplay(ccGreyAcqFifoPtrh fifo);`

Enables live display of images acquired through the specified acquisition FIFO. Returns true if the operation was successful, false otherwise.

Parameters

fifo The acquisition FIFO to use for the live display.

- `bool startLiveDisplay(ccRGB16AcqFifoPtrh fifo);`

Enables live display of images acquired through the specified acquisition FIFO. Returns true if the operation was successful, false otherwise.

Parameters

fifo The acquisition FIFO to use for the live display.

- `bool startLiveDisplay(ccRGB32AcqFifoPtrh fifo);`

Enables live display of images acquired through the specified acquisition FIFO. Returns true if the operation was successful, false otherwise.

Parameters

fifo The acquisition FIFO to use for the live display.

stopLiveDisplay

```
virtual void stopLiveDisplay();
```

Stops the live display thread started by **startLiveDisplay()**.

isLiveEnabled

```
virtual bool isLiveEnabled() const;
```

Returns true if live display has started and is active, otherwise false.

liveFrameRate `virtual double liveFrameRate() const;`

Returns the live display frame rate in frames per second.

hasImage `virtual bool hasImage() const;`

Returns true if the display has an image.

imageSize `virtual ccIPair imageSize() const;`

Returns the image size as a (width, height) pair if the display has an image. Otherwise it returns (0,0).

imageOffset `virtual ccIPair imageOffset() const;`

Returns the offset of the image as an (x,y) pair if the display has an image. Otherwise if returns (0,0).

toolsPopupMenuEnabled

```
bool toolsPopupMenuEnabled() const;
void toolsPopupMenuEnabled(bool enabled);
```

When enabled, a tools pop-up menu appears when you right-click the mouse in a **ccWin32Display** window.

- `bool toolsPopupMenuEnabled() const;`

  Returns true if the tools pop-up menu is enabled.

- `void toolsPopupMenuEnabled(bool enabled);`

  Enables or disables the tools pop-up menu. The pop-up menu contains standard functionality for zooming, panning, etc.

  Parameters

  enabled True if the pop-up menu is enabled.

getDisplayedImage

```
void getDisplayedImage(ccPelBuffer<c_UInt8>& buf,
 ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);

void getDisplayedImage(ccPelBuffer<ccPackedRGB16Pel>& buf,
 ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);

void getDisplayedImage(ccPelBuffer<ccPackedRGB32Pel>& buf,
 ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);
```

Retrieves the image and graphics displayed on the specified layer. The default is a combined image comprising both the image layer and the overlay layer.

The displayed image is stored to the specified pel buffer. If the desktop color depth does not match the pel buffer type, then the image data are automatically converted to the format of the pel buffer that is to receive the data. To prevent loss of data during conversion, choose the overload that matches the current desktop depth.

These functions always use display coordinates (*eDisplayCoords*). That is, the upper left corner of *buf* is the upper left corner of the display, and not the upper left corner of the currently displayed image.

- ```
  void getDisplayedImage(ccPelBuffer<c_UInt8>& buf,
   ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);
  ```

  Places the image currently being displayed on this **ccWin32Display** into the supplied **ccPelBuffer<c_UInt8>**.

  Parameters

  buf — A reference to the 8-bit pel buffer into which the image will be copied. Must be presized to the size of the image you want to save.

  layer — If *ccUITablet::eImageLayer*, then only image pixels are copied. If *ccUITablet::eOverlayLayer*, then only graphics from the overlay layer are copied. If *ccUITablet::eUnspecifiedLayer*, then both image and graphics are copied.

  Notes

  Use this overload if your desktop is set to 8 bits.

  Throws

  OverlayLayerNotEnabled — The overlay layer is not enabled and the specified layer is *ccUITablet::eOverlayLayer*.
  ```

- `void getDisplayedImage(ccPelBuffer<ccPackedRGB16Pel>& buf, ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);`

  Places the image currently being displayed on this **ccWin32Display** into the supplied **ccPelBuffer<ccPackedRGB16Pel>**.

  Parameters

  buf — A reference to the 16-bit RGB pel buffer into which the image will be copied. Must be presized to the size of the image you want to save.

  layer — If *ccUITablet::eImageLayer*, then only image pixels are copied. If *ccUITablet::eOverlayLayer*, then only graphics from the overlay layer are copied. If *ccUITablet::eUnspecifiedLayer*, then both image and graphics are copied.

  Notes

  Use this overload if your desktop is set to 16 bits.

  Throws

  OverlayLayerNotEnabled — The overlay layer is not enabled and the specified layer is *ccUITablet::eOverlayLayer*.

- `void getDisplayedImage(ccPelBuffer<ccPackedRGB32Pel>& buf, ccUITablet::Layers layer=ccUITablet::eUnspecifiedLayer);`

  Places the image currently being displayed on this **ccWin32Display** into the supplied **ccPelBuffer<ccPackedRGB32Pel>**. By default, both the image and any overlay graphics are copied.

  Parameters

  buf — A reference to the 32-bit RGB pel buffer into which the image will be copied. Must be presized to the size of the image you want to save.

  layer — If *ccUITablet::eImageLayer*, then only image pixels are copied. If *ccUITablet::eOverlayLayer*, then only graphics from the overlay layer are copied. If *ccUITablet::eUnspecifiedLayer*, then both image and graphics are copied.

  Notes

  Use this overload if your desktop is set to 32 bits.

  Throws

  OverlayLayerNotEnabled — The overlay layer is not enabled and the specified layer is *ccUITablet::eOverlayLayer*.

getPassThroughValue

```
virtual void getPassThroughValue(c_UInt8 &passval) const;

virtual void getPassThroughValue(
  ccPackedRGB16Pel &passval) const;

virtual void getPassThroughValue(
  ccPackedRGB32Pel &passval) const;
```

Retrieves the pass-through value used for overlay display buffers. The pass-through value is the pixel value in the overlay layer that allows pixels in the underlying image layer to show through. These are Win32 implementations of methods inherited from the **ccDisplay** base class.

- `virtual void getPassThroughValue(c_UInt8 &passval) const;`

  Gets the pass-through value used for overlay display buffers.

  Parameters

  passval — Return parameter for the pass-through color used for overlay display buffers on 8-bit displays.

- ```
  virtual void getPassThroughValue(
    ccPackedRGB16Pel &passval) const;
  ```

  Gets the pass-through value used for overlay display buffers.

  Parameters

  passval — Return parameter for the pass-through color used for overlay display buffers on 16-bit displays.

- ```
  virtual void getPassThroughValue(
    ccPackedRGB32Pel &passval) const;
  ```

  Gets the pass-through value used for overlay display buffers.

  Parameters

  passval — Return parameter for the pass-through color used for overlay display buffers on 32-bit displays.

multiSelectKey

```
void multiSelectKey(ccKeyBoardEvent::VirtualKey k);
ccKeyBoardEvent::VirtualKey multiSelectKey() const;
```

- `void multiSelectKey(ccKeyBoardEvent::VirtualKey k);`

Sets the virtual key used for multiple selections. When the user holds this key down while clicking the mouse, multiple items are selected instead of just one. Valid keys are *<Shift>*, *<Ctrl>*, or none. The default is the *<Shift>* key.

Parameters

k The virtual key that enables multiple selections. Must be one of:

ccKeyBoardEvent::eShift
ccKeyboardEvent::eControl
ccKeyboardEvent::eNoVKey

Throws

ccUIError::BadKeyValue
The input is not one of the three valid values.

Notes

As each key can have only one function assigned to it at a time, the setting for **ccWin32Display::multiSelectKey()** interacts with that for **ccWin32Display::panKey()**. If you change the multiselect key from *ccKeyboardEvent::eShift* to *ccKeyboardEvent::eControl*, the pan key is assigned the value *ccKeyboardEvent::eNoVKey*. You can change this with a subsequent call to **ccWin32Display::panKey()**.

- `ccKeyBoardEvent::VirtualKey multiSelectKey() const;`

Retrieves the virtual key used for multiple selections.

panKey

```
void panKey(ccKeyboardEvent::VirtualKey k);
ccKeyboardEvent::VirtualKey panKey() const;
```

- `void panKey(ccKeyboardEvent::VirtualKey k);`

Sets the key used to activate panning with the mouse. When the user holds down the specified key, the mouse cursor changes to a hand so that the image can be panned. The pan key can be either *<Ctrl>, <Shift>*, or none. The *<Ctrl>* key is the default.

Parameters

k — The virtual key that enables panning. Must be one of:

ccKeyboardEvent::eShift
ccKeyboardEvent::eControl
ccKeyboardEvent::eNoVKey

Throws

ccUIError::BadKeyValue
The input is not one of the three valid values.

Notes

As each key can have only one function assigned to it at a time, the setting for **ccWin32Display::panKey()** interacts with that for **ccWin32Display::multiSelectKey()**. If you change the pan key from to *ccKeyboardEvent::eControl* to *ccKeyboardEvent::eShift*, the multiselect key is assigned the value *ccKeyboardEvent::eNoVKey*. You can change this with a subsequent call to **ccWin32Display::multiSelectKey()**.

- `ccKeyboardEvent::VirtualKey panKey() const;`

  Retrieves the virtual key that activates panning.

waitForVerticalBlank

```
void waitForVerticalBlank(bool set);
```

Specifies whether to synchronize the image display to the vertical blank of the monitor. Not all host platforms support this feature with reasonable CPU usage.

Parameters

set — If true, the display is synchronized to the vertical blank of the monitor. If false, it is not synchronized.

activeLockedScope

```
ccWin32UIScope* activeLockedScope() const;
```

For Cognex internal use only.

Static Functions

platformCompatibility

```
static bool platformCompatibility();
```

For Cognex internal use only.

Deprecated Members

The following **ccWin32Display** methods are all deprecated.

chromaKey

```
void chromaKey(COLORREF color);
COLORREF chromaKey() const;
```

chromaKeyingEnabled

```
bool chromaKeyingEnabled() const;
```

enableChromaKeying

```
void enableChromaKeying(bool enable);
```

getDC

```
HDC getDC();
```

releaseDC

```
void releaseDC(HDC dc);
```

ccWorkerThreadManager

```
#include <ch_cvl/workmgr.h>

class ccWorkerThreadManager;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	No

ccWorkerThreadManager implements three static functions that let you control the system-wide creation of worker threads by multi-core-optimized image processing and vision tools.

Public Member Functions

configure

```
static void configure(
   const ccWorkerThreadManagerParams &params);
```

Applies the worker thread creation settings defined in the supplied **ccWorkerThreadManagerParams** object to this system. The settings apply to the currently running application

Parameters

params The thread creation parameters to apply.

Notes

This function does not affect any already-running worker threads created by running CVL tools. If you call this function to change the number of allowed worker threads, then the original threads will complete normally, but may contend for resources with the newly created worker threads until they complete their work.

activateMax

```
static void activateMax();
```

A convenience function that enables the creation of a worker thread for each core detected on the current system.

Notes

This function does not affect any already-running worker threads created by running CVL tools. If you call this function, all currently running worker threads will complete normally, but may contend for resources with the newly created worker threads until they complete their work.

deactivate `static void deactivate();`

Disables the creation of worker threads.

ccWorkerThreadManagerDefs

```
#include <ch_cvl/workmgr.h>

class ccWorkerThreadManagerDefs;
```

Enumerations

DesiredWorkerThreads

```
enum DesiredWorkerThreads;
```

This enumeration specifies number of worker threads created by multi-processor-optimized vision and image processing tools.

Value	Meaning
eWorkerThreadsNone	Do not create any worker threads.
eWorkerThreadsMax	Create one worker thread for each core.
eWorkerThreadsSpecified	Create a specific number of worker threads.
kDefaultWorkerThreads	The default value for this enumeration.

ccWorkerThreadManagerDefs

ccWorkerThreadManagerParams

```
#include <ch_cvlworkmgr.h>

class ccWorkerThreadManagerParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

ccWorkerThreadManagerParams encapsulates the parameters for configuring the Work Manager, which lets you control the number of worker threads created by multi-core-optimized vision and image processing tools.

Constructors/Destructors

ccWorkerThreadManagerParams

```
ccWorkerThreadManagerParams();
```

Constructs a **ccWorkerThreadManagerParams** object with the following default values:

- **desiredWorkerThreads** set to *ccWorkerThreadManagerDefs::eWorkerThreadsMax*
- **workerThreadCount** set to 1

Public Member Functions

desiredWorkerThreads

```
ccWorkerThreadManagerDefs::DesiredWorkerThreads
   desiredWorkerThreads() const;

void desiredWorkerThreads(
   ccWorkerThreadManagerDefs::DesiredWorkerThreads
   workerThreads);
```

- `ccWorkerThreadManagerDefs::DesiredWorkerThreads desiredWorkerThreads() const;`

  Returns the number of worker threads that will be created by multi-core-optimized vision and image processing tools. The returned value is one of the following:

  ccWorkerThreadManagerDefs::eWorkerThreadsNone
  ccWorkerThreadManagerDefs::eWorkerThreadsMax
  ccWorkerThreadManagerDefs::eWorkerThreadsSpecified

- `void desiredWorkerThreads( ccWorkerThreadManagerDefs::DesiredWorkerThreads workerThreads);`

  Sets the number of worker threads that will be created by multi-core-optimized vision and image processing tools. You can specify that no threads be created, that a discrete number of threads (controlled by **workerThreadCount()**) be created, or that one thread be created for every core found on this system (the default).

  Parameters

  workerThreads The number of worker threads to create. *workerThreads* must be one of the following values:

  ccWorkerThreadManagerDefs::eWorkerThreadsNone
  ccWorkerThreadManagerDefs::eWorkerThreadsMax
  ccWorkerThreadManagerDefs::eWorkerThreadsSpecified

  Throws

  ccWorkerThreadManagerDefs::BadParams
  workerThreads is not a member of the **ccWorkerThreadManagerDefs::DesiredWorkerThreads** enumeration.

workerThreadCount

```
c_Int32 workerThreadCount() const;

void workerThreadCount(c_Int32 workerThreadCount);
```

- `c_Int32 workerThreadCount() const;`

  Returns the number of worker threads to create if **desiredWorkerThreads()** is *ccWorkerThreadManagerDefs::eWorkerThreadsSpecified*.

- `void workerThreadCount(c_Int32 workerThreadCount);`

  Sets the number of worker threads to create if **desiredWorkerThreads()** is *ccWorkerThreadManagerDefs::eWorkerThreadsSpecified*. This value is ignored for other values of **desiredWorkerThreads()**.

  The default value is 1.

  Parameters

  workerThreadCount
  The number of worker threads to create.

  Notes

  This function does not compare the supplied value against the actual number of cores on the current system. Specifying a value that is greater than the actual number of cores can reduce the performance of your application.

  Throws

  ccWorkerThreadManagerDefs::BadParams
  workerThreadCount is less than or equal to 0.

ccWorkerThreadManagerParams

cc_FeatureRange

```
#include <ch_cvl/pmifproc.h>

class cc_FeatureRange;
```

Class Properties

Copyable	No
Derivable	No
Archiveable	Simple

This class describes a range of boundary points within a PatInspect feature. You use the member functions of this class to obtain information about **ccFeatureSegment**s and **ccMouseBite**s, both of which are derived from this class.

Note You should not instantiate this class directly.

Constructors/Destructors

cc_FeatureRange

```
cc_FeatureRange();
```

Constructs a **cc_FeatureRange**.

Public Member Functions

startPos

```
int startPos() const;
```

Return the index of the first boundary point in this range of boundary points.

numPoints

```
int numPoints() const;
```

Return the number of boundary points in this feature range.

cc_FeatureRange

cc_PelBuffer

```
#include <ch_cvl/pelbuf.h>

class cc_PelBuffer;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This is an abstract class used to define **ccPelBuffer** and **ccPelBuffer_const**. It describes type-independent attributes of windows on root images.

Note This chapter uses the term “window” to describe a rectangular region of a root image. The term “pel buffer” is also used to describe the same thing.

Constructors/Destructors

The constructors and destructors of this class are used only by Cognex-supplied derived classes **ccPelBuffer** and **ccPelBuffer_const**.

Operators

These operators are available to the Cognex-supplied derived classes **ccPelBuffer** and **ccPelBuffer_const**.

operator=

```
cc_PelBuffer& operator= (const cc_PelBuffer& pelbuf);
```

Makes this window have the same root image, root offset, offset, size, and transform as *pelbuf*.

Parameters

pelbuf The window whose attributes you wish to copy.

Notes

If *pelbuf* is unbound, this window becomes unbound.

operator== `bool operator== (const cc_PelBuffer& pelbuf) const;`

Returns true if this window and *pelbuf* have the same root image and have the same size, offset and root offset. The transforms of the two pel buffers are not compared.

Parameters

pelbuf The window to compare.

Notes

If both pel buffers are unbound, but have the same offset, root offset and size, this function returns true.

operator!= `bool operator!= (const cc_PelBuffer& pelbuf) const;`

Returns true if this window and *pelbuf* do not have the same root image, the same size, the same offset, and the same root offset. The transforms of the two pel buffers are not compared.

Parameters

pelbuf The window to compare.

Public Member Functions

bind `bool bind(const cc_PelBuffer& pelbuf, bool clip = false);`

Makes this window have the same root image as *pelbuf*. *Pelbuf*'s root offset, offset, transform, and size are ignored. If *pelbuf* is unbound, this window becomes unbound. Returns true if the result was clipped to fit within the new image; false otherwise.

This window's root offset, offset and size are not modified unless clipping is required. If *clip* is true, the result is clipped to the extent of the new root image (possibly resulting in a null window result if the window's location is entirely outside of the new root image). This window's transform is not changed.

Parameters

pelbuf The window whose root image you want to bind this window to.

clip If true, clip to the extent of the new root image.

Throws

ccPel::BadWindow

The window's location does not fit entirely within this window's new root image, and *clip* is false.

isBound `bool isBound() const;`

Return true if this window is bound to a root image.

setUnbound `void setUnbound();`

Make this window unbound.

Notes

An unbound window retains its root-offset, offset and size information. See **bind()**.

width `c_Int32 width() const;`

Returns the width of this window, in pixels.

height `c_Int32 height() const;`

Returns the height of this window, in rows.

size `ccIPair size() const;`

Returns a pair containing this window's width as the x component, and its height as the y component.

rowUpdate `c_Int32 rowUpdate() const;`

Returns the value, in pixels, to be added to a pixel pointer to move the pointer to the next row, staying in the same column.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

Notes

rowUpdate() will be different from the **width()** if the window does not span the width of the entire root image or if the root image is padded.

alignModulus `c_Int32 alignModulus() const;`

Returns the alignment modulus that was used when constructing this window's root image. See **ccPelRoot** on page 2391.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

root `cc_PelRoot* root() const;`

Returns a pointer to this window's root image.

Throws

ccPel::UnboundWindow
This window is not bound to any root image.

Notes

Do not cache the returned pointer.

disconnectRoot

```
cc_PelRoot* disconnectRoot();
```

Disconnects this window from its root image, causing the window to become unbound, but does not delete root image. Returns the disconnected root image.

sharesPels

```
bool sharesPels(const cc_PelBuffer& pelbuf) const;
```

Returns true if this window and *pelbuf* have same root image and if they have one or more pixels in common.

Parameters

pelbuf The window to compare with this window.

Notes

If this window or *pelbuf* are unbound, this function returns false. The offset has no effect on this operation.

subWindow

```
void subWindow(c_Int32 x, c_Int32 y, c_Int32 width,
  c_Int32 height);

void subWindow(const ccIPair& origin, const ccIPair& size);
```

- ```
  void subWindow(c_Int32 x, c_Int32 y, c_Int32 width,
    c_Int32 height);
  ```

Makes this window a subwindow of itself. *X* and *y* are added to the window's origin (the offset) before the change. The window's transform is not changed.

Parameters

x The amount to add to the x-coordinate of the window's offset.

y The amount to add to the y-coordinate of the window's offset.

width The new width of the window.

height The new height of the window.

Throws
  ```

ccPel::BadWindow
The new subwindow does not fit entirely within this window. This error is also raised if width or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

- `void subWindow(const ccIPair& origin, const ccIPair& size);`

Makes this window a subwindow of itself. *Origin* is relative to the window's origin (the offset) before the change. The window's transform is not changed.

Parameters

origin The x and y amounts to add to the window's current offset.

size The width (x component) and height (y component) of the subwindow.

Throws

ccPel::BadWindow
The new subwindow does not fit entirely within this window. This error is also raised if width or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

window

```
ccPelRect window() const;

bool window(c_Int32 x, c_Int32 y, c_Int32 width,
  c_Int32 height, bool clip=false);

bool window(const ccIPair& origin, const ccIPair& size,
  bool clip=false);

bool window(const ccPelRect& region, bool clip=false);
```

- `ccPelRect window() const;`

Returns the window's rectangle. The top, left coordinate of this rectangle is the window's offset. The size is the window's size.

- ```
  bool window(c_Int32 x, c_Int32 y, c_Int32 width,
    c_Int32 height, bool clip=false);
  ```

  Changes the location and dimensions of this window. *X* and *y* are given in the window's coordinate system, that is relative to the window's offset. Returns true if the window was clipped to fit the root image; false otherwise.

  If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

  Parameters

x	The new x-coordinate of the window's origin, in window coordinates.
y	The new y-coordinate of the window's origin, in window coordinates.
width	The new width of the window in pixels.
height	The new height of the window in rows.
clip	If true, the window is clipped to the extent of the root image.

  Throws

  ccPel::BadWindow
  The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

  ccPel::UnboundWindow
  This window is not bound to any root image.

- ```
  bool window(const ccIPair& origin, const ccIPair& size,
    bool clip=false);
  ```

  Changes the location and dimensions of this window. Returns true if the window was clipped to fit the root image; false otherwise.

  Origin is given in the window's coordinate system, that is relative to the window's offset. If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

  Parameters

origin	The new origin of the window in window coordinates.
size	The new size of the window.

clip If true, the window is clipped to the extent of the root image.

Throws

ccPel::BadWindow
The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

- `void window(const ccPelRect& region, bool clip=false);`

Changes the location and dimensions of this window. Returns true if the window was clipped to fit the root image; false otherwise.

Region is given in the window's coordinate system, that is relative to the window's offset. If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

Parameters

region A rectangle, in window coordinates, that describes the new location of the window.

clip If true, the window is clipped to the extent of the root image.

Throws

ccPel::BadWindow
The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

windowRoot

```
ccPelRect windowRoot() const;

bool windowRoot(c_Int32 x, c_Int32 y, c_Int32 width,
  c_Int32 height, bool clip=false);

bool windowRoot(const ccIPair& origin, const ccIPair& size,
  bool clip=false);

bool windowRoot(const ccPelRect& region, bool clip=false);
```

- `ccPelRect windowRoot() const;`

  Returns the window's position in the root image. This function returns a rectangle whose top, left coordinate is the window's root offset and whose size is the window's size.

- `bool windowRoot(c_Int32 x, c_Int32 y, c_Int32 width, c_Int32 height, bool clip=false);`

  Changes the location and dimensions of this window within the root image. Returns true if the window was clipped to fit the root image; false otherwise.

  X and *y* are given in the root image's coordinate system. The window's offset (its origin) is adjusted by the change in the root offset.

  If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

  Parameters

x	The new x-coordinate of the window's root offset, in root image coordinates.
y	The new y-coordinate of the window's root offset, in root image coordinates.
width	The new width of the window in pixels.
height	The new height of the window in rows.
clip	If true, the window is clipped to the extent of the root image.

  Throws

  ccPel::BadWindow

  The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

- `bool windowRoot(const ccIPair& origin, const ccIPair& size, bool clip=false);`

Changes the location and dimensions of this window within the root image. Returns true if the window was clipped to fit the root image; false otherwise.

Origin is given in the root image's coordinate system. The window's offset (its origin) is adjusted by the change in the root offset.

If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

Parameters

origin The new origin of the window in root image coordinates.

size The new size of the window.

clip If true, the window is clipped to the extent of the root image.

Throws

ccPel::BadWindow
The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

- `bool windowRoot(const ccPelRect& region, bool clip=false);`

Changes the location and dimensions of this window within the root image. Returns true if the window was clipped to fit the root image; false otherwise

Region is given in the root image's coordinate system. The window's offset (its origin) is adjusted by the change in the root offset.

If *clip* is true, the resulting window is clipped to root image, possibly resulting in a null window if the new location is entirely outside the root image. The window's transform is not changed.

Parameters

region A rectangle, in root image coordinates, that describes the new location of the window.

clip If true, the window is clipped to the extent of the root image.

Throws

ccPel::BadWindow
The requested window does not fit entirely within this window's root image, and clip is false. This error is also raised if width and/or height are negative.

ccPel::UnboundWindow
This window is not bound to any root image.

offsetRoot

```
ccIPair offsetRoot() const;
```

Returns the root offset of this window relative to its root image origin. The root offset is the distance from the top, left corner of the root image to the top, left corner of the window. The top, left coordinate of the root image is always (0,0).

offset

```
ccIPair offset() const;
void offset(c_Int32 left, c_Int32 top);
void offset(const ccIPair& origin);
```

- `ccIPair offset() const;`

Returns the window's offset, a pair that gives the image coordinates of this window's top, left corner. The offset allows you to provide an arbitrary coordinate system for the window independent of the root image's coordinates.

- `void offset(c_Int32 left, c_Int32 top);`

Sets the origin (the offset) of the window to *(left, top).* Note that this function changes the window's coordinate system and does not change the location of the window with respect to the root image. The window's transform is not changed.

Parameters

left The x-coordinate of the window's origin.

top The y-coordinate of the window's origin.

- `void offset(const ccIPair& origin);`

Sets the origin (the offset) of the window to *origin.* Note that this function changes the window's coordinate system and does not change the location of the window with respect to the root image. The window's transform is not changed.

Parameters

origin The coordinates of the window's origin.

copyXforms

```
void copyXforms(const cc_PelBuffer& win);
```

Sets this window's transformation object to be the same as another window's transformation object. This function is the most efficient way to make to windows (pel buffers) use the same transformation object.

Parameters

win The window that has the transformation object to copy.

clientFromImageXformBase

```
cc2XformBasePtrh_const clientFromImageXformBase() const;

void clientFromImageXformBase(
  const cc2XformBasePtrh_const& xform, bool copy = true);

void clientFromImageXformBase(const cc2XformBase& xform);
```

- `cc2XformBasePtrh_const clientFromImageXformBase() const;`

  Returns this window's transformation object such that it is suitable for transforming the window's image coordinates to the client's reference coordinates.

  Example

  To get the client coordinates of the center of the top, left pixel in this window, you would use the following:

  ```
  cc2Vect clientPt = (*clientFromImageXformBase()) *
                  cc2Vect(offset().x + 0.5), offset().y + 0.5);
  ```

  To transform an arbitrary location (x, y) in this window's image coordinates to client coordinates, you would use the following:

  ```
  cc2Vect clientPt = (*clientFromImageXformBase()) *
                      cc2Vect(x,y);
  ```

- ```
  void clientFromImageXformBase(
    const cc2XformBasePtrh_const& xform, bool copy = true);
  ```

  Sets this window's transformation object suitable for transforming the window's image coordinates to the client's reference coordinates. Setting a new transformation does not affect the window's offset.
  ```

Parameters

xform	A pointer handle to the transformation object.
copy	If true, this window is assigned a copy of *xform*. If false, this window is assigned a reference to *xform*.

Notes

If *copy* is false, you must ensure that *xform* will not change during this window's lifetime.

- `void clientFromImageXformBase(const cc2XformBase& xform);`

Sets this window's transformation object suitable for transforming the window's image coordinates to the client's reference coordinates. Setting a new transformation does not affect the window's offset.

Parameters

xform	A transformation object.

Notes

This setter always makes a copy of *xform*.

Both **imageFromClientXformBase()** and **clientFromImageXformBase()** setters set the same object. Use one or the other, but not both. The deprecated functions **imageFromClientXform()** and **clientFromImageXform()** setters also operate on the same object.

imageFromClientXformBase

```
cc2XformBasePtrh_const imageFromClientXformBase() const;

void imageFromClientXformBase(
  const cc2XformBasePtrh_const& xform, bool copy = true);

void imageFromClientXformBase(const cc2XformBase& xform);
```

- `cc2XformBasePtrh_const imageFromClientXformBase() const;`

Returns this window's transformation object suitable for transforming the client's reference coordinates to the window's image coordinates.

- ```
  void imageFromClientXformBase(
    const cc2XformBasePtrh_const& xform, bool copy = true);
  ```

  Sets this window's transformation object suitable for transforming the client's reference coordinates to the window's image coordinates. Setting a new transformation does not affect the window's offset.

  Parameters

  xform A pointer handle to the transformation object.

  copy If true, this window is assigned a copy of *xform*. If false, this window is assigned a reference to *xform*.

  Notes

  If *copy* is false, you must ensure that *xform* will not change during this window's lifetime.

- ```
  void imageFromClientXformBase(const cc2XformBase& xform);
  ```

  Sets this window's transformation object suitable for transforming the client's reference coordinates to the window's image coordinates. Setting a new transformation does not affect the window's offset.

  Parameters

  xform A transformation object.

  Notes

  This setter always makes a copy of *xform*.

  Both **imageFromClientXformBase()** and **clientFromImageXformBase()** setters set the same object. Use one or the other, but not both. The deprecated functions **imageFromClientXform()** and **clientFromImageXform()** setters also operate on the same object.

clientFromImageXform

```
cc2Xform clientFromImageXform() const;

void clientFromImageXform(const cc2Xform& xform);
```

- ```
  cc2Xform clientFromImageXform() const;
  ```

  Returns this window's 6-degree-of-freedom transformation object suitable for transforming the window's image coordinates to the client's reference coordinates.
  ```

Example

To get the client coordinates of the center of the top, left pixel in this window, you would use the following:

```
cc2Vect clientPt = clientFromImageXform() *
                   cc2Vect(offset().x + 0.5), offset().y + 0.5);
```

To transform an arbitrary location (x, y) in this window's image coordinates to client coordinates, you would use the following:

```
cc2Vect clientPt = clientFromImageXform() * cc2Vect(x,y);
```

- `void clientFromImageXform(const cc2Xform& xform);`

Sets this window's 6-degree-of-freedom transformation object suitable for transforming the window's image coordinates to the client's reference coordinates. Setting a new transformation does not affect the window's offset.

Parameters

xform The new transformation object for the window.

Notes

Both **imageFromClientXform()** and **clientFromImageXform()** setters, as well as the **imageFromClientXformBase()** and **clientFromImageXformBase()** setters, set the same object.

imageFromClientXform

```
cc2Xform imageFromClientXform() const;

void imageFromClientXform(const cc2Xform& xform);
```

- `cc2Xform imageFromClientXform() const;`

Returns this window's 6-degree-of-freedom transformation object suitable for transforming the client's reference coordinates to the window's image coordinates.

- `void imageFromClientXform(const cc2Xform& xform);`

Sets this window's 6-degree-of-freedom transformation object suitable for transforming the client's reference coordinates to the window's coordinates. Setting a new transformation does not affect the window's offset.

Parameters

xform The new transformation object for the window.

Notes

Both **imageFromClientXform()** and **clientFromImageXform()** setters, as well as the **imageFromClientXformBase()** and **clientFromImageXformBase()** setters, set the same object.

isEntire

```
bool isEntire() const;
```

Returns true if window encompasses the entire root image.

Notes

If this window is unbound, returns false.

setEntire

```
void setEntire();
```

Sets the window's offset (origin) and size to encompass the entire root image. The window's offset (origin) is modified appropriately.

Throws

ccPel::UnboundWindow

This window is not bound to any root image.

windowEntire

```
ccPelRect windowEntire() const;
```

Returns a rectangle object whose origin is the upper left corner of the window's root in image coordinates (offset) and whose size is the size of this window's root.

refc

```
c_Int32 refc() const;
```

Returns the number of windows (including this one) that reference the underlying root image.

cc_PelRoot

```
#include <ch_cvl/pelbuf.h>

class cc_PelRoot : public virtual ccPersistent, public ccRepbase,
  public ccRemoteObject;
```

Class Properties

Copyable	Yes
Derivable	Cognex-supplied classes only
Archiveable	Complex

This class should be considered part of class **ccPelRoot** (see **ccPelRoot** on page 2391). It describes type-independent attributes of root images.

Constructors/Destructors

The constructors for this class are protected. To create a root image, use class **ccPelRoot** instead.

Public Member Functions

width

```
c_Int32 width() const;
```

Returns the width of this root image in pixels. The result does not include any pad pixels.

height

```
c_Int32 height() const;
```

Returns the height of this root image, in rows.

rowUpdate

```
c_Int32 rowUpdate() const;
```

Returns the value, in pixels, to be added to a pixel pointer to move the pointer to the next row, staying in the same column.

Notes

The value returned by **rowUpdate()** may be different from the value returned by **width()** if the root image is padded. The number of pad pixels is **rowUpdate() – width()**.

alignModulus `c_Int32 alignModulus() const;`

Returns the alignment modulus value that was used when constructing this root image **ccPelRoot** on page 2391.

mutating `void mutating();`

Informs the persistence system that this root image's pixel values are about to change or have already changed.

release `void release();`

Mark this root image as no longer in use. Use this function instead of the **delete** operator when you are finished using an root image.

In order to reduce the overhead of creating root images, **cc_PelRoot** maintains a pool of preconstructed **cc_PelRoot** objects. Using the release function rather than the **delete** operator ensures that this root image returns to the pool. If this root image did not come from the pool (because you provided storage for the image), this function does delete this object.

cc_PMDefs

```
#include <ch_cvl/pmpbase.h>

class cc_PMDefs;
```

Note This is an abstract base class used to define enumerations and constants shared by all of the PatMax tools.

Enumerations

DOF `enum DOF`

This enumeration defines the degrees of freedom supported by PatMax.

Value	Meaning
kAngle = 1	Angle
kUniformScale = 2	Uniform scale
kXScale = 4	x-scale
kYScale = 8	y-scale

Algorithm `enum Algorithm`

This enumeration defines the algorithms supported by PatMax.

Value	Meaning
kPatquick = 1	Use the faster, less accurate PatQuick algorithm.
kPatmax = 2	Use the slower, more accurate PatMax algorithm.
kPatflex = 4	Use the PatFlex deformation algorithm.
kPatpersp = 16	Use the PatPersp deformation algorithm.

Refinement

`enum Refinement`

Algorithms for deformation refinement, used by PatFlex only.

Value	Meaning
kRefinementNone = 0	No refinement. There may be small errors in the transform's mapping.
kRefinementCoarse = 1	The transform will be refined to the accuracy limit of the coarse grain limit set for the pattern.
kRefinementMedium = 2	The transform will also be refined to resolve high-level deformation inaccuracies that can occur in some applications.
kRefinementFine = 3	The transform will be refined to the accuracy limit of the fine grain limit set for the pattern.

DeformationFit

`enum DeformationFit`

Transforms for deformation fitting, used by PatFlex only.

Value	Meaning
kFitNone = 0	No transform is computed.
kFitDeformation = 1	Computes a deformation transform. See **cc2XformDeform**.
kFitPerspective = 2	The computed transform includes perspective deformation correction. See **cc2XformPerspective**.

SensitivityMode

`enum SensitivityMode`

This enumeration defines the PatMax/PatQuick sensitivity modes.

Value	Meaning
kSensitivityModeStandard = 1	Normal PatMax/PatQuick mode.
kSensitivityModeHigh = 2	High sensitivity mode.

SaveMatchInfoMode

```
enum SaveMatchInfoMode
```

This enumeration defines the match information saving modes for PatMax.

Value	Meaning
kSaveMatchInfoModeNone = 0x0	No match information is saved.
kSaveMatchInfoModeClassic = 0x1	Match information about the pattern features is saved to allow display only, via **cc_PMResult::displayMatch()**. Match information is not persisted with the result.
kSaveMatchInfoModePattern = 0x2	Match information about the pattern features is saved to allow display via **cc_PMResult::displayMatch()** and also to allow direct access via **cc_PMResult::matchInfo()**. Match information is persisted with the result.
kSaveMatchInfoModeImage = 0x4	Match information about the run-time image features is saved to allow display and direct access via **cc_PMResult::matchInfo()**. Match information is persisted with the result.

Constants

The following constants provide default values for certain training-time and run-time parameters:

Value	Meaning
kDefaultNumToFind = 1	An integer specifying the default number of pattern instances to find.
kDefaultAcceptThresholdTimes1000 = 500	An integer specifying the default acceptance threshold times 1000.
kDefaultContrastThresholdTimes1000 = 10000	An integer specifying the default contrast threshold times 1000.
kDefaultZonesEnabled = 0	An integer specifying the default zones enabled.

Value	Meaning
kDefaultAngleNominal = 0	An integer specifying containing the default nominal angle value.
kDefaultUniformScaleNominal = 1	An integer specifying containing the default nominal uniform scale value.
kDefaultXScaleNominal = 1	An integer specifying containing the default nominal X scale value.
kDefaultYScaleNominal = 1	An integer specifying containing the default nominal Y scale value.
kDefaultXYOverlapTimes1000 = 800	An integer specifying the default area overlap threshold times 1000.
kDefaultUseClutter = 1	An integer specifying the default value for whether or not to consider clutter when scoring pattern instances.

cc_PMInspectFeature

```
#include <ch_cvl/bndpnts.h>

template <class BoundaryPoint>class cc_PMInspectFeature;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A base class for describing PatInspect features.

Note You should not instantiate this class directly.

Constructors/Destructors

cc_PMInspectFeature

```
cc_PMInspectFeature();

virtual ~cc_PMInspectFeature();
```

- `cc_PMInspectFeature();`

  Constructs a **cc_PMInspectFeature**.

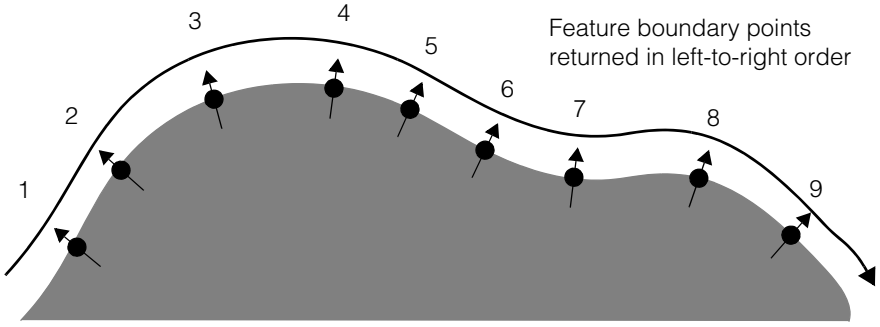
- `virtual ~cc_PMInspectFeature();`

  Destroys a **cc_PMInspectFeature**.

Public Member Functions

boundaryPoints `const cmStd vector<BoundaryPoint>& boundaryPoints() const;`

Return a vector of feature boundary points which specify the feature. The points are returned in left-to-right order based on the gradient direction, as shown in the following figure:



matchQuality `double matchQuality() const;`

Return the mean match quality for all the feature boundary points in this feature.

weight `double weight() const;`

Return mean weight for all the feature boundary points in this feature.

isClosed `bool isClosed() const;`

Returns true if this feature is closed, false if it is open.

cc_PMPattern

```
#include <ch_cvl/pmpbase.h>

class cc_PMPattern;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single trained PatMax pattern. This class includes functions to set the training parameters and a function to search for the pattern in a search image.

This is an abstract class used to define functions shared by all of the PatMax pattern classes. Do not instantiate this class directly.

Public Member Functions

trainClientFromPattern

```
cc2Xform trainClientFromPattern() const;

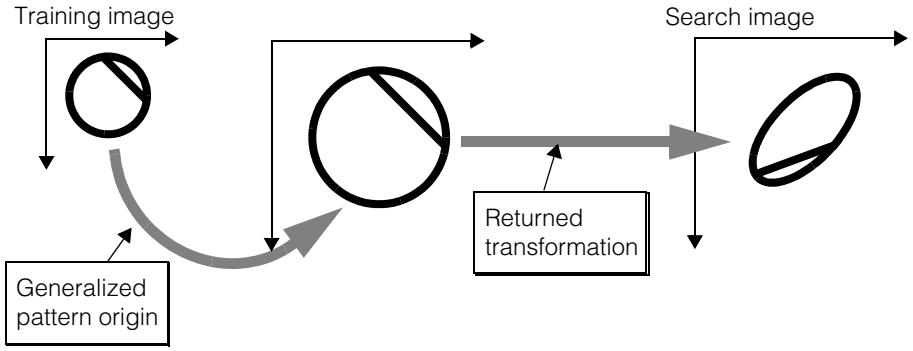
virtual void trainClientFromPattern(
  const cc2Xform& genOrigin);
```

- `cc2Xform trainClientFromPattern() const;`

  Retrieves the mapping from pattern coordinates to training image client coordinates.

- `virtual void trainClientFromPattern(`
  `const cc2Xform& genOrigin);`

Sets the mapping from pattern coordinates to training image client coordinates.:



Parameters

transform The new mapping from pattern coordinates to training image client coordinates. The default is the identity transform.

Notes

Pattern coordinates are a client-controlled coordinate system that specifies how PatMax should match the pattern to an image and report result poses. A result pose is a mapping from pattern coordinates to run-time client coordinates. Likewise, the generalized degrees of freedom (DOFs) define the search range as a mapping from pattern coordinates to run-time client coordinates. Pattern coordinates may be set in all six degrees of freedom, and can be set and changed at will before and after training. Pattern coordinates include the pattern's origin as its translation component. Setting the pattern coordinates with this member always sets the origin.

Training never modifies the pattern coordinates, which are relative to the client coordinates established by the most recent training, if any has taken place.

---

origin

```
cc2Vect origin() const;

virtual void origin(const cc2Vect& theOrigin);
```

- `cc2Vect origin() const;`

Retrieves the pattern origin in the client coordinate system of the training image. The origin is the translation component of the pattern coordinate system (see **trainClientFromPattern()**). The origin is a point that is attached to the pattern, but may reside outside of the pattern. When PatMax finds an instance of the pattern, the position of the origin in the search image defines the result location.

- `virtual void origin(const cc2Vect& theOrigin);`

Sets the pattern origin. *theOrigin* must be specified in the client coordinate system of the pattern training image. PatMax returns the location of patterns in search images in terms of the location of the pattern origin in the search image client coordinate system.

Parameters

theOrigin The origin. The origin can be located outside the pattern training image. The default origin is (0,0).

Notes

Calling **trainClientFromPattern()** changes the origin. Setting the origin changes the translation component of the generalized pattern origin, but not any of the geometric components (for example, the matrix portion of the transform).

The origin can be read or written for either trained or untrained patterns. Changing the origin does not require the pattern to be retrained.

Setting the origin affects the location of the result as well as the pose.

ignorePolarity

```
virtual bool ignorePolarity() const;
virtual void ignorePolarity(bool thePolarity);
```

- `virtual bool ignorePolarity() const;`

Returns the state of the *ignorePolarity* flag.

- `virtual void ignorePolarity(bool thePolarity);`

Specifies whether PatMax should consider the polarity of features to be significant.

Parameters

thePolarity If true, PatMax will ignore polarity of features. If *false* (the default), only patterns whose features have matching polarity are found.

Notes

If this pattern is currently trained, its state is updated immediately.

elasticity

```
double elasticity() const;
void elasticity(double e);
```

- `double elasticity() const;`

Returns this **cc_PMPattern**'s elasticity value.

- `void elasticity(double e);`

  Sets this **cc_PMPattern**'s elasticity value. The elasticity value is the amount of feature variance, in pixels, that the tool allows.

  Setting a nonzero elasticity value permits the tool to find pattern instances with nonlinear geometric variation to be found.

  Parameters

  e The elasticity value in pixels.

  Throws

  cc_PMDefs::BadParams

  e is less than 0.

  Notes

  If this pattern is currently trained, its state is updated immediately.

autoSelectGrainLimits

```
bool autoSelectGrainLimits() const;

void autoSelectGrainLimits(bool autoSelect);
```

- `bool autoSelectGrainLimits() const;`

  Returns whether or not this **cc_PMPattern** is configured to automatically select coarse and fine granularity limits for feature detection.

- `void autoSelectGrainLimits(bool autoSelect);`

  Controls whether or not this **cc_PMPattern** automatic selects coarse and fine granularity limits for feature detection at training time.

  Parameters

  autoSelect If true, PatMax selects the granularity limits automatically. If false, PatMax uses the granularity limits you specify by calling **grainLimits()**.

  Notes

  The default is true. Enabling automatic selection generally doubles training time.

coarseGrainLimit

```
float coarseGrainLimit() const;
```

Returns the coarse granularity limit for feature detection. The default is 4.0.

fineGrainLimit `float fineGrainLimit() const;`

Returns the fine granularity limit for feature detection. The default is 1.0.

grainLimits `void grainLimits(float coarse, float fine);`

Sets the coarse and fine granularity limits used for feature detection during pattern training.

The automatically set values are appropriate for almost all applications. For information on granularity limits, see the *CVL Vision Tools Guide*.

Parameters

coarse The coarse granularity limit.

fine The fine granularity limit.

Throws

cc_PMDefs::BadParams
Either *coarse* or *fine* is less than 1.0 or greater than 25.5 or *coarse* is less than *fine*.

Notes

If you call this function after training a pattern, the limits you specify will be used for feature detection in the run-time image.

customize `ccCvlString customize(const ccCvlString& pcp);`

Loads the supplied PatMax Customization Pack (PCP). A PCP is a non-human-readable string which contains object code fragments and configuration data.

Loading a PCP only affects the object into which it is loaded, and only a single PCP can be active for a given object at a given time. Call **train()** after loading a PCP.

This function returns a string containing encrypted diagnostic information for use by Cognex.

Parameters

pcp The PCP to load. If *pcp* is NULL, all internal parameters are reset to their default values.

customizeFromFile

```
ccCvlString customizeFromFile(
  const ccCvlString& filename);
```

Loads the supplied PatMax Customization Pack (PCP) file. A PCP is a non-human-readable string which contains object code fragments and configuration data.

Loading a PCP only affects the object into which it is loaded, and only a single PCP can be active for a given object at a given time. Call **train()** after loading a PCP.

This function returns a string containing encrypted diagnostic information for use by Cognex.

Parameters

filename The PCP file to load. If *pcp* is NULL, all internal parameters are reset to their default values.

customizeString

```
ccCvlString customizeString() const;
```

Returns the last customization string set by either **customize()** or **customizeFromFile()**. If neither has been called, this function returns an empty string.

isTrained

```
bool isTrained() const;
```

Returns true if this **cc_PMPattern** is currently trained, *false* otherwise.

algorithms

```
c_UInt32 algorithms() const;
```

Returns a **c_UInt32** formed by ORing together all the algorithms for which this **cc_PMPattern** is trained. The returned value is formed by ORing together one or more of the following values:

cc_PMDefs::kPatquick
cc_PMDefs::kPatmax
cc_PMDefs::kPatflex
cc_PMDefs::kPatpersp

Scope the enumerations for the algorithm using the appropriate name space class such as **cc_PMDefs**.

Throws

cc_PMDefs::NotTrained
If this pattern is not trained for any algorithms.

trainClientFromImage

```
const cc2XformBasePtrh_const trainClientFromImage() const;
```

Returns the client from image transform with which this pattern was trained.

Throws

cc_PMDefs::NotTrained
This pattern is not trained.

---

sensitivityMode

```
cc_PMDefs::SensitivityMode sensitivityMode() const;

void sensitivityMode(cc_PMDefs::SensitivityMode);
```

Controls the sensitivity mode used by PatQuick and PatMax. The sensitivity mode can be either *standard*, or *high*. High sensitivity mode is designed to improve PatQuick and PatMax performance for noisy images and/or patterns with extremely low contrast. PatQuick and PatMax will run slower in high sensitivity mode than in standard sensitivity mode. The default is *cc_PMDefs::kSensitivityModeStandard*.

When using high sensitivity mode, you can control the sensitivity with the sensitivity parameter. See **sensitivityParameter()** below.

Sensitivity mode is added in CVL 6.2. *Standard* sensitivity mode corresponds to PatQuick/PatMax behavior in releases prior to CVL 6.2.

Notes

ccPMInspectPattern derives from **cc_PMPattern** so the sensitivity mode is available to PatInspect as well. However, high sensitivity mode was not designed for use with PatInspect and is not considered useful for that application. Therefore, when using PatInspect always use the default, *cc_PMDefs::kSensitivityModeStandard*.

- `cc_PMDefs::SensitivityMode sensitivityMode() const;`

  Returns the current sensitivity mode.

- `void sensitivityMode(cc_PMDefs::SensitivityMode mode);`

  Sets the sensitivity mode. You should retrain the pattern if the sensitivity mode is changed.

  Parameters

  mode The new sensitivity mode.

  Throws

  cc_PMDefs::BadParams
  If *mode* is not one of the **cc_PMDefs::SensitivityMode** enums.

sensitivityParameter

```
float sensitivityParameter() const;

void sensitivityParameter(float sensitivityParameter);
```

Controls the sensitivity parameter used by PatQuick and PatMax when running in high sensitivity mode. See **sensitivityMode()** above.

The sensitivity parameter must be in the range 1.0 through 10.0. When set to 1.0 PatMax and PatQuick use minimum noise rejection. When set to 10.0 PatMax and PatQuick use maximum noise rejection. Usually the default value 2.0 produces optimal results.

Notes

This is an advanced parameter and should usually be left set to its default value. Before changing **sensitivityParameter** see the *PatMax* chapter of the *Vision Tools Guide* for more information.

- `float sensitivityParameter() const;`

Returns the current sensitivity parameter.

- `void sensitivityParameter(float sensitivityParameter);`

Sets the sensitivity parameter. You should retrain the pattern if you change the sensitivity parameter.

Parameters

sensitivityParameter

The new sensitivity parameter.

Throws

cc_PMDefs::BadParams

If *sensitivityParameter* is outside the range 1.0 through 10.0.

displayFeatures

```
void displayFeatures(ccGraphicList& graphList,
  bool fineGrain, const ccColor& c=ccColor::green)
  const;
```

Draws a feature diagnostic display in the specified color in the supplied **ccGraphicList**. Each feature boundary point detected by PatMax is drawn as a line segment. The line segment is drawn through the center of the feature boundary point and normal to the direction of the feature boundary point.

You can specify that the features detected at the coarsest or finest granularity be drawn.

Parameters

graphList	The graphic list used to draw the feature display.
fineGrain	If true, the features detected at the fine granularity limit are drawn. If false, the features detected at the coarse granularity limit are drawn.
color	The color in which features are drawn. The default is green.

Notes

If this pattern is not trained, no features are drawn.

infoStrings

```
cmStd vector<ccCvlString> infoStrings() const;
```

Returns a vector of training-time diagnostic message strings. For additional information about the diagnostic messages, see the *CVL Vision Tools Guide*.

infoIds

```
cmStd vector<c_UInt32> infoIds() const;
```

Returns a vector of training-time diagnostic message IDs. For a list and description of the diagnostic message IDs, see the *CVL Vision Tools Guide*.

trainTime

```
double trainTime() const;
```

Returns the number of seconds it took to train the pattern.

isAdvancedTrained

```
bool isAdvancedTrained() const;
```

Returns true if this pattern was trained with **ccPMAlignPattern::trainAdvanced()**, false if it was trained using the standard training method (**train()**).

useTrainEdgeThreshold

```
bool useTrainEdgeThreshold() const;

void useTrainEdgeThreshold(bool useTrainEdgeThreshold);
```

- `bool useTrainEdgeThreshold() const;`

  Returns true if PatMax only considers image features with strength above **trainEdgeThreshold()** when training this pattern, false otherwise.

- `void useTrainEdgeThreshold(bool useTrainEdgeThreshold);`

  Sets whether or not to use the edge threshold defined by **trainEdgeThreshold()** when training this pattern. If set to true, the direction of edges with strength less than the threshold are not considered during pattern training. If false, PatMax's dynamically computed edge threshold is used.

  The default value is false.

  Parameters

  useTrainEdgeThreshold

  true to use the **trainEdgeThreshold()** value, false to use the dynamically computed value.

  Notes

  The **trainEdgeThreshold()** value is only used during training. A separate run-time edge threshold, **cc_PMRunParams::edgeThreshold()**, is available.

  trainEdgeThreshold() is an advanced parameter. In most cases, the dynamically computed threshold should be used.

trainEdgeThreshold

```
double trainEdgeThreshold() const;

void trainEdgeThreshold(double trainEdgeThreshold);
```

- `double trainEdgeThreshold() const;`

  Returns the user-selected training edge threshold.

  Notes

  This function does not return PatMax's internally computed threshold, regardless of the value of **useTrainEdgeThreshold()**.

- `void trainEdgeThreshold(double trainEdgeThreshold);`

  If **useTrainEdgeThreshold()** is true, then the value you supply for this function is used during training-time feature extraction. The orientation of image edges with a strength (defined as the difference in grey-level values across the edge) are randomized. If false, PatMax's dynamically computed training edge threshold is used.

  The supplied value must be in the range from 0.0 through 255.0.

  The default value is 10.0.

Parameters

trainEdgeThreshold

The training edge threshold.

Throws

cc_PMDefs::BadParams

edgeThreshold is less than 0.0 or greater than 255.0.

Notes

The **trainEdgeThreshold()** value is only used during training. A separate run-time edge threshold, **cc_PMRunParams::edgeThreshold()**, is available.

trainEdgeThreshold() is an advanced parameter. In most cases, the dynamically computed threshold should be used.

expectedDeformationRate

```
double expectedDeformationRate() const;

void expectedDeformationRate(double e);
```

An estimated pattern deformation rate used with the PatFlex algorithm.

The default is 0.3.

Notes

The expected deformation rate has no effect unless the PatMax algorithm is *kPatflex*. It has no effect on normal PatMax patterns.

If this pattern is currently trained, changing this value will have no effect unless the pattern is retrained.

- `double expectedDeformationRate() const;`

Returns the expected deformation rate.

- `void expectedDeformationRate(double e);`

Sets the expected deformation rate.

Parameters

e The new expected deformation rate.

Throws

cc_PMDefs::BadParams

If $e < 0$, or $e > 1.0$.

id

```
c_Int32 id() const;
```

Returns an identifier used by Multi-Model classes **ccPMMultiModel** and **ccPMMultiModelResultSet** to identify individual PatMax models.

Notes

If the model is not a component of a Multi-Model, then the id will be zero.

Deprecated Members

The following method was deprecated as of CVL 5.5.1.

displayFeatures

```
void displayFeatures(ccUITablet& tablet, bool fineGrain,
  const ccColor& c=ccColor::green) const;
```

Use the overload that takes a **ccGraphicList** reference as the first argument for new development.

cc_PMResult

```
#include <ch_cvl/pmpbase.h>

class cc_PMResult;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single PatMax search result.

Note This is an abstract class used to define functions shared by all of the PatMax result classes. You should not instantiate this class directly.

Constructors/Destructors

cc_PMResult

```
cc_PMResult();
```

Constructs a **cc_PMResult** containing no meaningful information.

Public Member Functions

location

```
cc2Vect location() const;
```

For this result, returns the location of the pattern origin in the client coordinate system of the search image.

pose

```
const cc2Xform& pose() const;
```

For this result, returns a **cc2Xform** that transforms points in the client coordinate system (offset by any pattern origin) of the pattern training image to the client coordinate system of the search image. You can use this **cc2Xform** to determine the location of any point in the trained pattern in the search image.

If PatMax is run with PatFlex or PatPersp, it returns a linear transform that is the best approximation over the pattern area.

angle

```
ccDegree angle() const;
```

For this result, returns the angle from the x-axis of the search image client coordinate system to the x-axis of the training image client coordinate system (offset by any pattern origin).

xScale

```
double xScale() const;
```

For this result, returns the x-axis scale difference between the trained pattern and the pattern found in the search image.

yScale

```
double yScale() const;
```

For this result, returns the y-axis scale difference between the trained pattern and the pattern found in the search image.

score

```
double score() const;
```

Returns the score that this result received. The score is between 0.0 and 1.0 with higher values indicating a closer match between the trained pattern and the pattern in the search image.

contrast

```
double contrast() const;
```

Returns the contrast score that this result received. The contrast score is the average difference in grey-level values for all of the pattern features that PatMax matched between the trained pattern and this result.

fitError

```
double fitError() const;
```

Returns a **double** that indicates the degree to which the pattern in the search image conforms to the contour of the trained pattern. The value returned by this function ranges from 0.0, which indicates a perfect fit, to infinity, which indicates a poor fit.

The value returned by **fitError()** does not consider the degree to which parts of the pattern are missing, only the closeness of fit.

Notes

Returns -1 if fit error is not available.

coverage

```
double coverage() const;
```

Returns the coverage score that this result received. The coverage score is the percentage of features in the trained pattern that are also present in this result. The value returned by this function ranges from 0.0 to 1.0.

Notes

Returns -1 if coverage is not available.

clutter

```
double clutter() const;
```

Returns the clutter score that this result received. The clutter score is the number of extraneous features present in this result divided by the number of features in the trained pattern. The value returned by this function ranges from 0.0 to infinity.

Notes

Returns -1 if clutter score is not available.

outsideRegionFeatureProportion

```
double outsideRegionFeatureProportion() const;
```

outsideRegionAreaProportion

```
double outsideRegionAreaProportion() const;
```

Returns useful information when you have used **cc_PMRunParams::outsideRegionThreshold()**. Function **outsideRegionFeatureProportion()** specifies what proportion of the pattern's features fall outside the runtime search region. Function **outsideRegionAreaProportion()** specifies what proportion of the pattern's area falls outside the runtime search region, where area is the rectangular training region mapped by the found pose.

Notes

If **cc_PMRunParams::outsideRegionThreshold()** is not used, then both values return exactly 0.0

Outside region measures are available for PatMax only. The returned values are –1.0 if outside region measures are not available, for example, when the specified algorithm is *kPatflex*.

accepted

```
bool accepted() const;
```

Returns true if the score received by this result is greater than or equal to the score threshold specified for this search.

matchRegion

```
ccAffineRectangle matchRegion() const;
```

Returns a **ccAffineRectangle** which describes the location of the matched pattern in the run-time image's client coordinate system.

imageRegion `ccPelRect imageRegion() const;`

Returns the smallest rectangle in the run-time image's image coordinate system which completely contains the matched pattern.

imageFromClientAtCenter
`const cc2Xform& imageFromClientAtCenter() const;`

Returns a **cc2Xform** that describes the transformation from the client coordinates of the run-time image used to produce this result to the image coordinates of the same image, at the center point of this result.

If the client coordinates of the image are linear, this transformation will be identical for all results and will simply be the image's client coordinates. If the client coordinates of the image are nonlinear, the transformation will represent the linearization of these coordinates at the center of this pattern instance.

isFineStage `bool isFineStage() const;`

Returns true if the final result (pose, score, etc.) came from the fine stage of processing;. Returns false if the final result came from the coarse stage of processing. If there was only one processing stage performed, this function returns true.

Usually, results do come from the fine stage which is more accurate. However, under some circumstances PatMax will decide that the coarse stage result is actually the more reliable and will return the coarse result as the final result.

Notes

Results stored under older releases that did not contain this information will have **isFineStage**() set to true when loaded.

coarseStageResult
`const cc_PMStageResult& coarseStageResult() const;`

fineStageResult `const cc_PMStageResult& fineStageResult() const;`

Returns the coarse or fine stage result. The fine stage result is the final stage of alignment and is typically the most accurate, and the coarse stage result is from a coarser and typically less accurate stage of alignment. If only one stage of processing was performed, both of these results will be the same.

infoStrings

```
cmStd vector<ccCvlString> infoStrings() const;
```

Returns a vector of search-time diagnostic message strings for this individual search result. For additional information about the diagnostic messages, see the *Vision Tool Guide*.

If no diagnostic information is available, the function returns a vector with a size of 0.

infoIds

```
cmStd vector<c_UInt32> infoIds() const;
```

Returns a vector of search-time diagnostic message IDs for this individual search result. For a list and description of the diagnostic message IDs, see the *Vision Tool Guide*.

If no diagnostic information is available, the function returns a vector with a size of 0.

displayMatch

```
void displayMatch(ccUITablet& tablet) const;

void displayMatch(ccGraphicList& graphList) const;
```

Creates a graphic display of the pattern features matched in this PatMax/Align search result. In the resulting display, features drawn in red indicate poor matches (corresponding to a coverage score of less than 0.20), features drawn in yellow indicate fair matches (corresponding to a coverage score from 0.20 to 0.67)), and features drawn in green indicate good matches (corresponding to a coverage score from 0.67 to 1.0).

Notes

This function only produces a graphic display if the search that produces the result is performed using the *ccPMAlignDefs::kPatmax* algorithm and the run-time parameters used for the search are configured to generate and save match information.

For example, you configure a **ccPMAlignRunParams** to generate and save match information by calling **ccPMAlignRunParams::saveMatchInfo()** with an argument of true.

Match information is not saved when you archive a **ccPMAlignResult**.

If match info is unavailable, because the PatQuick algorithm was run, **saveMatchInfoModes()** is *kSaveMatchInfoModeNone*, or the result was restored from an archive, this call will do nothing.

If you are running the PatFlex algorithm, the refinement mode must be set to *kRefinementFine* for this method to have an effect.

- `void displayMatch(ccUITablet& tablet) const;`

  Creates a graphic display in a **ccUITablet** object.

  Parameters

  tablet The tablet where the display is created.

- `void displayMatch(ccGraphicList& graphList) const;`

  Creates a graphics display using a **ccGraphicList** object.

  Parameters

  graphList The display in graphics list format.

saveMatchInfoModes

```
c_UInt32 saveMatchInfoModes() const;
```

Returns the types of match data available, as a bitwise-OR of values from **cc_PMDefs::SaveMatchInfoMode**.

matchInfo

```
const ccPMMatchInfo& matchInfo() const;
```

Returns data about how the pattern features matched the run-time image and/or how the run-time image features matched the pattern.

Notes

If the match data is unavailable, an empty object is returned.

flexResult

```
const ccPMFlexResult &flexResult() const;
```

Returns the PatFlex result object. If the algorithm run was not *kPatflex*, there is no PatFlex result and this function returns a default-constructed **ccPMFlexResult** object.

modelId

```
c_Int32 modelId() const;
```

Returns an identifier used by Multi-Model classes **ccPMMultiModel** and **ccPMMultiModelResultSet** to identify individual PatMax models. The id returned here identifies the model that generated this result.

Notes

If the model used to generate this result is not a component of a Multi-Model, then the id will be zero.

perspectiveResult

```
const ccPMPerspectiveResult &perspectiveResult() const;
```

Returns the PatPersp result object. If the algorithm run was not *kPatpersp*, this result will be default constructed.

maxCoarseAcceptThreshold

```
double maxCoarseAcceptThreshold()const;
```

Returns the maximum coarse accept threshold that would allow this result to be found. This is intended as a guide to setting **cc_PMRunParams::coarseAcceptFrac()**.

Deprecated Members

startPose

```
const cc2Xform& startPose() const;
```

Returns the identity transform. This function is deprecated and is maintained for backward compatibility only.

cc_PMResult

cc_PMRunParams

```
#include <ch_cvl/pmpbase.h>

class cc_PMRunParams;
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains the run-time parameters used to control a PatMax search.

Note This is an abstract base class used to define functions shared by all of the PatMax run-time parameter classes. Do not instantiate this class directly.

Constructors/Destructors

cc_PMRunParams

```
cc_PMRunParams();
```

Constructs a **cc_PMRunParams** using the default values.

Public Member Functions

acceptThreshold

```
double acceptThreshold() const;

void acceptThreshold(double a);
```

- `double acceptThreshold() const;`

  Returns the threshold score configured for this **cc_PMRunParams**.

- `void acceptThreshold(double a);`

  Sets the threshold score for this **cc_PMRunParams**. Only instances of the pattern that receive scores greater than or equal to *thresh* are marked as accepted. Increasing the value of *thresh* reduces the time required to perform a search.

Parameters

a The threshold. Must be in the range 0.0 through 1.0. The default value is 0.5.

Throws

cc_PMDefs::BadParams

a is less than 0.0 or greater than 1.0.

useCoarseAcceptFrac

```
bool useCoarseAcceptFrac() const;

void useCoarseAcceptFrac(bool useCoarseAcceptFrac);
```

- `bool useCoarseAcceptFrac() const;`

  Returns true if **coarseAcceptFrac()** is used to screen coarse results, false otherwise.

- `void useCoarseAcceptFrac(bool useCoarseAcceptFrac);`

  Sets whether or not to use the coarse accept threshold fraction value specified for **coarseAcceptFrac()**. If true, coarse candidates will be screened using the specified fraction of the **acceptThreshold()** value. If false, the internally computed value is used.

  Parameters

  useCoarseAcceptFrac

  true to use the **coarseAcceptFrac()** value, false to use the internal value.

coarseAcceptFrac

```
double coarseAcceptFrac() const;

void coarseAcceptFrac(double coarseAcceptFrac);
```

- `double coarseAcceptFrac() const;`

  Returns the current coarse accept threshold fraction value. If **useCoarseAcceptFrac()** is true, then this value is used as the accept threshold during the coarse search.

- `void coarseAcceptFrac(double coarseAcceptFrac);`

  Sets the current coarse accept threshold fraction value. If **useCoarseAcceptFrac()** is true, then this value is used as the accept threshold during the coarse search.

  Setting this value allows you to control the behavior of PatMax when it searches using coarse granularity. Reducing this value will exclude more potential matches, speeding up PatMax. Increasing this value forces PatMax to consider more candidates, slowing the search but ensuring that valid candidates are not discarded.

  The default is 0.66.

  Parameters

  coarseAcceptFrac
  The coarse accept threshold fraction.

  Throws

  cc_PMDefs::BadParams
  coarseAcceptFrac is less than 0 or greater than 1.

contrastThreshold

```
double contrastThreshold() const;

void contrastThreshold(double contrast);
```

- `double contrastThreshold() const;`

  Returns the contrast threshold of this **cc_PMRunParams**.

- `void contrastThreshold(double contrast);`

  Sets the contrast threshold of this **cc_PMRunParams**. Only pattern instances where the average difference in pixel values across all feature boundaries exceeds the contrast threshold are considered by PatMax. The default contrast is 10.

  Parameters

  contrast The contrast threshold. If you specify 0 for *contrast*, PatMax considers *all* pattern instances.

  Throws

  cc_PMDefs::BadParams
  contrast is less than 0.

useEdgeThreshold

```
bool useEdgeThreshold() const;

void useEdgeThreshold(bool useEdgeThreshold);
```

- `bool useEdgeThreshold() const;`

  Returns true if PatMax only considers image features with strength above **edgeThreshold()**, false otherwise.

- `void useEdgeThreshold(bool useEdgeThreshold);`

  Sets whether or not to use the edge threshold defined by **edgeThreshold()** when extracting features. If set to true, the direction of edges with strength less than the threshold are randomized. If false, PatMax's dynamically computed edge threshold is used.

  The default value is false.

  Parameters

  useEdgeThreshold

  true to use the **edgeThreshold()** value, false to use the dynamically computed value.

  Notes

  The edge threshold determines which edges are considered during feature detection. The contrast threshold, as controlled by contrastThreshold(), determines whether a particular *result* is discarded or kept, based on the average contrast of all of the features in the result.

  This is an advanced parameter. In most cases, the default value should be used.

edgeThreshold

```
double edgeThreshold() const;

void edgeThreshold(double edgeThreshold);
```

- `double edgeThreshold() const;`

  Returns the user-selected edge threshold.

  Notes

  This function does not return PatMax's internally computed threshold, regardless of the value of **useEdgeThreshold()**.

- `void edgeThreshold(double edgeThreshold);`

  If **useEdgeThreshold()** is true, then the value you supply for this function is used during feature extraction. The orientation of image edges with a strength (defined as the difference in grey-level values across the edge) are randomized. If false, PatMax's dynamically computed edge threshold is used.

  The supplied value must be in the range from 0.0 through 255.0.

  The default value is 5.0.

  Parameters

  edgeThreshold The edge threshold.

  Throws

  cc_PMDefs::BadParams

  edgeThreshold is less than 0.0 or greater than 255.0.

  Notes

  The edge threshold determines which edges are considered during feature detection. The contrast threshold, as controlled by contrastThreshold(), determines whether a particular *result* is discarded or kept, based on the average contrast of all of the features in the result.

  This is an advanced parameter. In most cases, the default value should be used.

scoreUsingClutter

```
bool scoreUsingClutter() const;

void scoreUsingClutter(bool useClutter);
```

- `bool scoreUsingClutter() const;`

  Returns whether or not this **cc_PMRunParams** considers extraneous features (clutter) when computing the score of a pattern instance. If the function returns true, extraneous features are considered; if it returns false, extraneous features are ignored.

- `void scoreUsingClutter(bool useClutter);`

  Sets whether or not this **cc_PMRunParams** considers extraneous features (clutter) when computing the score of a pattern instance.

  The default is to consider clutter when computing the score of a pattern instance.

Parameters

useClutter True (the default) tells PatMax to consider extraneous features when scoring a pattern instance. False tells PatMax to ignore extraneous features when scoring a pattern instance.

numToFind

```
c_Int32 numToFind() const;
void numToFind(c_Int32 count);
```

- `c_Int32 numToFind() const;`

  Returns the number of results to search for.

- `void numToFind(c_Int32 n);`

  Sets the number of results to search for. In some cases, PatMax may return more or fewer results than you request. This function returns one result by default.

  Parameters

  n The number of results. The default is one.

  Throws

  cc_PMDefs::BadParams
  count is less than one.

zoneEnable

```
c_UInt32 zoneEnable() const;
void zoneEnable(c_UInt32 enable);
```

- `c_UInt32 zoneEnable() const;`

  Returns a **c_UInt32** that indicates which degrees of freedom are enabled in this **cc_PMRunParams**. The value returned by this function is either 0 or a value formed by ORing together one or more of the following values:

  cc_PMDefs::kAngle
  cc_PMDefs::kUniformScale
  cc_PMDefs::kXScale
  cc_PMDefs::kYScale

- `void zoneEnable(c_UInt32 enable);`

  Sets which degrees of freedom are included in the search space defined by this **cc_PMRunParams**. For each specified degree of freedom, PatMax will search for instances of the pattern with values between the low zone limit and high zone limit.

  For each degree of freedom that is *not* specified, PatMax only searches for instances of the pattern with the specified nominal value for that degree of freedom, and PatMax only returns the nominal value for the degree of freedom.

  By default, no degrees of freedom are enabled.

  Parameters

  enable — A value formed by bit-wise ORing together 0 or more of the following values:

  cc_PMDefs::kAngle
  cc_PMDefs::kUniformScale
  cc_PMDefs::kXScale
  cc_PMDefs::kYScale

  Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

  Throws

  cc_PMDefs::BadParams

  enable is neither 0 nor a value formed by bit-wise ORing together the values defined in **cc_PMDefs::DOF**.

---

nominal

```
double nominal(cc_PMDefs::DOF dof) const;

void nominal(cc_PMDefs::DOF dof, double val);
```

- `double nominal(cc_PMDefs::DOF dof) const;`

  Returns the nominal value for the specified degree of freedom.

  Parameters

  dof — The degree of freedom; *dof* must be one of the following values:

  cc_PMDefs::kAngle
  cc_PMDefs::kUniformScale
  cc_PMDefs::kXScale
  cc_PMDefs::kYScale

- `void nominal(cc_PMDefs::DOF dof, double val);`

  Sets the nominal value for the specified degree of freedom. If the specified degree of freedom has not been enabled, PatMax only searches for instances of the pattern with the specified nominal value for the specified degree of freedom, and PatMax only returns the nominal value for the degree of freedom.

  Parameters

  dof — The degree of freedom for which to set a nominal value; *dof* must be one of the following values:

  cc_PMDefs::kAngle
  cc_PMDefs::kUniformScale
  cc_PMDefs::kXScale
  cc_PMDefs::kYScale

  Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

  val — The nominal value.

  The default value for *cc_PMDefs::kAngle* is 0.0.

  The default value for *cc_PMDefs::kUniformScale*, *cc_PMDefs::kXScale*, and *cc_PMDefs::kYScale* is 1.0. These *dof*s must be assigned a value greater than 0.

  Throws

  cc_PMDefs::BadParams
  val does not meet the requirements described above.

zoneLow `double zoneLow (cc_PMDefs::DOF dof) const;`

Returns the lower zone limit for the specified degree of freedom.

Parameters

dof — The degree of freedom for which to return the lower zone limit. Must be one of the following values:

cc_PMDefs::kAngle
cc_PMDefs::kUniformScale
cc_PMDefs::kXScale
cc_PMDefs::kYScale

Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

Throws

cc_PMDefs::BadParams
If *dof* is not one of the values listed above.

zoneHigh

```
double zoneHigh (cc_PMDefs::DOF dof) const;
```

Returns the upper zone limit for the specified degree of freedom.

Parameters

dof The degree of freedom for which to return the upper zone limit. Must be one of the following values:

cc_PMDefs::kAngle
cc_PMDefs::kUniformScale
cc_PMDefs::kXScale
cc_PMDefs::kYScale

Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

Throws

cc_PMDefs::BadParams
If *dof* is not one of the values listed above.

zone

```
void zone(cc_PMDefs::DOF dof, double low, double high);
```

Sets the lower and upper zone limits for the specified degree of freedom. If the specified degree of freedom has been enabled, PatMax only returns results for instances of the trained pattern found in the search image that exhibit transformations within the specified zones of the specified degrees of freedom.

Parameters

dof The degree of freedom for which to set the zone limits; *dof* must be one of the following values:

cc_PMDefs::kAngle
cc_PMDefs::kUniformScale
cc_PMDefs::kXScale
cc_PMDefs::kYScale

Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

low The lower zone limit. Default values are as follows

DOF	Default
cc_PMDefs::kAngle	-45°
cc_PMDefs::kUniformScale	0.8
cc_PMDefs::kXScale	0.8
cc_PMDefs::kYScale	0.8

high The upper zone limit. Default values are as follows:

DOF	Default
cc_PMDefs::kAngle	+45°
cc_PMDefs::kUniformScale	1.2
cc_PMDefs::kXScale	1.2
cc_PMDefs::kYScale	1.2

Notes

For the uniform scale DOF, the scales are equal in both the x and y dimensions, while the x-scale and y-scale DOFs scale only in the given dimension. For all of these DOFs, the lower zone limit must be less than or equal to the upper zone limit.

The scale DOFs are specified as a multiplier of the trained pattern size. For example, a uniform scale of 1.25 implies that the runtime (client coordinate) size of the pattern is 25% larger in both dimensions than the trained pattern.

The angle zone is always searched from the low to high. If the lower zone limit is greater than the upper zone limit, the range of angles that is searched is inverted. For example, setting **zoneLow()** to 0 and **zoneHigh()** to 180 searches one half of the 360° angle range; setting **zoneHigh()** to 0 and **zoneLow()** to 180 searches the other half.

Throws

cc_PMDefs::BadParams

dof is not one of the values listed above,
or *dof* is not equal to *kAngle* and *low* is greater than *high,*
or *dof* is not equal to *kAngle* and *low* is less than 0.

xyOverlap

```
double xyOverlap() const;
void xyOverlap(double overlapThresh);
```

- `double xyOverlap() const;`

  Returns the percentage of area overlap that this **cc_PMRunParams** requires before treating overlapping pattern instances as a single pattern. Two results are considered overlapping if the value returned by this function is greater than **overlapThresh()**.

  Notes

  The overlap value is approximately the ratio of the overlap area to the total area of the pattern. Meaningful values range from 0.0 to 1.0. The default overlap is 0.8

- `void xyOverlap(double overlapThresh);`

  Sets the percentage of area overlap that this **cc_PMRunParams** requires before treating overlapping pattern instances as a single pattern.

  Parameters

  overlapThresh The percentage of overlap from 0.0 to 1.0.

  A value of 0.0 means that all pattern instances with any non-zero amount of intersection are considered overlapping, and are treated as a single pattern.

  A value of 1.0 means that no pattern instances that intersect each other are considered overlapping (overlap is disabled). Each pattern instance is treated separately.

  The default overlap threshold is 0.8.

  Throws

  cc_PMDefs::BadParams

  overlapThresh is outside of the range of 0.0 through 1.0.

zoneOverlap

```
double zoneOverlap(cc_PMDefs::DOF dof) const;
void zoneOverlap(cc_PMDefs::DOF dof, double overlapThresh);
```

- `double zoneOverlap(cc_PMDefs::DOF dof) const;`

  Returns the overlap threshold for the specified degree of freedom. When two pattern instances lie within the specified overlaps for all enabled degrees of freedom and within the area overlap threshold, PatMax discards weaker pattern instances.

Parameters

dof The degree of freedom for which to return the zone overlap; *dof* must be one of the following values:

cc_PMDefs::kAngle
cc_PMDefs::kUniformScale
cc_PMDefs::kXScale
cc_PMDefs::kYScale

Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

- `void zoneOverlap(cc_PMDefs::DOF dof, double overlapThresh);`

Sets the overlap threshold for the specified degree of freedom. When two pattern instances lie within the specified overlaps for all enabled degrees of freedom and within the area overlap threshold, PatMax discards weaker pattern instances.

Parameters

dof The degree of freedom for which to set the zone overlap; *dof* must be one of the following values:

cc_PMDefs::kAngle
cc_PMDefs::kUniformScale
cc_PMDefs::kXScale
cc_PMDefs::kYScale

Scope the enumerations for the degree of freedom using the appropriate name space class such as **ccPMParamsDefs**.

overlapThresh The overlap threshold.

The units in which the overlap threshold is expressed vary depending on the degree of freedom you specify.

For the angle degree of freedom, the overlap threshold is expressed as the absolute difference between the angles of the instances.

For any scale degree of freedom, the overlap threshold is expressed as the ratio of the scale of the instance with a larger scale to the scale of the instance with the smaller scale.

For example, if you specify 1.2 for *overlapThresh* and two instances had scales of 1.25 and 2.50, they would not meet the overlap threshold because the ratio of 2.5 to 1.25 (2.0) is greater than the threshold value (1.2).

The default overlap threshold for the angle DOF is 360.0. The default overlap threshold for any of the scale DOFs is 1.4.

Throws

cc_PMDefs::BadParams

overlap is invalid for the specified degree of freedom.

timeOut

```
double timeOut() const;
void timeOut(double timeInSeconds);
```

- `double timeOut() const;`

Returns the timeout value for this **cc_PMRunParams**.

- `void timeOut(double timeInSeconds);`

Sets the timeout value for this **cc_PMRunParams**. The timeout value limits how long **ccPMAlignPattern::run()** or **ccPMInspectPattern::run()** execute before throwing a *ccTimeout::Expired* error. If this error is thrown, the tool does not return any valid results.

Parameters

timeInSeconds The timeout value in seconds. The default timeout is *HUGE_VAL*, which allows infinite execution time.

Notes

The timeout value is intended as an approximate upper limit. Due to internal latencies, the actual execution time can exceed the requested maximum by up to 0.02 seconds (on a 200 Mhz Pentium I). Typical latencies are much lower. Latencies will also be lower on faster CPUs.

The timeout is implemented using the **ccTimeout** class defined in *<ch_cvl/attent.h>*. User-created **ccTimeout** objects can also terminate the **run()** function.

Throws

cc_PMDefs::BadParams

timeInSeconds is less than 0.

flexRunParams

```
ccPMFlexRunParams flexRunParams() const;
void flexRunParams(const ccPMFlexRunParams &params);
```

Specifies the PatFlex run-time parameters used with the PatFlex algorithm.

Notes

This function has no effect unless the PatMax algorithm is *kPatflex*.

This function has no effect on normal PatMax patterns.

- `ccPMFlexRunParams flexRunParams() const;`

  Returns the PatFlex run-time parameters object.

- `void flexRunParams(const ccPMFlexRunParams &params);`

  Sets a new PatFlex run-time parameters object.

Parameters

params	The new PatFlex run-time parameters object.

outsideRegionThreshold

```
double outsideRegionTheshold() const;

void outsideRegionThreshold(double
                                outsideRegionThreshold);
```

Gets and sets the outside region threshold used by PatMax and PatQuick. Setting *outsideRegionThreshold* greater than 0 enables patterns that extend outside the search region to be found by PatMax without penalizing the score. That is, a pattern that extends partially outside the search region can still achieve a score of 1.0.

The *outsideRegionThreshold* parameter specifies what proportion of the pattern's features can be outside the search region without penalizing the score. If the proportion of pattern features lying outside the search region is greater than *outsideRegionThreshold,* then the pattern will not be found.

This functionality allows users to train an entire field of view, and then search for that trained field of view on a runtime image. By setting *outsideRegionThreshold*, PatMax can accommodate translation between the trained field of view and the runtime scene.

Often, using a larger training region improves discrimination between candidate matches. This functionality allows users to train larger patterns without worrying that the entire pattern must appear in the runtime image.

- `double outsideRegionTheshold() const;`

  Returns the current *outsideRegionThreshold* setting.

- `void outsideRegionThreshold(double outsideRegionThreshold);`

  Sets the outside region threshold for this **cc_PMRunParams**. The default value is 0.0.

  Parameters

  outsideRegionThreshold

  A value between 0.0 and 0.999, inclusive, representing the proportion of pattern features that can fall outside the search region without penalizing the score amount. For example, *outsideRegionThreshold* = 0.20 specifies that 20% of the pattern's features can fall outside the search region.

  Notes

  Setting an outside region threshold value significantly increases the running time for PatMax and PatQuick.

  Once you have made a test run of PatMax with *outsideRegionThreshold* > 0, you can use the value reported by **cc_PMResult::outsideRegionFeatureProportion()** to hone in on a more accurate *outsideRegionThreshold* setting. However, in some cases, for the pattern to be found, *outsideRegionThreshold* must be set 0.05 to 0.10 larger than the measured result reported by **outsideRegionFeatureProportion()**. For this reason, Cognex recommends setting *outsideRegionThreshold* so that it exceeds the maximum expected outside region proportion by 0.10. That is, set *outsideRegionThreshold* = (maximum expected outside region proportion) + 0.10.

  The *outsideRegionThreshold* parameter trades off speed for robustness. PatMax runs faster when a smaller *outsideRegionThreshold* value is used, but PatMax may miss the pattern if the threshold is too small.

  Throws

  BadParams

  If *outsideRegionThreshold* is less than 0.0 or greater than 0.999.

  Notes

  ccPMAlignPattern::run() throws *NotImplemented* if you specify both an algorithm of *kPatflex* or *kPatpersp* and *outsideRegionThreshold* > 0.0.

cc_PMRunParams

cc_PMStageResult

```
#include <ch_cvl/pmpbase.h>

class cc_PMStageResult
```

Class Properties

Copyable	Yes
Derivable	No
Archiveable	Simple

A class that contains a single PatMax search result from one stage of alignment.

Constructors/Destructors

cc_PMStageResult

```
cc_PMStageResult();
```

Constructs an empty PatMax Stage Result object.

Public Member Functions

location

```
cc2Vect location() const;
```

Returns the location of the pattern origin (in the client coordinate system of the runtime image).

pose

```
const cc2Xform& pose() const;
```

Returns a transform from the training time client coords (translated to the pattern origin) to runtime client coords. Map **cc2Vect(0,0)** through this to get the location of the pattern origin in runtime client coords.

angle

```
ccDegree angle() const;
```

Returns the angle of the located pattern (in the client coordinate system of the runtime image).

xScale

```
double xScale() const;
```

Returns the x-scale of the located pattern.

yScale `double yScale() const;`

Returns the y-scale of the located pattern.

score `double score() const;`

Returns the score, a number between 0.0 and 1.0.

fitError `double fitError() const;`

A PatMax quality measure in the range 0.0 (best) to infinity (worst). While there is no upper limit, *fitError* is typically less than 10. A -1 is returned if the measure is not available.

coverage `double coverage() const;`

A PatMax quality measure in the range 0.0 (worst) to 1.0 (best). A -1 is returned if the measure is not available.

clutter `double clutter () const;`

A PatMax quality measure in the range 0.0 (best) to infinity (worst). While there is no upper limit, *clutter* is typically less than 10. A -1 is returned if the measure is not available.

matchRegion `ccAffineRectangle matchRegion() const;`

Returns an affine rectangle which describes the location of the matched pattern in the runtime image's client coordinates.

imageRegion `ccPelRect imageRegion() const;`

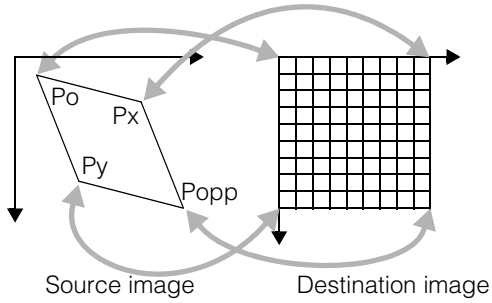
Returns the smallest rectangle in runtime image's image coordinates which completely contains the matched model.

cfAffineTransformImage()

```
#include <ch_cvl/afftrans.h>

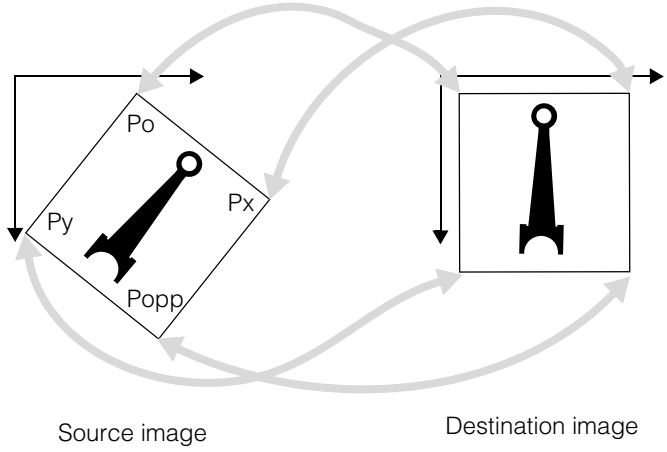
cfAffineTransformImage();
```

Global function to perform an affine sampling transformation on an input image. An affine rectangle in the source image is sampled according to a set of affine sampling parameters and the sampled points are transformed to a destination image through a destination client coordinate transform that the routine creates. The transformed affine rectangle maps the destination image as shown below for the general case:



Note that the outermost corners of the corner pixels (not the pixel center) in the destination image map to the corners of the affine rectangle in the input image. (Also see the **ccAffineRectangle** and **ccAffineSamplingParams** reference pages).

A common use of this function is for image rotation or for small corrections to scale. For example the following transformation corrects for rotation:



The function has three overloads which perform the following:

a. The first overload maps a source image to a destination image. The destination image can be bound or unbound. The handling of these bound and unbound cases is described below. If the affine rectangle clips the source image (falls outside the source image), the function throws and error.

b. The second overload is similar to (a) above except that it allows clipping. You supply it a *weights* image which it fills in to mark transformed pixels when clipping occurs.

c. The third overload takes only a source image and then returns a transformed destination image that it creates. Like (a) above, if the affine rectangle clips the source image, the function throws and error.

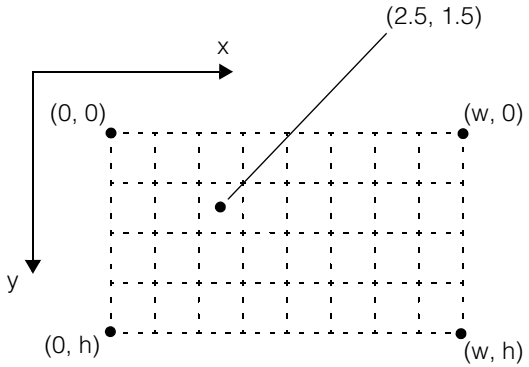
Unbound destination images

If the destination image you provide is unbound, the resulting destination *clientFromImage* transform will map image coordinates to source client coordinates as follows:

Destination image coordinates		Source client coordinates
(0, 0)	---- Maps to ---->	Po
(w, 0)	---- Maps to ---->	Px
(0, h)	---- Maps to ---->	Py
(w, h)	---- Maps to ---->	Popp

Where w and h are the width and height of the destination image as specified in the sampling parameters. Po, Px, Py, and Popp are defined in the **ccAffineRectangle** reference page and also shown in the diagrams on the previous page.

It is important to realize that the image coordinate points (0, 0), (h, w), and so on, represent the outer corners of the image pixels and not the pixel centers. See the following destination image diagram:



Destination image

When the destination pel buffer is unbound it contains no useful information about the destination image pixels. For unbound destination images the routine creates a new bound **ccPelBuffer** of the appropriate size for the transformation, and copies it into the destination pel buffer provided. All offsets are set to zero.

Bound destination images

If the destination is bound, samples are written to the destination as if the following steps had taken place:

1. A temporary destination image, TMP, was created using the rules stated above for unbound destination images.
2. The function **cfPelCopy(**TMP, *destination***)** was used to transfer pixels from TMP to the bound destination. This operation will only copy pixels within the Greatest Common Rectangle (GCR) of TMP and destination. (That is, when the TMP pel buffer is superimposed onto the destination pel buffer, only pixel coordinates common to both pel buffers are copied).

The actual implementation may be different, but will have the same result. You should be certain that you understand the steps above to ensure correct operation. In some cases it may be necessary to shift the destination image offset to achieve the desired result. This function does not re-size, re-allocate, or alter the offsets of a bound destination.

A bound destination image must not share any of the source image pixels that will be sampled.

cfAffineTransformImage

```
template<class T>
void cfAffineTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  ccPelBuffer<T>& dstImage,
  const ccAffineSamplingParams& params);

template<class T>
void cfAffineTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  ccPelBuffer<T>& dstImage,
  ccPelBuffer<T>& weights,
  const ccAffineSamplingParams& params,
  bool& clipped);

template<class T>
ccPelBuffer<T> cfAffineTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  const ccAffineSamplingParams& params);
```

-
```
template<class T>
void cfAffineTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  ccPelBuffer<T>& dstImage,
  const ccAffineSamplingParams& params);
```

Samples the *srcImage* as specified by *params*, and places the results in *dstImage*. The client coordinate transform of the destination image is created by the routine and it transforms points in the destination image to points in the source image.

Parameters

T — A template parameter specifying the type of the source and destination images. *T* must be **c_UInt8** or **c_UInt16**.

srcImage — The image to sample

dstImage — The image in which to place the sampled image

params — The sampling parameters to use

Throws

ccAffTransDefs::UnboundWindow
If *srcImage* is unbound.

ccAffTransDefs::Clipped
If clipping occurs in the source image. For example, if any sampled point is outside the source image.

ccPelFunc::Overlap
: *dstImage* is bound and shares pixels with *srcImage*.

ccAffineSamplingParams::NotImplemented
: *params.interpolation* is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

- ```
  template<class T>
  void cfAffineTransformImage(
    const ccPelBuffer_const<T>& srcImage,
    ccPelBuffer<T>& dstImage,
    ccPelBuffer<T>& weights,
    const ccAffineSamplingParams& params,
    bool& clipped);
  ```

  Functions identically to the overload above, except it allows source image clipping.

  If the input image is clipped by the supplied **ccAffineSamplingParams**, a *weights* image is computed and placed in the *weights* pel buffer you provide, and the *clipped* flag is set true. The *weights* image is filled with mask values between 0 and 255 to indicate which corresponding pixels in the destination image represent valid transformations. The mask values have the following meaning:

  - A mask value of 255 indicates that the corresponding destination pixel value was derived entirely from pixels within the source image (no clipping).
  - A mask value of 0 indicates that the corresponding destination pixel value was derived entirely from pixels outside the source image (total clipping). Pixels outside the source image are assumed to be 0.
  - Mask values from 1 through 254 correspond to boundary samples where the sample was derived from both pixels in the source image and clipped pixels. When the sampling algorithm includes clipped pixels in its calculations, it uses the value 0 for these pixels.

  Parameters

T	A template parameter specifying the type of the source and destination images. *T* must be **c_UInt8** or **c_UInt16**.
srcImage	The image to sample
dstImage	The image in which to place the sampled image
weights	The weights image as described above
params	The sampling parameters to use
  ```

clipped If *true*, clipping occurred. If *false*, no clipping occurred and *weights* was not modified.

ccAffineSamplingParams::NotImplemented
params.interpolation is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

Throws

ccAffTransDefs::UnboundWindow
If *srcImage* is unbound.

ccPelFun::Overlap
dstImage is bound and shares pixels with *srcImage*.

- ```
  template<class T>
  ccPelBuffer<T> cfAffineTransformImage(
    const ccPelBuffer_const<T>& srcImage,
    const ccAffineSamplingParams& params);
  ```

Samples the *srcImage* as specified by *params*, and returns the results in a newly constructed destination image. This is essentially the same as the first overload (unbound) except that the created destination pel buffer is returned to the caller.

Parameters

T A template parameter specifying the type of the source and destination images. *T* must be **c_UInt8** or **c_UInt16**.

srcImage The image to sample

params The sampling parameters to use

Throws

ccAffTransDefs::UnboundWindow
If *srcImage* is unbound.

ccAffTransDefs::Clipped
If clipping occurs in the source image. For example, if any sampled point is outside the source image.

ccAffineSamplingParams::NotImplemented
params.interpolation is *ccAffineSamplingParams::eBilinearApprox* or
  ```

ccAffineSamplingParams::eHighPrecision and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

cfAffineTransformImage()

cfAutoSelect()

```
#include <ch_cvl/atslptmx.h> // If using PatMax
#include <ch_cvl/atslcnls.h> // If using CNLSearch

cfAutoSelect();
```

A templated global function that runs the Auto-select tool on an input image.

Note If running Auto-select with PatMax, you must include the *<ch_cvl/atslptmx.h>* header file. If running Auto-select with CNLSearch, you must include the *<ch_cvl/atslcnls.h>* header file. Omitting the proper header file for the vision tool you are running will cause linker errors.

The **cfAutoSelect()** function is instantiated for the following types:

- **ccCnlSearchRunParams**
- **ccPMAlignRunParams**

To invoke the **cfAutoSelect()** function, allocate and initialize an instance of one of the supported types for *P*, then supply it to **cfAutoSelect()**. The function will locate and return an appropriate region for use as a model with the specified pattern-location tool. If this function does not return any model candidates, try selecting a different sampling rate and specifying a different model size.

Inputs to all overloads of the **cfAutoSelect()** function are an input image, a **ccAutoSelectParams** object specifying the auto-selection parameters, an object specifying the runtime parameters of the pattern-location tool (see above two bullets), and a container to hold the **ccAutoSelectResult** instances that the Auto-select tool returns. Optional inputs are an image/position mask and a vector of specific locations to query, both of which are valid only when running the tool in enhanced mode.

cfAutoSelect

```
template<class P>
void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
  const ccAutoSelectParams& params,
  const P& modelRunParams,
  cmStd vector<ccAutoSelectResult>& results);

template<class P>
void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
  const cmStd vector<ccIPair>& at,
  const ccAutoSelectParams& params,
  const P& modelRunParams,
  cmStd vector<ccAutoSelectResult>& results);

template<class P>
void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
```

```
  const ccAutoSelectParams& params,
  const P& modelRunParams,
  cmStd vector<ccAutoSelectResult>& results);

template<class P>
void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const cmStd vector<ccIPair>& at,
  const ccAutoSelectParams& params,
  const P& modelRunParams,
  cmStd vector<ccAutoSelectResult>& results);
```

- ```
  template<class P>
  void cfAutoSelect(
    const ccPelBuffer_const<c_UInt8>& image,
    const ccAutoSelectParams& params,
    const P& modelRunParams,
    cmStd vector<ccAutoSelectResult>& results);
  ```

  Runs a search operation of the Auto-select tool without any image/position mask.

  Parameters

  image The image in which to locate an appropriate model.

  params **ccAutoSelectParams** containing the parameters for the Auto-select tool.

  modelRunParams
  A run-time parameters object for the pattern-location tool for which you want to locate a model.

  results A reference to a vector of **ccAutoSelectResult** into which the results will be placed. Any existing contents of *results* are cleared.

  Throws

  ccAutoSelectDefs::BadModel
  The model size specified in *params* is too small or too large to allow reliable extraction of data.

  ccAutoSelectDefs::BadSample
  The sub-sampling factor specified in *params* is less than or equal to 0.

  ccAutoSelectDefs::BadWeights
  Any one of the score combination weights specified in *params* is less than 0, or all of the weights are 0.
  ```

ccAutoSelectDefs::BadResults
The maximum number of results specified in *params* is less than or equal to 0.

ccAutoSelectDefs::NotImplemented
The score combination method or direction provided in *params* is not supported.

- ```
  template<class P>
  void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
    const cmStd vector<ccIPair>& at,
    const ccAutoSelectParams& params,
    const P& modelRunParams,
    cmStd vector<ccAutoSelectResult>& results);
  ```

  Runs a query operation of the Auto-select tool without any image/position mask.

  Parameters

  image The image in which to locate an appropriate model.

  at Vector of locations at which to run the query.

  params **ccAutoSelectParams** containing the parameters for the Auto-select tool.

  modelRunParams
  A run-time parameters object for the pattern-location tool for which you want to locate a model.

  results A reference to a vector of **ccAutoSelectResult** into which the results will be placed. Any existing contents of *results* are cleared.

  Throws

  ccAutoSelectDefs::BadModel
  The model size specified in *params* is too small or too large to allow reliable extraction of data.

  ccAutoSelectDefs::BadSample
  The sub-sampling factor specified in *params* is less than or equal to 0.

  ccAutoSelectDefs::BadWeights
  Any one of the score combination weights specified in *params* is less than 0, or all of the weights are 0.
  ```

ccAutoSelectDefs::BadResults
The maximum number of results specified in *params* is less than or equal to 0.

ccPel::BadCoord
Any of the query locations specified for a query operation results in a window location that is either too close to the edge of the image or extends beyond it.

ccAutoSelectDefs::NotEnhancedMode
A query operation is being invoked, but the enhanced mode is not enabled (that is, **ccAutoSelectParams::isEnhancedMode()** returns false).

ccAutoSelectDefs::NotImplemented
The score combination method or direction provided in *params* is not supported.

- ```
  template<class P>
  void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccAutoSelectParams& params,
    const P& modelRunParams,
    cmStd vector<ccAutoSelectResult>& results);
  ```

  Runs a search operation of the Auto-select tool with an image/position mask.

  Parameters

  image The image in which to locate an appropriate model.

  mask Image/position mask used to filter out certain areas of the input image from the analysis.

  params **ccAutoSelectParams** containing the parameters for the Auto-select tool.

  modelRunParams
  A run-time parameters object for the pattern-location tool for which you want to locate a model.

  results A reference to a vector of **ccAutoSelectResult** into which the results will be placed. Any existing contents of *results* are cleared.

  Throws

  ccAutoSelectDefs::BadModel
  The model size specified in *params* is too small or too large to allow reliable extraction of data.
  ```

ccAutoSelectDefs::BadSample
The sub-sampling factor specified in *params* is less than or equal to 0.

ccAutoSelectDefs::BadWeights
Any one of the score combination weights specified in *params* is less than 0, or all of the weights are 0.

ccAutoSelectDefs::BadResults
The maximum number of results specified in *params* is less than or equal to 0.

ccAutoSelectDefs::NotEnhancedMode
An image/position mask is being provided and the enhanced mode is not enabled.

ccAutoSelectDefs::BadMask
The window mask supplied in *params* is a bound pel buffer of any size other than the model size specified in *params*, or the size of *mask* differs from that of the search image.

ccAutoSelectDefs::NotImplemented
The score combination method or direction provided in *params* is not supported.

-
```
template<class P>
void cfAutoSelect(const ccPelBuffer_const<c_UInt8>& image,
  const ccPelBuffer_const<c_UInt8>& mask,
  const cmStd vector<ccIPair>& at,
  const ccAutoSelectParams& params,
  const P& modelRunParams,
  cmStd vector<ccAutoSelectResult>& results);
```

Runs a query operation of the Auto-select tool with an image/position mask.

Parameters

image The image in which to locate an appropriate model.

mask Image/position mask used to filter out certain areas of the input image from the analysis.

at Vector of locations at which to run the query operation.

params **ccAutoSelectParams** containing the parameters for the Auto-select tool.

modelRunParams
A run-time parameters object for the pattern-location tool for which you want to locate a model.

results A reference to a vector of **ccAutoSelectResult** into which the results will be placed. Any existing contents of *results* are cleared.

Throws

ccAutoSelectDefs::BadModel
The model size specified in *params* is too small or too large to allow reliable extraction of data.

ccAutoSelectDefs::BadSample
The sub-sampling factor specified in *params* is less than or equal to 0.

ccAutoSelectDefs::BadWeights
Any one of the score combination weights specified in *params* is less than 0, or all of the weights are 0.

ccAutoSelectDefs::BadResults
The maximum number of results specified in *params* is less than or equal to 0.

ccAutoSelectDefs::NotEnhancedMode
An image/position mask is being provided, but the enhanced mode is not enabled.
A query operation is being invoked, but the enhanced mode is not enabled (that is, **ccAutoSelectParams::isEnhancedMode()** returns false).

ccPel::BadCoord
Any of the query locations specified for a query operation results in a window location that is either too close to the edge of the image or extends beyond it.

ccAutoSelectDefs::BadMask
The window mask supplied in *params* is a bound pel buffer of any size other than the model size specified in *params*, or the size of *mask* differs from that of the search image.

ccAutoSelectDefs::NotImplemented
The score combination method or direction provided in *params* is not supported.

cfAutoTrigger()

```
#include <ch_cvl/trigmodl.h>

cfAutoTrigger();
```

Global function to retrieve an auto trigger model object reference.

cfAutoTrigger

```
const ccTriggerModel& cfAutoTrigger();
```

When you specify **cfAutoTrigger()** as the trigger model, the application automatically starts an acquisition when there is a transition on the trigger input line. The auto trigger model is sometimes called a “hardware trigger.” There is a fixed association between camera ports and trigger input lines.

If **ccTriggerProp::triggerEnable()** is set to false, transitions on the input line are ignored. For acquisitions to proceed, **ccTriggerProp::triggerEnable()** must be set to true.

Notes

If you change property values while **ccTriggerProp::triggerEnable()** is set to true, the changes will take place after an unspecified number of acquisitions. To force changes in property values to take effect with the next acquisition, set **triggerEnable()** to false, change the properties, then set **triggerEnable()** to true. Alternatively, you may want to consider using the semi trigger model.

If you call **ccAcqFifo::start()** when the auto trigger model is selected, your application throws *ccAcqFifo::StartNotAllowed*.

The default behavior is for a low-to-high transition on the trigger input line to trigger an acquisition. You can change this behavior to cause a high-to-low transition to trigger an acquisition by setting **ccTriggerProp::triggerLowToHigh()** to false.

cfAutoTrigger()

cfBlobAnalysis()

```
#include <ch_cvl/blobtool.h>

cfBlobAnalysis();
```

Global function to perform blob analysis on an input image.

cfBlobAnalysis

```
template<class T>
void cfBlobAnalysis(const T& image,
  const ccBlobParams& params, ccBlobResults& results,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);
```

Performs a blob analysis of the specified image using the specified parameters.

This is a templated function that supports both standard **ccPelBuffer<c_UInt8>** images and **ccRLEBuffer** images.

Parameters

image — The image to analyze. You can specify either a **ccPelBuffer<c_UInt8>** image or a **ccRLEBuffer** image.

params — A reference to a **ccBlobParams** that specifies the parameters to use.

results — A reference to a **ccBlobResults**. The results of the blob analysis are placed in *results*.

dObj — An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags — The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccBlobDefs::BadParams
The analysis is equal to *ccBlobSceneDescription::eWholeImageGreyScale* and **params.connectivityCleanup()** is not equal to *ccBlobSceneDescription::eNone*.
The image is unbound or degenerate.

cfBlobAnalysis()

cfBoundaryTracker()

```
#include <ch_cvl/bndtrckr.h>

cfBoundaryTracker();
```

Global function to apply the Boundary Tracker tool to an input image. For more information, see the chapter *Boundary Tracker Tool* in the *CVL Vision Tools Guide*.

cfBoundaryTracker

```
void cfBoundaryTracker(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccBoundaryTrackerRunParams& params,
  ccBoundaryTrackerResult& result);
```

Optionally locates, then tracks the boundary of an object in the supplied image.

Parameters

image	The image in which to track an object boundary. *image* must exhibit a bimodal distribution of pixel values between object and background pixels.
params	A reference to a **ccBoundaryTrackerRunParams** that specifies the searching and tracking parameters.
result	A reference to a **ccBoundaryTrackerResult** into which the results are placed.

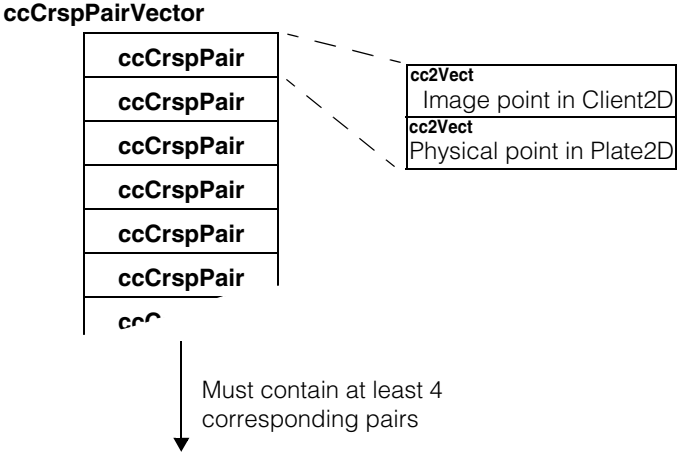
cfBoundaryTracker()

cfCalib2VertexFeatureExtract()

```
#include <ch_cvl/calibftr.h>

cfCalib2VertexFeatureExtract();
```

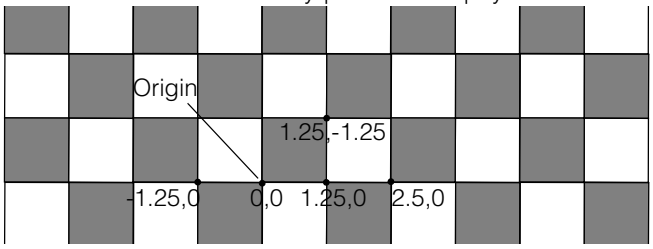
This global function resizes and initializes the supplied *client2DPlate2DPairs* vector with extracted vertex points and their corresponding coordinates in the Plate2D coordinate system. The first **cc2Vect** in each **ccCrspPair** represents the Client2D location of the vertex, while the second **cc2Vect** represents its Plate2D position. See the following diagram.



The *image points* in the diagram above are reported in Client2D units as transformed by the source image client coordinate transform. This differs from the grid-of dots calibration where source image locations are described in image coordinates. If you are using the default client coordinate transform of the source image pel buffer (the identity transform), then client units are the same as pixels and *image points* and pixel coordinates are the same.

The *physical points* in the diagram above report the physical location of the found features in Plate2D. You can define Plate2D in several ways. See **ccCalib2VertexFeatureDefs::CorrespondMethod**. The *physical point* location is a

multiple of the checkerboard pitch which you specify in **ccCalib2VertexFeatureParams**. The following diagram shows an example of physical points for a checkerboard with an x- and y-pitch of 1.25 physical units.



The **ccCrspPair** point pairs in the **ccCrspPairVector** are ordered in a raster fashion using their physical position coordinates.

Requires that the size of checkers in the image be at least 15x15 pixels. If Data Matrix codes are used as calibration fiducials, the Data Matrix codes should have a minimum resolution of 4 ppm.

cfCalib2VertexFeatureExtract

```
void cfCalib2VertexFeatureExtract(
  const ccPelBuffer_const<c_UInt8>& srcImg,
  const ccCalib2VertexFeatureParams& params,
  ccCrspPairVector& client2DPlate2DPairs,
  ccDiagObject* diagObj=0,
  c_UInt32 diagFlags=0
);

void cfCalib2VertexFeatureExtract(
  const ccPelBuffer_const<c_UInt8>& srcImg,
  const ccCalib2VertexFeatureParams& params,
  ccCrspPairWeightedVector& client2DPlate2DPairs,
  ccDiagObject* diagObj=0,
  c_UInt32 diagFlags=0
);

void cfCalib2VertexFeatureExtract(
  const ccPelBuffer_const<c_UInt8>& srcImg,
  const ccCalib2VertexFeatureParams& params,
  ccCalib2VertexFeatureResult& result,
  ccDiagObject* diagObj=0,
  c_UInt32 diagFlags=0
);
```

-
```
void cfCalib2VertexFeatureExtract(
  const ccPelBuffer_const<c_UInt8>& srcImg,
  const ccCalib2VertexFeatureParams& params,
  ccCrspPairVector& client2DPlate2DPairs,
```

```
  ccDiagObject* diagObj=0,
  c_UInt32 diagFlags=0
);
```

Parameters

srcImg The image containing the calibration plate. The size of checkerboard squares in the image must be at least 15x15 pixels. If Data Matrix codes are used as calibration fiducials, the Data Matrix codes should have a minimum resolution of 4 ppm.

params The run-time parameters for this function.

client2DPlate2DPairs
The results vector where the function places the results.

diagObj An optional **ccDiagObject**. If you supply a value for diagObj, then the tool will record diagnostic information in the supplied object.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

If **params.labelMode()** is *eUseDataMatrixWithGridPitch*, then each Data Matrix code on the calibration plate must encode the grid pitch in addition to the grid position. The value of grid pitch encoded in the Data Matrix code is used by the tool, **params.physicalGridPitch()** is ignored.

If **params.labelMode()** is *eUseDataMatrix*, then each Data Matrix code must encode the grid position and may optionally encode the grid pitch. However, the value of grid pitch encoded in the Data Matrix codes will not be used by the tool. The tool will use **params.physicalGridPitch()**.

Throws

ccPel::UnboundWindow
If *srcImg* is not bound to any root image.

ccCalib2VertexFeatureDefs::BadParam
If client transform of *srcImg* is not linear.

ccCalib2VertexFeatureDefs::BadParam
: If **params.algorithm()** is *eExhaustiveMultiRegion* and **params.labelMode()** is neither *eDataMatrix* nor *eDataMatrixWithGridPitch*

ccCalib2VertexFeatureDefs::FailedCorrespondence
: If consistent labeling of the vertices could not be carried out. This throw may occur due to out-of-focus images or images with severe light gradient or very small checker size in images, and so on.

ccCalib2VertexFeatureDefs::FiducialNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseFiducial* mode and the expected fiducial feature is not found.

ccCalib2VertexFeatureDefs::DataMatrixNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix could be found in *srcImg*.

ccCalib2VertexFeatureDefs::DataMatrixDecodeError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code that was successfully found in *srcImg* could be successfully decoded.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code in *srcImg* that was successfully decoded could be successfully parsed.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If **labelMode()** is *eUseDataMatrixWithGridPitch* and either component of the grid pitch extracted from any Data Matrix code in <*srcImg*> is less than or equal to zero.

- ```
  void cfCalib2VertexFeatureExtract(
    const ccPelBuffer_const<c_UInt8>& srcImg,
    const ccCalib2VertexFeatureParams& params,
    ccCrspPairWeightedVector& client2DPlate2DPairs,
  ```
  ```

```
  ccDiagObject* diagObj=0,
  c_UInt32 diagFlags=0
);
```

Parameters

srcImg The image containing the calibration plate. The size of checkerboard squares in the image must be at least 15x15 pixels. If Data Matrix codes are used as calibration fiducials, the Data Matrix codes should have a minimum resolution of 4 ppm.

params The run-time parameters for this function.

client2DPlate2DPairs
The weighted results vector where the function places the results.

diagObj An optional **ccDiagObject**. If you supply a value for diagObj, then the tool will record diagnostic information in the supplied object.

diagFlags Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

If **params.labelMode()** is *eUseDataMatrixWithGridPitch*, then each Data Matrix code on the calibration plate must encode the grid pitch in addition to the grid position. The value of grid pitch encoded in the Data Matrix code is used by the tool, **params.physicalGridPitch()** is ignored.

If **params.labelMode()** is *eUseDataMatrix*, then each Data Matrix code must encode the grid position and may optionally encode the grid pitch. However, the value of grid pitch encoded in the Data Matrix codes will not be used by the tool. The tool will use **params.physicalGridPitch()**.

Throws

ccPel::UnboundWindow
If *srcImg* is not bound to any root image.

ccCalib2VertexFeatureDefs::BadParam
If client transform of *srcImg* is not linear.

ccCalib2VertexFeatureDefs::BadParam
: If **params.algorithm()** is *eExhaustiveMultiRegion* and **params.labelMode()** is neither *eDataMatrix* nor *eDataMatrixWithGridPitch*

ccCalib2VertexFeatureDefs::FailedCorrespondence
: If consistent labeling of the vertices could not be carried out. This throw may occur due to out-of-focus images or images with severe light gradient or very small checker size in images, and so on.

ccCalib2VertexFeatureDefs::FiducialNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseFiducial* mode and the expected fiducial feature is not found.

ccCalib2VertexFeatureDefs::DataMatrixNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix could be found in *srcImg*.

ccCalib2VertexFeatureDefs::DataMatrixDecodeError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code that was successfully found in *srcImg* could be successfully decoded.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code in *srcImg* that was successfully decoded could be successfully parsed.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If **labelMode()** is *eUseDataMatrixWithGridPitch* and either component of the grid pitch extracted from any Data Matrix code in <*srcImg*> is less than or equal to zero.

- ```
  void cfCalib2VertexFeatureExtract(
    const ccPelBuffer_const<c_UInt8>& srcImg,
    const ccCalib2VertexFeatureParams& params,
    ccCalib2VertexFeatureResult& result,
    ccDiagObject* diagObj=0,
    c_UInt32 diagFlags=0
  );
  ```

  Extracts calibration features from <*srcImage*> based on the specified params.
  ```

Parameters

srcImg	The image containing the calibration plate. The size of checkerboard squares in the image must be at least 15x15 pixels. If Data Matrix codes are used as calibration fiducials, the Data Matrix codes should have a minimum resolution of 4 ppm.
params	The run-time parameters for this function.
result	The result of the extraction.
diagObj	An optional **ccDiagObject**. If you supply a value for diagObj, then the tool will record diagnostic information in the supplied object.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

Notes

If **params.labelMode()** is neither *eUseDataMatrix* nor *eUseDataMatrixWithGridPitch*, the vector symbolInfo in <*result*> will be empty.

If **params.labelMode()** is either *eUseDataMatrix* or *eUseDataMatrixWithGridPitch*, the vector symbolInfo in <*result*> will contain an element corresponding to each Data Matrix code that was succesfully found, decoded and parsed by the tool.

The current implementation of the tool stops searching for Data Matrix codes after any single Data Matrix code in the image is succesfully found, decoded and parsed. As a result, the size of this vector will not be greater than one.

If **params.labelMode()** is *eUseDataMatrixWithGridPitch*, then each Data Matrix code on the calibration plate must encode the grid pitch in addition to the grid position. The value of grid pitch encoded in the Data Matrix code is used by the tool, **params.physicalGridPitch()** is ignored.

If **params.labelMode()** is *eUseDataMatrix*, then each Data Matrix code must encode the grid position and may optionally encode the grid pitch. The value of grid pitch encoded in the Data Matrix codes will not be used by the tool, but it will be stored in <*result*>. The tool will use **params.physicalGridPitch()**.

Throws

ccPel::UnboundWindow
: If *srcImg* is not bound to any root image.

ccCalib2VertexFeatureDefs::BadParam
: If client transform of *srcImg* is not linear.

ccCalib2VertexFeatureDefs::BadParam
: If **params.algorithm()** is *eExhaustiveMultiRegion* and **params.labelMode()** is neither *eDataMatrix* nor *eDataMatrixWithGridPitch*

ccCalib2VertexFeatureDefs::FailedCorrespondence
: If consistent labeling of the vertices could not be carried out. This throw may occur due to out-of-focus images or images with severe light gradient or very small checker size in images, and so on.

ccCalib2VertexFeatureDefs::FiducialNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseFiducial* mode and the expected fiducial feature is not found.

ccCalib2VertexFeatureDefs::DataMatrixNotFound
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix could be found in *srcImg*.

ccCalib2VertexFeatureDefs::DataMatrixDecodeError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code that was successfully found in *srcImg* could be successfully decoded.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If running in *ccCalib2VertexFeatureDefs::eUseDataMatrix* mode or *ccCalib2VertexFeatureDefs::eUseDataMatrixWithGridPitch* mode and no Data Matrix code in *srcImg* that was successfully decoded could be successfully parsed.

ccCalib2VertexFeatureDefs::DataMatrixParseError
: If **labelMode()** is *eUseDataMatrixWithGridPitch* and either component of the grid pitch extracted from any Data Matrix code in <*srcImg*> is less than or equal to zero.

cfCalibrateLineScanCamera

```
#include <ch_cvl/ccalibls.h>

cfCalibrateLineScanCamera();
```

Global function to perform calibration of a line scan camera using the supplied image.

cfCalibrateLineScanCamera

```
void cfCalibrateLineScanCamera(
   const cmStd vector<cc2Vect> &imagePoints,
   const cmStd vector<cc2Vect> &physicalPoints,
   const ccCalibrateLineScanCameraParams &params,
   double &rmsResidual, double &maxResidual,
   cc2XformCalib2 &imageFromPhysicalXform);

void cfCalibrateLineScanCamera(
   const ccCrspPairVector &imagePointsPhysicalPoints,
   const ccCalibrateLineScanCameraParams &params,
   double &rmsResidual, double &maxResidual,
   cc2XformCalib2 &imageFromPhysicalXform);
```

- ```
  void cfCalibrateLineScanCamera(
     const cmStd vector<cc2Vect> &imagePoints,
     const cmStd vector<cc2Vect> &physicalPoints,
     const ccCalibrateLineScanCameraParams &params,
     double &rmsResidual, double &maxResidual,
     cc2XformCalib2 &imageFromPhysicalXform);
  ```

  Perform line scan camera calibration using the supplied vectors of corresponded image points and physical points.

  The image from which the image points are extracted must have been acquired from a line scan camera, and the positive y-axis direction must correspond to the direction of apparent camera motion (increasing y-values correspond to successively acquired rows of pixels).

  Parameters

imagePoints	The locations of the calibration plate vertices in image coordinates.
physicalPoints	The physical coordinates of the plate vertices.
params	The calibration parameters.
rmsResidual	The computed RMS residual error across all points.
maxResidual	The maximum residual error for any single point.
  ```

imageFromPhysicalXform
The computed calibration.

Throws

cfCalibrateLineScanCameraDefs::BadParams
The number of physical points differs from the number of image points or *params* specifies that the supplied camera-to-target distance be used, but the supplied distance is either less than or equal to 0 or HUGE_VAL.

ccCalibrateLineScanCameraDefs::InsufficientPoints
Fewer than four points are supplied.

ccMathError::Singular
A transformation cannot be computed. This can occur if all of the supplied points are collinear.

- ```
  void cfCalibrateLineScanCamera(
     const ccCrspPairVector &imagePointsPhysicalPoints,
     const ccCalibrateLineScanCameraParams &params,
     double &rmsResidual, double &maxResidual,
     cc2XformCalib2 &imageFromPhysicalXform);
  ```

Perform line scan camera calibration using the supplied vectors of corresponded image points and physical points.

The image from which the image points are extracted must have been acquired from a line scan camera, and the positive y-axis direction must correspond to the direction of apparent camera motion (increasing y-values correspond to successively acquired rows of pixels).

Parameters

imagePointsPhysicalPoints
A vector of correspondence pairs, where each pair includes an image point and the corresponding physical point. The first point in each correspondence pair must be the image point, the second point the physical point.

params The calibration parameters.

rmsResidual The computed RMS residual error across all points.

maxResidual The maximum residual error for any single point.

imageFromPhysicalXform
The computed calibration.
  ```

Throws

cfCalibrateLineScanCameraDefs::BadParams

The number of physical points differs from the number of image points or *params* specifies that the supplied camera-to-target distance be used, but the supplied distance is either less than or equal to 0 or HUGE_VAL.

ccCalibrateLineScanCameraDefs::InsufficientPoints

Fewer than four points are supplied.

ccMathError::Singular

A transformation cannot be computed. This can occur if all of the supplied points are collinear.

cfCalibrateLineScanCamera

cfCalibrationRun()

```
#include <ch_cvl/calib.h>

cfCalibrationRun();
```

Global function to perform calibration using the supplied image.

cfCalibrationRun

```
void cfCalibrationRun(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccGridCalibParams& params,
  ccGridCalibResults& results);
```

Applies the Calibration tool to the supplied input image using the supplied parameters. The input image must be of a calibration grid that meets the following requirements:

- It must be a grid of circular dots.
- The grid must not be rotated more than +/- 30° with respect to the image coordinate system.
- The grid must contain at least three dots for a linear calibration, ten for a third-order polynomial calibration and 21 for a fifth-order polynomial calibration.
- The dots must be at least 10 pixels in diameter.
- The image contrast between the dots and background must be at least 12.

Parameters

image The input image. This must be an image of a valid calibration grid.

params A **ccGridCalibParams** that specifies the calibration parameters

results A **ccGridCalibResults** into which the calibration results are placed

Throws

ccCalibDefs::GridAngleTooLarge
The grid is rotated excessively with respect to the image coordinate system.

ccCalibDefs::InvalidMap
A valid transformation could not be computed.

ccCalibDefs::TooFewDotsFound
The input image does not contain enough dots.

ccCalibDefs::BadCorrespondence
: The tool could not determine the location and orientation of the grid from the position of the dots.

ccCalibDefs::BadParam
: One or more illegal values were specified in *params*.

Notes

The minimum recommended grid size for the different calibrations are:
eGridLinear: 4x4
ePolynomialOrder3: 8x8
ePolynomialOrder5: 8x8 (12x12 is preferable, if possible)

cfCaliperFindCircle()

```
#include <ch_cvl/clpfind.h>

cfCaliperFindCircle();
```

Global function to find a circle in an image.

cfCaliperFindCircle

```
void cfCaliperFindCircle (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccCaliperFinderBaseRunParams &runParams,
  ccCaliperCircleFinderResult& result);
```

Parameters

image An image containing a circle you wish to find.

runParams A run-time parameters object. Default constructed *runParams* are not valid. You must set parameters such as *numCalipers*, *caliperSize*, and *caliperSampling* to valid values.

result Where to put the results.

Throws

ccCaliperFinderBaseDefs::UnboundImage
If the image is unbound.

ccCaliperFinderBaseDefs::BadParams
If the *runParams* and *result* are not for the same shape,
or if *runParams* is invalid,
or if the *runParams* sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

Notes

Any failure as the caliper runs will mark the edge as not found. For example, if the *caliperRunParams* is set to **autoClip(false)** and the affine rectangle extends past the image, the edge will be marked as not found.

The regions (affine rectangles) where we apply the calipers depend upon the start pose. Each caliper has a nominal region. At run time, that nominal region is mapped by the start pose to determine the actual region where the caliper is applied.

If your application processes many images in a loop, the finder tool will run faster if you reuse the same caliper result set object because some information is cached in this object.

Only the highest scoring edge of each caliper is passed to the fitter tool. Therefore, be certain that the applied calipers will only find edges corresponding to the desired feature. If the caliper finds an unexpected edge, the results may be inaccurate.

cfCaliperFindEllipse()

```
#include <ch_cvl/clpfind.h>

cfCaliperFindEllipse();
```

Global function to find a ellipse in an image.

cfCaliperFindEllipse

```
void cfCaliperFindEllipse (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccCaliperFinderBaseRunParams &runParams,
  ccCaliperEllipseFinderResult& result);
```

Parameters

image	An image containing a ellipse you wish to find.
runParams	A run-time parameters object. Default constructed *runParams* are not valid. You must set parameters such as *numCalipers*, *caliperSize*, and *caliperSampling* to valid values.
result	Where to put the results.

Throws

ccCaliperFinderBaseDefs::UnboundImage
If the image is unbound.

ccCaliperFinderBaseDefs::BadParams
If the *runParams* and *result* are not for the same shape,
or if *runParams* is invalid,
or if the *runParams* sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

Any failure as the caliper runs will mark the edge as not found. For example, if the *caliperRunParams* is set to **autoClip(false)** and the affine rectangle extends past the image, the edge will be marked as not found.

The regions (affine rectangles) where we apply the calipers depend upon the start pose. Each caliper has a nominal region. At run time, that nominal region is mapped by the start pose to determine the actual region where the caliper is applied.

If your application processes many images in a loop, the finder tool will run faster if you reuse the same caliper result set object because some information is cached in this object.

Only the highest scoring edge of each caliper is passed to the fitter tool. Therefore, be certain that the applied calipers will only find edges corresponding to the desired feature. If the caliper finds an unexpected edge, the results may be inaccurate.

cfCaliperFindLine()

```
#include <ch_cvl/clpfind.h>

cfCaliperFindLine();
```

Global function to find a line in an image.

cfCaliperFindLine

```
void cfCaliperFindLine (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccCaliperFinderBaseRunParams &runParams,
  ccCaliperLineFinderResult& result);
```

Parameters

image	An image containing a line you wish to find.
runParams	A run-time parameters object. Default constructed *runParams* are not valid. You must set parameters such as *numCalipers*, *caliperSize*, and *caliperSampling* to valid values.
result	Where to put the results.

Throws

ccCaliperFinderBaseDefs::UnboundImage
If the image is unbound.

ccCaliperFinderBaseDefs::BadParams
If the *runParams* and *result* are not for the same shape,
or if *runParams* is invalid,
or if the *runParams* sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

Any failure as the caliper runs will mark the edge as not found. For example, if the *caliperRunParams* is set to **autoClip(false)** and the affine rectangle extends past the image, the edge will be marked as not found.

The regions (affine rectangles) where we apply the calipers depend upon the start pose. Each caliper has a nominal region. At run time, that nominal region is mapped by the start pose to determine the actual region where the caliper is applied.

If your application processes many images in a loop, the finder tool will run faster if you reuse the same caliper result set object because some information is cached in this object.

Only the highest scoring edge of each caliper is passed to the fitter tool. Therefore, be certain that the applied calipers will only find edges corresponding to the desired feature. If the caliper finds an unexpected edge, the results may be inaccurate.

cfCaliperFindShape()

```
#include <ch_cvl/clpfind.h>

cfCaliperFindShape();
```

Global function to find a shape in an image.

You can use this function as an alternative to **cfCaliperFindLine()**, **cfCaliperFindCircle()**, or **cfCaliperFindEllipse()**. For example, if you call **cfCaliperFindShape()** with a circle run-time parameters object and a circle results object, the function will attempt to find a circle in the image.

cfCaliperFindShape

```
void cfCaliperFindShape (
  const ccPelBuffer_const<c_UInt8>& image,
  const ccCaliperFinderBaseRunParams &runParams,
  ccCaliperShapeFinderResult& result);
```

Parameters

image	An image containing a shape you wish to find.
runParams	A run-time parameters object. Default constructed *runParams* are not valid. You must set parameters such as *numCalipers*, *caliperSize*, and *caliperSampling* to valid values.
result	Where to put the results.

Throws

ccCaliperFinderBaseDefs::UnboundImage
If the image is unbound.

ccCaliperFinderBaseDefs::BadParams
If the *runParams* and *result* are not for the same shape,
or if *runParams* is invalid,
or if the *runParams* sampling rate causes an overflow,
or if the resulting number of samples is less than (1, 1).

Any failure as the caliper runs will mark the edge as not found. For example, if the *caliperRunParams* is set to **autoClip(false)** and the affine rectangle extends past the image, the edge will be marked as not found.

The regions (affine rectangles) where we apply the calipers depend upon the start pose. Each caliper has a nominal region. At run time, that nominal region is mapped by the start pose to determine the actual region where the caliper is applied.

If your application processes many images in a loop, the finder tool will run faster if you reuse the same caliper result set object because some information is cached in this object.

Only the highest scoring edge of each caliper is passed to the fitter tool. Therefore, be certain that the applied calipers will only find edges corresponding to the desired feature. If the caliper finds an unexpected edge, the results may be inaccurate.

cfCaliperRun()

```
#include <ch_cvl/caliper.h>

cfCaliperRun();
```

Global function to apply the Caliper tool to an input image.

cfCaliperRun

```
void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
  const ccAffineSamplingParams& affSamplParams,
  const ccCaliperRunParams& runParams,
  ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);

void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
  const ccCaliperProjectionParams& projParams,
  const ccCaliperRunParams& runParams,
  ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);

void cfCaliperRun(
  const ccPelBuffer_const<c_UInt32>& projImage,
  const c_UInt32 nPelsPerBin,
  const cc2Vect& clientOrigin,
  const ccCaliperRunParams& runParams,
  ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);

void cfCaliperRun(
  const ccPelBuffer_const<c_UInt32>& projImage,
  const ccPelBuffer_const<c_UInt32>& weights,
  const cc2Vect& clientOrigin,
  const ccCaliperRunParams& runParams,
  ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
  c_UInt32 dFlags=0);

void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
  const cmStd vector<ccAffineSamplingParams>&
  affSamplParams,
```

```
  const cmStd vector<ccCaliperRunParams>& runParams,
  cmStd vector<ccCaliperResultSet>& resultSet,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
  const ccAffineSamplingParams& affSamplParams,
  const ccCaliperCorrelationRunParams& runParams,
  ccCaliperCorrelationResultSet& resultSet,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void cfCaliperRun(
  const ccPelBuffer_const<c_UInt32>& projImage,
  const c_UInt32 nPelsPerBin, const cc2Vect& clientOrigin,
  const ccCaliperCorrelationRunParams& runParams,
  ccCaliperCorrelationResultSet& resultSet,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void cfCaliperRun(
  const ccPelBuffer_const<c_UInt32>& projImage,
  const ccPelBuffer_const<c_UInt32>& weights,
  const cc2Vect& clientOrigin,
  const ccCaliperCorrelationRunParams& runParams,
  ccCaliperCorrelationResultSet& resultSet,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);

void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
  const cmStd vector<ccAffineSamplingParams>&
  affSamplParams,
  const cmStd vector<ccCaliperCorrelationRunParams>&
  runParams,
  cmStd vector<ccCaliperCorrelationResultSet>& resultSet,
  ccDiagObject* dObj=0, c_UInt32 dFlags=0);
```

- ```
  void cfCaliperRun (
    const ccPelBuffer_const<c_UInt8>& image,
    const ccAffineSamplingParams& affSamplParams,
    const ccCaliperRunParams& runParams,
    ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied input image using the supplied parameters.

  Parameters

image	The input image
affSamplParams	The projection region within *image*
runParams	A **ccCaliperRunParams**
  ```

resultSet A reference to a **ccCaliperResultSet** into which the results are placed

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void cfCaliperRun (
    const ccPelBuffer_const<c_UInt8>& image,
    const ccCaliperProjectionParams& projParams,
    const ccCaliperRunParams& runParams,
    ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied input image using the supplied parameters.

  Parameters

  image The input image

  projParams The projection region within *image*

  runParams A **ccCaliperRunParams**

  resultSet A reference to a **ccCaliperResultSet** into which the results are placed

  dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

  dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

  ccDiagDefs::eInputs
  ccDiagDefs::eIntermediate
  ccDiagDefs::eResults

  with one of the following values:
  ```

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Notes

You should not use this overload. Instead, specify the projection region using a **ccAffineSamplingParams** by calling the next overload.

- ```
  void cfCaliperRun (
    const ccPelBuffer_const<c_UInt32>& projImage,
    const c_UInt32& nPelsPerBin, const cc2Vect& clientOrigin,
    const ccCaliperRunParams& runParams,
    ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied projection image using the supplied parameters. Use this overload if you have already created a one-dimensional projection image in which you want to locate and score edges.

  Parameters

projImage	The projection image
nPelsPerBin	The number of pixels which were summed to produce the values in each pixel of *projImage*
clientOrigin	The location with respect to which results are to be returned
runParams	A **ccCaliperRunParams**
resultSet	A reference to a **ccCaliperResultSet** into which the results are placed
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*
  ```

- ```
  void cfCaliperRun(
    const ccPelBuffer_const<c_UInt32>& projImage,
    const ccPelBuffer_const<c_UInt32>& weights,
    const cc2Vect& clientOrigin,
    const ccCaliperRunParams& runParams,
    ccCaliperResultSet& resultSet, ccDiagObject* dObj=0,
    c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied projection image using the supplied parameters. Use this overload if not all pixels in the projection image were summed using the same number of pixels; you supply a weights image that contains the number of pixels that were summed to produce the corresponding pixel in the projection image.

  Parameters

projImage	The projection image
weights	The weights image
clientOrigin	The location with respect to which results are to be returned
runParams	A **ccCaliperRunParams**
resultSet	A reference to a **ccCaliperResultSet** into which the results are placed
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

- ```
  void cfCaliperRun (
    const ccPelBuffer_const<c_UInt8>& image,
    const vector<ccAffineSamplingParams>& affSamplParams,
  ```

```
const vector<ccCaliperRunParams>& runParams,
vector<ccCaliperResultSet>& resultSet,
ccDiagObject* dObj=0, c_UInt32 dFlags=0);
```

Applies the Caliper tool to the supplied input image multiple times, once for each element of the supplied vector of **ccAffineSamplingParams**. The number of elements in the supplied vector of **ccAffineSamplingParams** *must* match the number of elements in the supplied vector of **ccCaliperResultSet**.

If you supply a vector of **ccCaliperRunParams** with a single element, then the same **ccCaliperRunParams** will be used for each application of the Caliper tool. If the supplied vector of **ccCaliperRunParams** contains more than 1 element, it must contain the same number of elements as the supplied vectors of **ccAffineSamplingParams** and **ccCaliperResultSet**.

Parameters

image The input image

affSamplParams A vector of **ccAffineSamplingParams** that specify the projection regions within *image*

runParams A vector of **ccCaliperRunParams**

resultSet A vector to a **ccCaliperResultSet** into which the results are placed

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccCaliperDefs::BadParams

If the number of elements in *runParams* is 1, then the number of elements in *affSamplParams* must match the number of elements in *resultSet*. If the number of elements in *runParams* is greater than 1, then the number of elements in *runParams* must match the number of elements in *affSamplParams* and *resultSet*.

- ```
  void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
    const ccAffineSamplingParams& affSamplParams,
    const ccCaliperCorrelationRunParams& runParams,
    ccCaliperCorrelationResultSet& resultSet,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied input image using the supplied correlation-mode parameters.

  Parameters

image	The input image
affSamplParams	The projection region within *image*
runParams	A **ccCaliperCorrelationRunParams**
resultSet	A reference to a **ccCaliperCorrelationResultSet** into which the results are placed
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

- ```
  void cfCaliperRun(
    const ccPelBuffer_const<c_UInt32>& projImage,
    const c_UInt32 nPelsPerBin, const cc2Vect& clientOrigin,
    const ccCaliperCorrelationRunParams& runParams,
    ccCaliperCorrelationResultSet& resultSet,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied projection image using the supplied correlation-mode parameters. Use this overload if you have already created a one-dimensional projection image in which you want to locate a pattern.

Parameters

projImage	The projection image
nPelsPerBin	The number of pixels which were summed to produce the values in each pixel of *projImage*
clientOrigin	The location with respect to which results are to be returned
runParams	A **ccCaliperCorrelationRunParams**
resultSet	A reference to a **ccCaliperCorrelationResultSet** into which the results are placed
dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

- ```
  void cfCaliperRun(
    const ccPelBuffer_const<c_UInt32>& projImage,
    const ccPelBuffer_const<c_UInt32>& weights,
    const cc2Vect& clientOrigin,
    const ccCaliperCorrelationRunParams& runParams,
    ccCaliperCorrelationResultSet& resultSet,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied projection image using the supplied correlation-mode parameters. Use this overload if not all pixels in the projection image were summed using the same number of pixels; you supply a weights image that contains the number of pixels that were summed to produce the corresponding pixel in the projection image.

  Parameters

projImage	The projection image
weights	The weights image
clientOrigin	The location with respect to which results are to be returned
  ```

runParams A **ccCaliperCorrelationRunParams**

resultSet A reference to a **ccCaliperCorrelationResultSet** into which the results are placed

dObj An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.

dFlags The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

- ```
  void cfCaliperRun(const ccPelBuffer_const<c_UInt8>& image,
    const cmStd vector<ccAffineSamplingParams>&
    affSamplParams,
    const cmStd vector<ccCaliperCorrelationRunParams>&
    runParams,
    cmStd vector<ccCaliperCorrelationResultSet>& resultSet,
    ccDiagObject* dObj=0, c_UInt32 dFlags=0);
  ```

  Applies the Caliper tool to the supplied input image multiple times, once for each element of the supplied vector of **ccAffineSamplingParams**. The number of elements in the supplied vector of **ccAffineSamplingParams** *must* match the number of elements in the supplied vector of **ccCaliperCorrelationResultSet**.

  If you supply a vector of **ccCaliperCorrelationRunParams** with a single element, then the same **ccCaliperCorrelationRunParams** will be used for each application of the Caliper tool. If the supplied vector of **ccCaliperCorrelationRunParams** contains more than 1 element, it must contain the same number of elements as the supplied vectors of **ccAffineSamplingParams** and **ccCaliperCorrelationResultSet**.

  Parameters

  image The input image

  affSamplParams A vector of **ccAffineSamplingParams** that specify the projection regions within *image*

  runParams A vector of **ccCaliperCorrelationRunParams**

  resultSet A vector to a **ccCaliperCorrelationResultSet** into which the results are placed
  ```

cfCaliperRun()

dObj	An optional **ccDiagObject**. If you supply a value for *dObj*, then the tool will record diagnostic information in the supplied object.
dFlags	The optional diagnostic flags. *dFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

cfCircleFit()

```
#include <ch_cvl/fit.h>

cfCircleFit();
```

Global function to fit a circle to a set of points.

cfCircleFit

```
void cfCircleFit(
  const ccCircleFitParams &params,
  cmStd vector<cc2Vect> &pts,
  ccCircleFitResults &results);
```

A global function that fits a circle to the supplied set of points using the supplied **ccCircleFitParams**.

Parameters

params — A **ccCircleFitParams** describing the fitting method, number of outliers to ignore, and maximum RMS error threshold.

pts — A vector of points specified in a single coordinate system.

results — A reference to a **ccCircleFitResults** into which the results will be placed. Any existing contents of *results* are cleared.

Throws

ccMathError::Singular
The number of points in *pts* is less than 3, after subtracting the number of points to ignore specified in params,
or *pts* does not include three points which are not colinear.

cfCircleFit()

cfColorMatch()

```
#include <ch_cvl/colmatch.h>

class ccColorMatchResult;
```

Calculates the results of a color match between an image (or single color) and a set of reference colors.

cfColorMatch

```
void cfColorMatch(const ccColorValue& color,
       const cmStd vector<ccColorValue>& referenceColors,
       const ccColorMatchRunParams &runParams,
       ccColorMatchResult &result);

void cfColorMatch(const cc3PlanePelBuffer& image,
       const cmStd vector<ccColorValue>& referenceColors,
       const ccColorMatchRunParams &runParams,
       ccColorMatchResult &result);

void cfColorMatch(const cc3PlanePelBuffer& image,
       const ccShapePtrh& region,
       const cmStd vector<ccColorValue>& referenceColors,
       const ccColorMatchRunParams &runParams,
       ccColorMatchResult &result);

void cfColorMatch(const cc3PlanePelBuffer& image,
       const ccPelBuffer_const<c_UInt8>& mask,
       const cmStd vector<ccColorValue>& referenceColors,
       const ccColorMatchRunParams &runParams,
       ccColorMatchResult &result);
```

- ```
  void cfColorMatch(const ccColorValue& color,
         const cmStd vector<ccColorValue>& referenceColors,
         const ccColorMatchRunParams &runParams,
         ccColorMatchResult &result);
  ```

  Performs a color match between *color* and *referenceColors*.

  If necessary the color spaces of *color* and *referenceColors* are converted to the same color space as *runParams*.

  Parameters

color	The color.
referenceColors	The reference colors.
runParams	A **ccColorMatchRunParams** object that specifies the color space, distance metric, and weights to perform the match.
  ```

result A **ccColorMatchResult** object that contains the results of performing the match.

Throws

ccColorMatchDefs::BadParams
referenceColors is empty

ccColorMatchDefs::BadColorSpace
either the color space of *color* or *referenceColors* could not be converted to the same color space as *runParams*.

ccColorMatchDefs::BadColorSpace
referenceColors has the color space **ccColorSpaceDefs::eUnknown**.

- ```
  void cfColorMatch(const cc3PlanePelBuffer& image,
         const cmStd vector<ccColorValue>& referenceColors,
         const ccColorMatchRunParams &runParams,
         ccColorMatchResult &result);
  ```

Uses **cfGetSimpleColorFromImage()** to compute the mean color from *image* and matches it with the collection of colors in *referenceColors*.

If necessary the color spaces of *color* and *referenceColors* are converted to the same color space as *runParams*.

Parameters

image The image.

referenceColors The reference colors.

runParams A **ccColorMatchRunParams** object that specifies the color space, distance metric, and weights to perform the match.

result A **ccColorMatchResult** object that contains the results of performing the match. If the size of *referenceColors* is 1, the **ccColorMatchResult**::**confidenceScore()** is 1.0 and **ccColorMatchResult**::**label()** is 0.

Throws

ccColorMatchDefs::BadParams
referenceColors is empty

ccColorMatchDefs::BadColorSpace
either the color space of *color* or *referenceColors* could not be converted to the same color as *runParams*.
  ```

ccColorMatchDefs::BadColorSpace
referenceColors has the color space **ccColorSpaceDefs::eUnknown**.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image satisfy the constraints of *runParams*.

- ```
  void cfColorMatch(const cc3PlanePelBuffer& image,
        const ccShapePtrh& region,
        const cmStd vector<ccColorValue>& referenceColors,
        const ccColorMatchRunParams &runParams,
        ccColorMatchResult &result);
  ```

Uses **cfGetSimpleColorFromImageRegion()** to compute the mean color from the region of *image* described by *region* and matches it with the collection of colors in *referenceColors*.

Region is defined in image's client coordinate system and can partially overlap *image*. In that case the intersection is used. If more than 50% of a pel falls inside the region, it is considered as being completely inside the region

If necessary the color spaces of *color* and *referenceColors* are converted to the same color space as *runParams*.

Parameters

image The image.

region A shape that defines a region. If *region* is NULL, the whole image is used.

referenceColors The reference colors.

runParams A **ccColorMatchRunParams** object that specifies the color space, distance metric, and weights to perform the match.

result A **ccColorMatchResult** object that contains the results of performing the match. If the size of *referenceColors* is 1, the **ccColorMatchResult**::**confidenceScore()** is 1.0 and **ccColorMatchResult**::**label()** is 0.

Throws

ccColorMatchDefs::BadParams
referenceColors is empty

ccColorMatchDefs::BadColorSpace
either the color space of *color* or *referenceColors* could not be converted to the same color space as *runParams*.
  ```

ccColorMatchDefs::BadColorSpace
referenceColors has the color space **ccColorSpaceDefs::eUnknown**.

ccColorMatchDefs::NotEnoughSamples
region and *image* do not intersect

Not enough pels (< 1) in the image satisfy the constraints of *runParams* or *region*.

ccColorMatchDefs::ShapeIsNotRegion
region is not a region shape.

ccColorMatchDefs::NonLinearXform
the image from client transform is nonlinear

- ```
  void cfColorMatch(const cc3PlanePelBuffer& image,
         const ccPelBuffer_const<c_UInt8>& mask,
         const cmStd vector<ccColorValue>& referenceColors,
         const ccColorMatchRunParams &runParams,
         ccColorMatchResult &result);
  ```

Uses **cfGetSimpleColorFromImage()** to compute the mean color from *image* (using hte supplied *mask*) and matches it with the collection of colors in *referenceColors*.

If necessary the color spaces of *color* and *referenceColors* are converted to the same color space as *runParams*.

Parameters

image The image.

mask An image mask. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

referenceColors The reference colors.

runParams A **ccColorMatchRunParams** object that specifies the color space, distance metric, and weights to perform the match.

result A **ccColorMatchResult** object that contains the results of performing the match. If the size of *referenceColors* is 1, the **ccColorMatchResult**::**confidenceScore()** is 1.0 and **ccColorMatchResult**::**label()** is 0.

Throws

ccColorMatchDefs::BadParams
referenceColors is empty
  ```

ccColorMatchDefs::BadColorSpace
either the color space of *color* or *referenceColors* could not be converted to the same color space as *runParams*.

ccColorMatchDefs::BadColorSpace
referenceColors has the color space **ccColorSpaceDefs::eUnknown**.

ccColorMatchDefs::NotEnoughSamples
Not enough pels (< 1) in the image satisfy the constraints of *mask* or *runParams*.

cfColorMatch()

cfConvertCDBtoVDB()

```
#include <ch_cvl/cdb.h>

cfConvertCDBtoVDB();
```

Global function that converts a CDB file to a VDB file.

cfConvertCDBtoVDB

```
cfConvertCDBtoVDB(const ccCvlString &cdbFile,
  const ccCvlString &vdbFile,
  ccCvlOStream *out = 0);
```

Converts CDB file named *cdbFile* to the VDB file named *vdbFile*.

Parameters

cdbFile	The name of the CDB file to convert.
vdbFile	The name of the VDB file to write.
out	An optional output stream to report errors and diagnostic messages.

Notes

Only records of *IMAGE_TYPE* and *ACQUIRE_TYPE* are written into destination file.

cfConvertCDBtoVDB()

cfConvertDisplayFormat2ImageFormat()

```
#include <ch_cvl/display.h>

cfConvertDisplayFormat2ImageFormat();
```

Global function to convert **DisplayFormat** values to their corresponding **ceImageFormat** values.

cfConvertDisplayFormat2ImageFormat

```
cfConvertDisplayFormat2ImageFormat(ccDisplay::DisplayFormat);
```

Converts the specified **DisplayFormat** value to its corresponding **ceImageFormat** value.

Notes

This function is intended to be used when constructing **ccAcqFifo**s that will be used exclusively with **startLiveDisplay()**.

Example

The following code fragment illustrates the use of this function.

```
// Determine the acquisition image format that matches the
// current display settings.
ceImageFormat ideal =
  cfConvertDisplayFormat2ImageFormat(myDisplay.displayFormat());

// Create a FIFO to acquire in the ideal format, if supported
ccAcqFifoPtrh fifo;
if (fg.isSupportedEx(vidfmt, ideal))
    fifo = vidfmt->newAcqFifoEx(fg, ideal);

// Otherwise, acquire in the format specified in the video format
else
  fifo = vidfmt->newAcqFifoEx(fg);

// Display a live image using the newly created fifo.
myDisplay.startLiveDisplay(fifo);
```

cfConvertDisplayFormat2ImageFormat()

cfConvertPel()

```
#include <ch_cvl/colorpel.h>

cfConvertPel();
```

Global function to convert pixels of one type to another.

cfConvertPel

```
void cfConvertPel (ccPackedRGB15Pel& t,
 const c_UInt8& p)

void cfConvertPel (ccPackedRGB15Pel& t,
 const ccPackedRGB15Pel& p)

void cfConvertPel (ccPackedRGB15Pel& t,
 const ccPackedRGB16Pel& p)

void cfConvertPel (ccPackedRGB15Pel& t,
 const ccPackedRGB24Pel& p)

void cfConvertPel (ccPackedRGB15Pel& t,
 const ccPackedRGB32Pel& p)

void cfConvertPel (ccPackedRGB16Pel& t, const c_UInt8& p)

void cfConvertPel (ccPackedRGB16Pel& t,
 const ccPackedRGB15Pel& p)

void cfConvertPel (ccPackedRGB16Pel& t,
 const ccPackedRGB16Pel& p)

void cfConvertPel (ccPackedRGB16Pel& t,
 const ccPackedRGB24Pel& p)

void cfConvertPel (ccPackedRGB16Pel& t,
 const ccPackedRGB32Pel& p)

void cfConvertPel (ccPackedRGB24Pel& t, const c_UInt8& f)

void cfConvertPel (ccPackedRGB24Pel& t,
 const ccPackedRGB15Pel& p)

void cfConvertPel (ccPackedRGB24Pel& t,
 const ccPackedRGB16Pel& p)

void cfConvertPel (ccPackedRGB24Pel& t,
 const ccPackedRGB24Pel& p)

void cfConvertPel (ccPackedRGB24Pel& t,
 const ccPackedRGB32Pel& p)
```

```
void cfConvertPel (ccPackedRGB32Pel& t, const c_UInt8& p)

void cfConvertPel (ccPackedRGB32Pel& t,
 const ccPackedRGB15Pel& p)

void cfConvertPel (ccPackedRGB32Pel& t,
 const ccPackedRGB16Pel& p)

void cfConvertPel (ccPackedRGB32Pel& t,
 const ccPackedRGB24Pel& p)

void cfConvertPel (ccPackedRGB32Pel& t,
 const ccPackedRGB32Pel& p)

void cfConvertPel (c_UInt8& t, const c_UInt8& f)

void cfConvertPel (c_UInt8& t, const ccPackedRGB15Pel& f)

void cfConvertPel (c_UInt8& t, const ccPackedRGB16Pel& f)

void cfConvertPel (c_UInt8& t, const ccPackedRGB24Pel& p)

void cfConvertPel (c_UInt8& t, const ccPackedRGB32Pel& f)
```

- `void cfConvertPel (ccPackedRGB15Pel& t, const c_UInt8& p)`

  Converts the 8-bit pel *p* to a **ccPackedRGB15Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- `void cfConvertPel (ccPackedRGB15Pel& t, const ccPackedRGB15Pel& p)`

  Converts the **ccPackedRGB15Pel** pel *p* to a **ccPackedRGB15Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- `void cfConvertPel (ccPackedRGB15Pel& t, const ccPackedRGB16Pel& p)`

  Converts the **ccPackedRGB16Pel** pel *p* to a **ccPackedRGB15Pel** and copies it to *t*.

Parameters

to The converted pixel.

from The pixel to conver.

- `void cfConvertPel (ccPackedRGB15Pel& t, const ccPackedRGB24Pel& p)`

  Converts the **ccPackedRGB24Pel** pel *p* to a **ccPackedRGB15Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB15Pel& t, const ccPackedRGB32Pel& p)`

  Converts the **ccPackedRGB32Pel** pel *p* to a **ccPackedRGB15Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB16Pel& t, const c_UInt8& p)`

  Converts the 8-bit pel *p* to a **ccPackedRGB16Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB16Pel& t, const ccPackedRGB15Pel& p)`

  Converts the **ccPackedRGB15Pel** pel *p* to a **ccPackedRGB16Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB16Pel& t, const ccPackedRGB16Pel& p)`

  Converts the **ccPackedRGB16Pel** pel *p* to a **ccPackedRGB16Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

from The pixel to conver.

- `void cfConvertPel (ccPackedRGB16Pel& t, const ccPackedRGB24Pel& p)`

  Converts the **ccPackedRGB24Pel** pel *p* to a **ccPackedRGB16Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB16Pel& t, const ccPackedRGB32Pel& p)`

  Converts the **ccPackedRGB32Pel** pel *p* to a **ccPackedRGB16Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB24Pel& t, const c_UInt8& f)`

  Converts the 8-bit pel *p* to a **ccPackedRGB24Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB24Pel& t, const ccPackedRGB15Pel& p)`

  Converts the **ccPackedRGB15Pel** pel *p* to a **ccPackedRGB24Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- `void cfConvertPel (ccPackedRGB24Pel& t, const ccPackedRGB16Pel& p)`

  Converts the **ccPackedRGB16Pel** pel *p* to a **ccPackedRGB24Pel** and copies it to *t*.

  Parameters

  to The converted pixel.

  from The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB24Pel& t,
    const ccPackedRGB24Pel& p)
  ```

  Converts the **ccPackedRGB24Pel** pel *p* to a **ccPackedRGB24Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB24Pel& t,
    const ccPackedRGB32Pel& p)
  ```

  Converts the **ccPackedRGB32Pel** pel *p* to a **ccPackedRGB24Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB32Pel& t, const c_UInt8& p)
  ```

  Converts the 8-bit pel *p* to a **ccPackedRGB32Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB32Pel& t,
    const ccPackedRGB15Pel& p)
  ```

  Converts the **ccPackedRGB15Pel** pel *p* to a **ccPackedRGB32Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB32Pel& t,
    const ccPackedRGB16Pel& p)
  ```

  Converts the **ccPackedRGB16Pel** pel *p* to a **ccPackedRGB32Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.
  ```

- ```
  void cfConvertPel (ccPackedRGB32Pel& t,
    const ccPackedRGB24Pel& p)
  ```

  Converts the **ccPackedRGB24Pel** pel *p* to a **ccPackedRGB32Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (ccPackedRGB32Pel& t,
    const ccPackedRGB32Pel& p)
  ```

  Converts the **ccPackedRGB32Pel** pel *p* to a **ccPackedRGB32Pel** and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (c_UInt8& t, const c_UInt8& f)
  ```

  Converts the 8-bit pel *p* to an 8-bit pel and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (c_UInt8& t, const ccPackedRGB15Pel& f)
  ```

  Converts the **ccPackedRGB15Pel** pel *p* to an 8-bit pel and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (c_UInt8& t, const ccPackedRGB16Pel& f)
  ```

  Converts the **ccPackedRGB16Pel** pel *p* to an 8-bit pel and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

- ```
  void cfConvertPel (c_UInt8& t, const ccPackedRGB24Pel& p)
  ```

  Converts the **ccPackedRGB24Pel** pel *p* to an 8-bit pel and copies it to *t*.

Parameters

to	The converted pixel.
from	The pixel to conver.

- `void cfConvertPel (c_UInt8& t, const ccPackedRGB32Pel& f)`

  Converts the **ccPackedRGB32Pel** pel p to an 8-bit pel and copies it to *t*.

  Parameters

to	The converted pixel.
from	The pixel to conver.

cfConvertPel()

cfConvertString()

```
#include <ch_cvl/unicode.h>

cfConvertString();
```

Global function to convert string between ANSI and Unicode formats. All of these functions throw *ccBadUnicodeChar* if a Unicode character cannot be converted to ANSI.

cfConvertString

```
void cfConvertString (cmStd string& to,
  const cmStd wstring& from);

void cfConvertString (cmStd wstring& to,
  const cmStd string& from);

void cfConvertString (cmStd wstring& to,
  int from);

static inline void cfConvertString (cmStd wstring& to,
  const cmStd wstring& from);

void cfConvertString (cmStd string& to, int from);

static inline void cfConvertString (cmStd string& to,
  const cmStd string& from);

void cfConvertString (char* to, const wchar_t* from);

void cfConvertString (wchar_t* to, const char* from);

static inline void cfConvertString (char* to,
  const char* from);

static inline void cfConvertString (wchar_t* to,
  const wchar_t* from);

void cfConvertString (wchar_t* to, const char* from,
  int len);

static inline void cfConvertString (char* to,
  const char* from, int len);

static inline void cfConvertString (wchar_t* to,
  const wchar_t* from, int len)
```

- ```
  void cfConvertString (cmStd string& to,
    const cmStd wstring& from);
  ```

  Converts and copies the contents of the Unicode string *from* to the ANSI string *to*.
  ```

Parameters

to	The ANSI string to receive the converted string.
from	The Unicode string to convert to ANSI.

- ```
  void cfConvertString (cmStd wstring& to,
    const cmStd string& from);
  ```

  Converts and copies the contents of the ANSI string *from* to the Unicode string *to*.

  Parameters

to	The Unicode string to receive the converted string.
from	The ANSI string to convert to Unicode.

- ```
  void cfConvertString (cmStd wstring& to, int from);
  ```

  Converts integer *from* into characters and places the result in the Unicode string *to*.

  Parameters

to	The Unicode string to receive the converted integer.
from	The integer string to convert to Unicode characters.

- ```
  static inline void cfConvertString (cmStd wstring& to,
    const cmStd wstring& from);
  ```

  Copies the Unicode string *from* to the Unicode string *to*.

  Parameters

to	The Unicode string to receive the copy.
from	The Unicode string to be copied.

- ```
  void cfConvertString (cmStd string& to, int from);
  ```

  Converts integer *from* into characters and places the result in the ANSI string *to*.

  Parameters

to	The ANSI string to receive the converted integer.
from	The integer string to convert to ANSI characters.

- `static inline void cfConvertString (cmStd string& to, const cmStd string& from);`

  Copies the ANSI string *from* to the ANSI string *to*.

  Parameters

to	The ANSI string to receive the copy.
from	The ANSI string to be copied.

- `void cfConvertString (char* to, const wchar_t* from);`

  Converts and copies the null-terminated Unicode character vector *from* to the null-terminated ANSI character vector *to*.

  Parameters

to	The ANSI character vector to receive the copy. The vector must be large enough to hold all the characters in *from*.
from	The Unicode character vector to be copied.

- `void cfConvertString (wchar_t* to, const char* from);`

  Converts and copies the null-terminated ANSI character vector *from* to the null-terminated Unicode character vector *to*.

  Parameters

to	The Unicode character vector to receive the copy. The vector must be large enough to hold all the characters in *from*.
from	The ANSI character vector to be copied.

- `static inline void cfConvertString (char* to, const char* from);`

  Copies the null-terminated ANSI character vector *from* to the null-terminated ANSI character vector *to*.

  Parameters

to	The ANSI character vector to receive the copy. The vector must be large enough to hold all the characters in *from*.
from	The ANSI character vector to be copied.

cfConvertString()

- ```
  static inline void cfConvertString (wchar_t* to,
    const wchar_t* from);
  ```

  Copies the null-terminated Unicode character vector *from* to the null-terminated Unicode character vector *to*.

  Parameters

to	The Unicode character vector to receive the copy. The vector must be large enough to hold all the characters in *from*.
from	The Unicode character vector to be copied.

- ```
  void cfConvertString (wchar_t* to, const char* from,
    int len);
  ```

  Converts and copies up to *len* characters of the null-terminated ANSI character vector *from* to the null-terminated Unicode character vector *to*.

  Parameters

to	The Unicode character vector to receive the copy. The vector must be large enough to hold *len* characters.
from	The ANSI character vector to be copied.
len	The maximum number of characters to copy.

- ```
  static inline void cfConvertString (char* to,
    const char* from, int len);
  ```

  Converts and copies up to *len* characters of the null-terminated ANSI character vector *from* to the null-terminated ANSI character vector *to*.

  Parameters

to	The ANSI character vector to receive the copy. The vector must be large enough to hold *len* characters.
from	The ANSI character vector to be copied.
len	The maximum number of characters to copy.

- ```
  static inline void cfConvertString (wchar_t* to,
    const wchar_t* from, int len);
  ```

  Copies up to *len* characters of the null-terminated Unicode character vector *from* to the null-terminated Unicode character vector *to*.

Parameters

to	The Unicode character vector to receive the copy. The vector must be large enough to hold *len* characters.
from	The Unicode character vector to be copied.
len	The maximum number of characters to copy.

cfConvertString()

cfConvertToFeaturelet()

```
#include <ch_cvl/edge.h>

cfConvertToFeaturelet();
```

Global function that converts an edgelet to a featurelet. Edgelets are described in the **ccEdgelet** reference page and featurelets are described in the **ccFeaturelet** reference page.

cfConvertToFeaturelet

```
static inline ccFeaturelet cfConvertToFeaturelet(
  const ccEdgelet &edgelet);
```

Returns a featurelet corresponding to the given edgelet.

The featurelet will have the edgelet's position, angle, and magnitude. The featurelet's *weight* is set to 1 and *isMod180* is set to false.

Parameters

edgelet	The edgelet to convert.

cfConvertToFeaturelet()

cfConvertToFeaturelets()

```
#include <ch_cvl/edge.h>

cfConvertToFeaturelets();
```

Global function that converts a set of edgelets to an array of featurelets. Edgelets are described in the **ccEdgelet** and **ccEdgeletSet** reference pages and featurelets are described in the **ccFeaturelet** reference page.

cfConvertToFeaturelets

```
void cfConvertToFeaturelets (
  const ccEdgeletSet &edgeletSet,
  cmStd vector<ccFeaturelet> &featurelets);
```

Parameters

edgeletSet	The edgelet set to convert.
featurelets	The converted edgelets are placed here.

The following conversions are made for each edgelet:

Edgelet	Featurelet
position	*position* mapped by the edgelet set's *clientFromImageXform.*
angle	The function computes the edgelet tangent angle and maps that angle by the edgelet set's *clientFromImageXform.* The featurelet *angle* is then computed as the normal to this mapped edgelet angle.
magnitude	*magnitude*, same as edgelet.
	weight set to 1.
	isMod180 set to false.

Notes

The featurelets will be in the same order as the edgelets and correspond one-to-one with the edgelets in **edgelet.edges()**.

During initialization the *featurelets* array is cleared. Any featurelets provided on input are discarded.

If the *edgeletSet* is empty the *featurelets* array will be empty. The function does not throw an error for this case.

cfConvertToFeaturelets()

cfConvertToFeatures()

```
#include <ch_cvl/edge.h>
#include <ch_cvl/bndtrckr.h>
#include <ch_cvl/blobdesc.h>

cfConvertToFeatures();
```

This is a global function that converts vision tool results to featurelet chain sets. It has three overloads as follows:

1. Edge tool

   Converts a set of edgelets and an associated index chain list to a featurelets chain set. Edgelets are described in the **ccEdgelet** and **ccEdgeletSet** reference pages and index chain lists are described in **ccIndexChainList**.

2. Boundary Tracker tool

   Converts a boundary tracker result into a featurelet chain list. A boundary tracker result is described in the **ccBoundaryTrackerResult** reference page.

3. Blob tool

   Converts a blob scene description into a featurelet chain list. A blob scene description is described in the **ccBlobSceneDescription** reference page.

See **ccFeatureletChainSet** for information about featurelet chain sets.

Notes

The Edge tool overload is in *edge.h*, the Boundary Tracker tool overload is in *bndtrckr.h*, and the Blob tool overload is in *blobdesc.h*.

cfConvertToFeatures()

cfConvertToFeatures

```
ccFeatureletChainSetPtrh cfConvertToFeatures(
  const ccEdgeletSet& set,
  const ccIndexChainList& chains);

cmImport_cogip
ccFeatureletChainSetPtrh cfConvertToFeatures(
  ccBoundaryTrackerResult& result,
  bool decreasingAngleSideFirst = true,
  bool isWhiteOnBlack = false);

cmImport_cogblob
ccFeatureletChainSetPtrh cfConvertToFeatures(
  const ccBlobSceneDescription *bsd,
  bool isInverted = false,
  bool onlyTopLevel = false);
```

-
```
ccFeatureletChainSetPtrh cfConvertToFeatures(
  const ccEdgeletSet& set,
  const ccIndexChainList& chains);
```

Returns a featurelet chain set for the given edgelet set and index chain list.

Parameters

set	The edgelet set to convert.
chains	The index chain list for *edgeletSet*.

Throws

ccEdgeletDefs::BadParams

If the input chains have any out of bounds pointers to edgelets or edgelet indices.

There will be one chain in the returned featurelet chain set for each edgelet chain, and the featurelet chains will be in the same order as the edgelet chains.

A featurelet chain will be closed if and only if its corresponding edgelet chain is closed. Each featurelet chain will contain a featurelet for each edgelet in the corresponding edgelet chain, and in the same chain order.

The following conversions are made for each edgelet:

Edgelet	Featurelet
position	The edgelet *position* mapped by the edgelet set's *clientFromImageXform*
angle	The function computes the edgelet tangent angle by subtracting 90° from the edgelet's **angle()** and then mapping that tangent angle by the edgelet set's *clientFromImageXform*. The featurelet angle is then computed as the normal to this mapped tangent angle.
magnitude	Same as edgelet *magnitude*.
	weight set to 1.
	isMod180 set to false.

Notes

If the *edgeletSet* is empty the featurelets chain set will be empty. The function does not throw an error for this case.

-
```
cmImport_cogip
ccFeatureletChainSetPtrh cfConvertToFeatures(
  ccBoundaryTrackerResult& result,
  bool decreasingAngleSideFirst = true,
  bool isWhiteOnBlack = false);
```

Returns a featurelet chain set for the given boundary tracker result. The featurelet chain set will contain a single chain. The chain will contain a featurelet for each boundary tracker point, and in the same order. The chain will be open if, and only if, the *eOpenBoundary* status flag is set.

The *decreasingAngleSideFirst* and *isBlackOnWhite* parameters must be the same parameters used to generate the *result*. *isWhiteOnBlack* corresponds to the *eWhiteOnBlack* boundary tracker run-time parameter.

Parameters

result The boundary tracker result to be converted.

decreasingAngleSideFirst
The boundary tracker parameter used to generate *result*.

isWhiteOnBlack The boundary tracker parameter used to generate *result*.

The following conversions are made from boundary tracker results:

Boundary tracker	Featurelet
position	*position*, same as boundary tracker (client coordinates).
angle	*angle* normal to the boundary tracker angle and in the direction towards the white side of the shape. The featurelet angles are in the gradient direction (from negative to positive) normal to the **ccBoundaryTrackerPoint** angles which are in the tangent direction.
	magnitude is set to 0.
	weight set to 1.
	isMod180 set to false.

Notes

If no valid boundary has been tracked, or if the boundary tracker **statusFlags()** = 0, this function returns an empty featurelet chain set.

-
```
cmImport_cogblob
ccFeatureletChainSetPtrh cfConvertToFeatures(
  const ccBlobSceneDescription *bsd,
  bool isInverted = false,
  bool onlyTopLevel = false);
```

Returns a featurelet chain set for the given blob scene description. There is exactly one chain for each blob (except for non-top-level blobs which are ignored when the *onlyTopLevel* parameter is true). In each chain, there is exactly one featurelet for each *boundaryChainCode* element. The positions of the featurelets correspond to the points on the walk specified by the *boundaryChainCode* (transformed by the scene's clientFromImageXform). For example, if the blob scene description includes a single blob of a single pixel, then the featurelet chain set would include one featurelet chain, and the featurelet chain would include 4 featurelets, one at each corner of the pixel (corresponding to the boundary chain code which has four elements).

If *isInverted* is true, the featurelet chain set will correspond to a dark-on-bright region. If *onlyTopLevel* is true, the featurelet chain set only includes the top level blobs; otherwise, the featurelet chain set includes all of the blobs.

Parameters

bsd The blob scene description to convert.

isInverted Blob polarity inverted; true or false.

onlyTopLevel Convert all of the blobs, or just the top level; true or false.

The following conversions are made from blob scene description:

Blob	Featurelet
position	*position*, same as positions of *boundaryChainCode* elements, transformed by the blob scene's *clientFromImageXform*.
angle	The tangent angle at each point is computed in image coordinates as the average of the two incident vectors to the two adjacent points, and in the direction of the walk in the image. This tangent angle is then mapped by the scene's *clientFromImageXform*. The featurelet angle is computed as the normal of this mapped tangent angle, in client coordinates.
	magnitude is set to 0.
	weight set to 1.
	isMod180 set to false.

Notes

If the blob scene description is NULL, this function returns an empty featurelet chain set.

Because of the way blobs and featurelet chains are measured, measures such as area, center of mass, and bounding box computed from a featurelet chain set may be different than the same measures computed from the original blob scene description.

Boundaries corresponding to blobs with an odd depth (for example, the number of levels from the top-level blob) will have opposite handedness of the top-level blobs. Even depth blobs will have the same handedness of the top-level blobs.

Nominally, the featurelet chains corresponding to top-level blobs will be right-handed. If *isInverted* is true, the featurelet chains corresponding to top-level blobs will be left-handed.

cfConvertToFeatures()

cfConvertVDBtoCDB()

```
#include <ch_cvl/cdb.h>

cfConvertVDBtoCDB();
```

Global function that converts a CDB file to a VDB file.

cfConvertVDBtoCDB

```
cfConvertVDBtoCDB(const ccCvlString &vdbFile,
  const ccCvlString &cdbFile,
  ccCvlOStream *out = 0);
```

Converts VDB file named *vdbFile* to the CDB file named *cdbFile*.

Parameters

vdbFile	The name of the VDB file to convert.
cdbFile	The name of the CDB file to write.
out	An optional output stream to report errors and diagnostic messages.

Notes

Only records with acquired images are written into destination file.

cfConvertVDBtoCDB()

cfConvolve()

```
#include <ch_cvl/convolve.h>

cfConvolve();
```

Global function to convolve an image with a user-defined 3x3 kernel. You specify optional convolution parameters by supplying a **ccConvolveParams** object.

cfConvolve

```
template<class S, class D, class K> void cfConvolve(
  const ccPelBuffer_const<S>& src,
  const ccPelBuffer_const<K>& kernel, ccPelBuffer<D>& dst);

template<class S, class D, class K> void cfConvolve(
  const ccPelBuffer_const<S>& src,
  const ccPelBuffer_const<K>& kernel,
  const ccConvolveParams& params, ccPelBuffer<D>& dst);

template<class S, class K> ccPelBuffer<S> cfConvolve(
  const ccPelBuffer_const<S>& src,
  const ccPelBuffer_const<K>& kernel);

template<class S, class K> ccPelBuffer<S> cfConvolve(
  const ccPelBuffer_const<S>& src,
  const ccPelBuffer_const<K>& kernel,
  const ccConvolveParams& params);
```

- ```
  template<class S, class D, class K> void cfConvolve(
    const ccPelBuffer_const<S>& src,
    const ccPelBuffer_const<K>& kernel, ccPelBuffer<D>& dst);
  ```

  Convolves the supplied image with the supplied kernel using the default convolution parameters (automatic kernel prescaling and normalization and a kernel origin in the center of the kernel).

  Parameters

S	Template parameter specifying the type of the pixels in *src*. *S* must be **c_UInt8**.
D	Template parameter specifying the type of the pixels in *dst*. *D* must be **c_UInt8** or **c_Int16** and it must be the same as *K*.
K	Template parameter specifying the type of the pixels in *kernel*. *K* must be **c_UInt8** or **c_Int16** and it must be the same as *D*
src	The source image. *src* must be bound.
kernel	The kernel. *kernel* must be 3x3 in size and it must be bound.
  ```

dst The destination image.

If *dst* is bound, the only pixels in *src* that the tool considers are those that would produce convolved pixels lying within the greatest common region of *src* and *dst*.

If *dst* is unbound, a root image for *dst* is allocated all the pixels in *src* are convolved.

Throws

ccConvolveParams::NotImplemented
kernel is not 3x3 in size.

ccConvolveParams::UnboundWindow
src or *kernel* is unbound.

ccConvolveParams::BadArgument
The width or height of *src* is less than 3.

- ```
  template<class S, class D, class K> void cfConvolve(
    const ccPelBuffer_const<S>& src,
    const ccPelBuffer_const<K>& kernel,
    const ccConvolveParams& params, ccPelBuffer<D>& dst);
  ```

Convolves the supplied image with the supplied kernel using the specified convolution parameters.

Parameters

S Template parameter specifying the type of the pixels in *src*. *S* must be **c_UInt8**.

D Template parameter specifying the type of the pixels in *dst*. *D* must be **c_UInt8** or **c_Int16** and it must be the same as *K*.

K Template parameter specifying the type of the pixels in *kernel*. *K* must be **c_UInt8** or **c_Int16** and it must be the same as *D*

src The source image. *src* must be bound.

kernel The kernel. *kernel* must be 3x3 in size and it must be bound.

params A **ccConvolveParams** specifying the convolution parameters.

dst The destination image.

If *dst* is bound, the only pixels in *src* that the tool considers are those that would produce convolved pixels lying within the greatest common region of *src* and *dst*.
  ```

If *dst* is unbound, a root image for *dst* is allocated all the pixels in *src* are convolved.

Throws

ccConvolveParams::NotImplemented
kernel is not 3x3 in size.

ccConvolveParams::UnboundWindow
src or *kernel* is unbound.

ccConvolveParams::BadArgument
The width or height of *src* is less than 3; *params* specifies a negative normalization coefficient; or *params* specifies a kernel origin that does not lie within *kernel*.

- ```
  template<class S, class K> ccPelBuffer<S> cfConvolve(
    const ccPelBuffer_const<S>& src,
    const ccPelBuffer_const<K>& kernel);
  ```

Convolves the supplied image with the supplied kernel using the default convolution parameters (automatic kernel prescaling and normalization and a kernel origin in the center of the kernel) and returns the resulting convolved image.

Parameters

S Template parameter specifying the type of the pixels in *src*. *S* must be **c_UInt8**. The returned image will also be of type *S*.

K Template parameter specifying the type of the pixels in *kernel*. *K* must be **c_UInt8**.

src The source image. *src* must be bound.

kernel The kernel. *kernel* must be 3x3 in size and it must be bound.

Throws

ccConvolveParams::NotImplemented
kernel is not 3x3 in size.

ccConvolveParams::UnboundWindow
src or *kernel* is unbound.

ccConvolveParams::BadArgument
The width or height of *src* is less than 3.
  ```

- ```
  template<class S, class K> ccPelBuffer<S> cfConvolve(
    const ccPelBuffer_const<S>& src,
    const ccPelBuffer_const<K>& kernel,
    const ccConvolveParams& params);
  ```

  Convolves the supplied image with the supplied kernel using the specified convolution parameters and returns the resulting convolved image.

  Parameters

  S — Template parameter specifying the type of the pixels in *src*. *S* must be **c_UInt8**. The returned image will also be of type *S*.

  K — Template parameter specifying the type of the pixels in *kernel*. *K* must be **c_UInt8**.

  src — The source image. *src* must be bound.

  kernel — The kernel. *kernel* must be 3x3 in size and it must be bound.

  params — A **ccConvolveParams** specifying the convolution parameters.

  Throws

  ccConvolveParams::NotImplemented
  kernel is not 3x3 in size.

  ccConvolveParams::UnboundWindow
  src or *kernel* is unbound.

  ccConvolveParams::BadArgument
  The width or height of *src* is less than 3; *params* specifies a negative normalization coefficient; or *params* specifies a kernel origin that does not lie within *kernel*.
  ```

cfCreateThread()

```
#include <ch_cvl/threads.h>

cfCreateThread();
```

Global function to create a non-MFC thread.

Note This function is deprecated in CVL 6.0.1 and later.

In applications built with Microsoft Visual C++ .NET, you can no longer call MFC functions from non-MFC threads. Use the CVL global function **cfCreateThreadMFC()** to create an MFC thread, or **cfCreateThreadCVL()** to create a non-MFC thread.

For an overview of this subject, see the chapter Writing Multithreaded CVL Applications in the *CVL User's Guide*.

cfCreateThread()

cfCreateThreadCVL()

```
#include <ch_cvl/threads.h>

cfCreateThreadCVL();
```

Global function to create a non-MFC thread.

In applications built with Microsoft Visual C++.NET, you can no longer call MFC functions from non-MFC threads. Use **cfCreateThreadCVL()** rather than **cfCreateThread()**, which has been deprecated, to create a non-MFC thread. Use **cfCreateThreadMFC()** to create an MFC thread. For an overview of threads, see the chapter Writing Multithreaded CVL Applications in the *CVL User's Guide*.

cfCreateThreadCVL

```
ccThreadID cfCreateThreadCVL(
  void (* proc)(void *),
  void *arg,
  cePriority priority=cePriorityDefault,
  c_Int32 stackSize=-1);
```

Starts a new thread with the specified priority. Execution of the new thread begins with the supplied function.

Parameters

proc — The function with which to begin the thread. The supplied function must have the following signature:

```
void myThreadFunction(void *arg);
```

The *arg* argument will contain the value you supply when you call **cfCreateThreadCVL()**.

arg — The argument to be supplied to *proc* when it is invoked.

priority — The priority to assign to the new thread. *priority* must be one of the following values:

cePriorityDefault
cePriorityIdle
cePriorityLowest
cePriorityBelowNormal
cePriorityNormal
cePriorityAboveNormal
cePriorityHighest
cePriorityTimeCritical

If you specify *cePriorityDefault* (which is the default value) then the new thread is assigned the same priority as the current thread.

In CVL applications that will execute on the MVS-82400, do not create threads of priority *cePriorityTimeCritical*. If your application creates threads at this priority, your application on the embedded processor may experience problems with **ccTimer** objects and delays in image acquisition.

stackSize Size of the stack (specified in bytes) to reserve for this thread. A value of -1 means to use the operating system default. On the C80, the default stack size is 8K (8192 bytes).

Notes

Beginning with Visual C++ .NET, MFC will assert if you make MFC function calls from non-MFC threads. Always use MFC threads if a thread makes calls either to MFC functions or to CVL classes that use MFC (such as **ccDisplayConsole**). You can create MFC threads with either the CVL global function **cfCreateThreadMFC()** or the MFC function **AfxBeginThread()**.

Any errors thrown by the new thread are output to a **cogDebug** window before the thread terminates.

Throws

ccThreadID::CreateFailed
The thread could not be created.

cfCreateThreadMFC()

```
#include <ch_cvl/thrdsmfc.h>

cfCreateThreadMFC();
```

Global function to create an MFC worker thread. You should call MFC functions, and methods of objects that use MFC (such as **ccDisplayConsole**), only from MFC threads.

cfCreateThreadMFC

```
ccThreadID cfCreateThreadMFC(
  void (* proc)(void *),
  void *arg,
  cePriority priority=cePriorityDefault,
  c_Int32 stackSize=-1);
```

Creates a new MFC worker thread with the specified priority. The new thread starts execution with the supplied function **proc(arg)**.

Parameters

proc — The function with which to begin the thread. The supplied function must have the following signature:

```
void myFunctionName(void *arg);
```

arg — An argument that will be supplied to *proc* when it is invoked.

priority — The priority to assign to the new thread. Must be one of the following values:

cePriorityDefault
cePriorityIdle
cePriorityLowest
cePriorityBelowNormal
cePriorityNormal
cePriorityAboveNormal
cePriorityHighest
cePriorityTimeCritical

If the priority is *cePriorityDefault*, then the new thread is assigned the same priority as the calling thread.

In CVL applications that will execute on the MVS-82400, do not create threads of priority *cePriorityTimeCritical*. If your application creates threads at this priority, your application on the embedded processor may experience problems with **ccTimer** objects and delays in image acquisition.

stackSize Size of the stack (specified in bytes) to reserve for this thread. A value of -1 means to use the operating system default. On the C80, the default stack size is 8K (8192 bytes).

Notes

Beginning with Microsoft Visual C++ .NET, MFC will assert if you make MFC function calls from non-MFC threads. Always use MFC threads if a thread makes calls either to MFC functions or to CVL classes that use MFC (such as **ccDisplayConsole**). You can create MFC threads with either the CVL global function **cfCreateThreadMFC()** or the MFC function **AfxBeginThread()**.

Any errors thrown by the new thread are output to a **cogDebug** window before the thread terminates.

Throws

ccThreadID::CreateFailed
The MFC thread could not be created.

cfDefaultPelRootPool()

```
#include <ch_cvl/pelpool.h>

cfDefaultPelRootPool();
```

Global function to obtain the default root image pool (pel root pool).

Notes

This function does not apply to MVS-8600 and MVS-8600e frame grabbers. For these frame grabbers see **cc8600::sizePelRoot()**.

cfDefaultPelRootPool

```
const ccPelRootPoolPtrh& cfDefaultPelRootPool();

const ccPelRootPoolPtrh& cfDefaultPelRootPool(
  size_t size);
```

- `const ccPelRootPoolPtrh& cfDefaultPelRootPool();`

  Constructs a static pel root pool and returns a reference to it. The first time the function is called, the pel root pool is constructed. Later calls simply return a reference to the same pel root pool. Retrieve the size of the pool with **cfDefaultPelRootPoolSize** on page 3621.

- `const ccPelRootPoolPtrh& cfDefaultPelRootPool(size_t size);`

  Constructs a static pel root pool and returns a reference to it. The first time the function is called, the pel root pool is constructed. Later calls simply return a reference to the same pel root pool.

  Parameters

size	The size of the root image pool in bytes.

  Notes

  The default pel root pool size is determined the first time that **cfDefaultPelRootPool(size)** is called. If this function is not called directly, the first time it is called is normally the first time any FIFO is constructed. Acquisition FIFO construction fills the *pelRootPool* property with the return value from this function.

  You can change the default pel root pool size by calling **cfDefaultPelRootPool(size)** before constructing any FIFO. The return value can be dropped since it is the side effect of constructing the pel root pool that is important. Calling this function after a FIFO has been constructed will have no effect as the pel root pool will already have been constructed with the default 4MB size.

The default 4 MB pool can supply 9 full resolution CCIR buffers or 13 full resolution RS-170 pel roots. This may not be enough if buffers are held for some time instead of being recycled quickly.

Notes for the MVS-8100L:

The MVS-8100L normally uses two pel roots at a time when performing acquisitions. This is different than with other boards such as the MVS-8100M where only one pel root at a time is claimed for acquisition. This difference can show up as buffer starvation on the MVS-8100L in multiboard situations where the MVS-8100M does not show any problem.

cfDefaultPelRootPoolSize()

```
#include <ch_cvl/pelpool.h>

cfDefaultPelRootPoolSize();
```

Global function to obtain the default size of the default root image pool.

cfDefaultPelRootPoolSize

```
size_t cfDefaultPelRootPoolSize();
```

Returns the default size of the default root image pool in bytes. The default pel root pool size is 4 MB, unless the pool has been resized or the default size was overridden. You can retrieve the current size of the pool with **cfDefaultPelRootPool().size()**.

cfDefaultPelRootPoolSize()

cfDetectMouseBites()

```
#include <ch_cvl/pmifproc.h>

cfDetectMouseBites();
```

Global function to detect mousebites within a PatInspect feature.

cfDetectMouseBites

```
cmStd vector<ccMouseBite> cfDetectMouseBites(
  const ccPMInspectMatchedFeature& feature,
  c_Int32 minSize, double alpha);
```

Segments the supplied **cc_PMInspectFeature** into one or more **ccFeatureSegment**s.

Parameters

feature — A PatInspect feature.

minSize — Only mousebites larger than *minSize* are returned by the function. *minSize* is specified as the minimum number of feature boundary points in a mousebite.

alpha — The threshold value for mousebites. Only feature boundary points that have a distance from their expected position greater than *alpha* times the mean variation from the expected position of all points are considered as mousebites.

Note that if you run this function using the training image as the run-time image, the results may include unexpected mousebites. This happens because the feature boundary points are identical between the two images.

cfDetectMouseBites()

cfDetectSceneAngle()

```
#include <ch_cvl/scnangle.h>

cfDetectSceneAngle();
```

Global function to determine the angle of the predominant features in an image.

Notes

The first two overloads determine the scene angle using the Scene Angle Finder tool. The third overload determines the scene angle using the Scene Angle Finder-II tool.

cfDetectSceneAngle

```
void cfDetectSceneAngle (
  const ccPelBuffer_const<c_UInt8>& pelBufInputROI,
  const ccSceneAngleFinderRunParams& runParams,
  ccSceneAngleFinderResultSet& resultSet);

void cfDetectSceneAngle(
  const ccPelBuffer_const<c_UInt8>& pelBufInputROI,
  const ccEdgeletSet& edgeletSet,
  const ccSceneAngleFinderRunParams& runParams,
  ccSceneAngleFinderResultSet& resultSet);

void cfDetectSceneAngle(
  const ccPelBuffer_const<c_UInt8>& image,
   const ccSceneAngleFinderIIRunParams& runParams,
   ccSceneAngleFinderIIResultSet& resultSet);
```

- ```
  void cfDetectSceneAngle (
    const ccPelBuffer_const<c_UInt8>& pelBufInputROI,
    const ccSceneAngleFinderRunParams& runParams,
    ccSceneAngleFinderResultSet& resultSet);
  ```

  Computes and returns the angle of the predominant features within the supplied image using the Scene Angle Finder tool. The returned angle is the angle from the client coordinate x-axis to the positive gradient direction of the predominant features.

  Parameters

pelBufInputROI	The image whose scene angle is computed.
runParams	A **ccSceneAngleFinderRunParams** that contains the run-time parameters.
resultSet	A **ccSceneAngleFinderResultSet** into which the results are placed.
  ```

cfDetectSceneAngle()

- ```
  void cfDetectSceneAngle(
    const ccPelBuffer_const<c_UInt8>& pelBufInputROI,
    const ccEdgeletSet& edgeletSet,
    const ccSceneAngleFinderRunParams& runParams,
    ccSceneAngleFinderResultSet& resultSet);
  ```

  Computes and returns the angle of the predominant features described by the supplied **ccEdgeletSet** using the Scene Angle Finder tool. The returned angle is the angle from the client coordinate x-axis of the supplied image to the positive gradient direction of the predominant features in the **ccEdgeletSet** plus 90°.

  The contrast threshold, smoothing, and subsampling offset values in the supplied **ccSceneAngleFinderRunParams** are ignored by this function.

  Parameters

pelBufInputROI	An image whose client coordinate system should be the same as the client coordinate system associated with *edgeletSet*.
edgeletSet	A **ccEdgeletSet** that contains the subpixel edge information from which the scene angle is computed.
runParams	A **ccSceneAngleFinderRunParams** that contains the run-time parameters.
resultSet	A **ccSceneAngleFinderResultSet** into which the results are placed.

- ```
  void cmImport_cogip cfDetectSceneAngle(
    const ccPelBuffer_const<c_UInt8>& image,
     const ccSceneAngleFinderIIRunParams& runParams,
     ccSceneAngleFinderIIResultSet& resultSet);
  ```

  Computes and returns the angle of the predominant features within the supplied image using the Scene Angle Finder-II tool. The returned angle is the angle from the client coordinate x-axis to the positive gradient direction of the predominant features plus 90°.

  Parameters

image	The image whose scene angle is computed.
runParams	A **ccSceneAngleFinderIIRunParams** that contains the run-time parameters.
resultSet	A **ccSceneAngleFinderIIResultSet** into which the results are placed.

  Notes

  image must be at least 32x32 pixels in size.

cfDrawSynthetic()

```
#include <ch_cvl/genpoly.h>

cfDrawSynthetic();
```

Note This function is deprecated. Use **cfRasterize()** instead.

Global function to draw a synthetic version of the supplied closed shape in the supplied pel buffer. The clientFromShape transform specifies how this shape maps into the client coordinates of the pel buffer. The inside of the shape is rendered in the supplied grey value. Pixels that fall atop any segment are rendered in an interpolated grey level that is between the inside grey level and the background grey level in the area immediately outside the generalized polygon at that pixel.

cfDrawSynthetic

```
void cfDrawSynthetic(const ccGenPoly& shape,
  const cc2Xform& clientFromShape,
  ccPelBuffer<c_UInt8>& pelbuf,
  c_UInt8> insideGrayLevel);

void cfDrawSynthetic(const ccGenPoly& shape,
  const cc2XformBasePtrh_const& clientFromShape,
  ccPelBuffer<c_UInt8>& pelbuf,
  c_UInt8 insideGrayLevel);
```

- ```
  void cfDrawSynthetic(const ccGenPoly& shape,
    const cc2Xform& clientFromShape,
    ccPelBuffer<c_UInt8>& pelbuf,
    c_UInt8> insideGrayLevel);
  ```

  Draws a synthetic version of the supplied closed shape in the supplied pel buffer.

  Parameters

  shape The closed shape

  clientFromShape Transform that maps the shape into the client coordinates of the pel buffer. The transform is provided as a two-dimensional transformation object (**cc2Xform**).

  pelbuf The pel buffer in which the synthetic shape is to be drawn

  insideGrayLevel The pixel value of the area inside the border of the closed shape

  Throws

  ccShapesError::BadGeom
  shape is not closed
  ```

- ```
  void cfDrawSynthetic(const ccGenPoly& shape,
    const cc2XformBasePtrh_const& clientFromShape,
    ccPelBuffer<c_UInt8>& pelbuf,
    c_UInt8 insideGrayLevel);
  ```

  Draws a synthetic version of the supplied closed shape in the supplied pel buffer.

  Parameters

  shape The closed shape

  clientFromShape Transform that maps the shape into the client coordinates of the pel buffer. The transform is provided as a constant pointer handle to a generic two-dimensional transformation object (**cc2XformBasePtrh_const**).

  pelbuf The pel buffer in which the synthetic shape is to be drawn

  insideGrayLevel The pixel value of the area inside the border of the closed shape

  Throws

  ccShapesError::BadGeom
  shape is not closed
  ```

cfEdgeDetect()

```
#include <ch_cvl/edge.h>

cfEdgeDetect();
```

Global function to apply the Edge tool to an input image.

cfEdgeDetect

```
template<class S, class D>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params,
  ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
  ccDiagObject* obj, c_UInt32 diagFlags);

template<class S>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params, ccEdgeletSet& dst,
  ccDiagObject* obj, c_UInt32 diagflags);

template<class S, class D>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params,
  ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
  ccEdgeletSet& dstSet,
  ccDiagObject* obj, c_UInt32 diagFlags);

template<class S, class D>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params,
```

```
  ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
  ccEdgeletSet& dstSet, ccIndexChainList& chains,
  ccDiagObject* obj, c_UInt32 diagFlags);

template<class S>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params,

  ccDiagObject* obj, c_UInt32 diagFlags);

template<>
void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
  const ccEdgeletParams& params,
  ccEdgeletSet& dstSet, ccIndexChainList& chains,
  ccDiagObject* obj, c_UInt32 diagFlags);
```

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Edge magnitude and edge angle images are written to the supplied pel buffers. Diagnostic information is written to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**.
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

- ```
  template<class S>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params, ccEdgeletSet& dst,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dst	The edgelet set in which to store the edgelet objects.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Edge magnitude and edge angle images are written to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
  ```

```
ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
ccEdgeletSet& dstSet, ccIndexChainList& chains,
ccDiagObject* obj, c_UInt32 diagFlags);
```

Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

-
```
template<class S>
void cfEdgeDetect(const ccPelBuffer_const<S>& src,
  const ccEdgeletParams& params,
  ccEdgeletSet& dstSet, ccIndexChainList& chains,
  ccDiagObject* obj, c_UInt32 diagFlags);
```

Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstSet	The edgelet set in which the edgelet objects are stored.

chains Index chain list ordering the edgelets in the edgelet set.

obj The diagnostic object in which to store diagnostic information.

diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Edge magnitude and edge angle images are stored to the supplied pel buffers. Creates an empty diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.

  dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccDiagObject* obj);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Stores diagnostic information to the supplied diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.

dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

obj The diagnostic object in which to store diagnostic information.

- ```
  template<class S>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dst);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Creates a empty diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

  params The edgelet parameters used for edge detection.

  dst The edgelet set in which the edgelet objects are stored.

- ```
  template<class S>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dst, ccDiagObject* obj);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

  params The edgelet parameters used for edge detection.

  dst The edgelet set in which the edgelet objects are stored.

  obj The diagnostic object in which to store diagnostic information.

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Creates an empty diagnostic object with diagnostic flags set to zero.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet, ccDiagObject* obj);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object with diagnostic flags set to zero.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

dstSet The edgelet set in which the edgelet objects are stored.

obj The diagnostic object in which to store diagnostic information.

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet, ccIndexChainList& chains);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Creates an empty diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.

  dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

  dstSet The edgelet set in which the edgelet objects are stored.

  chains Index chain list ordering the edgelets in the edgelet set.

- ```
  template<class S, class D>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<D>& dstMag, ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet, ccIndexChainList& chains,
    ccDiagObject* obj);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object with diagnostic flags set to zero.

  Parameters

  src The input image. Must be of type **c_UInt8** or **c_Int16**

params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound. *dstMag* must be of type **c_UInt8**.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.
obj	The diagnostic object in which to store diagnostic information.

- ```
  template<class S>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dstSet, ccIndexChainList& chains);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Creates an empty diagnostic object with diagnostic flags set to zero.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**
params	The edgelet parameters used for edge detection.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.

- ```
  template<class S>
  void cfEdgeDetect(const ccPelBuffer_const<S>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dstSet, ccIndexChainList& chains,
    ccDiagObject* obj);
  ```

  Applies the Edge tool to the supplied input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object with diagnostic flags set to zero.

  Parameters

src	The input image. Must be of type **c_UInt8** or **c_Int16**

params The edgelet parameters used for edge detection.

dstSet The edgelet set in which the edgelet objects are stored.

chains Index chain list ordering the edgelets in the edgelet set.

obj The diagnostic object in which to store diagnostic information.

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_UInt8>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
    ccPelBuffer<c_UInt8>& dstAng,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 8-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

  src The 8-bit input image.

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.

  dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

  obj The diagnostic object in which to store diagnostic information.

  diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_UInt8>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dstSet,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 8-bit input image using the supplied edgelet parameters. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

  src The 8-bit input image.

  params The edgelet parameters used for edge detection.

dstSet	The edgelet set in which the edgelet objects are stored.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_UInt8>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
    ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 8-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

src	The 8-bit input image.
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_UInt8>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
  ```

```
ccPelBuffer<c_UInt8>& dstAng,
ccEdgeletSet& dstSet, ccIndexChainList& chains,
ccDiagObject* obj, c_UInt32 diagFlags);
```

Applies the Edge tool to the supplied 8-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The 8-bit input image.
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

-
```
template<>
void cfEdgeDetect(const ccPelBuffer_const<c_UInt8>& src,
  const ccEdgeletParams& params,
  ccEdgeletSet& dstSet, ccIndexChainList& chains,
  ccDiagObject* obj, c_UInt32 diagFlags);
```

Applies the Edge tool to the supplied 8-bit input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The 8-bit input image.
params	The edgelet parameters used for edge detection.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.

obj The diagnostic object in which to store diagnostic information.

diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
    ccPelBuffer<c_UInt8>& dstAng,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 16-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

  src The 16-bit input image.

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.

  dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

  obj The diagnostic object in which to store diagnostic information.

  diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
    const ccEdgeletParams& params,
    ccEdgeletSet& dstSet,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 16-bit input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

  src The 16-bit input image.

  params The edgelet parameters used for edge detection.

  dstSet The edgelet set in which the edgelet objects are stored.

obj The diagnostic object in which to store diagnostic information.

diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
    ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 16-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

  Parameters

  src The 16-bit input image.

  params The edgelet parameters used for edge detection.

  dstMag The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.

  dstAng The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.

  dstSet The edgelet set in which the edgelet objects are stored.

  obj The diagnostic object in which to store diagnostic information.

  diagFlags The diagnostic flags (see **ccDiagDefs**).

- ```
  template<>
  void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
    const ccEdgeletParams& params,
    ccPelBuffer<c_UInt8>& dstMag,
    ccPelBuffer<c_UInt8>& dstAng,
    ccEdgeletSet& dstSet, ccIndexChainList& chains,
    ccDiagObject* obj, c_UInt32 diagFlags);
  ```

  Applies the Edge tool to the supplied 16-bit input image using the supplied edgelet parameters. Stores edge magnitude and edge angle images to the supplied pel buffers. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The 16-bit input image.
params	The edgelet parameters used for edge detection.
dstMag	The pel buffer in which to store the edge magnitude image. If *dstMag* is unbound, a root image is allocated and bound.
dstAng	The pel buffer in which to store the edge angle image. If *dstAng* is unbound, a root image is allocated and bound.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

-
```
template<>
void cfEdgeDetect(const ccPelBuffer_const<c_Int16>& src,
  const ccEdgeletParams& params,
  ccEdgeletSet& dstSet, ccIndexChainList& chains,
  ccDiagObject* obj, c_UInt32 diagFlags);
```

Applies the Edge tool to the supplied 16-bit input image using the supplied edgelet parameters. Returns an edgelet set containing an edgelet object for each edge in the input image. Returns an index chain list ordering the edgelets in the edgelet set. Stores diagnostic information to the supplied diagnostic object using the supplied diagnostic flags.

Parameters

src	The 16-bit input image.
params	The edgelet parameters used for edge detection.
dstSet	The edgelet set in which the edgelet objects are stored.
chains	Index chain list ordering the edgelets in the edgelet set.
obj	The diagnostic object in which to store diagnostic information.
diagFlags	The diagnostic flags (see **ccDiagDefs**).

cfEllipseFit()

```
#include <ch_cvl/fit.h>

cfEllipseFit();
```

Global function to fit an ellipse to a set of points.

cfEllipseFit

```
void cfEllipseFit(
  const ccEllipseFitParams &params,
  cmStd vector<cc2Vect> &pts,
  ccEllipseFitResults &results);
```

A global function that fits an Ellipse to the supplied set of points using the supplied **ccEllipseFitParams**.

Parameters

params — A **ccEllipseFitParams** describing the fitting method, number of outliers to ignore, and maximum RMS error threshold.

pts — A vector of points specified in a single coordinate system.

results — A reference to a **ccEllipseFitResults** object into which the results will be placed. Any existing contents of *results* are cleared.

Throws

ccMathError::Singular

If **params.numIgnore()** > **pts.size()** - 5,
or if an ellipse cannot be fitted to the given data points (*pts*) using the given parameters.

cfEllipseFit()

cfEqualize_1()

```
#include <ch_cog/equalize.h>

cfEqualize_1();
```

Global function to equalize brightness and contrast on a dual-tap **ccAcqFifo**.

cfEqualize_1

```
bool cfEqualize_1(ccGreyAcqFifoPtrh fifo);
```

This function automatically acquires a series of images from the supplied **ccAcqFifo** and adjusts the brightness and contrast values on the two channels (starting with the odd channel) until they are balanced.

The residual difference in grey level values between the fields after calling this function depends on the initial contrast value that is specified for the supplied **ccAcqFifo**. The following table shows the maximum residual grey level difference between the fields after calling this function with different initial contrast levels.

Contrast	Maximum Residual Difference
0.0	± 2 grey levels
0.5	± 4 grey levels
0.75	± 8 grey levels

Note that if you call **cfEqualize_1()** on a **ccAcqFifo** that is already balanced within the limits shown in the preceding table, the function may *increase* the imbalance, although the residual imbalance will remain within the limits shown in the preceding table.

This function returns true if the supplied **ccAcqFifo** was balanced. It returns false if it was unable to balance the fields due to an internal error.

Parameters

fifo The **ccAcqFifo** to equalize.

Notes

You must include the file *ch_cog/equalize.h* in your source file to use this function.

This function saves and restores the current input lookup table associated with *fifo*. The equalization is performed using the *positive8BitLut* linear 8-bit lookup table.

If you change the contrast or brightness of the **ccAcqFifo** after calling this function, the field balance may be lost. You should always call **cfEqualize_1()** after adjusting the **ccAcqFifo**'s brightness or contrast.

cfEqualize_1()

cfFilterConvolve()

```
#include <ch_cvl/filtconv.h>

cfFilterConvolve();
```

Templated global function to perform discrete convolution using a variable-sized kernel.

cfFilterConvolve

```
void cfFilterConvolve(const ccPelBuffer_const<S>& src,
     const ccFilterConvolveParams& params,
     const ccFilterConvolveKernel<K>& kernel,
     ccPelBuffer<D>& dst);

ccPelBuffer<K> cfFilterConvolve(
     const ccPelBuffer_const<S>& src,
     const ccFilterConvolveParams& params,
     const ccFilterConvolveKernel<K>& kernel);
```

- ```
  void cfFilterConvolve(const ccPelBuffer_const<S>& src,
       const ccFilterConvolveParams& params,
       const ccFilterConvolveKernel<K>& kernel,
       ccPelBuffer<D>& dst);
  ```

  Convolves the source image using the supplied kernel and convolution parameters object.

  Parameters

src	The image to convolve. This must be of type **c_UInt8**.
params	The convolution parameters to use.
kernel	The convolution kernel. This may be of type **c_UInt8** or **c_UInt16** and it must be of the same type as *dst*.
dst	The destination image. This may be of type **c_UInt8** or **c_UInt16** and it must be of the same type as *kernel*.

- ```
  ccPelBuffer<K> cfFilterConvolve(
       const ccPelBuffer_const<S>& src,
       const ccFilterConvolveParams& params,
       const ccFilterConvolveKernel<K>& kernel);
  ```

  Convolves the source image using the supplied kernel and convolution parameters object. This overload returns the convolved image.

  Parameters

src	The image to convolve. This must be of type **c_UInt8**.

params	The convolution parameters to use.
kernel	The convolution kernel. This may be of type **c_UInt8** or **c_UInt16** and it must be of the same type as *dst*.

cfFilterEdgeletChains()

```
#include <ch_cvl/edgefilt.h>

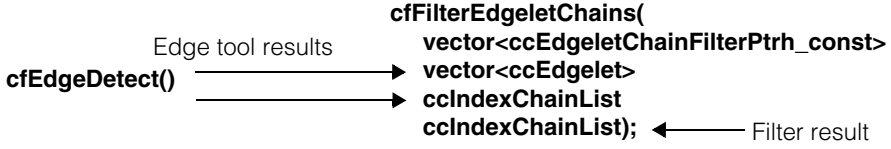
cfFilterEdgeletChains();
```

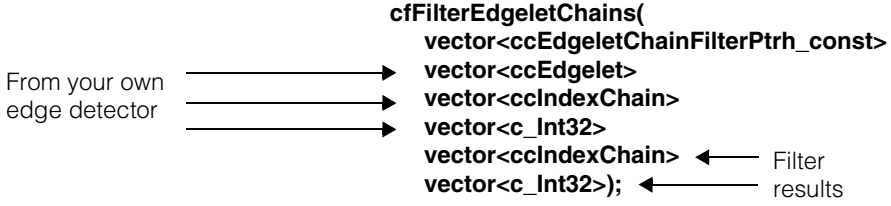
Global function to run the Edgelet Chain Filter tool.

An edgelet is a data structure that defines an edge at a sub-pixel location along with its angle and magnitude. Vision tools such as the Edge tool find edgelets in images and store them in a result array. The Edge tool also produces an edgelet chain list which is an associated array describing groups (chains) of related edgelets.

After running an Edge tool and acquiring the raw edgelets, you may wish to run a filter on the edgelets to eliminate certain edgelets and keep only the edgelets most pertinent to your application. You call **cfFilterEdgeletChains()** to do this filtering.

cfFilterEdgeletChains() has two overloads as shown below. The first overload is designed to work with Cognex Edge tool results as shown. The second overload is a general purpose filter intended to be used with an edge detector you design.





cfFilterEdgeletChains()

cfFilterEdgeletChains

```
void cfFilterEdgeletChains(
  const cmStd vector<ccEdgeletChainFilterPtrh_const>
                                                  &filters,
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains);

void cfFilterEdgeletChains(
  const cmStd vector<ccEdgeletChainFilterPtrh_const>
                                                  &filters,
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const cmStd vector<ccIndexChain> &inputChains,
  const cmStd vector<c_Int32> &inputIndexVector,
  cmStd vector<ccIndexChain> &filteredChains,
  cmStd vector<c_Int32> &filteredIndexVector);
```

This function performs filtering on the provided edgelet chains. The filtering is performed by calling the virtual member function **filter()** of each routine in *filters*. The filter at vector index 0 is called first, and subsequent filters are called in their vector position order. The resulting chains from running each filter are fed to the next filter in the vector. The final result is the result of the last filter.

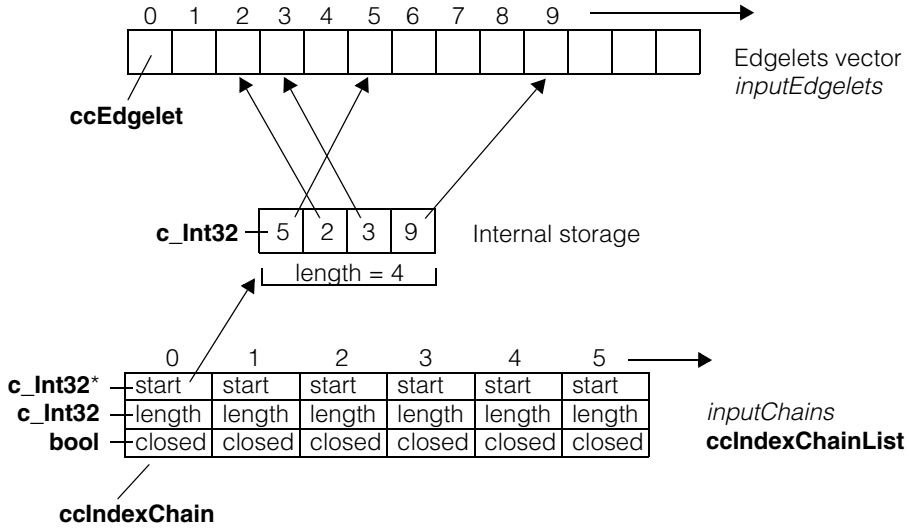
The filtering will be performed correctly even if *inputChains* and *filteredChains* are references to the same vector.

Any existing elements in *filteredChains* will be discarded before the filtering starts.

-
```
void cfFilterEdgeletChains(
  const cmStd vector<ccEdgeletChainFilterPtrh_const>
                                                  &filters,
  const cmStd vector<ccEdgelet> &inputEdgelets,
  const ccIndexChainList &inputChains,
  ccIndexChainList &filteredChains);
```

This overload is intended to be used with the Cognex Edge tool. The *inputEdgelets* and *inputChains* parameters are Edge tool outputs.

The following simple example shows how the edgelets are linked together into chains. In this example, the first chain is an open chain of four edgelets.



The filtered output is simply a reconfigured *inputChains* contained in *filteredChains*. The *inputEdgelets* vector is not changed.

Parameters

filters	A vector of filter routines you wish to run on the edgelets. The filters are run in the order they appear in the vector.
inputEdgelets	The edgelets to be filtered.
inputChains	The input edgelet chains used with the first filter. All filters except the first filter use the previous filter result (in *filteredChains*) as the input chain.
filteredChains	The filtered results.

Throws

This function does not mask any throws from the filter routines.

- ```
  void cfFilterEdgeletChains(
    const cmStd vector<ccEdgeletChainFilterPtrh_const>
                                                    &filters,
    const cmStd vector<ccEdgelet> &inputEdgelets,
    const cmStd vector<ccIndexChain> &inputChains,
    const cmStd vector<c_Int32> &inputIndexVector,
    cmStd vector<ccIndexChain> &filteredChains,
    cmStd vector<c_Int32> &filteredIndexVector);
  ```

  This overload is intended for users that do not use the Cognex Edge tool. The edgelet chaining is more general purpose and may be easier to use when you are creating your own edgelet chains.

  The following simple example shows how the edgelets are linked together into chains. In this example, the first chain is an open chain of four edgelets. The *inputIndexVector* contains indices into the *inputEdgelets* vector.

  The filtered output is simply a reconfigured *inputChains* contained in *filteredChains*, and a reconfigured *inputIndexVector* contained in *filteredIndexVector*. The *inputEdgelets* vector is not changed.

  Parameters

filters	A vector of filter routines you wish to run on the edgelets. The filters are run in the order they appear in the vector.
inputEdgelets	The edgelets to be filtered.
inputChains	The input edgelet chains.
  ```

inputIndexVector The input indices into the edgelets vector.

filteredChains The filtered chains.

filteredIndexVector
The filtered indices into the edgelets vector.

Throws

This function does not mask any throws from the filter routines.

cfFilterEdgeletChains()

cfFilterMedian()

```
#include <ch_cvl/filtmed.h>

cfFilterMedian();
```

Global function to perform a median filter using a variable-sized kernel.

cfFilterMedian

```
void cfFilterMedian(const ccPelBuffer_const<c_UInt8>& src,
     const ccFilterMedianParams& params,
     const ccFilterMaskKernel& kernel,
     ccPelBuffer<c_UInt8>& dst);

void cfFilterMedian(const ccPelBuffer_const<c_UInt8>& src,
     const ccPelBuffer_const<c_UInt8>& mask,
     const ccFilterMedianParams& params,
     const ccFilterMaskKernel& kernel,
     ccPelBuffer<c_UInt8>& dst);

ccPelBuffer<c_UInt8> cfFilterMedian(
     const ccPelBuffer_const<c_UInt8>& src,
     const ccFilterMedianParams& params,
     const ccFilterMaskKernel& kernel);

ccPelBuffer<c_UInt8> cfFilterMedian(
     const ccPelBuffer_const<c_UInt8>& src,
     const ccPelBuffer_const<c_UInt8>& mask,
     const ccFilterMedianParams& params,
     const ccFilterMaskKernel& kernel);
```

-
```
void cfFilterMedian(const ccPelBuffer_const<c_UInt8>& src,
     const ccFilterMedianParams& params,
     const ccFilterMaskKernel& kernel,
     ccPelBuffer<c_UInt8>& dst);
```

Filters the supplied image using the supplied kernel and places the result in the supplied reference.

Parameters

src	The image to process.
params	A **ccFilterMedianParams** object specifying the filtering parameters.
kernel	The kernel with which to filter the image.
dst	A reference into which to place the filtered image.

cfFilterMedian ()

- ```
  void cfFilterMedian(const ccPelBuffer_const<c_UInt8>& src,
      const ccPelBuffer_const<c_UInt8>& mask,
      const ccFilterMedianParams& params,
      const ccFilterMaskKernel& kernel,
      ccPelBuffer<c_UInt8>& dst);
  ```

  Filters the supplied image using the supplied kernel and places the result in the supplied reference. Only image pixels that correspond to care pixels (255) in the supplied mask are processed.

  Parameters

src	The image to process.
params	A **ccFilterMedianParams** object specifying the filtering parameters.
mask	The mask image.
kernel	The kernel with which to filter the image.
dst	A reference into which to place the filtered image.

- ```
  ccPelBuffer<c_UInt8> cfFilterMedian(
      const ccPelBuffer_const<c_UInt8>& src,
      const ccFilterMedianParams& params,
      const ccFilterMaskKernel& kernel);
  ```

  Filters the supplied image using the supplied kernel and returns the result.

  Parameters

src	The image to process.
params	A **ccFilterMedianParams** object specifying the filtering parameters.
kernel	The kernel with which to filter the image.

- ```
  ccPelBuffer<c_UInt8> cfFilterMedian(
      const ccPelBuffer_const<c_UInt8>& src,
      const ccPelBuffer_const<c_UInt8>& mask,
      const ccFilterMedianParams& params,
      const ccFilterMaskKernel& kernel);
  ```

  Filters the supplied image using the supplied kernel and returns the result. Only image pixels that correspond to care pixels (255) in the supplied mask are processed.

  Parameters

src	The image to process.
  ```

params	A **ccFilterMedianParams** object specifying the filtering parameters.
mask	The mask image.
kernel	The kernel with which to filter the image.

cfFilterMedian ()

cfFilterMorphology()

```
#include <ch_cvl/filtmorph.h>

cfFilterMorphology();
```

Global function to perform grey-scale morphology using a variable-sized kernel.

cfFilterMorphology

```
void cfFilterMorphology(
     const ccPelBuffer_const<c_UInt8>& src,
     ccFilterMorphologyDefs::Operation operation,
     const ccFilterMorphologyParams& params,
     const ccFilterMorphologyStructuringElement& kernel,
     ccPelBuffer<c_UInt8>& dst);

void cfFilterMorphology(
     const ccPelBuffer_const<c_UInt8>& src,
     const ccPelBuffer_const<c_UInt8>& mask,
     ccFilterMorphologyDefs::Operation operation, const
     ccFilterMorphologyParams& params, const
     ccFilterMorphologyStructuringElement& kernel,
     ccPelBuffer<c_UInt8>& dst);

ccPelBuffer<c_UInt8> cfFilterMorphology(
     const ccPelBuffer_const<c_UInt8>& src,
     ccFilterMorphologyDefs::Operation operation, const
     ccFilterMorphologyParams& params, const
     ccFilterMorphologyStructuringElement& kernel);

ccPelBuffer<c_UInt8> cfFilterMorphology(
     const ccPelBuffer_const<c_UInt8>& src,
     const ccPelBuffer_const<c_UInt8>& mask,
     ccFilterMorphologyDefs::Operation operation, const
     ccFilterMorphologyParams& params, const
     ccFilterMorphologyStructuringElement& kernel);
```

- ```
  void cfFilterMorphology(
       const ccPelBuffer_const<c_UInt8>& src,
       ccFilterMorphologyDefs::Operation operation, const
       ccFilterMorphologyParams& params, const
       ccFilterMorphologyStructuringElement& kernel,
       ccPelBuffer<c_UInt8>& dst);
  ```

  Applies the specified morphological operator to the supplied source image using the supplied structuring element and places the result in the supplied reference.

  Parameters

  src The image to process.
  ```

operation	The morphological operation. Must be one of *ccFilterMorphologyDefs:::eDilate* *ccFilterMorphologyDefs:::eErode* *ccFilterMorphologyDefs:::eOpen* *ccFilterMorphologyDefs:::eClose*
params	A **ccFilterMorphologyParams** object specifying the filtering parameters.
kernel	The structuring element.
dst	A reference into which to place the filtered image.

- ```
  void cfFilterMorphology(
      const ccPelBuffer_const<c_UInt8>& src, const
      ccPelBuffer_const<c_UInt8>& mask,
      ccFilterMorphologyDefs::Operation operation, const
      ccFilterMorphologyParams& params, const
      ccFilterMorphologyStructuringElement& kernel,
      ccPelBuffer<c_UInt8>& dst);
  ```

  Applies the specified morphological operator to the supplied source image using the supplied structuring element and places the result in the supplied reference. Only image pixels that correspond to care pixels (255) in the supplied mask are processed.

  Parameters

src	The image to process.
mask	The mask image.
operation	The morphological operation. Must be one of *ccFilterMorphologyDefs:::eDilate* *ccFilterMorphologyDefs:::eErode* *ccFilterMorphologyDefs:::eOpen* *ccFilterMorphologyDefs:::eClose*
params	A **ccFilterMorphologyParams** object specifying the filtering parameters.
kernel	The structuring element.
dst	A reference into which to place the filtered image.
  ```

- ```
  ccPelBuffer<c_UInt8> cfFilterMorphology(
      const ccPelBuffer_const<c_UInt8>& src,
      ccFilterMorphologyDefs::Operation operation, const
      ccFilterMorphologyParams& params, const
      ccFilterMorphologyStructuringElement& kernel);
  ```

  Applies the specified morphological operator to the supplied source image using the supplied structuring element returns the result.

  Parameters

src	The image to process.
operation	The morphological operation. Must be one of *ccFilterMorphologyDefs:::eDilate* *ccFilterMorphologyDefs:::eErode* *ccFilterMorphologyDefs:::eOpen* *ccFilterMorphologyDefs:::eClose*
params	A **ccFilterMorphologyParams** object specifying the filtering parameters.
kernel	The structuring element.

- ```
  ccPelBuffer<c_UInt8> cfFilterMorphology(
      const ccPelBuffer_const<c_UInt8>& src, const
      ccPelBuffer_const<c_UInt8>& mask,
      ccFilterMorphologyDefs::Operation operation, const
      ccFilterMorphologyParams& params, const
      ccFilterMorphologyStructuringElement& kernel);
  ```

  Applies the specified morphological operator to the supplied source image using the supplied structuring element and returns the result. Only image pixels that correspond to care pixels (255) in the supplied mask are processed.

  Parameters

src	The image to process.
mask	The mask image.
operation	The morphological operation. Must be one of *ccFilterMorphologyDefs:::eDilate* *ccFilterMorphologyDefs:::eErode* *ccFilterMorphologyDefs:::eOpen* *ccFilterMorphologyDefs:::eClose*
params	A **ccFilterMorphologyParams** object specifying the filtering parameters.

kernel The structuring element.

Notes

If the structuring element has *useOffsetImage* set to false, then its *offsetImage* (if any) is ignored.

Refer to <*ch_cvl/filtcomm.h*> for more detailed descriptions shared by all NxM image processing filters.

cfFreeRunTrigger()

```
#include <ch_cvl/trigmodl.h>

cfFreeRunTrigger();
```

Global function to retrieve a free run trigger model object reference.

cfFreeRunTrigger

```
const ccTriggerModel& cfFreeRunTrigger();
```

When you specify **cfFreeRunTrigger()** as the trigger model, the software attempts to acquire at the maximum rate possible from the connected camera. The application should not call **ccAcqFifo::start()** to initiate image acquisitions.

If you call **ccAcqFifo::start()** when the free run trigger model is selected, your application throws *ccAcqFifo::StartNotAllowed*.

When **triggerEnable()** is false, no acquistions are performed. To allow the acquisitions to continue, **triggerEnable()** must be set to true.

Notes

If you change property values while **ccTriggerProp::triggerEnable()** is set to true, the changes will take place after an unspecified number of acquisitions. To force changes in property values to take effect with the next acquisition, set **triggerEnable()** to false, change the properties, then set **triggerEnable()** to true. Alternatively, you may want to consider using the semi trigger model.

Throws

ccAcqFifo::StartNotAllowed

You called **ccAcqFifo::start()**, which is not supported and not allowed with **cfFreeRunTrigger()**.

cfFreeRunTrigger()

cfGaussSample()

```
#include <ch_cvl/gaussmpl.h>

cfGaussSample();
```

Global function to perform Gaussian smoothing and sampling of an input image.

cfGaussSample

```
template<class T>
ccPelBuffer<T> cfGaussSample(
  const ccPelBuffer_const<T>& src,
  const ccGaussSampleParams& params);

template<class T>
void cfGaussSample(
  const ccPelBuffer_const<T>& src, ccPelBuffer<T>& dst,
  const ccGaussSampleParams& params);

template<class T>
void cfGaussSample(
  const ccPelBuffer_const<T>& src, ccPelBuffer<U>& dst,
  const ccGaussSampleParams& params);
```

- ```
  template<class T>
  ccPelBuffer<T> cfGaussSample(
    const ccPelBuffer_const<T>& src,
    const ccGaussSampleParams& params);
  ```

  Computes and returns an image by applying a Gaussian filter to the supplied input image using the supplied **ccGaussSampleParams**.

  This overload is instantiated for 8-bit input and output pel buffers.

  Parameters

  src — The input image. It must be of type **c_UInt8**.

  params — A **ccGaussSampleParams** specifying the sampling and smoothing parameters.

  Throws

  ccGaussSampleParams::BadParams
  The sampling rate specified in *params* is such that an output image with a height or width of zero would be produced.
  ```

- ```
  template<class T>
  void cfGaussSample(
    const ccPelBuffer_const<T>& src, ccPelBuffer<T>& dst,
    const ccGaussSampleParams& params);
  ```

  Computes an image by applying a Gaussian filter to the supplied input image using the supplied **ccGaussSampleParams**.

  This overload is instantiated for 8-bit input and output pel buffers.

  Parameters

  src — The input image. It must be of type **c_UInt8**.

  dst — The image into which the output image is placed. If *dst* is unbound, a root image is allocated and bound. The destination image must be of type **c_UInt8**.

  params — A **ccGaussSampleParams** specifying the sampling and smoothing parameters

  Throws

  ccGaussSampleParams::BadParams
  The sampling rate specified in *params* is such that an output image with a height or width of zero would be produced.

  ccPelFunc::Overlap
  src and *dst* contain one or more pixels in common.

- ```
  template<class T>
  void cfGaussSample(
    const ccPelBuffer_const<T>& src, ccPelBuffer<U>& dst,
    const ccGaussSampleParams& params);
  ```

  Computes an image by applying a Gaussian filter to the supplied input image using the supplied **ccGaussSampleParams**.

  This overload is instantiated for an 8-bit input pel buffer and a 16-bit output pel buffer.

  Parameters

  src — The input image. It must be of type **c_UInt8**.

  dst — The image into which the output image is placed. If *dst* is unbound, a root image is allocated and bound. The destination image must be of type **c_UInt16**.

  params — A **ccGaussSampleParams** specifying the sampling and smoothing parameters

Throws

ccGaussSampleParams::BadParams

The sampling rate specified in *params* is such that an output image with a height or width of zero would be produced.

ccPelFunc::Overlap

src and *dst* contain one or more pixels in common.

cfGaussSample()

cfGenerateOcrChecksum()

```
#include <ch_cvl/acuread.h>

cfGenerateOcrChecksum();
```

Global function to generate a checksum for a string.

cfGenerateOCRChecksum

```
ccCvlString cfGenerateOcrChecksum(
   ccAcuReadDefs::Checksum checksum,
   const ccCvlString &str);
```

Returns the string that you supply (*str*) with a valid checksum appended.

Parameters

checksum The checksum to compute. *checksum* must be one of the following values:

ccAcuReadDefs::eSemi
ccAcuReadDefs::eBC412
ccAcuReadDefs::eIBM412

str The string to compute a checksum for.

Throws

ccAcuReadDefs::BadParams
str contains invalid characters; *checksum* is *ccAcuReadDefs::eSemi* and *str* is longer than *ccAcuReadDefs::kMaxStringLength* -2; *checksum* is *ccAcuReadDefs::eBC412* or *ccAcuReadDefs::eBC412* and *str* is longer than *ccAcuReadDefs::kMaxStringLength* -1; or *checksum* is *ccAcuReadDefs::eNone* or *ccAcuReadDefs::eVirtual*.

cfGenerateOcrChecksum()

cfGetColorRangeFromImage()

```
#include <ch_cvl/coltool.h>
```

`cfGetColorRangeFromImage()`

Calculates the mean color and gets the color range and standard deviations of a three-plane image. See **cfGetColorRangeFromImageRegion()** for a version that uses shapes instead of a mask to define a region.

cfGetColorRangeFromImage

```
void cfGetColorRangeFromImage(
                    const cc3PlanePelBuffer& image,
                    ccColorRange& color,
                    cc3Vect& standardDeviations,
                    const ccColorStatisticsParams &params,
                    double standardDeviationScaleFactor);

void cfGetColorRangeFromImage(
                    const cc3PlanePelBuffer& image,
                    const ccPelBuffer_const<c_UInt8>& mask,
                    ccColorRange& color,
                    cc3Vect& standardDeviations,
                    const ccColorStatisticsParams &params,
                    double standardDeviationScaleFactor);
```

- ```
  void cfGetColorRangeFromImage(
                      const cc3PlanePelBuffer& image,
                      ccColorRange& color,
                      cc3Vect& standardDeviations,
                      const ccColorStatisticsParams &params,
                      double standardDeviationScaleFactor);
  ```

  Calculates the mean color and returns the color range of *image* in *color* and the standard deviations in *standardDeviations*.

  Parameters

  image The three-plane color image.

  color The returned color range.

  standardDeviations
  The returned standard deviations.

  params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.
  ```

standardDeviationScaleFactor
A factor to scale the high and low tolerance of the returned color range. If omitted, the value is 1.0.

Throws

ccColorToolDefs::BadImage
image is not bound

ccColorToolDefs::NotEnoughSamples
Not enough pels (< 1) in the image satisfy the constraints of *params*.

ccColorToolDefs::BadColorSpace
image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.

- ```
  void cfGetColorRangeFromImage(
                      const cc3PlanePelBuffer& image,
                      const ccPelBuffer_const<c_UInt8>& mask,
                      ccColorRange& color,
                      cc3Vect& standardDeviations,
                      const ccColorStatisticsParams &params,
                      double standardDeviationScaleFactor);
  ```

Calculates the mean color and returns the color range of the portion of *image* described by *mask* in *color* and the standard deviations in *standardDeviations*.

Parameters

image The three-plane color image.

mask An image mask. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

color The returned color range.

standardDeviations
The returned standard deviations.

params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.

standardDeviationScaleFactor
A factor to scale the high and low tolerance of the returned color range. If omitted, the value is 1.0.
  ```

Throws

ccColorToolDefs::BadImage
image or *mask* is not bound
image window is not the same as *mask* window
mask contains pel whose values are other than 0 and 255

ccColorToolDefs::NotEnoughSamples
Not enough pels (< 1) in the image satisfy the constraints of *mask* or *params*.

ccColorToolDefs::BadColorSpace
image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.

cfGetColorRangeFromImage()

cfGetColorRangeFromImageRegion()

```
#include <ch_cvl/coltool.h>
```

`cfGetColorRangeFromImageRegion()`

Gets the color range and standard deviations of a three-plane image. See **cfGetColorRangeFromImage()** for a version that uses masks instead of shapes to define a region.

cfGetColorRangeFromImageRegion

```
void cfGetColorRangeFromImageRegion(
                    const cc3PlanePelBuffer& image,
                    const ccShapePtrh& region,
                    ccColorRange& color,
                    cc3Vect& standardDeviations,
                    const ccColorStatisticsParams &params,
                    double standardDeviationScaleFactor);
```

Calculates the mean color and returns the color range of the intersection of *image* and *region* in *color* and the standard deviations in *standardDeviations*.

Region is defined in image's client coordinate system and can partially overlap *image*. In that case the intersection is used. If more than 50% of a pel falls inside the region, it is considered as being completely inside the region

Parameters

image The three-plane color image.

region A shape that defines a region. If *region* is NULL, the whole image is used.

color The returned color range.

standardDeviations
The returned standard deviations.

params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.

standardDeviationScaleFactor
A factor to scale the high and low tolerance of the returned color range. If omitted, the value is 1.0.

Throws

ccColorToolDefs::BadImage
image is not bound

ccColorToolDefs::NotEnoughSamples
region and *image* do not intersect

Not enough pels (< 1) in the image satisfy the constraints of *params* or *region*.

If only one pel satisfies the constraints of *params* or *region*, the standard deviations in the result are defined to be cc3Vect(0,0,0), and no error is thrown.

ccColorToolDefs::ShapeIsNotRegion
region is not a region shape.

ccColorToolDefs::BadColorSpace
image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.

ccColorToolDefs::NonLinearXform
the image from client transform is nonlinear

cfGetColorStatisticsFromImage()

```
#include <ch_cvl/coltool.h>
```

`cfGetColorStatisticsFromImage()`

Global function to get statistics from a three-plane image. See **cfGetColorRangeFromImageRegion()** for a version that uses shapes instead of a mask to define a region.

cfGetColorStatisticsFromImage

```
void cfGetColorStatisticsFromImage(
            const cc3PlanePelBuffer& image,
            const ccColorStatisticsParams &params,
            ccColorStatisticsResult &result);

void cfGetColorStatisticsFromImage(
            const cc3PlanePelBuffer& image,
            const ccPelBuffer_const<c_UInt8>& mask,
            const ccColorStatisticsParams &params,
            ccColorStatisticsResult &result);
```

- ```
  void cfGetColorStatisticsFromImage(
              const cc3PlanePelBuffer& image,
              const ccColorStatisticsParams &params,
              ccColorStatisticsResult &result);
  ```

  Gets the mean color and standard deviations for *image* and returns it in *result*.

  Parameters

  image The three-plane color image.

  params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation.

  result a **ccColorStatisticsResult** that contains the computed mean color and standard deviations.

  Throws

  ccColorToolDefs::BadImage
  image is not bound

  ccColorToolDefs::NotEnoughSamples
  Not enough pels (< 1) in the image satisfy the constraints of *params*.

  If only one pel satisfies the constraints of params, the standard deviations in the result are defined to be cc3Vect(0,0,0), and no error is thrown.
  ```

ccColorToolDefs::BadColorSpace
image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.

- ```
  void cfGetColorStatisticsFromImage(
              const cc3PlanePelBuffer& image,
              const ccPelBuffer_const<c_UInt8>& mask,
              const ccColorStatisticsParams &params,
              ccColorStatisticsResult &result);
  ```

Gets the mean color and standard deviations for *image* and returns it in *result*.

Parameters

image The three-plane color image.

mask An image mask. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation.

result a **ccColorStatisticsResult** that contains the computed mean color and standard deviations.

Throws

ccColorToolDefs::BadImage
image or *mask* is not bound
image window is not the same as *mask* window
mask contains pel whose values are other than 0 and 255

ccColorToolDefs::NotEnoughSamples
Not enough pels (< 1) in the image satisfy the constraints of *mask* or *params*.

If only one pel satisfies the constraints of mask or params, the standard deviations in the result are defined to be cc3Vect(0,0,0), and no error is thrown.

ccColorToolDefs::BadColorSpace
image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.
  ```

cfGetColorStatisticsFromImageRegion()

```
#include <ch_cvl/coltool.h>
```

`cfGetColorStatisticsFromImageRegion()`

Global function to get statistics from a three-plane image. See **cfGetColorStatisticsFromImage()** for a version that uses masks instead of shapes to define a region.

cfGetColorStatisticsFromImageRegion

```
void cfGetColorStatisticsFromImageRegion(
          const cc3PlanePelBuffer& image,
          const ccShapePtrh& region,
          const ccColorStatisticsParams &params,
          ccColorStatisticsResult &result);
```

Gets the mean color and standard deviations for the intersection of *image* and *region*, and returns it in *result*.

Region is defined in image's client coordinate system and can partially overlap *image*. In that case the intersection is used. If more than 50% of a pel falls inside the region, it is considered as being completely inside the region

Parameters

image The three-plane color image.

region A shape that defines a region. If *region* is NULL, the whole image is used.

params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation.

result a **ccColorStatisticsResult** that contains the computed mean color and standard deviations.

Throws

ccColorToolDefs::BadImage
image is not bound

ccColorToolDefs::NotEnoughSamples
region and *image* do not intersect

Not enough pels (< 1) in the image satisfy the constraints of *params* or *region*.

If only one pel satisfies the constraints of *params* or *region*, the standard deviations in the result are defined to be cc3Vect(0,0,0), and no error is thrown.

ccColorToolDefs::ShapeIsNotRegion
: *region* is not a region shape.

ccColorToolDefs::BadColorSpace
: *image's* color space is **ccColorSpaceDefs::eUnknown** or illegal value.

ccColorToolDefs::NonLinearXform
: the image from client transform is nonlinear

cfGetCompileTimeCvlVersion()

```
#include <ch_cvl/version.h>

cfGetCompileTimeCvlVersion();
```

Global function that retrieves the CVL version used at compile time.

cfGetCompileTimeCvlVersion

```
ccVersion cfGetCompileTimeCvlVersion();
```

Retrieves the CVL version used for compilation.

cfGetCompileTimeCvlVersion()

cfGetCurrentThreadID()

```
#include <ch_cvl/threads.h>

cfGetCurrentThreadID();
```

Global function to return a **ccThreadID** that refers to the current thread.

cfGetCurrentThreadID

```
ccThreadID cfGetCurrentThreadID();
```

Notes

You can use the returned **ccThreadID** to set a thread termination callback function, to break all the locks on a thread (by calling the static function **cc_Resource::breakLocks()**), or to block one thread until another thread completes.

cfGetCurrentThreadID()

cfGetRunTimeCvlVersion()

```
#include <ch_cvl/version.h>
```

```
cfGetRunTimeCvlVersion();
```

Global function that retrieves the CVL version used at run time.

cfGetRunTimeCvlVersion

```
ccVersion cfGetRunTimeCvlVersion();
```

Returns the CVL version used at run time. If the vision application is linked against CVL static libraries, then this function returns the compile time version.

cfGetRunTimeCvlVersion()

cfGetThreadPriority()

```
#include <ch_cvl/threads.h>

cfGetThreadPriority();
```

Global function to return the thread priority of the current thread.

cfGetThreadPriority

```
cePriority cfGetThreadPriority ();
```

cfGetThreadPriority() returns one of the following values:

cePriorityDefault
cePriorityIdle
cePriorityLowest
cePriorityBelowNormal
cePriorityNormal
cePriorityAboveNormal
cePriorityHighest
cePriorityTimeCritical

cfGetThreadPriority()

cfGetSimpleColorFromImage()

```
#include <ch_cvl/coltool.h>
```

`cfGetSimpleColorFromImage()`

Gets the mean color from a color image.

cfGetSimpleColorFromImage

```
void cfGetSimpleColorFromImage(
                    const cc3PlanePelBuffer& image,
                    ccColorValue& meanColor,
                    const ccColorStatisticsParams &params);

void cfGetSimpleColorFromImage(
                    const cc3PlanePelBuffer& image,
                    const ccPelBuffer_const<c_UInt8>& mask,
                    ccColorValue& meanColor,
                    const ccColorStatisticsParams &params);
```

- ```
  void cfGetSimpleColorFromImage(
                      const cc3PlanePelBuffer& image,
                      ccColorValue& meanColor,
                      const ccColorStatisticsParams &params);
  ```

  Returns, in *meanColor*, the mean color of *image*.

  Parameters

  image The color image

  meanColor The returned mean color in *image*. The mean color has the same color space as *image*.

  params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.

  Throws

  ccColorToolDefs::BadImage
  image is not bound

  ccColorToolDefs::NotEnoughSamples
  Not enough pels (< 1) in the image satisfy the constraints of *params*.

  ccColorToolDefs::BadColorSpace
  image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.
  ```

cfGetSimpleColorFromImage()

- ```
  void cfGetSimpleColorFromImage(
                      const cc3PlanePelBuffer& image,
                      const ccPelBuffer_const<c_UInt8>& mask,
                      ccColorValue& meanColor,
                      const ccColorStatisticsParams &params);
  ```

  Returns, in *meanColor*, the mean color of *image* described by *mask*.

  Parameters

  image — The color image

  mask — An image mask. Pels whose value is 0 are don't care pixels; pels whose values are 255 are care pixels. All other values throw an error.

  meanColor — The returned mean color in *image*. The mean color has the same color space as *image*.

  params — a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.

  Throws

  ccColorToolDefs::BadImage
  image or *mask* is not bound
  image window is not the same as *mask* window
  mask contains pel whose values are other than 0 and 255

  ccColorToolDefs::NotEnoughSamples
  Not enough pels (< 1) in the image satisfy the constraints of *mask* or *params*.

  ccColorToolDefs::BadColorSpace
  image's color space is **ccColorSpaceDefs::eUnknown** or illegal value.
  ```

cfGetSimpleColorFromImageRegion()

```
#include <ch_cvl/coltool.h>
```

`cfGetSimpleColorFromImageRegion()`

Gets the mean color from an image. See **cfGetSimpleColorFromImage()** for a version that uses masks instead of shapes to define a region

cfGetSimpleColorFromImageRegion

```
void cfGetSimpleColorFromImageRegion(
                    const cc3PlanePelBuffer& image,
                      const ccShapePtrh& region,
                      ccColorValue& meanColor,
                      const ccColorStatisticsParams &params);
```

Gets the mean color for the intersection of *image* and *region*, and returns it in *meanColor*

Region is defined in image's client coordinate system and can partially overlap *image*. In that case the intersection is used. If more than 50% of a pel falls inside the region, it is considered as being completely inside the region

Parameters

image The three-plane color image.

region A shape that defines a region. If *region* is NULL, the whole image is used.

meanColor The returned mean color in *image*. The mean color has the same color space as *image*.

params a **ccColorStatisticsParams** object to specify the minimum intensity and minimum saturation. If omitted, the default values of zero are used.

Throws

ccColorToolDefs::BadImage
image is not bound

ccColorToolDefs::NotEnoughSamples
region and *image* do not intersect

Not enough pels (< 1) in the image satisfy the constraints of *params* or *region*.

If only one pel satisfies the constraints of *params* or *region*, the standard deviations in the result are defined to be cc3Vect(0,0,0), and no error is thrown.

ccColorToolDefs::ShapeIsNotRegion
: *region* is not a region shape.

ccColorToolDefs::BadColorSpace
: *image's* color space is **ccColorSpaceDefs::eUnknown** or illegal value.

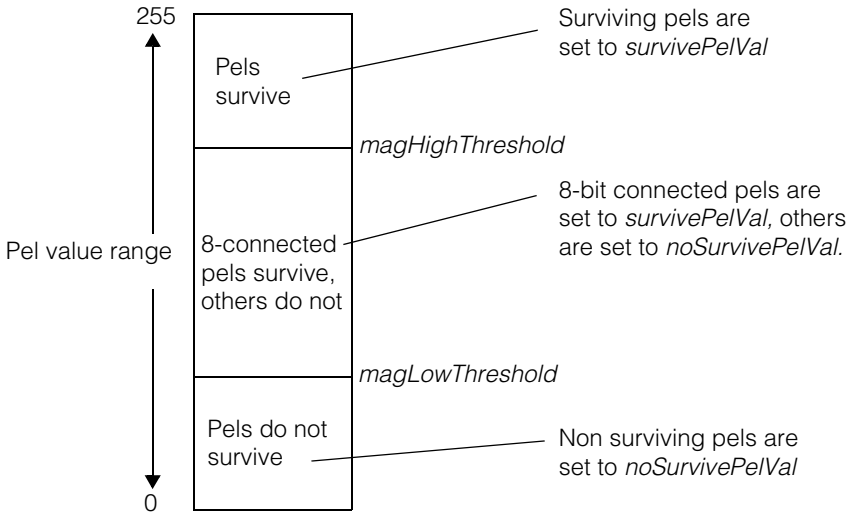
ccColorToolDefs::NonLinearXform
: the image from client transform is nonlinear

cfHysteresisThreshold()

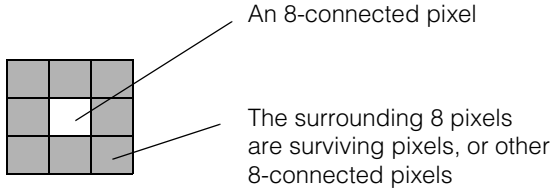
```
#include <ch_cvl/edge.h>

cfHysteresisThreshold();
```

This function performs hysteresis thresholding on the supplied edge magnitude image. The result image contains a binarized edge map. The following diagram shows the primary parameters used by the function to produce pixels in the binarized result. This example is for 8-bit pel values.



All pixels in the supplied image with values less than *magLowThreshold* do not survive and are set to *noSurvivePelVal*. All pixels in the supplied image with values greater than or equal to *magHighThreshold* are set to *survivePelVal*. All pixels in the supplied image with values greater than or equal to *magLowThreshold* and less than *magHighThreshold* are set to *survivePelVal* if they are 8-connected to a pixel with a value greater than or equal to *magHighThreshold*, either directly or through other 8-connected pixels. The following diagram shows an 8-bit connected pixel.



Pixels with values greater than or equal to *magLowThreshold* but less than *magHighThreshold* that are not 8-connected do not survive and are set to *noSurvivePelVal*.

cfHysteresisThreshold()

cfHysteresisThreshold

```
template<class T>
void cfHysteresisThreshold(
  const ccPelBuffer_const<T>& magImage,
  ccPelBuffer<c_UInt8>& dst,
  T magLowThreshold,
  T magHighThreshold,
  c_Int32* nSurvivors = 0,
  c_Int32 nPels = -1,
  T noSurvivePelVal = 0,
  T survivePelVal = 1);

template<class T>
  ccPelBuffer<c_UInt8> cfHysteresisThreshold(
  const ccPelBuffer_const<T>& magImage,
  T magLowThreshold,
  T magHighThreshold,
  c_Int32* nSurvivors = 0,
  c_Int32 nPels = -1,
  T noSurvivePelVal = 0,
  T survivePelVal = 1);
```

-
```
template<class T>
void cfHysteresisThreshold(
  const ccPelBuffer_const<T>& magImage,
  ccPelBuffer<c_UInt8>& dst,
  T magLowThreshold,
  T magHighThreshold,
  c_Int32* nSurvivors = 0,
  c_Int32 nPels = -1,
  T noSurvivePelVal = 0,
  T survivePelVal = 1);
```

Performs hysteresis thresholding on the supplied input edge magnitude image (*magImage*) and places the result in the (*dst*) image you supply.

Notes

Although this is a templated function, the current implementation only handles **c_UInt8**.

Parameters

magImage	The input edge magnitude image. *magImage* must be of type **c_UInt8**.
dst	The image produced by edge hysteresis thresholding. If *dst* is unbound, a root image is allocated and bound. *dst* must be of type **c_UInt8**.

magLowThreshold

The low threshold

magHighThreshold

The high threshold

nSurvivors If *nSurvivors* is not *NULL*, the number of nonzero pixels in the returned image is written to the **c_Int32** pointed to by *nSurvivors*.

nPels If the number of nonzero pixels in *magImage* is known, you can reduce the amount of memory required for this function by passing this value in *nPels*.

If you do not know the number of nonzero pixels in *magImage*, set *nPels* equal to -1.

noSurvivePelVal The pixel value assigned to non-surviving pels.

survivePelVal The pixel value assigned to surviving pels.

- ```
  template<class T>
   ccPelBuffer<c_UInt8> cfHysteresisThreshold(
   const ccPelBuffer_const<T>& magImage,
   T magLowThreshold,
   T magHighThreshold,
   c_Int32* nSurvivors = 0,
   c_Int32 nPels = -1,
   T noSurvivePelVal = 0,
   T survivePelVal = 1);
  ```

  Performs hysteresis thresholding on the supplied input edge magnitude image (*magImage*) and returns the resulting image.

  Notes

  Although this is a templated function, the current implementation only handles **c_UInt8**.

  Parameters

  magImage The input edge magnitude image. *magImage* must be of type **c_UInt8**.

  magLowThreshold

  The low threshold

  magHighThreshold

  The high threshold
  ```

nSurvivors	If *nSurvivors* is not *NULL*, the number of nonzero pixels in the returned image is written to the **c_Int32** pointed to by *nSurvivors*.
nPels	If the number of nonzero pixels in *magImage* is known, you can reduce the amount of memory required for this function by passing this value in *nPels*. If you do not know the number of nonzero pixels in *magImage*, set *nPels* equal to -1.
noSurvivePelVal	The pixel value assigned to non-surviving pels.
survivePelVal	The pixel value assigned to surviving pels.

cfIDDecode()

```
#include <ch_cvl/id.h>

cfIDDecode();
```

Global function to find, decode, and grade symbols in an image.

cfIDDecode

```
void cfIDDecode(const ccPelBuffer_const<c_UInt8>& image,
      const ccIDSearchParams& searchParams,
      const ccIDDecodeParams& decodeParams,
      ccIDResultSet& resultSet, ccDiagObject* diagobj = 0,
      c_UInt32 diagFlags = 0);
```

Searches for and decodes symbols in the supplied image using the supplied search and decode parameters.

Parameters

image	The image to search.
searchParams	The search parameters.
decodeParams	The decoding parameters.
resultSet	The result set into which the results are placed.
diagobj	A container class object that holds diagnostic records created during the run of the tool. If you supply a value, the tool records diagnostic information as specified by *diagFlags*.
diagFlags	Set to 0 to record no diagnostic information. Otherwise *diagFlags* is composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

Throws

ccIDDefs::BadParams
: No symbology is enabled in *decodeParams*.

ccIDDefs::BadImage
: *image* is unbound.

ccIDDefs::ImageTooSmall
: *image* is smaller than 16x16 pixels.

ccTimeout::Expired
: The user-specified timeout expires. Any completed results are returned in *resultSet*.

ccIDDefs::InternalError
: An unexpected error occurred.

cfImageRegister()

```
#include <ch_cvl/imgreg.h>

cfImageRegister();
```

Global function invoke the Image Registration tool. The tool will locate the reference image within the source image, given an appropriate starting location.

cfImageRegister

```
void cfImageRegister(const ccPelBuffer_const<T>& src,
  const ccPelBuffer_const<T>& ref,
  const ccImageRegisterParams& params,
  ccImageRegisterResults &results);

void cfImageRegister(const ccPelBuffer_const<T>& src,
  const ccPelBuffer_const<T>& ref,
  const cmStd vector<ccPelRect> &rects,
  const ccImageRegisterParams& params,
  ccImageRegisterResults &results);

ccImageRegisterResults cfImageRegister(
  const ccPelBuffer_const<T>& src,
  const ccPelBuffer_const<T>& ref,
  const ccImageRegisterParams& params);

ccImageRegisterResults cfImageRegister(
  const ccPelBuffer_const<T>& src,
  const ccPelBuffer_const<T>& ref,
  const cmStd vector<ccPelRect> &rects,
  const ccImageRegisterParams& params);
```

- ```
  void cfImageRegister(const ccPelBuffer_const<T>& src,
    const ccPelBuffer_const<T>& ref,
    const ccImageRegisterParams& params,
    ccImageRegisterResults &results);
  ```

  Locates the supplied reference image within the supplied source image using the supplied parameters.

  Parameters

src	The source image. *src* can be of type **c_UInt8**.
ref	The reference image. *ref* must be smaller than, and of the same type as, *src*.
params	A **ccImageRegisterResults** containing the parameters to use for this image registration.
results	A **ccImageRegisterResults** into which the results are placed.
  ```

Throws

ccImgRegDefs::UnboundWindow
: *src* or *ref* is unbound.

ccImgRegDefs::BadStartPosition
: When placed at the starting position specified in *params*, the reference image is not completely contained within *src*.

ccImgRegDefs::ModelNotContainedInSource
: *ref* is either taller or wider than *src*.

- ```
  void cfImageRegister(const ccPelBuffer_const<T>& src,
    const ccPelBuffer_const<T>& ref,
    const cmStd vector<ccPelRect> &rects,
    const ccImageRegisterParams& params,
    ccImageRegisterResults &results);
  ```

Locates the supplied reference image within the supplied source image using the supplied parameters.

Only reference image pixels which lie within the supplied rectangles are considered.

Parameters

src	The source image. *src* can be of type **c_UInt8**.
ref	The reference image. *ref* must be smaller than, and of the same type as, *src*.
rects	A vector of rectangles, specified in the reference image's image coordinate system. Only pixels within these rectangles are considered by the tool. If a pixel is contained within more than one rectangle, it is evaluated once for each rectangle that contains it.
params	A **ccImageRegisterResults** containing the parameters to use for this image registration.
results	A **ccImageRegisterResults** into which the results are placed.

Throws

ccImgRegDefs::UnboundWindow
: *src* or *ref* is unbound.

ccImgRegDefs::BadStartPosition
: When placed at the starting position specified in *params*, the reference image is not completely contained within *src*.
  ```

ccImgRegDefs::ModelNotContainedInSource
ref is either taller or wider than *src*.

ccImgRegDefs::RectNotContainedInModel
One or more of the rectangles in *rects* is not completely contained within *ref*.

- ```
  ccImageRegisterResults cfImageRegister(
    const ccPelBuffer_const<T>& src,
    const ccPelBuffer_const<T>& ref,
    const ccImageRegisterParams& params);
  ```

  Locates the supplied reference image within the supplied source image using the supplied parameters.

  Parameters

  src The source image. *src* can be of type **c_UInt8**.

  ref The reference image. *ref* must be smaller than, and of the same type as, *src*.

  params A **ccImageRegisterResults** containing the parameters to use for this image registration.

  results A **ccImageRegisterResults** into which the results are placed.

  Throws

  ccImgRegDefs::UnboundWindow
  src or *ref* is unbound.

  ccImgRegDefs::BadStartPosition
  When placed at the starting position specified in *params*, the reference image is not completely contained within *src*.

  ccImgRegDefs::ModelNotContainedInSource
  ref is either taller or wider than *src*.

- ```
  ccImageRegisterResults cfImageRegister(
    const ccPelBuffer_const<T>& src,
    const ccPelBuffer_const<T>& ref,
    const cmStd vector<ccPelRect> &rects,
    const ccImageRegisterParams& params);
  ```

  Locates the supplied reference image within the supplied source image using the supplied parameters.

  Only reference image pixels which lie within the supplied rectangles are considered.

cfImageRegister()

Parameters

src The source image. *src* can be of type **c_UInt8**.

ref The reference image. *ref* must be smaller than, and of the same type as, *src*.

rects A vector of rectangles, specified in the reference image's image coordinate system.

Only pixels within these rectangles are considered by the tool. If a pixel is contained within more than one rectangle, it is evaluated once for each rectangle that contains it.

params A **ccImageRegisterResults** containing the parameters to use for this image registration.

Throws

ccImgRegDefs::UnboundWindow
src or *ref* is unbound.

ccImgRegDefs::BadStartPosition
When placed at the starting position specified in *params*, the reference image is not completely contained within *src*.

ccImgRegDefs::ModelNotContainedInSource
ref is either taller or wider than *src*.

ccImgRegDefs::RectNotContainedInModel
One or more of the rectangles in *rects* is not completely contained within *ref*.

cfImageSharpness()

```
#include <ch_cvl/imgsharp.h>

cfImageSharpness();
```

Global function to determine the sharpness of an image. You call this function to run the Image Sharpness tool.

The primary purpose of this tool is to automate focusing a camera lens on a scene. You acquire an image and run the tool to obtain a sharpness score. You then refocus the lens changing nothing else, acquire another image and score it. By iteratively refocusing, scoring, and comparing the sharpness scores you can home in on the highest score which is the best camera focus you can obtain for your application. A second global function, **cfImageSharpnessFocusSearch()**, is provided to help you implement this iterative procedure.

Note that a single sharpness score conveys no information about the absolute sharpness of an image. Also, comparing sharpness scores of different scenes has no meaning.

When you call **cfImageSharpness()** you pass it an image to score, and a parameters object that specifies how the score should be calculated. The scoring parameters specify one of five algorithms which are discussed below:

	Score range		
Algorithm	**Low (Blurred image)**	**High (Sharp image)**	**Parameters used**
eAutoCorrelation	0	1000	*noiseLevel*
eAbsDiff	0	255	*sx, sy*
eEdgeGradient **Note**: This algorithm is deprecated	0	255	
eBandPass	0	No upper limit	***freqBand***
eGradientEnergy[1]	0	No upper limit	***lowPassSmoothing***

(1) Most applications achieve the best results using this algorithm.

Notes

1. *eAutoCorrelation* algorithm:

   The sharpness score is based on the local variation of the autocorrelation function. When correlation scores are high (near 1.0) the image is blurry. When correlation scores are low (near 0) the image has sharp edges. The following formula is used to calculate the auto-correlation score where r is the composite correlation score for the image.

   $$1000 - (1000r)$$

2. *eAbsDiff* algorithm:

   The sharpness score is based on the selective sum of absolute differences of image samples separated by specified distances *sx* and *sy* in x and y directions respectively. You set *sx* and *sy* in the *params* object based on your knowledge of the underlying pattern. (For example, the frequency of interest you wish to resolve).

   Pixel intensity is compared at (x,y) and (x, y+sy), then (x,y) and (x+sx, y), for all pixels in the image valid region. The image sharpness score is the mean of the average sharpness in the x-direction and the average sharpness in the y-direction over the entire valid region.

3. *eEdgeGradient* algorithm: (**Note**: This algorithm is deprecated)

   The sharpness score is based on the average edge gradient in the image. In *eEdgeGradient* mode **cfImageSharpness()** applies a Sobel edge operator to the source image and computes magnitudes of all edge gradients in the image. The mean of these edge magnitudes is returned as the sharpness score.

4. *eBandPass* algorithm:

   The sharpness score is based on frequencies occurring in the band of frequencies, **ccSharpnessParams::freqBand()**. Sharp edges produce high frequencies and blurred edges produce low frequencies. You choose this frequency band based on expected frequencies occurring in the image.

5. *eGradientEnergy* algorithm:

   The sharpness score is based on the sum of the squares of the edge gradients. See the *Image Sharpness Tool* chapter of the *CVL Vision Tools Guide* for information about how this algorithm works.

6. The same image may yield very different sharpness scores depending on which algorithm is used. Also, comparison of sharpness scores of multiple images using the same algorithm is meaningful only if the images used are of the same physical scene and differ only in sharpness or focus settings. For example, if you use the *eAutoCorrelation* algorithm to obtain sharpness scores for images of two different scenes, there is no relationship between the two scores. The image with the highest score in not necessarily sharper than the other image.
7. The **cfImageSharpness()** function does not use the client transform in the image.

For a detailed discussion of the sharpness algorithms see the *Image Sharpness Tool* chapter of the *Vision Tools Guide*.

cfImageSharpness

```
double cfImageSharpness(
  const ccPelBuffer_const<c_UInt8>& src,
  const ccSharpnessParams& params);

double cfImageSharpness(
  const ccPelBuffer_const<c_UInt8>& src,
  const ccPelBuffer_const<c_UInt8>& mask,
  const ccSharpnessParams& params);

double cfImageSharpness(
  const ccPelBuffer_const<c_UInt16>& src,
  const ccSharpnessParams& params);
```

Returns a sharpness score for input image (*src*) using the sharpness parameters (*params*). See the introduction to this reference page and the *Image Sharpness Tool* chapter of the *Vision Tools Guide* for information on how this tool works.

Notes

The client coordinate transforms of *src* and *mask* are not used.

Errors (**Throws**) are dependent on the overload called, and the algorithm specified in *params*. The following **Throws** are shown by algorithm. Unless noted, these throws apply to all three **cfImageSharpness()** overloads.

1. eAutoCorrelation

Throws

ccPel::BadWindow
If the *src* image is smaller than 3x3 pels.

ccImageSharpnessDefs::NotImplemented
If the overload with mask is called.

2. eAbsDiff

Throws

ccPel::BadWindow
If either *src* image dimension is 0.

ccPel::BadCoord(sx,sy)
If *sx* and *sy* do not lie within the valid range. Valid ranges are:
sx range (0 through **src.width()** - 1)
sy range (0 through **src.height()** - 1)

ccImageSharpnessDefs::NotImplemented
If the overload with mask is called.

3. *eEdgeGradient* (Deprecated)

Throws

ccPel::BadWindow
If the *src* image is smaller than 3x3 pels.

ccImageSharpnessDefs::NotImplemented
If the overload with mask is called.

4. eBandPass

Throws

ccImageSharpnessDefs::InternalError
If the sharpness score could not be computed.

ccImageSharpnessDefs::UnboundWindow
If the image is unbound.

ccImageSharpnessDefs::NotImplemented
If the overload with mask is called.

5. eGradientEnergy

Throws

ccImageSharpnessDefs::ImageTooSmall
If the sharpness score could not be computed because of small image dimensions.

ccImageSharpnessDefs::UnboundWindow
If either the *src* image or *mask* is unbound.

ccImageSharpnessDefs::BadMask
If the *mask* image dimensions are different than the *src* image dimensions.

ccImageSharpnessDefs::NotImplemented
If the overload with the `c_UInt16` image is called.

- ```
  double cfImageSharpness(
    const ccPelBuffer_const<c_UInt8>& src,
    const ccSharpnessParams& params);
  ```

  Parameters

  src The image to score.

  params The sharpness parameters.

- ```
  double cfImageSharpness(
    const ccPelBuffer_const<c_UInt8>& src,
    const ccPelBuffer_const<c_UInt8>& mask,
    const ccSharpnessParams& params);
  ```

  Notes

  This overload is only supported for the *eGradientEnergy* algorithm.

  The *mask* image must have the same dimensions as the *src* image. *src* image pixels are used if the corresponding *mask* pixel value is 255. *src* image pixels are ignored if the corresponding *mask* pixel value is 0. All other *mask* pixel values are invalid.

  Parameters

  src The image to score.

  mask Apply this mask to the *src* image.

  params The sharpness parameters.

- ```
  double cfImageSharpness(
    const ccPelBuffer_const<c_UInt16>& src,
    const ccSharpnessParams& params);
  ```

  Notes

  This overload is not supported for the *eGradientEnergy* algorithm.

  Parameters

  src The image to score.

  params The sharpness parameters.
  ```

Deprecated Members

The following functions are deprecated and included here for backward compatibility only.

cfImageSharpness

```
template<class T>
T cfImageSharpness(const ccPelBuffer_const<T>& src,
  c_UInt32 sx, c_UInt32 sy);

template<class T>
  c_Int16 cfImageSharpness(
  const ccPelBuffer_const<T>& src);
```

```
template<class T>
T cfImageSharpness(const ccPelBuffer_const<T>& src,
  c_UInt32 sx, c_UInt32 sy);
```

Determines the image sharpness using image difference mode at the specified x and y offset. Image sharpness is measured by computing the average difference in pixel intensity value between each pixel in the input image and the pixel within the image offset by the specified amount.

The higher the returned value, the sharper the image. Return values can be in the range 0 to the maximum value supported by the template type *T*.

Parameters

src	The input image.
sx	The x offset, in image coordinate units, at which to measure image difference.
sy	The y offset, in image coordinate units, at which to measure image difference.

-
```
template<class T>
  c_Int16 cfImageSharpness(
  const ccPelBuffer_const<T>& src);
```

Determines the image sharpness using auto-correlation mode. Image blurriness is measured by computing the correlation coefficient at 1-pixel offsets. The highest correlation coefficient is the image blurriness. This function returns a value equal to

$$1000 - (1000r)$$

where r is the image blurriness. The returned value can be in the range 0 to 1000.

Parameters

src	The input image.

cfImageSharpness()

cfImageSharpnessFocusSearch()

```
#include <ch_cvl/imgsharp.h>

cfImageSharpnessFocusSearch();
```

This is a global function you can use along with **cfImageSharpness()** to find the number of motor steps required to reach the best camera position (sharpest image focus) within a specified tolerance. This function searches for and finds the optimal depth of focus. You may wish to call this function in your application initialization code to focus your camera before beginning a production run.

To use the function you must write a routine that controls your application and will physically move the camera focus to a new location. You also must write a routine that acquires an image at the new focus and evaluates the image sharpness at this location. It is intended that you call **cfImageSharpness()** to obtain the image sharpness score.

The function is defined by two overloads that both accomplish the same objective. The first overload uses a focus range from 0 through a maximum, measured in focus increments. The second overload defines the focus range with minimum and maximum values. Also, the first overload requires that you write the move and sharpness evaluation routines separately, whereas the second overload combines these into one function that also takes a parameter you can provide.

cfImageSharpnessFocusSearch

```
c_Int32 cfImageSharpnessFocusSearch (
  c_Int32 range,
  c_Int32 tolerance,
  c_Int32 (*evaluateSharpness)(),
  void (*move)(c_Int32 position));

c_Int32 cfImageSharpnessFocusSearch(
  c_Int32 rangeMin,
  c_Int32 rangeMax,
  c_Int32 tolerance,
  void* userParam,
  c_Int32 (*moveAndEval)
                    (void* userParam, c_Int32 position));
```

- ```
  c_Int32 cfImageSharpnessFocusSearch (
    c_Int32 range,
    c_Int32 tolerance,
    c_Int32 (*evaluateSharpness)(),
    void (*move)(c_Int32 position));
  ```

  Returns an integer which indicates the number of motor steps required to reach the best camera position (sharpest image focus) for the specified tolerance.

  The search strategy iteratively calls a sharpness evaluation function that you write and a camera move function you also write to hunt down the best depth of focus within the specified tolerance. This strategy works best when the depth of focus range specified results in a unimodal distribution of image sharpness coefficients. For example:

  
  Working within the range (0 through *range*), **cfImageSharpnessFocusSearch()** iteratively calls the *move* function to move the camera and calls the sharpness function to obtain the sharpness score at various positions. As it homes in on the best score position, the camera movements become smaller and smaller. When the camera movements become smaller than *tolerance*, the procedure ends and the function returns.

  Due to the nature of the algorithm *range* must be less than 701408733.

  Parameters

  range — The number of steps (in depth of focus increments) that the search is performed over. The search starts at zero and will move the camera up to *range* steps to find the best focus within this range. The sharpest focus point must lie within this range for **cfImageSharpnessFocusSearch()** to be successful.

  tolerance — The least number of depth of focus increments by which the position (depth of focus) should change in order to end the search. During the search, if the change in the position does not change by at least *tolerance* increments, the search ends.

  evaluateSharpness — A pointer to a sharpness evaluation function you write. The sharpness evaluation function takes no arguments. It returns an
  ```

image sharpness score (for example, using **cfImageSharpness()**) computed from the image at the current depth of focus. Generally, this is a wrapper function you write that calls **cfImageSharpness()**.

move — A pointer to a function which performs the necessary action to change the camera depth of focus as required during the search. It takes one argument (*position*) which specifies the absolute position where the camera should be set.

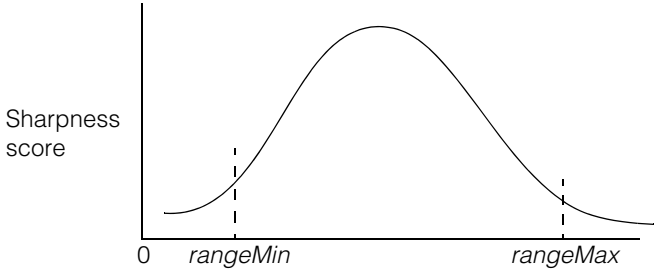
Throws

ccImageSharpnessDefs::BadParams
If *range* < *0*,
or if *range* >= 701408733,
or if *tolerance* < 1,
or if *tolerance* >= *range*.

- ```
  c_Int32 cfImageSharpnessFocusSearch(
    c_Int32 rangeMin,
    c_Int32 rangeMax,
    c_Int32 tolerance,
    void* userParam,
    c_Int32 (*moveAndEval)
                        (void* userParam, c_Int32 position));
  ```

Returns an integer which indicates the number of motor steps required to reach the best camera position (sharpest image focus) for the specified tolerance.

The search strategy iteratively calls a move and evaluation function that you write to hunt down the best depth of focus within the specified tolerance. This strategy works best when the depth of focus range specified results in a unimodal distribution of image sharpness coefficients. For example:



Working within the range (*rangeMin* through *rangeMax*), **cfImageSharpnessFocusSearch()** iteratively calls the *moveAndEval* function to move the camera and obtain sharpness scores at various positions in the range. As it homes
  ```

in on the best score position, the camera movements become smaller and smaller. When the camera movements become smaller than *tolerance*, the procedure ends and the function returns.

Due to the nature of the algorithm *rangeMax-rangeMin* must be less than 701408733.

Parameters

rangeMin — The beginning of the range (in depth of focus increments) where the search is performed. The search starts at *rangeMin* and will move the camera up to *rangeMax* to find the best focus within this range. The sharpest focus point must lie within this range for **cfImageSharpnessFocusSearch()** to be successful.

rangeMax — The end of the range (in depth of focus increments) where the search is performed. The search starts at *rangeMin* and will move the camera up to *rangeMax* to find the best focus within this range. The sharpest focus point must lie within this range for **cfImageSharpnessFocusSearch()** to be successful.

tolerance — The least number of depth of focus increments by which the position (depth of focus) should change in order to end the search. During the search, if the change in the position does not change by at least *tolerance* increments, the search ends.

userParam — A user parameter you define that is passed to the *moveAndEval* function you write. See below.

moveAndEval — A pointer to a function you write that moves the camera focus to a new location, and then evaluates the sharpness of an image acquired at this new location. *position* defines the new location in focus increments measured from 0, and *userParam* is a pointer to a parameter you define that is passed to your routine.

The sharpness evaluation function returns an image sharpness score (for example, by using **cfImageSharpness()**) computed from the image at the current depth of focus. In most cases your *moveAndEval* function should call **cfImageSharpness()** to obtain the sharpness score.

Throws

ccImageSharpnessDefs::BadParams

If *rangeMax* < *rangeMin*,
or if *rangeMax-rangeMin* >= 701408733,
or if *tolerance* < 1,
or if *tolerance* >= *rangeMax-rangeMin*.

cfInitializeDisplayResources()

```
#include <ch_cvl/windisp.h>

cfInitializeDisplayResources();
```

Global function to initialize the resources used by **ccDisplayConsole** and **ccWin32Display** when used from within a DLL.

cfInitializeDisplayResources

```
void cfInitializeDisplayResources();
```

You must call this function to initialize GUI resources before using a **ccDisplayConsole** or **ccWin32Display** from within a DLL.

Notes

If you create your own DLL that initializes CVL display objects and calls their functions, then you must call **cfInitializeDisplayResources()** in your application's initialization and setup code.

Your application *must* call **cfInitializeDisplayResources()** if your application instantiates a **ccWin32Display** or **ccDisplayConsole** object in a DLL instead of in your application's executable.

In all other cases, the work performed by **cfInitializeDisplayResources()** is redundant and benign, but your application can call it without producing an error.

cfInitializeDisplayResources()

cfLabelHistogram()

```
#include <ch_cvl/lablproj.h>

cfLabelHistogram();
```

Global function that computes the labeled histogram of an image.

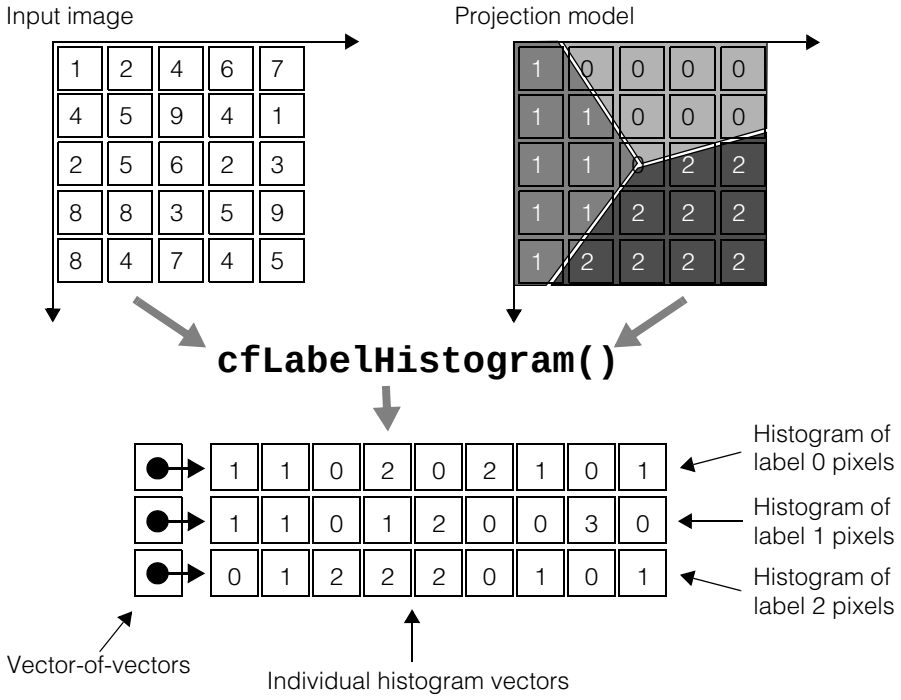
cfLabelHistogram

```
template<class M, class I>
void cfLabelHistogram(
  const ccLabeledProjectionModel<M> &model,
  const ccPelBuffer_const<I> &image,
  cmStd vector<cmStd vector<c_Uint32>> &histograms,
  bool preClearHist = true);
```

Computes the labeled histogram of *image* using the supplied **ccLabeledProjectionModel**.

A labeled histogram is actually a collection of individual histograms, one for each label value defined in the projection model. The function collects all of the pixels which have a given label, then computes the histogram of those pixels. The function places the labeled histogram in the vector of vectors that you supply by reference to the function. The individual vectors within the vector-of-vectors are the individual histograms.

The following figure shows how **cfLabelHistogram** computes a labeled histogram from a simple input image and projection model:



The size of the vector-of-vectors is equal to the largest label value in the projection model. Note that the individual histogram vectors actually have 256 elements, even though only the first 9 elements have nonzero values.

Parameters

M and I Template parameters specifying the type of the projection model and source image. You must specify one of the following combinations of types:

M	I
c_UInt8	**c_UInt8**
c_UInt16	**c_UInt8**

model The labeled projection model to use.

image The input image.

histograms A vector of histograms. If **histograms.size()** is zero, it is resized to **model.projectionLength()**.

Any individual histograms within *histograms* that have a length of zero are resized to have a length of 256 (for 8-bit images) or to have a length equal to the largest pixel value for the input image.

Individual histograms that have a length greater than 256 are resized to have a length of 256.

preClearHist If *preClearHist* is true, this function will initialize the contents of all the individual histograms to zero. If *preClearHist* is false, then the existing histogram contents are added to.

Throws

ccLabeledProjection::HistogramTooShort
histograms.size() is greater than zero but less than **model.projectionLength()**.

cfLabelHistogram()

cfLabelProject()

```
#include <ch_cvl/lablproj.h>

cfLabelProject();
```

Global function to compute both a normalized and non-normalized projection image using the supplied **ccLabeledProjectionModel** and the supplied input image.

cfLabelProject

```
template<class M, class I, class R, class N>
void cfLabelProject (
  const ccLabeledProjectionModel<M> &model,
  const ccPelBuffer_const<I> &image,
  const ccPelBuffer<N> &normProjection,
  const ccPelBuffer<R> &rawProjection,
  bool preClearProj=true);
```

Computes the specified labeled projection, producing both normalized and non-normalized projection images.

Parameters

M, *I*, *R*, and *N* — Template parameters specifying the type of the projection model, source image, normalized projection image, and raw projection image. You must specify one of the following combinations of types:

M	I	R	N
c_UInt8	**c_UInt8**	**c_UInt32**	**c_UInt32**
c_UInt16	**c_UInt8**	**c_UInt16**	**c_UInt16**
c_UInt8	**c_UInt8**	**c_UInt32**	**c_UInt8**
c_UInt16	**c_UInt8**	**c_UInt16**	**c_UInt8**

model — The labeled projection model to use.

image — The input image.

normProjection — A reference to a **ccPelBuffer<N>** into which to place the normalized projection image.

rawProjection — A reference to a **ccPelBuffer<R>** into which to place the non-normalized projection image. The pixel type of *rawProjection* must be large enough to contain the product of the largest pixel value in *image* times the number of pixels in *model* with the most frequent label value.

In general, *rawProjection* should be of type **ccPelBuffer<c_UInt32>**.

preClearProj If *preClearProj* is true, this function will initialize the contents of *normProjection* and *rawProjection* to zero before projecting *image*.

If *preClearProj* is false, then this function will perform a raw projection of *image* into a temporary image, add the temporary image to *rawProjection*, then normalize the temporary image, then add the normalized image to *normProjection*.

cfLabelProjectNorm()

```
#include <ch_cvl/ch_cvl/lablproj.h>

cfLabelProjectNorm();
```

Global function to compute a normalized projection image using the supplied **ccLabeledProjectionModel** and the supplied input image.

cfLabelProjectNorm

```
template<class M, class I, class N>
void cfLabelProjectNorm (
  const ccLabeledProjectionModel<M> &model,
  const ccPelBuffer_const<I> &image,
  const ccPelBuffer<N> &normProjection, bool preClearProj);
```

Computes the specified labeled projection, producing a normalized projection image.

Parameters

M, *I*, and *N* — Template parameters specifying the type of the projection model, source image, and normalized projection image. You must specify one of the following combinations of types:

M	I	N
c_UInt8	**c_UInt8**	**c_UInt32**
c_UInt16	**c_UInt8**	**c_UInt16**

model — The labeled projection model to use.

image — The input image.

normProjection — A reference to a **ccPelBuffer<N>** into which to place the normalized projection image.

preClearProj — If *preClearProj* is true, this function will initialize the contents of *normProjection* to zero before projecting *image*.

If *preClearProj* is false, then this function will perform a raw projection of *image* into a temporary image, normalize the temporary image, then add the normalized image to *normProjection*.

Notes

The pixel type of *normProjection* must be large enough to contain the product of the largest pixel value in *image* times the number of pixels in *model* with the most frequent label value.

If you want to create a projection image of type **ccPelBuffer<c_UInt8>** but you expect intermediate values larger than 255, you should use the function **cfLabelProject()** and supply a second image with larger pixel values to store the raw pixel values.

Caution **cfLabelProjectNorm()** *does not throw an error if the projection values overflow the size of pixels in* normProjection.

cfLabelProjectRaw()

```
#include <ch_cvl/lablproj.h>
```

`cfLabelProjectRaw`();

Global function to compute a non-normalized projection image using the supplied **ccLabeledProjectionModel** and the supplied input image.

cfLabelProjectRaw

```
template<class M, class I, class R>
void cfLabelProjectRaw(
  const ccLabeledProjectionModel<M> &model,
  const ccPelBuffer_const<I> &image,
  const ccPelBuffer<R> &rawProjection,
  bool preClearProj);
```

Computes the specified labeled projection, producing a non-normalized projection image.

Parameters

M, *I*, and *R* — Template parameters specifying the type of the projection model, source image, and raw projection image. You must specify one of the following combinations of types:

M	I	R
c_UInt8	**c_UInt8**	**c_UInt32**
c_UInt16	**c_UInt8**	**c_UInt16**
c_UInt8	**c_UInt8**	**c_UInt32**

model — The labeled projection model to use.

image — The input image.

rawProjection — A reference to a **ccPelBuffer<N>** into which to place the non-normalized projection image. The pixel type of *rawProjection* must be large enough to contain the product of the largest pixel value in *image* times the number of pixels in *model* with the most frequent label value.

In general, *rawProjection* should be of type **ccPelBuffer<c_UInt32>**.

preClearProj — If *preClearProj* is true, this function will initialize the contents of *rawProjection* to zero before projecting *image*.

cfLabelProjectRaw()

cfLineFit()

```
#include <ch_cvl/circfit.h>

cfLineFit();
```

Global function to fit a line to a set of points.

cfLineFit

```
void cfLineFit(
  const ccLineFitParams &params,
  cmStd vector<cc2Vect> &pts,
  ccLineFitResults &results);
```

A global function that fits a line to the supplied set of points using the supplied **ccLineFitParams**.

Parameters

params — A **ccLineFitParams** describing the fitting method, number of outliers to ignore, and a maximum error threshold.

pts — A vector of points specified in a single coordinate system.

results — A reference to a **ccLineFitResults** into which the results will be placed. Any existing contents of *results* are cleared.

Throws

ccMathError::Singular
The number of points in *pts* is less than 2 after subtracting the number of points to ignore specified in *params*, or *pts* does not include two different points.

cfLineFit()

cfManualTrigger()

```
#include <ch_cvl/trigmodl.h>

cfManualTrigger();
```

Global function to retrieve a manual trigger model object reference.

cfManualTrigger

```
const ccTriggerModel& cfManualTrigger();
```

When you specify manual trigger as the trigger model, the application must call **ccAcqFifo::start()** to initiate each acquisition. Since no external input lines are involved, this trigger model is sometimes called a “software trigger.”

This is the default trigger model.

Notes

When **ccTriggerProp::triggerEnable()** is set to false, invocations of **ccAcqFifo::start()** cause acquisitions to queue. For acquisitions to proceed, **ccTriggerProp::triggerEnable()** must be set to true.

cfManualTrigger()

cfOCChangeCurrentKey()

```
#include <ch_cvl/oc.h>

cfOCChangeCurrentKey();
```

Global function to change the current key for a specified line position.

cfOCChangeCurrentKey

```
ccOCLineArrangementPtrh cfOCChangeCurrentKey(
  const ccOCLineArrangement& arr,
  c_Int32 lineIndex,
  c_Int32 posIndex,
  c_Int32 newKey);

ccOCLineArrangementPtrh cfOCChangeCurrentKey(
  const ccOCLineArrangement& arr,
  c_Int32 lineIndex,
  c_Int32 posIndex);
```

- ```
  ccOCLineArrangementPtrh cfOCChangeCurrentKey(
    const ccOCLineArrangement& arr,
    c_Int32 lineIndex,
    c_Int32 posIndex,
    c_Int32 newKey);
  ```

  Returns a new arrangement that is a copy of the supplied line arrangement, *arr*, with the exception that the current keys for the specified line and position are changed (replaced). The current key is directly replaced by the supplied *newKey*.

  Notes

  If current key replacement is made to change a character verified by an **ccOCVTool** object which has previously been trained with the line arrangement *arr*, it will be necessary to call the **retrain()** member function of that tool with the new arrangement returned by this function.

  Parameters

arr	A line arrangement.
lineIndex	The index of the line within the arrangement.
posIndex	The index of the position within the line for which to change the current key.
newKey	The new value for the current key.

  Throws
  ```

ccOCDefs::BadParams
The line or position index is not valid for the supplied arrangement.

ccOCDefs::BadKey
newkey is not in the key set for the specified position.

- ```
  ccOCLineArrangementPtrh cfOCChangeCurrentKey(
    const ccOCLineArrangement& arr,
    c_Int32 lineIndex,
    c_Int32 posIndex);
  ```

Returns a new arrangement that is a copy of the supplied line arrangement, *arr*, with the exception that the current keys for the specified line and position are changed (replaced). The current keys are directly replaced by a wildcard character.

Notes

If current key replacements are made to change characters verified by an **ccOCVTool** object which has previously been trained with the line arrangement *arr*, it will be necessary to call the **retrain()** member function of that tool with the new arrangement returned by this function.

Parameters

arr A line arrangement.

lineIndex The index of the line within the arrangement.

posIndex The index of the position within the line for which to change the current key.

Throws

ccOCDefs::BadParams
Either the line or position index is not valid for the supplied arrangement.
  ```

cfOCChangeCurrentKeys()

```
#include <ch_cvl/oc.h>

cfOCChangeCurrentKeys();
```

Global function to change the current keys for a specified line position.

cfOCChangeCurrentKeys

```
ccOCLineArrangementPtrh cfOCChangeCurrentKeys(
  const ccOCLineArrangement& arr,
  c_Int32 lineIndex,
  c_Int32 posIndex,
  const cmStd vector<c_Int32>& newKeys);

ccOCLineArrangementPtrh cfOCChangeCurrentKeys(
  const ccOCLineArrangement& arr,
  c_Int32 lineIndex,
  c_Int32 posIndex,
  const ccCvlString& newName);
```

- ```
  ccOCLineArrangementPtrh cfOCChangeCurrentKeys(
    const ccOCLineArrangement& arr,
    c_Int32 lineIndex,
    c_Int32 posIndex,
    const cmStd vector<c_Int32>& newKeys);
  ```

  Returns a new arrangement that is a copy of the supplied line arrangement, *arr*, with the exception that the current keys for the specified line and position are changed (replaced). The current keys are directly replaced by the supplied *newKeys*.

  Notes

  If current key replacements are made to change characters verified by an **ccOCVTool** object which has previously been trained with the line arrangement *arr*, it will be necessary to call the **retrain()** member function of that tool with the new arrangement returned by this function.

  Parameters

arr	A line arrangement.
lineIndex	The index of the line within the arrangement.
posIndex	The index of the position within the line for which to change the current key or keys.
newKeys	The new values for the current keys.
  ```

Throws

ccOCDefs::BadParams
The line or position index is not valid for the supplied arrangement.

ccOCDefs::BadKey
newKeys is not in the key set for the specified position.

- ```
  ccOCLineArrangementPtrh cfOCChangeCurrentKeys(
    const ccOCLineArrangement& arr,
    c_Int32 lineIndex,
    c_Int32 posIndex,
    const ccCvlString& newName);
  ```

Returns a new arrangement that is a copy of the supplied line arrangement, *arr*, with the exception that the current keys for the specified line and position are changed (replaced). The current keys are directly replaced by the supplied *newKeys*. The current keys are replaced by a single key that corresponds to the supplied character name.

Notes

If current key replacements are made to change characters verified by an **ccOCVTool** object which has previously been trained with the line arrangement *arr*, it will be necessary to call the **retrain()** member function of that tool with the new arrangement returned by this function.

Despite the name of this function, you cannot use it to specify more than a single current key.

Parameters

arr A line arrangement.

lineIndex The index of the line within the arrangement.

posIndex The index of the position within the line for which to change the current key.

newName The name of the character to select as the current key.

Throws

ccOCDefs::BadParams
Either the line or position index is not valid for the supplied arrangement.

ccOCDefs::BadKey
The key specified by *newName* does not correspond to a character in the alphabet for the line specified by the supplied line index.
  ```

cfOCRReclassifyAfterFielding()

```
#include <ch_cvl/ocrglue.h>

cfOCRReclassifyAfterFielding();
```

Global function to compute the classifier result according to the fielding.

cfOCRReclassifyAfterFielding

```
cmImport_cogocr void cfOCRReclassifyAfterFielding(
  const ccOCRDictionaryFielding &fielding,
  const ccOCRDictionaryResult& fieldingResult,
  const ccOCRClassifierLineResult &classifierResult,
  const ccOCSwapCharSet &swapCharSet,
  bool computeConfusionUsingOnlyAllowableCharacters,
  ccOCRClassifierLineResult &computedResult);
```

Computes the classifier result according to the fielding (based on the given *fieldingResult* and the given *classifierResult*).

Parameters

fielding The fielding.

fieldingResult The fielding result.

classifierResult The classifier result.

swapCharSet The swap character set.

computeConfusionUsingOnlyAllowableCharacters
If true, confusion is computed using only the allowable characters.

computedResult The computed result.

Notes

The output *computedResult* has the same number of character elements as the *fieldingResult resultString*, and they are in 1-1 correspondence.

The output *computedResult* may have a different number of character elements than the input *classifierResult*.

If characters are inserted in the fielding result, they will be reflected in the *computedResult* as position results with status *eFailed*, score 0, *characterCode eUnknown*.

If the confusion is not limited to only allowable characters, that is, *computeConfusionUsingOnlyAllowableCharacters* == false, then all the non-primary characters will be included as alternative characters (regardless of

whether they agree with the fielding). In other words, if *computeConfusionUsingOnlyAllowableCharacters* == false, then only the primary character is constrained to agree with the fielding.

If the fieldings vector is empty (**fielding.size()**==0), then the *classifierResult* is copied to the *computedResult.*

For each position, if the highest scoring character that satisfies the *allowableCharacterCodes* constraints does not satisfy the accept threshold, then the status is set to *eFailed*. Correspondingly, if the status is *eFailed*, then the primary character is unknown.

If *computeConfusionUsingOnlyAllowableCharacters* == false, then for each position, the confusion character is set to the highest scoring non-primary character; consequently, for each position, the *confusionCharacter* may be valid even if the primary character is unknown and the classifier status is failed.

For each position, if the primary character is the only matching character, the confusion character is set to a default constructed character.

Throws

ccOCRDictionaryDefs::BadParams

classifierResult.positionResults().size() != **fieldingResult.inputStringMulti().size()**

cfOCSegmentCharacters()

```
#include <ch_cvl/ocsegmnt.h>

cfOCSegmentCharacters();
```

Global function for segmenting.

cfOCSegmentCharacters

```
void cfOCSegmentCharacters(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAffineRectangle& searchRegion,
  const ccOCCharSegmentRunParams& params,
  ccOCCharSegmentParagraphResult& result,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);

void cfOCSegmentCharacters(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccOCCharSegmentRunParams& params,
  ccOCCharSegmentParagraphResult& result,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);

void cfOCSegmentCharacters(
  const ccPelBuffer_const<c_UInt8>& image,
  const cmStd vector<ccAffineRectangle>& searchRegions,
  const ccOCCharSegmentRunParams& params,
  ccOCCharSegmentResult& result,
  ccDiagObject* diagobj=0,
  c_UInt32 diagFlags=0);
```

-
```
void cfOCSegmentCharacters(
  const ccPelBuffer_const<c_UInt8>& image,
  const ccAffineRectangle& searchRegion,
  const ccOCCharSegmentRunParams& params,
```

```
ccOCCharSegmentParagraphResult& result,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

Segments one line of characters contained in the image within the region of interest (ROI) specified by *searchRegion*.

The ROI should contain one line of characters and surrounding featureless, but possibly nonuniform and/or noisy background; there should be no strong features in the ROI other than the one line of characters.

The ROI is specified in the client coordinates of the input image. The x-axis should be approximately parallel to the baseline of the contained line of characters, with its positive direction pointing along the reading direction.

The skew should be the approximate value of the skew of the line of characters.

If **params.angleHalfRange()** is greater than zero, the angle of the line is refined. If **params.skewHalfRange()** is greater than zero, the skew of the line is refined.

Even if no characters are found, the paragraph result contains exactly one line result.

Parameters

image	The input image for the OCR Segmenter tool.
searchRegion	The ROI.
params	The set of input parameters.
result	The result of the segmentation.
diagobj	An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.
diagFlags	The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values: *ccDiagDefs::eInputs* *ccDiagDefs::eIntermediate* *ccDiagDefs::eResults* with one of the following values: *ccDiagDefs::eRecordOn* *ccDiagDefs::eRecordOff*

Throws

ccOCRDefs::UnboundWindow
image is unbound.

ccOCRDefs::NotImplemented
image.imageFromClientXformBase()->**isLinear()** returns false, or
searchRegion is partially outside the input image.

ccOCRDefs::BadParams
searchRegion is degenerate, or
searchRegion is entirely outside the input image, or
any of the following is true:

- **params.useCharacterMaxWidth()** == true && **params.characterMinWidth()** > **params.characterMaxWidth()**
- **params.useCharacterMaxHeight()** == true && **params.characterMinHeight()** > **params.characterMaxHeight()**
- **params.spaceParams().spaceMinWidth()** > **params.spaceParams().spaceMaxWidth()**
- *searchRect* corresponds to less than 1 pel in either x or y.

- ```
  void cfOCSegmentCharacters(
    const ccPelBuffer_const<c_UInt8>& image,
    const ccOCCharSegmentRunParams& params,
    ccOCCharSegmentParagraphResult& result,
    ccDiagObject* diagobj=0,
    c_UInt32 diagFlags=0);
  ```

  Segments one line of characters contained in the image.

  The ROI is the entire image window.

  The ROI should contain one line of characters and surrounding featureless, but possibly nonuniform and/or noisy background; there should be no strong features in the ROI other than the one line of characters.

  The contained line of characters should have its baseline approximately horizontal in the image, with the reading direction being from left to right.

  If **params.angleHalfRange()** is greater than zero, the angle of the line is refined. If **params.skewHalfRange()** is greater than zero, the skew of the line is refined.

  Even if no characters are found, the paragraph result contains exactly one line result.

  Parameters

image	The input image for the OCR Segmenter tool.
params	The set of input parameters.
result	The result of the segmentation.
  ```

diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccOCRDefs::UnboundWindow
image is unbound.

ccOCRDefs::NotImplemented
image.imageFromClientXformBase()->**isLinear()** returns false.

ccOCRDefs::BadParams
Any of the following is true:

- **params.useCharacterMaxWidth()** == true && **params.characterMinWidth()** > **params.characterMaxWidth()**
- **params.useCharacterMaxHeight()** == true && **params.characterMinHeight()** > **params.characterMaxHeight()**
- **params.spaceParams().spaceMinWidth()** > **params.spaceParams().spaceMaxWidth()**
- *image* is smaller than 1 pel in either x or y.

- ```
  void cfOCSegmentCharacters(
    const ccPelBuffer_const<c_UInt8>& image,
    const cmStd vector<ccAffineRectangle>& searchRegions,
    const ccOCCharSegmentRunParams& params,
  ```
  ```

```
ccOCCharSegmentResult& result,
ccDiagObject* diagobj=0,
c_UInt32 diagFlags=0);
```

Segments one or more paragraphs of characters contained in the image within regions of interest specified by *searchRegions*.

Each ROI is segmented as described in the single-ROI overload of **cfOCSegmentCharacters()** above.

result contains one paragraph result for each ROI, even if no characters are found in a given ROI.

Each ROI is treated completely independently. For example, lines in different ROIs may have different angles and/or skews.

Parameters

image The input image for the OCR Segmenter tool.

searchRegions The ROIs.

params The set of input parameters.

result The result of the segmentation.

diagobj An optional **ccDiagObject**. If you supply a value for *diagobj*, then the tool will record diagnostic information in the supplied object.

diagFlags The optional diagnostic flags. *diagFlags* must be composed by ORing together one or more of the following values:

ccDiagDefs::eInputs
ccDiagDefs::eIntermediate
ccDiagDefs::eResults

with one of the following values:

ccDiagDefs::eRecordOn
ccDiagDefs::eRecordOff

Throws

ccOCRDefs::UnboundWindow
image is unbound.

ccOCRDefs::BadParams
Any of the following is true:

- The vector *searchRegions* is empty.
- Any element of *searchRegions* is degenerate.

- Any element of *searchRegions* is entirely outside the input image.
- **params.useCharacterMaxWidth()** == true && **params.characterMinWidth()** > **params.characterMaxWidth()**
- **params.useCharacterMaxHeight()** == true && **params.characterMinHeight()** > **params.characterMaxHeight()**
- **params.spaceParams().spaceMinWidth()** > **params.spaceParams().spaceMaxWidth()**
- Any of the *searchRects* correspond to less than 1 pel in either x or y.

ccOCRDefs::NotImplemented

image.imageFromClientXformBase()->**isLinear()** returns false, or
any element of *searchRegions* is partially outside the input image.

cfPDF417Decode()

```
#include <ch_cvl/pdf417.h>

cfPDF417Decode();
```

Global function to find and decode a PDF417 stacked barcode symbol.

cfPDF417Decode

```
void cfPDF417Decode(
  const ccPelBuffer_const<c_UInt8>& image,
  ccPDF417Result &result);
```

- ```
  void cfPDF417Decode(
    const ccPelBuffer_const<c_UInt8>& image,
    ccPDF417Result &result);
  ```

  Finds the PDF417 symbol in a given image and decodes it. Returns a result via the result object. The PDF417 symbol tool is able to detect the encoded information directly from the image. Therefore, no learning phase is needed before decoding.

  Parameters

image	Image that contains the PDF417 barcode symbol. The image must have at least quiet zones 4X wide on each side of the symbol, where X is the width of the narrowest bar.
result	Object in which to store the result.

  Throws

  ccPDF417Defs::BadImage
  Image is unbound.
  ```

cfPDF417Decode()

cfPelAdd()

```
#include <ch_cvl/pelfunc.h>

cfPelAdd();
```

Global function to add the pixels of two windows.

Note When this function computes the greatest common region of two images it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

cfPelAdd

```
template<class P>
ccPelBuffer<P> cfPelAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);

template<class P>
ccPelBuffer<P> cfPelAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2, c_Int32 output_mode);

template<class S1, class S2, class D>
void cfPelAdd(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);

template<class S1, class S2, class D>
void cfPelAdd(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2,
  ccPelBuffer<D>& dest, c_Int32 output_mode);
```

-
```
template<class P>
ccPelBuffer<P> cfPelAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);
```

Adds the pixels in the greatest common region of *src1* and *src2* using the default output mode (*ccPelFunc::eAddDefault*), writes the resulting pixels values to a new root image, and returns a window that is bound to that image.

Parameters

P	Template parameter specifying the type of the windows whose pixels are being added and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
src1	A bound window.
src2	A bound window.

Throws

ccPel::UnboundWindow
src1 or *src2* is unbound.

- ```
  template<class P>
  ccPelBuffer<P> cfPelAdd(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2, c_Int32 output_mode);
  ```

  Applies the user-specified method of handling overflow as it adds the pixels in the greatest common region of *src1* and *src2*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the windows whose pixels are being added and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src1 — A bound window.

  src2 — A bound window.

  output_mode — The method to use to handle overflow. *output_mode* must be one of the following values:

  ccPelFunc::eAddDefault
  ccPelFunc::eAddAbs
  ccPelFunc::eAddClamp
  ccPelFunc::eAddShft
  ccPelFunc::eAddLimit

  See **add_mode** on page 2384.

  Throws

  ccPel::UnboundWindow
  src1 or *src2* is unbound.

  ccPelFunc::BadParams
  output_mode is not a valid addition mode.

- ```
  template<class S1, class S2, class D>
  void cfPelAdd(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
  ```

  Adds the pixels in the region of *src1* and *src2* defined by greatest common region of *src1* and *src2* and *dest* using the default output mode (*ccPelFunc::eAddDefault*), and writes the resulting pixel values to *dest*.

Parameters

S1, S2, D Template parameters that specify the type of the two source windows and the destination window. The following combinations of types are permitted for *S1, S2,* and *D:*

S1	S2	*D*
c_UInt8	c_UInt8	c_UInt8
c_UInt16	c_UInt16	c_UInt16
c_UInt32	c_UInt32	c_UInt32
c_UInt8	c_UInt16	c_UInt16
c_UInt8	c_UInt32	c_UInt32

src1 A bound window.

src2 A bound window.

dest A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be added and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1* and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then added and the resulting values are written to *dest*.

Throws

ccPel::UnboundWindow

src1 or *src2* is unbound.

- ```
  template<class S1, class S2, class D>
  void cfPelAdd(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2,
    ccPelBuffer<D>& dest, c_Int32 output_mode);
  ```

  Applies the user-specified method of handling overflow as it adds the pixels in the region of *src1* and *src2* defined by greatest common region of *src1* and *src2* and *dest,* and writes the resulting pixels values to *dest*.
  ```

Parameters

S1, S2, D

Template parameters that specify the type of the two source windows and the destination window. The following combinations of types are permitted for *S1, S2,* and *D:*

S1	S2	*D*
c_UInt8	**c_UInt8**	**c_UInt8**
c_UInt16	**c_UInt16**	**c_UInt16**
c_UInt32	**c_UInt32**	**c_UInt32**
c_UInt8	**c_UInt16**	**c_UInt16**

src1

A bound window.

src2

A bound window.

dest

A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be added and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1* and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then added and the resulting values are written to *dest*.

output_mode

The method to use to handle overflow. *output_mode* must be one of the following values:

ccPelFunc::eAddDefault
ccPelFunc:: eAddAbs
ccPelFunc::eAddClamp
ccPelFunc::eAddShft
ccPelFunc::eAddLimit

See **add_mode** on page 2384.

Throws

ccPel::UnboundWindow

src1 or *src2* is unbound.

ccPelFunc::BadParams

output_mode is not a valid addition mode.

cfPelClear()

```
#include <ch_cvl/pelfunc.h>

cfPelClear();
```

Global function to set all pixels of a window to zero.

P Template parameter specifying the type of the pixels in *win*. *P* must be one of **c_UInt8**, **c_UInt16**, **c_UInt32**, **double**, **ccPackedRGB16Pel**, **ccPackedRGB32Pel**.

cfPelClear

```
template<class P> void cfPelClear(
  const ccPelBuffer<P>& win);
```

Clears a window by setting its pixels to zero.

Parameters

win A bound window.

Throws

ccPel::UnboundWindow
win is unbound.

cfPelClear()

cfPelCopy()

```
#include <ch_cvl/pelfunc.h>

cfPelCopy();
```

Global function to copy the pixels in a window.

cfPelCopy

```
template<class P>
ccPelBuffer<P> cfPelCopy(const ccPelBuffer_const<P>& src);

template<class S, class D>
void cfPelCopy(const ccPelBuffer_const<S>& src,
 ccPelBuffer<D>& dest);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelCopy(const ccPelBuffer_const<P>& src);
  ```

  Copies the pixels in *src* to a new root image and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the window to be returned by the function and of the pixels in *src*. *P* must be one of **c_UInt8**, **c_UInt16**, **c_UInt32** or **double**.

  src — A bound window.

  Throws

  ccPel::UnboundWindow — *src* is unbound.

- ```
  template<class S, class D>
  void cfPelCopy(const ccPelBuffer_const<S>& src,
   ccPelBuffer<D>& dest);
  ```

  Copies the pixels in *src* to *dest*.

  Parameters

  S — Template parameter specifying the type of the pixels in *src*. *S* must be one of **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, or **ccPackedRGB32Pel**.

D Template parameter specifying the type of the pixels in *dest*. *D* must be either the same type or a larger type than *S*.

If *S* is	*D* must be one of
c_UInt8	**c_UInt8**, **c_UInt16**, or **c_UInt32**
c_UInt16	**c_UInt16** or **c_UInt32**
c_UInt32	**c_UInt32**
ccPackedRGB16Pel	**ccPackedRGB16Pel**
ccPackedRGB32Pel	**ccPackedRGB32Pel**
cc3PlanePelBuffer	**cc3PlanePelBuffer**

src A bound window.

dest A bound or unbound window. If *dest* is bound, the pixels in the region of *src* determined by the greatest common region of *src* and *dest* are copied. If *dest* is unbound, a root image for *dest* is allocated and all the pixels in *src* are copied to *dest*.

Throws

ccPel::UnboundWindow
src is unbound.

Notes

When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

cfPelDivideByVal()

```
#include <ch_cvl/pelfunc.h>

cfPelDivideByVal();
```

Global function to divide the pixels in a window by a specified value.

cfPelDivideByVal

```
template<class P, class Div>
ccPelBuffer<P> cfPelDivideByVal(
  const ccPelBuffer_const<P>& src, Div divisor);

template<class S, class D, class Div>
void cfPelDivideByVal(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest, Div divisor);
```

- ```
  template<class P, class Div>
  ccPelBuffer<P> cfPelDivideByVal(
    const ccPelBuffer_const<P>& src, Div divisor);
  ```

  Divides the pixels in *src* by the specified *divisor*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the windows whose pixels are being divided and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  Div — Template parameter specifying the type of the divisor. *Div* must always be **double**.

  src — A bound window.

  divisor — The nonzero value by which the pixels in *src* are divided.

  Throws

  ccPel::UnboundWindow — *src* is unbound.

- ```
  template<class S, class D, class Div>
  void cfPelDivideByVal(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest, Div divisor);
  ```

  In the greatest common region of *src* and *dest*, divides the pixels in *src* by the value of *divisor* and writes the resulting pixel values to *dest*.

Parameters

S Template parameter specifying the type of the windows whose pixels are being divided and of the window that the function returns. *S* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

D Template parameter specifying the type of the pixels in *dest*. *D* must be either the same type or a smaller type than *S*.

If *S* is	***D* must be one of**
c_UInt8	**c_UInt8**
c_UInt16	**c_UInt8** or **c_UInt16**
c_UInt32	**c_UInt8**, **c_UInt16**, **c_UInt32**

Div Template parameter specifying the type of the divisor. *Div* must always be **double**.

src A bound window.

dest A bound or unbound window. If *dest* is bound, the pixels in the region of *src* determined by the greatest common region of *src* and *dest* are divided by *divisor*. If *dest* is unbound, a root image for *dest* is allocated, the pixels in *src* are divided, and the resulting pixel values are written to *dest*.

divisor A nonzero value by which the pixels in *src* are divided.

Throws

ccPel::UnboundWindow
src is unbound.

cfPelEqual()

```
#include <ch_cvl/pelfunc.h>

cfPelEqual();
```

Global function to compare the pixels in two windows.

cfPelEqual

```
template<class P1, class P2>
bool cfPelEqual(const ccPelBuffer_const<P1>& win1,
  const ccPelBuffer_const<P2>& win2);
```

Compares the pixels in the greatest common region of *win1* and *win2* and returns true if all the pixel values in the two windows are equal; otherwise the function returns false.

Parameters

P1, *P2*	Template parameters specifying the type of the pixels in *win1* and *win2*. *P1* and *P2* are always the same, and must be one of **c_UInt8**, **c_Int8**, **c_Int16**, **c_UInt16**, **c_UInt32** or **double**.
win1	A bound window.
win2	A bound window.

Notes

When this function computes the greatest common region of *win1* and *win2* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

If the greatest common region is of 0 size, that is, contains no pixels, **cfPelEqual()** returns true.

Throws

ccPel::UnboundWindow
win1 or *win2* is unbound.

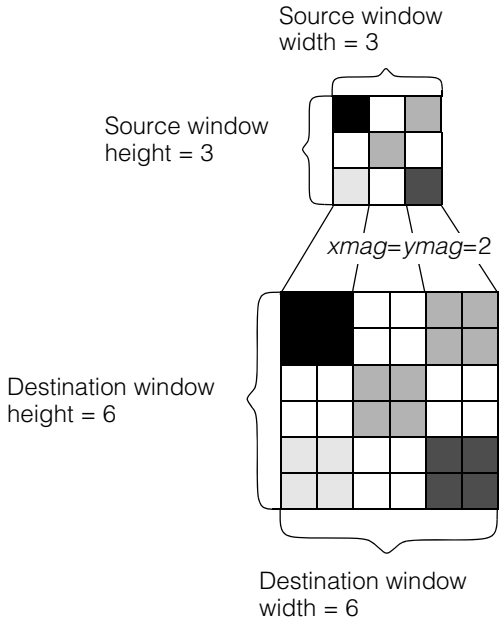
cfPelEqual()

cfPelExpand()

```
#include <ch_cvl/pelfunc.h>

cfPelExpand();
```

Global function to copy each pixel in the source window to a rectangular block of pixels in the destination window, enlarging the source image. The following figure shows an example of expansion.



The destination image is divided into blocks of pixels, starting at the upper left pixel, with *xmag* and *ymag* defining the size of the blocks. Then each block in the destination image is filled in with copies of the source pixel corresponding to the destination pixel block as shown above.

cfPelExpand()

cfPelExpand

```
template<class P>
ccPelBuffer<P> cfPelExpand(
  const ccPelBuffer_const<P>& src,
  c_Int32 xmag, c_Int32 ymag);

template<class S, class D>
void cfPelExpand(const ccPelBuffer_const<S>& src,
ccPelBuffer<D>& dest, c_Int32 xmag, c_Int32 ymag);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelExpand(
    const ccPelBuffer_const<P>& src,
    c_Int32 xmag, c_Int32 ymag);
  ```

  Expands the pixels in *src* by the values of *xmag* by *ymag*, writes the resulting pixels to a new root image, and returns a window that is bound to that image.

  Parameters

P	Template parameter specifying the type of the window whose pixels are being magnified and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**, **ccPackedRGB16Pel**, or **ccPackedRGB32Pel**.
src	A bound window.
xmag, ymag	The values by which source pixels are magnified in the x and y dimensions. *xmag* and *ymag* must be greater than 0.

  Throws

  ccPel::UnboundWindow
  src is unbound.

- ```
  template<class S, class D>
  void cfPelExpand(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest, c_Int32 xmag, c_Int32 ymag);
  ```

  Expands the pixels in *src* by the values of *xmag* by *ymag* and writes the resulting pixels to *dest*.

  Parameters

S, *D*	Template parameters specifying the type of the source and destination windows. *S* and *D* are always the same, and must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**, **ccPackedRGB16Pel**, or **ccPackedRGB32Pel**.
src	A bound window.
dest	A bound or unbound window.

If *dest* is unbound, a new root image is allocated to accommodate the results of the expansion, and *dest* is bound to the root image. All the pixels in *src* are then expanded and the results are written to *dest*.

If *dest* is bound, the function calculates the size that *src* would be after expansion, then determines the greatest common region of this expanded *src* with *dest* to determine how much of *src* is to be expanded.

When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

xmag, ymag — The values by which source pixels are magnified in the x and y dimensions. *xmag* and *ymag* must be greater than 0.

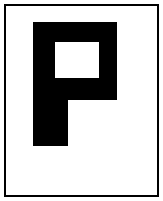
cfPelExpand()

cfPelFlipH()

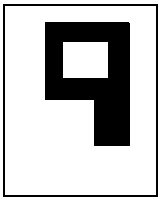
```
#include <ch_cvl/pelfunc.h>

cfPelFlipH();
```

Global function to flip the pixels in a window horizontally. The following figure shows an example of a horizontal flip.



Source window



Window after horizontal flip

cfPelFlipH

```
template<class P>
ccPelBuffer<P> cfPelFlipH(
  const ccPelBuffer_const<P>& src);

template<class S, class D>
void cfPelFlipH(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelFlipH(
    const ccPelBuffer_const<P>& src);
  ```

  Flips the pixels in *src* horizontally, copies them to a new root image, and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the window to be returned by the function and of the pixels in *src*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src — A bound window.

  Throws

  ccPel::UnboundWindow — *src* is unbound.
  ```

- ```
  template<class S, class D>
  void cfPelFlipH(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest);
  ```

  Flips the pixels in *src* and copies them to *dest*. If the same window is specified for *src* and *dest*, the operation is performed in place.

  Parameters

  S — Template parameter specifying the type of the pixels in *src*. *S* must be one of **c_UInt8**, **c_UInt16** or **c_UInt32**.

  D — Template parameter specifying the type of the pixels in *dest*. *D* must be the same type as *S*.

  src — A bound window.

  dest — A bound or unbound window. If *dest* is bound, the pixels in the region of *src* determined by the greatest common region of *src* and *dest* are flipped and copied. If *dest* is unbound, a root image for *dest* is allocated and all the pixels in *src* are flipped and copied to *dest*.

  When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

  Throws

  ccPel::UnboundWindow
  src is unbound.

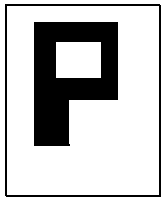
  ccPelFunc::Overlap
  src and *dest* overlap, but are not identical.
  ```

cfPelFlipV()

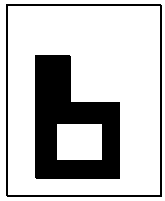
```
#include <ch_cvl/pelfunc.h>

cfPelFlipV();
```

Global function to flip the pixels in a window vertically. The following figure shows an example of a vertical flip.



Source window



Window after vertical flip

cfPelFlipV

```
template<class P>
ccPelBuffer<P> cfPelFlipV(
  const ccPelBuffer_const<P>& src);

template<class S, class D>
void cfPelFlipV(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelFlipV(
    const ccPelBuffer_const<P>& src);
  ```

  Flips the pixels in *src* vertically, copies them to a new root image, and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the window to be returned by the function and of the pixels in *src*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src — A bound window.

  Throws

  ccPel::UnboundWindow — *src* is unbound.
  ```

- ```
  template<class S, class D>
  void cfPelFlipV(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest);
  ```

  Flips the pixels in *src* and copies them to *dest*. If the same window is specified for *src* and *dest*, the operation is performed in place.

  Parameters

  S — Template parameter specifying the type of the pixels in *src*. *S* must be **c_UInt8**, **c_UInt16** or **c_UInt32**.

  D — Template parameter specifying the type of the pixels in *dest*. *D* must be the same type as *S*.

  src — A bound window.

  dest — A bound or unbound window. If *dest* is bound, the pixels in the region of *src* determined by the greatest common region of *src* and *dest* are flipped and copied. If *dest* is unbound, a root image for *dest* is allocated and all the pixels in *src* are flipped and copied to *dest*.

  When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

  Throws

  ccPel::UnboundWindow
  src is unbound.

  ccPelFunc::Overlap
  src and *dest* overlap, but are not identical.
  ```

cfPelHistogram()

```
#include <ch_cvl/histo.h>

cfPelHistogram();
```

Global function to compute the histogram of an input image.

cfPelHistogram

```
template<class P>
void cfPelHistogram(const ccPelBuffer_const<P>& image,
 cmStd vector<c_UInt32>& histogram);

template<class P>
void cfPelHistogram(const ccPelBuffer_const<P>& image,
 cmStd vector<c_UInt32>& histogram, bool& flag);
```

- ```
  template<class P>
  void cfPelHistogram(const ccPelBuffer_const<P>& image,
   cmStd vector<c_UInt32>& histogram);
  ```

  For each pixel in *image*, the value of the element of *histogram* with an index equal to the pixel's value is incremented. If *histogram* has a size of 0, **cfPelHistogram()** expands *histogram* so that it has an element at every index found in *image*. If *histogram* has a nonzero size, **cfPelHistogram()** does not perform any bounds checking as it computes the histogram.

  Note *histogram* is not cleared or initialized by this function.

  Caution *If you supply a nonzero size histogram to this function, you must ensure that it contains an element that corresponds to every value found in* image*. If it does not, your program will experience run-time memory corruption.*

  Parameters

  image The image for which to compute a histogram. *image* must be of type **c_UInt8** or **c_UInt16**.

  histogram An array of **c_UInt32** into which the histogram is written. If *histogram* has no elements, it is resized so that all values in *image* can be recorded in it. If *histogram* has any elements then it is not resized and no bounds checking is performed.

  Throws

  ccPel::UnboundWindow
  image is not bound.
  ```

- ```
  template<class P>
  void cfPelHistogram(const ccPelBuffer_const<P>& image,
    cmStd vector<c_UInt32>& histogram, bool& flag);
  ```

  For each pixel in *image*, the value of the element of *histogram* with an index equal to the pixel's value is incremented. If *histogram* does not contain an element at an index that corresponds to a pixel in *image*, the element of *histogram* closest to the value is incremented and *flag* is set to true.

Note *histogram* is not cleared or initialized by this function.

Caution *If you supply a nonzero size histogram to this function, you must ensure that it contains an element that corresponds to every value found in image. if it does not, your program will experience run-time memory corruption.*

Parameters

image The image for which to compute a histogram. *image* must be of type **c_UInt8**.

histogram An array of **c_UInt32** into which the histogram is written. *histogram* must have at least one element.

flag A reference to a **bool**. The value referred to by *flag* is set to true if clamping occurred.

Throws

ccPel::UnboundWindow
image is not bound.
  ```

cfPelMap()

```
#include <ch_cvl/pelmap.h>

cfPelMap();
```

Global function to map the pixels in a **ccPelBuffer** according to a table.

cfPelMap

```
template<class P>
ccPelBuffer<P> cfPelMap(
  const ccPelBuffer_const<P>& src,
  const cmStd vector<P>& pmap);

template<class S, class D>
void cfPelMap(
  const ccPelBuffer_const<S>& src,
  const cmStd vector<D>& pmap,
  ccPelBuffer<D>& dest);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelMap(
    const ccPelBuffer_const<P>& src,
    const cmStd vector<P>& pmap);
  ```

  Returns a new pel buffer that is a result of mapping each pixel in *src* to the corresponding value in *pmap*. Each pixel value in *src* is used as an index into *pmap*. The pixel value at that offset is used as the output pixel value.

  Parameters

P	Template parameter specifying the type of the pel buffer whose pixels are being mapped and of the pel buffer that the function returns. *P* must be **c_UInt8**.
src	The source pel buffer.
pmap	The mapping table. This is a vector of all the possible values in src. For an 8-bit image, for example, *pmap* must contain at least 256 elements.

  Throws

  ccPel::UnboundWindow
  src is not bound.
  ```

- ```
  template<class S, class D>
  void cfPelMap(
    const ccPelBuffer_const<S>& src,
    const cmStd vector<D>& pmap,
    ccPelBuffer<D>& dest);
  ```

  Returns in *dest* the result of mapping each pixel in *src* to the corresponding value in *pmap*. Each pixel value in *src* is used as an index into *pmap*. The pixel value at that offset is used as the output pixel value.

  Parameters

P	Template parameter specifying the type of the pel buffer whose pixels are being mapped. *P* must be **c_UInt8**.
D	Template parameter specifying the type of the pel buffer used to hold the results. *D* must be the same type as *P*.
src	The source pel buffer.
pmap	The mapping table. This is a vector of all the possible values in src. For an 8-bit image, for example, *pmap* must contain at least 256 elements.
dest	The destination pel buffer. If *dest* is unbound, a pel buffer of the same dimensions as *src* is allocated.

  Throws

  ccPel::UnboundWindow
  : *src* is not bound.

  ccPelFunc::Overlap
  : *src* and *dest* overlap.
  ```

cfPelMax()

```
#include <ch_cvl/pelfunc.h>

cfPelMax();
```

Global function to find the maximum pixel value in a window, or to compute an image where each pixel is the maximum of the values of the corresponding pixels in two input images.

cfPelMax

```
template<class P> P cfPelMax(
  const ccPelBuffer_const<P>& win);

template<class P> ccPelBuffer<P> cfPelMax(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);

template<class S1, class S2, class D> void cfPelMax(
  const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
```

- ```
  template<class P> P cfPelMax(
    const ccPelBuffer_const<P>& win);
  ```

  Returns the maximum pixel value in *win*.

  Parameters

  P — Template parameter specifying the type of the function's return value and of the pixels in *win*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  win — A bound window.

  Throws

  ccPel::UnboundWindow — *win* is unbound.

- ```
  template<class P> ccPelBuffer<P> cfPelMax(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2);
  ```

  Returns an image where each pixel is the maximum of the values of the corresponding pixels in *src1* and *src2*.

Parameters

P Template parameter specifying the type of pixels in *src1*, *src2*, and the returned window. *P* must be **c_UInt8**.

src1 A bound window.

src2 A bound window.

Throws

ccPel::UnboundWindow
src1 or src2 is unbound.

- ```
  template<class S1, class S2, class D> void cfPelMax(
    const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
  ```

Computes an image where each pixel is the maximum of the values of the corresponding pixels in *src1* and *src2* and places the image in *dest*.

Parameters

S1 Template parameter specifying the type of pixels in *src1*. *S1* must be **c_UInt8**.

S2 Template parameter specifying the type of pixels in *src2*. *S2* must be **c_UInt8**.

D Template parameter specifying the type of pixel in the destination window. *D* must be **c_UInt8**.

src1 A bound window.

src2 A bound window.

dest A window into which the result is placed. If *dest* is initially unbound, it is allocated to the same dimension as the greatest common region of *src1* and *src2*.

Throws

ccPel::UnboundWindow
src1 or src2 is unbound.

ccPelFunc::Overlap
src1 or src2 overlaps *dest* but they are not identical (after adjusting for the greatest common region).
  ```

cfPelMedian3x3()

```
#include <ch_cvl/pelfunc.h>

cfPelMedian3x3();
```

Global function that writes to a destination window the median value of each 3x3 neighborhood of pixels in the source window.

Pixels that are not at the center of a 3x3 neighborhood are not processed. This means that for a *src* window with a size of *width* x *height* pixels, the function returns a window that is, at most, (*width* - 2) x (*height* - 2) pixels.

cfPelMedian3x3

```
ccPelBuffer<c_UInt8> cfMedian3x3(
  const ccPelBuffer_const<c_UInt8>& src);

void cfPelMedian3x3(const ccPelBuffer_const<c_UInt8>& src,
  ccPelBuffer<c_UInt8>& dest);
```

- ```
  ccPelBuffer<c_UInt8> cfMedian3x3(
    const ccPelBuffer_const<c_UInt8>& src);
  ```

  Performs a 3x3 median filtering of the pixels in *src*, writes each resulting pixel value to a new root image, and returns a window that is bound to that image.

  Parameters

  src A bound window.

  Throws

  ccPel::UnboundWindow
  src is unbound.

- ```
  void cfPelMedian3x3(const ccPelBuffer_const<c_UInt8>& src,
    ccPelBuffer<c_UInt8>& dest);
  ```

  Performs a 3x3 median filtering of the pixels in *src* and writes each resulting pixel value to *dest*.

  Parameters

  src A bound window.

  dest A bound or unbound window.

  If *dest* is bound, the function determines the greatest common region of *src* with *dest* to determine how much of *src* is to be filtered. In calculating the greatest common region, the function

excludes the top and bottom rows and the left and right columns of pixels in *src* because they are not at the center of a 3x3 neighborhood.

If *dest* is unbound, a new root image is allocated to accommodate the results of the median filtering, and *dest* is bound to the root image. All the 3x3 neighborhoods in *src* are then filtered and the results are written to *dest*.

cfPelMin()

```
#include <ch_cvl/pelfunc.h>

cfPelMin();
```

Global function to find the minimum pixel value in a window, or to compute an image where each pixel is the minimum of the values of the corresponding pixels in two input images.

cfPelMin

```
template<class P> P cfPelMin(
  const ccPelBuffer_const<P>& win);

template<class P> ccPelBuffer<P> cfPelMin(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);

template<class S1, class S2, class D> void cfPelMin(
  const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
```

- ```
  template<class P> P cfPelMin(
    const ccPelBuffer_const<P>& win);
  ```

  Returns the minimum pixel value in *win*.

  Parameters

  P — Template parameter specifying the type of the function's return value and of the pixels in *win*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  win — A bound window.

  Throws

  ccPel::UnboundWindow — *win* is unbound.

- ```
  template<class P> ccPelBuffer<P> cfPelMin(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2);
  ```

  Returns an image where each pixel is the minimum of the values of the corresponding pixels in *src1* and *src2*.

Parameters

P Template parameter specifying the type of pixels in *src1*, *src2*, and the returned window. *P* must be **c_UInt8**.

src1 A bound window.

src2 A bound window.

Throws

ccPel::UnboundWindow
src1 or src2 is unbound.

- ```
  template<class S1, class S2, class D> void cfPelMin(
    const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
  ```

Computes an image where each pixel is the minimum of the values of the corresponding pixels in *src1* and *src2* and places the image in *dest*.

Parameters

S1 Template parameter specifying the type of pixels in *src1*. *S1* must be **c_UInt8**.

S2 Template parameter specifying the type of pixels in *src2*. *S2* must be **c_UInt8**.

D Template parameter specifying the type of pixel in *dest*. *D* must be **c_UInt8**.

src1 A bound window.

src2 A bound window.

dest A window into which the result is placed. If *dest* is initially unbound, it is allocated to the same dimension as the greatest common region of *src1* and *src2*.

Throws

ccPel::UnboundWindow
src1 or src2 is unbound.

ccPelFunc::Overlap
src1 or src2 overlaps *dest* but they are not identical (after adjusting for the greatest common region).
  ```

cfPelMinmax()

```
#include <ch_cvl/pelfunc.h>

cfPelMinmax();
```

Global function to find the minimum and maximum pixel values in a window.

cfPelMinmax

```
template<class P> void cfPelMinmax(
  const ccPelBuffer_const<P>& win, P& min, P& max);
```

Returns the minimum and maximum pixel values in *win*.

Parameters

P	Template parameter specifying the type of the pixels in *win* and of the *min* and *max* output parameters. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
win	A bound window.
min	A reference to an integer that will hold the window's minimum pixel value.
max	A reference to an integer that will hold the window's maximum pixel value.

Throws

ccPel::UnboundWindow
win is unbound.

cfPelMinmax()

cfPelMult()

```
#include <ch_cvl/pelfunc.h>

cfPelMult();
```

Global function to multiply the pixels of two windows.

Note When this function computes the greatest common region of two images it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

cfPelMult

```
template<class P>
ccPelBuffer<P> cfPelMult(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);

template<class P>
ccPelBuffer<P> cfPelMult(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2, c_Int32 output_mode);

template<class S1, class S2, class D>
void cfPelMult(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);

template<class S1, class S2, class D>
void cfPelMult(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2,
  ccPelBuffer<D>& dest, c_Int32 output_mode);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelMult(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2);
  ```

  Multiplies the pixels in the greatest common region of *src1* and *src2* using the default output mode (*ccPelFunc::eMultDefault*), writes the resulting pixels values to a new root image, and returns a window that is bound to that image.

  Parameters

P	Template parameter specifying the type of the windows whose pixels are being multiplied and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
src1	A bound window.
src2	A bound window.
  ```

Throws

ccPel::UnboundWindow
src1 or *src2* is unbound.

- ```
  template<class P>
  ccPelBuffer<P> cfPelMult(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2, c_Int32 output_mode);
  ```

Applies the user-specified method of handling overflow as it multiplies the pixels in the greatest common region of *src1* and *src2*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

Parameters

P Template parameter specifying the type of the windows whose pixels are being multiplied and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

src1 A bound window.

src2 A bound window.

output_mode The method to use to handle overflow. *output_mode* must be one of the following values:

ccPelFunc::eMultDefault (a * b)
ccPelFunc::eMultShft (a * b) >> 8

See **mult_mode** on page 2384.

ccPel::UnboundWindow
src1 or *src2* is unbound.

ccPelFunc::BadParams
output_mode is not a valid multiplication mode.

- ```
  template<class S1, class S2, class D>
  void cfPelMult(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
  ```

Multiplies the pixels in the region of *src1* and *src2* defined by greatest common region of *src1* and *src2* and *dest* using the default output mode (*ccPelFunc::eMultDefault*), and writes the resulting pixel values to *dest*.

Parameters

S1, S2, D — Template parameters that specify the type of the two source windows and the destination window. Not all combinations of *S1*, *S2*, and *D* are instantiated. See *pelfunc.h* to see which instantiations are available.

src1 — A bound window.

src2 — A bound window.

dest — A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be multiplied and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1* and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then multiplied and the resulting values are written to *dest*.

Throws

ccPel::UnboundWindow — *src1* or *src2* is unbound.

ccPelFunc::Overlap — The source window overlaps the destination window, but they are not identical (after adjusting for greatest common region).

- ```
  template<class S1, class S2, class D>
  void cfPelMult(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2,
    ccPelBuffer<D>& dest, c_Int32 output_mode);
  ```

  Applies the user-specified method of handling overflow as it multiplies the pixels in the region of *src1* and *src2* defined by greatest common region of *src1* and *src2* and *dest*, and writes the resulting pixels values to *dest*.

  Parameters

  S1, S2, D — Template parameters that specify the type of the two source windows and the destination window. Not all combinations of *S1*, *S2*, and *D* are instantiated. See *pelfunc.h* to see which instantiations are available.

  src1 — A bound window.

  src2 — A bound window.

  dest — A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be multiplied and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of
  ```

src1 and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then multiplied and the resulting values are written to *dest*.

output_mode The method to use to handle overflow. *output_mode* must be one of the following values:

ccPelFunc::eMultDefault
ccPelFunc::eMultShft

Throws

ccPel::UnboundWindow
src1 or *src2* is unbound.

ccPelFunc::Overlap
The source window overlaps the destination window, but they are not identical (after adjusting for greatest common region).

ccPelFunc::BadParams
output_mode is not a valid multiplication mode.

cfPelMultAdd()

```
#include <ch_cvl/pelfunc.h>

cfPelMultAdd();
```

Global function to multiply the pixels of two windows and add the pixels of a third window.

Note When this function computes the greatest common region of three images it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

cfPelMultAdd

```
template<class P>
ccPelBuffer<P> cfPelMultAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2,
  const ccPelBuffer_const<P>& src3);

template<class P>
ccPelBuffer<P> cfPelMultAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2,
  const ccPelBuffer_const<P>& src3,
  c_Int32 output_mode);

template<class S1, class S2, class S3, class D>
void cfPelMultAdd(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2,
  const ccPelbuffer_const<S3>& src3,
  ccPelBuffer<D>& dest);

template<class S1, class S2, class S3, class D>
void cfPelMultAdd(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2,
  const ccPelbuffer_const<S3>& src3,
  ccPelBuffer<D>& dest,
  c_Int32 output_mode);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelMultAdd(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2,
    const ccPelBuffer_const<P>& src3);
  ```

  Multiplies the pixels in the greatest common region of *src1*, *src2* and *src3* using the default output mode (*ccPelFunc::eMultAddDefault*), adds the pixels in *src3*, then writes the resulting pixels values to a new root image, and returns a window that is
  ```

bound to that image.

Parameters

P	Template parameter specifying the type of the windows whose pixels are being multiplied and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
src1	A bound window.
src2	A bound window.
src3	A bound window.

Throws

ccPel::UnboundWindow
src1, *src2,* or *src3* is unbound.

-
```
template<class P>
ccPelBuffer<P> cfPelMultAdd(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2,
  const ccPelBuffer_const<P>& src3,
  c_Int32 output_mode);
```

Applies the user-specified method of handling overflow as it operates on the pixels in the greatest common region of *src1*, *src2* and *src3,* multiplies *src1* and *src2*, adds the pixels in *src3*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

Parameters

P	Template parameter specifying the type of the windows whose pixels are being multiplied and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
src1	A bound window.
src2	A bound window.
src3	A bound window.
output_mode	The method to use to handle overflow. *output_mode* must be one of the following values: *ccPelFunc::eMultAddDefault* *ccPelFunc::eMultAddShft* See **mult_add_mode** on page 2385.

ccPel::UnboundWindow
src1, *src2,* or *src3* is unbound.

ccPelFunc::BadParams
output_mode is not a valid mode.

- ```
  template<class S1, class S2, class S3, class D>
  void cfPelMultAdd(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2,
    const ccPelbuffer_const<S3>& src3,
    ccPelBuffer<D>& dest);
  ```

Multiplies the pixels in the region of *src1* and *src2* and adds the pixels in *src3*, defined by greatest common region of *src1*, *src2*, *src3* and *dest* using the default output mode (*ccPelFunc::eMultAddDefault*), and writes the resulting pixel values to *dest*.

Parameters

S1, S2, S3, D — Template parameters that specify the type of the three source windows and the destination window. Not all combinations of *S1*, *S2*, *S3*, and *D* are instantiated. See *pelfunc.h* to see which instantiations are available.

src1 — A bound window.

src2 — A bound window.

src3 — A bound window.

dest — A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, *src3* and *dest* will be used and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1, src2* and *src3*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then multiplied, *src3* is added, and the resulting values are written to *dest*.

Throws

ccPel::UnboundWindow
src1, *src2,* or *src3* is unbound.

ccPelFunc::Overlap
The source window overlaps the destination window, but they are not identical (after adjusting for greatest common region).

- ```
  template<class S1, class S2, class S3, class D>
  void cfPelMultAdd(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2,
  ```

```
const ccPelbuffer_const<S3>& src3,
ccPelBuffer<D>& dest,
c_Int32 output_mode);
```

Applies the user-specified method of handling overflow as it multiplies the pixels in the region of *src1* and *src2* and adds the pixels in *src3*, defined by greatest common region of *src1*, *src2*, *src3* and *dest,* and writes the resulting pixels values to *dest*.

Parameters

S1, S2, S3, D — Template parameters that specify the type of the three source windows and the destination window. Not all combinations of *S1*, *S2*, *S3*, and *D* are instantiated. See *pelfunc.h* to see which instantiations are available.

src1 — A bound window.

src2 — A bound window.

src3 — A bound window.

dest — A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, *src3* and *dest* will be used and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1, src2* and *src3*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then multiplied, *src3* is added, and the resulting values are written to *dest*.

output_mode — The method to use to handle overflow. *output_mode* must be one of the following values:

ccPelFunc::eMultAddDefault (a * b +c)
ccPelFunc::eMultAddShft ((a * b) >> 8) + c

See **mult_add_mode** on page 2385.

Throws

ccPel::UnboundWindow
src1, *src2,* or *src3* is unbound.

ccPelFunc::Overlap
The source window overlaps the destination window, but they are not identical (after adjusting for greatest common region).

ccPelFunc::BadParams
output_mode is not a valid mode.

cfPelNoShare()

```
#include <ch_cvl/pelfunc.h>

cfPelNoShare();
```

Global function that provides a root image to which only one window is bound.

cfPelNoShare

```
template<class P> void cfPelNoShare(ccPelBuffer<P>& win);
```

If *win* is unbound or if the reference count of its root image is already 1 (the desired effect of this function), there is no effect. Otherwise, the root image is copied and *win* is rebound to the copied root image. The original root offset and size of *win* are preserved.

Parameters

P	Template parameter specifying the type of the pixels in *win*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
win	A window that the function will modify, if necessary, so that it is the only window bound to its root image.

cfPelNoShare()

cfPelPrint()

```
#include <ch_cvl/pelfunc.h>

cfPelPrint();
```

Global function to print the contents of a window to an output stream.

cfPelPrint

```
template<class P> void cfPelPrint(
  const ccPelBuffer_const<P>& win, ccCvlOStream& stream);
```

Prints the pixel values of a window to the specified stream buffer. Pixel values are printed with white space separation; each row of the window is printed on its own line.

Parameters

P	Template parameter specifying the type of the pixels in *win*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.
win	A bound window.
stream	A stream buffer.

Notes

You are expected to set up *stream* with the formatting options you want (radix, width, precision, and so on).

Throws

ccPel::UnboundWindow
win is unbound.

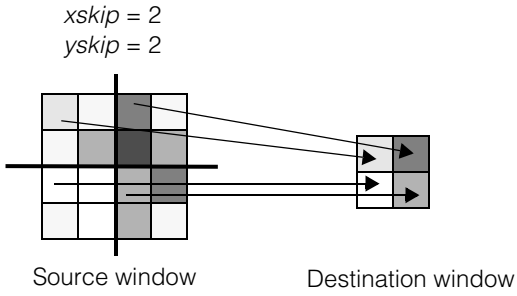
cfPelPrint()

cfPelSample()

```
#include <ch_cvl/pelfunc.h>

cfPelSample();
```

Global function to subsample the pixels in a window to produce a window of lower resolution and reduced size. The following figure shows an example of subsampling.



cfPelSample() subsamples a window by dividing its pixels into blocks and selecting the pixel closest to each block's center. When there is no pixel at the exact center of a subsampling block (as is the case in the figure), the pixel to the upper left of center is selected.

cfPelSample

```
template<class P>
ccPelBuffer<P> cfPelSample(const ccPelBuffer_const<P>&,
  c_Int32 xskip, c_Int32 yskip);

template<class S, class D>
void cfPelSample(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest, c_Int32 xskip, c_Int32 yskip);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelSample(const ccPelBuffer_const<P>&,
    c_Int32 xskip, c_Int32 yskip);
  ```

  Subsamples *src*, writes the selected pixel value from each subsampling block to a new root image, and returns a window that is bound to that image.
  ```

Parameters

P — Template parameter specifying the type of the window whose pixels are being subsampled and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, or **ccPackedRGB32Pel**.

src — A bound window.

xskip, yskip — The x and y dimensions of the subsampling blocks. *xskip* and *yskip* must be greater than 0.

Throws

ccPel::UnboundWindow
src is unbound.

- ```
  template<class S, class D>
  void cfPelSample(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest, c_Int32 xskip, c_Int32 yskip);
  ```

  Subsamples *src* and writes the selected pixel values to *dest*.

  Parameters

  S, *D* — Template parameters specifying the type of the source and destination windows. *S* and *D* are always the same, and must be one of **c_UInt8**, **c_UInt16**, **c_UInt32**, **ccPackedRGB16Pel**, or **ccPackedRGB32Pel**.

  src — A bound window.

  dest — A bound or unbound window.

  If *dest* is bound, the function calculates the size that *src* would be after sampling, then determines the greatest common region of this reduced *src* with *dest* to determine how much of *src* is to be sampled.

  If *dest* is unbound, a new root image is allocated to accommodate the results of the subsampling, and *dest* is bound to that root image. All the pixels in *src* are subsampled and the results are written to *dest*.

  When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

  xskip, yskip — The x and y dimensions of the subsampling blocks. *xskip* and *yskip* must be greater than 0.
  ```

cfPelSet()

```
#include <ch_cvl/pelfunc.h>

cfPelSet();
```

Global function to set each pixel in a window to a specified value.

cfPelSet

```
template<class P> void cfPelSet(
  const ccPelBuffer_const<P>& win, P val);
```

Sets the pixels in a window to a specified value.

Parameters

P	Template parameter specifying the type of the pixels in *win* and of the value to which those pixels will be set. *P* must be one of **c_UInt8**, **c_UInt16**, **c_UInt32**, **double**, **ccPackedRGB16Pel**, **ccPackedRGB32Pel**.
win	A bound window.
val	The value to which each pixel will be set.

Throws

ccPel::UnboundWindow
win is unbound.

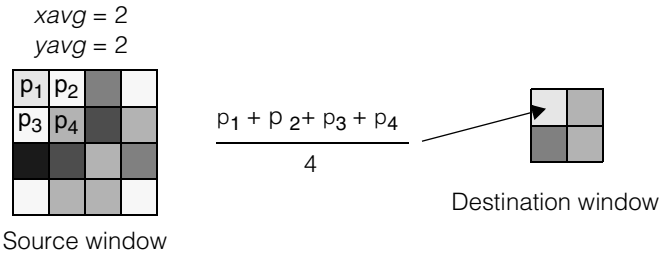
cfPelSet()

cfPelSpatialAvg()

```
#include <ch_cvl/pelfunc.h>

cfPelSpatialAvg();
```

Global function to perform a spatial averaging of the pixels in a window to produce a window of lower resolution and reduced size. The following figure shows an example of subsampling.



Spatial averaging divides the source window into blocks of the size indicated by the *xavg* and *yavg* arguments. The pixel values from each pixel in the block are summed, and the result is divided by the number of pixels in the block. The averaged pixel value from the block of pixels is then applied to a single pixel in the destination window. Partial source blocks are ignored during spatial averaging.

cfPelSpatialAvg

```
template<class P, class I>
ccPelBuffer<P> cfPelSpatialAvg(
  const ccPelBuffer_const<P>&, c_Int32 xavg, c_Int32 yavg,
  I dummy);

template<class S, class D, class I>
void cfPelSpatialAvg(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest, c_Int32 xavg, c_Int32 yavg,
  I dummy);
```

- ```
  template<class P, class I>
  ccPelBuffer<P> cfPelSpatialAvg(
    const ccPelBuffer_const<P>&, c_Int32 xavg, c_Int32 yavg,
    I dummy);
  ```

  Performs a spatial averaging of the pixels in *src* using sampling blocks of size *xavg* by *yavg*, writes the average pixel value of each block to a new root image, and returns a window that is bound to that image. The value of *dummy* is not used; only the type specified by the template parameter *I* is required by the function.
  ```

Parameters

P — Template parameter specifying the type of the window whose pixels are being averaged and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

I — This template parameter specifies a data type that the function uses internally. *I* must be **c_UInt32**.

src — A bound window.

xavg, *yavg* — The x and y dimensions of the sampling blocks. *xavg* and *yavg* must be greater than 0.

Throws

ccPel::UnboundWindow
src is unbound.

- ```
  template<class S, class D, class I>
  void cfPelSpatialAvg(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest, c_Int32 xavg, c_Int32 yavg,
    I dummy);
  ```

Performs a spatial averaging of the pixels in *src* using sampling blocks of size *xavg* by *yavg* and writes the average pixel value of each block to *dest*. The value of *dummy* is not used; only the type specified by the template parameter *I* is required by the function.

Parameters

S, *D* — Template parameters specifying the type of the source and destination windows. *S* and *D* are always the same, and must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

I — This template parameter specifies a data type that the function uses internally. *I* must be **c_UInt32**.

src — A bound window.

dest — A bound or unbound window.

If *dest* is unbound, a new root image is allocated to accommodate the results of the spatial averaging, and *dest* is bound to the root image. All the pixels in *src* are then averaged and the results are written to *dest*.

If *dest* is bound, the function calculates the size that *src* would be after spatial averaging, then determines the greatest common region of this reduced *src* with *dest* to determine how much of *src* is to be averaged.
  ```

When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

xavg, yavg — The x and y dimensions of the sampling blocks. *xavg* and *yavg* must be greater than 0.

cfPelSpatialAvg()

cfPelSub()

```
#include <ch_cvl/pelfunc.h>

cfPelSub();
```

Global function to subtract the pixels of two windows.

Note When this function computes the greatest common region of two images it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

cfPelSub

```
template<class P>
ccPelBuffer<P> cfPelSub(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);

template<class P>
ccPelBuffer<P> cfPelSub(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2, c_Int32 output_mode);

template<class S1, class S2, class D>
void cfPelSub(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);

template<class S1, class S2, class D>
void cfPelSub(const ccPelBuffer_const<S1>& src1,
  const ccPelBuffer_const<S2>& src2,
  ccPelBuffer<D>& dest, c_Int32 output_mode);
```

-
```
template<class P>
ccPelBuffer<P> cfPelSub(
  const ccPelBuffer_const<P>& src1,
  const ccPelBuffer_const<P>& src2);
```

In the greatest common region of *src1* and *src2*, subtracts the pixels in *src2* from the pixels in *src1* using the default output mode (*ccPelFunc:: eSubDefault)*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

Parameters

P Template parameter specifying the type of the windows whose pixels are being subtracted and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

src1 A bound window.

src2 A bound window.

Throws

ccPel::UnboundWindow
src1 or *src2* is unbound.

- ```
  template<class P>
  ccPelBuffer<P> cfPelSub(
    const ccPelBuffer_const<P>& src1,
    const ccPelBuffer_const<P>& src2, c_Int32 output_mode);
  ```

  In the greatest common region of *src1* and *src2*, applies the user-specified method of handling overflow as it subtracts the pixels in *src2* from the pixels in *src1*, writes the resulting pixel values to a new root image, and returns a window that is bound to that image.

  Parameters

  P Template parameter specifying the type of the windows whose pixels are being added and of the window that the function returns. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src1 A bound window.

  src2 A bound window.

  output_mode The method to use to handle overflow. *output_mode* must be one of the following values:

  ccPelFunc::eSubDefault
  ccPelFunc::eSubAbsDefault
  ccPelFunc::eSubAbs
  ccPelFunc::eSubZero
  ccPelFunc::eSubShft
  ccPelFunc::eSubNabs
  ccPelFunc::eSubLimit

  See **sub_mode** on page 2383.

  Throws

  ccPel::UnboundWindow
  src1 or *src2* is unbound.
  ```

ccPelFunc::BadParams
output_mode is not a valid subtraction mode.

- ```
  template<class S1, class S2, class D>
  void cfPelSub(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2, ccPelBuffer<D>& dest);
  ```

  In the greatest common region of *src1*, *src2*, and *dest*, subtracts the pixels in *src2* from the pixels in *src1* using the default output mode (*ccPelFunc:: eSubDefault)* and writes the resulting pixel values to *dest*.

  Parameters

  S1, S2, D — Template parameters that specify the type of the two source windows and the destination window. *S1, S2,* and *D* are always the same type, and must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src1 — A bound window.

  src2 — A bound window.

  dest — A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be subtracted and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1* and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then subtracted and the resulting values are written to *dest*.

  Throws

  ccPel::UnboundWindow
  src1 or *src2* is unbound.

- ```
  template<class S1, class S2, class D>
  void cfPelSub(const ccPelBuffer_const<S1>& src1,
    const ccPelBuffer_const<S2>& src2,
    ccPelBuffer<D>& dest, c_Int32 output_mode);
  ```

  In the greatest common region of *src1*, *src2*, and *dest*, applies the user-specified method of handling overflow as it subtracts the pixels in *src2* from the pixels in *src1* and writes the resulting pixel values to *dest*.

Parameters

S1, S2, D
Template parameters that specify the type of the two source windows and the destination window. *S1, S2,* and *D* are always the same type, and must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

src1
A bound window.

src2
A bound window.

dest
A bound or unbound window. If *dest* is bound, the pixels in the greatest common region of *src1*, *src2*, and *dest* will be subtracted and written to *dest*. If *dest* is unbound, a new root image is allocated whose size is equal to the greatest common region of *src1* and *src2*, after which *dest* is bound to the new root image. The pixels in the greatest common region of *src1* and *src2* are then subtracted and the resulting values are written to *dest*.

output_mode
The method to use to handle overflow. *output_mode* must be one of the following values:

ccPelFunc:: eSubDefault
ccPelFunc::eSubAbsDefault
ccPelFunc::eSubAbs
ccPelFunc::eSubZero
ccPelFunc::eSubShft
ccPelFunc::eSubNabs
ccPelFunc::eSubLimit

See **sub_mode** on page 2383.

Throws

ccPel::UnboundWindow
src1 or *src2* is unbound.

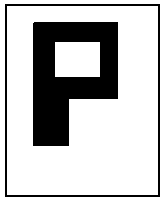
ccPelFunc::BadParams
output_mode is not a valid subtraction mode.

cfPelTranspose()

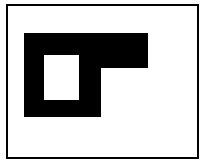
```
#include <ch_cvl/pelfunc.h>

cfPelTranspose();
```

Global function to transpose the pixels in a window. The following figure shows an example of a transposed window.



Source window



Transposed window

cfPelTranspose

```
template<class P>
ccPelBuffer<P> cfPelTranspose(
  const ccPelBuffer_const<P>& src);

template<class S, class D>
void cfPelTranspose(const ccPelBuffer_const<S>& src,
  ccPelBuffer<D>& dest);
```

- ```
  template<class P>
  ccPelBuffer<P> cfPelTranspose(
    const ccPelBuffer_const<P>& src);
  ```

  Transposes the pixels in *src*, copies them to a new root image, and returns a window that is bound to that image.

  Parameters

  P — Template parameter specifying the type of the window to be returned by the function and of the pixels in *src*. *P* must be one of **c_UInt8**, **c_UInt16**, or **c_UInt32**.

  src — A bound window.

  Throws

  ccPel::UnboundWindow — *src* is unbound.
  ```

- ```
  template<class S, class D>
  void cfPelTranspose(const ccPelBuffer_const<S>& src,
    ccPelBuffer<D>& dest);
  ```

  Transposes the pixels in *src* and writes them to *dest*. If the same window is specified for *src* and *dest*, the operation is performed in place. For this to work, the window must be square.

  Parameters

  S — Template parameter specifying the type of the pixels in *src*. *S* must be one of **c_UInt8**, **c_UInt16** or **c_UInt32**.

  D — Template parameter specifying the type of the pixels in *dest*. *D* must be the same type as *S*.

  src — A bound window.

  dest — A bound or unbound window. If *dest* is bound, the pixels in the region of *src* determined by the greatest common region of *src* and *dest* are transposed and written to *dest*. If *dest* is unbound, a root image for *dest* is allocated and all the pixels in *src* are transposed and copied to *dest*.

  When this function computes the greatest common region of *src* and *dest* it considers each image's image coordinate offset. For more information on image coordinates and image coordinate offset, see the chapter *Images and Coordinates* in the *CVL User's Guide*.

  Throws

  ccPel::UnboundWindow — *src* is unbound.

  ccPelFunc::Overlap — *src* and *dest* overlap but are not identical, or are identical but not square.
  ```

cfPMInspectDisplayFeatures()

```
#include <ch_cvl/pmifproc.h>

cfPMInspectDisplayFeatures();
```

Global function to create a graphical display of features detected by PatInspect.

cfPMInspectDisplayFeatures

```
void cfPMInspectDisplayFeatures(ccUITablet& tablet,
  ccPMInspectSimpleBoundaryDiffData& data,
  bool showMatch = true, bool showExtra = true,
  bool showMissing = true, bool showConnect = true,
  ccColor cmatch = ccColor::blueColor(),
  ccColor cextra = ccColor::redColor(),
  ccColor cmissing = ccColor::yellowColor(),
  ccColor cconnect = ccColor::whiteColor(),
  ccColor cpattern = ccColor::greenColor(),
  cc2Xform pose=cc2Xform::I);
```

Parameters

tablet	A **ccUITablet** into which the graphics are drawn.
data	The feature difference data returned by **ccPMInspectResult::getSimpleBoundaryDiff()**.
showMatch	If true, show the matched features' boundary points.
showExtra	If true, show the extra features' boundary points.
showMissing	If true, show the missing features' boundary points.
showConnect	If true, connect boundary points.
cmatch	The color in which to draw the matched features's boundary points.
cextra	The color in which to draw the extra features's boundary points.
cmissing	The color in which to draw the missing features's boundary points.
cconnect	The color in which to draw the line segments connecting boundary points.
cpattern	The color in which to draw the trained pattern's feature boundary points that correspond to match boundary points in the image. If *showMatch* is false, the pattern's feature boundary points are not displayed.

pose	A **cc2Xform** that tells how to transform the display of the feature boundary points. You can specify the pose returned by **ccPMInspectResult::pose()** to display the feature boundary points for a particular pattern instance in a run-time image.

cfPolarTransformImage()

```
#include <ch_cvl/polar.h>

cfPolarTransformImage();
```

Global function to perform a polar transformation on an input image. Polar transformation consists of sampling the source image at the grid location specified by the sampling parameters, and placing the samples into the corresponding pixels of the destination image.

If the destination image is unbound, a new **ccPelBuffer** of the appropriate size is allocated and bound to the specified destination with an offset of (0, 0).

If the destination image is bound, it must not share any of the source pixels that are sampled. Samples are written to the destination as if the following steps had been executed:

1. A temporary destination image, *TMP*, is created using the rules for unbound destination images.
2. The function **cfPelCopy(TMP, destination)** is used to transfer pixels from *TMP* to the bound destination. This operation only copies pixels within the Greatest Common Rectangle (GCR) of *TMP* and *destination*.

In some cases, it may be necessary to shift the image offset of the destination image to achieve the desired result. The **cfPolarTransformImage()** function does not resize, reallocate, or alter the offset of a destination.

See also the *Polar Coordinate Transformation Tools* section of the *Image Transformation Tools* chapter in the *CVL Vision Tools Guide*.

cfPolarTransformImage

```
template<class T> void
cfPolarTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  ccPelBuffer<T>& dstImage,
  const ccPolarSamplingParams& params);

template<class T> ccPelBuffer<T>
cfPolarTransformImage(
  const ccPelBuffer_const<T>& srcImage,
  const ccPolarSamplingParams& params);
```

Notes

CVL provides instantiations of both overloads for 8-bit source and destination images.

- ```
  template<class T> void
  cfPolarTransformImage(
    const ccPelBuffer_const<T>& srcImage,
    ccPelBuffer<T>& dstImage,
    const ccPolarSamplingParams& params);
  ```

  Performs a polar transformation of an image using the supplied sampling parameters.

  Parameters

  srcImage Source image on which to perform the polar transformation.

  dstImage Destination image in which to store the results of the polar transformation.

  params Sampling parameters that specify the grid location of the source image. The sampling parameters must be specified in the client coordinate system of the source image.

  Notes

  The polar transformation sets the destination image's client coordinate transform to **cc2Xform(cc2Matrix(1, 0, 0, 1), cc2Vect(0, 0))**. Use the **ccPolarSamplingParams** methods **mapImagePosition()** and **mapPolarPosition()** to map between source and polar images.

  Throws

  ccPolarTransDefs::UnboundWindow
  srcImage is an unbound pel buffer.

  ccPolarTransDefs::Clipped
  Clipping has occurred (that is, any of the sampling points require data that is outside of the source image). Use **ccPolarSamplingParams::willClip()** to test whether clipping will occur (without calling **cfPolarTransformImage()**).

- ```
  template<class T> ccPelBuffer<T>
  cfPolarTransformImage(
    const ccPelBuffer_const<T>& srcImage,
    const ccPolarSamplingParams& params);
  ```

  Performs a polar transformation of an image using the supplied sampling parameters and returns a new destination image. Does not require a supplied destination image.

  Parameters

  srcImage The source image on which to perform the polar transformation.

  params Sampling parameters that specify the grid location of the source image. The sampling parameters must be specified in the client coordinate system of the source image.

cfPolylineShapeModel()

```
#include <ch_cvl/shapemod.h>

cfPolylineShapeModel();
```

Global function to get a polyline shape model corresponding to a specified chain in a featurelet chain set.

cfPolylineShapeModel

```
ccPolylineShapeModelPtrh cfPolylineShapeModel(
  const ccFeatureletChainSet &featureletChainSet,
  c_Int32 chainIndex);
```

Retrieves the polyline shape model corresponding to the specified chain in the supplied featurelet chain set. The returned polyline simply connects the positions of the featurelets in order along the chain, and therefore has the same handedness and open/closed state as the featurelet chain.

Featurelet angles are used only indirectly to determine the *polarity* of the returned model. Specifically, the polarity is completely dependent on the value returned by **proportionPositiveCrossProduct()** for the specified chain. The polarity of the returned shape model is reversed if and only if this value is less than 0.5. The polarity of the returned shape model is ignored if and only if this value is exactly equal to 0.5.

The *weight* and *magnitude* of the returned shape model are the average weight and average magnitude of the featurelets in the chain, respectively.

Throws

ccFeatureletDefs::BadParams
chainIndex is less than zero or
greater than or equal to **featureletChainSet.numChains()**

cfPolylineShapeModel()

cfPolySetNearestPoints()

```
#include <ch_cvl/shapgeom.h>

cfPolySetNearestPoints();
```

Global function to return the nearest two points between two **ccPolyline** object sets. The returned points *p1* and *p2*, are on the **ccPolyline** sets *shapeTree1* and *shapeTree2*, respectively. The supplied **ccGeneralShapeTree** objects are assumed to have only **ccPolyline** objects as children.

cfPolySetNearestPoints

```
void cfPolySetNearestPoints(
  const ccGeneralShapeTree &shapeTree1,
  const ccGeneralShapeTree &shapeTree2,
  cc2Vect &p1, cc2Vect &p2);
```

Parameters

shapeTree1	The first **ccPolyline** object set.
shapeTree2	The second **ccPolyline** object set.
p1	The returned nearest point on *shapeTree1*.
p2	The returned nearest point on *shapeTree2*.

Throws

ccShapesError::BadParams
: Either of the two supplied shape trees includes objects of any type other than **ccPolyline**.

ccShapesError::EmptyShape
: Either of the two supplied shape trees is empty.

Notes

If more than one pair of points have the same nearest distance, this function returns an arbitrary pair among them.

cfPolySetNearestPoints()

cfProjectImage()

```
#include <ch_cvl/project.h>

cfProjectImage();
```

Global function to construct a 1-dimensional projection image using a 2-dimensional input image and a **ccAffineSamplingParams**.

cfProjectImage

```
template<class S>
void cfProjectImage(
  const ccPelBuffer_const<S>& srcImage,
  ccPelBuffer<c_UInt32>& dstImage,
  const ccAffineSamplingParams& params,
  c_UInt32& nPelsPerBin);

template<class S>
ccPelBuffer<c_UInt32> cfProjectImage(
  const ccPelBuffer_const<S>& srcImage,
  const ccAffineSamplingParams& params,
  c_UInt32& nPelsPerBin);

template<class S>
void cfProjectImage(
  const ccPelBuffer_const<S>& srcImage,
  ccPelBuffer<c_UInt32>& dstImage,
  ccPelBuffer<c_UInt32>& weights,
  const ccAffineSamplingParams& params,
  c_UInt32 &nPelsPerBin,
  bool& clipped);
```

-
```
template<class S>
void cfProjectImage(
  const ccPelBuffer_const<S>& srcImage,
  ccPelBuffer<c_UInt32>& dstImage,
  const ccAffineSamplingParams& params,
  c_UInt32& nPelsPerBin);
```

Projects the supplied input image into the supplied destination image using the supplied **ccAffineSamplingParams**.

Parameters

srcImage	The source image. *srcImage* must be of type **c_UInt8**.
dstImage	The destination image. If *dstImage* is unbound, the function will allocate a root image and bind *dstImage* to it.
params	A **ccAffineSamplingParams** that defines the projection region.

nPelsPerBin A reference to a **c_UInt32** into which the function will place the number of pixels in *srcImage* which were summed to form each pixel in *dstImage*.

Throws

ccAffTransDefs::Clipped
The projection region defined by *params* is clipped by *srcImage*. See below for a version of this function that allows clipping.

ccAffProjImgDefs::UnboundWindow
The source image is unbound.

ccAffineSamplingParams::NotImplemented
params.interpolation is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

Notes

The **cc2XForm** for *dstImage* will map locations in the *dstImage* client coordinate system to the corresponding locations within the affine rectangle specified by *params* in the client coordinates of *srcImage*.

- ```
  template<class S>
  ccPelBuffer<c_UInt32> cfProjectImage(
    const ccPelBuffer_const<S>& srcImage,
    const ccAffineSamplingParams& params,
    c_UInt32& nPelsPerBin);
  ```

Returns a newly constructed and bound **ccPelBuffer<c_UInt32>** into which the supplied source image has been projected according to the supplied **ccAffineSamplingParams**.

Parameters

srcImage The source image. *srcImage* must be of type **c_UInt8**.

params A **ccAffineSamplingParams** that defines the projection region.

nPelsPerBin A reference to a **c_UInt32** into which the function will place the number of pixels in *srcImage* which were summed to form each pixel in *dstImage*.

Throws

ccAffTransDefs::Clipped
The projection region defined by *params* is clipped by *srcImage*. See below for a version of this function that allows clipping.
  ```

ccAffProjImgDefs::UnboundWindow
The source image is unbound.

ccAffineSamplingParams::NotImplemented
params.interpolation is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

- ```
  template<class S>
  void cfProjectImage(
    const ccPelBuffer_const<S>& srcImage,
    ccPelBuffer<c_UInt32>& dstImage,
    ccPelBuffer<c_UInt32>& weights,
    const ccAffineSamplingParams& params,
    c_UInt32 &nPelsPerBin,
    bool& clipped);
  ```

  Projects the supplied input image into the supplied destination image using the supplied **ccAffineSamplingParams**.

  If the affine rectangle defined by **ccAffineSamplingParams** clips the source image, this function computes the projection based on the clipped source window, and *clipped* is set to true to indicated that clipping occurred. If clipping took place, the returned weights image contains the number of pixels that were summed to compute the corresponding pixel in the projection image.

  Parameters

  srcImage The source image. *srcImage* must be of type **c_UInt8**.

  dstImage The destination image. If *dstImage* is unbound, the function will allocate a root image and bind *dstImage* to it.

  weights If clipping took place, *weights* is filled with values that indicate how many sample pels were summed to compute the corresponding projection pel. If clipping did not take place, this buffer is not changed.

  params A **ccAffineSamplingParams** that defines the projection region.

  nPelsPerBin A reference to a **c_UInt32** into which the function will place the number of pixels in *srcImage* which were summed to form each pixel in *dstImage*.

  clipped True if clipping occurred, false otherwise.

  Throws
  ```

ccAffProjImgDefs::UnboundWindow
: The source image is unbound.

ccPel::BadCoord
: The affine rectangle is completely off the source window (that is, the intersection of the affine rectangle and the source window is empty).

ccAffineSamplingParams::NotImplemented
: *params.interpolation* is *ccAffineSamplingParams::eBilinearApprox* or *ccAffineSamplingParams::eHighPrecision* and *srcImage.rowUpdate()* or *srcImage.height()* is greater than or equal to 32768.

cfRasterize()

```
#include <ch_cvl/raster.h>

cfRasterize();
```

Global function to rasterize an image of a sampled **ccRegionTree** into a pel buffer. The **ccRegionTree** is first clipped by the pel buffer window and then sampled in image coordinates by the **ccShape::sample()** method using the specified sampling parameters.

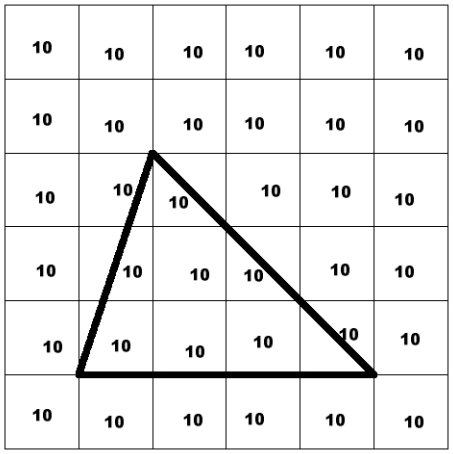
A *raster* is a scan pattern (as of the electron beam in a cathode-ray tube) in which an area is scanned from side to side in lines from top to bottom. To *rasterize* means to scan the image rows (or columns) and calculate the grey level of each pixel individually.

The main differences between rasterizing and drawing are the following:

- A rasterized shape is filled in. That is, more than just its boundary is shown.
- A rasterized shape is converted into a form that may be displayed on a grid of pixels. This can produce digitization errors near the edges of the shape because pixels have finite size.

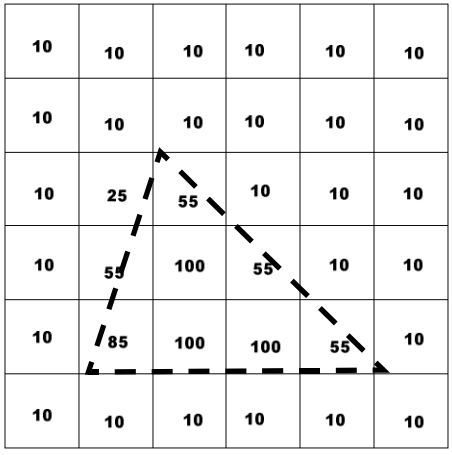
The **cfRasterize()** function performs this process by logically scanning each image row and determining whether each pixel should be assigned a new value on a per-pixel basis. The scan is performed *logically*, rather than physically, because the function takes some shortcuts, such as ignoring complete rows or finding the starting and ending columns for each row. The pixels of solid regions are set to the foreground grey level *fg*. Pixels of hole regions are not changed. Phantom holes (that is, hole regions that are not children of some enclosing solid region) are not rasterized.

The *boundaryFillMode* parameter specifies how to handle pel values that are on the boundary between solid and hole regions. The figures on the next few pages illustrate the various boundary fill mode options.

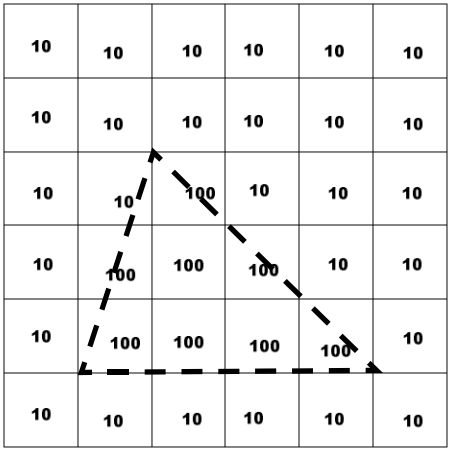


This figure shows a 6x6 pel buffer whose pels all contain a value of 10. A polygon is superimposed on this image to show the **ccRegionTree** boundary to be rasterized on this pel buffer.

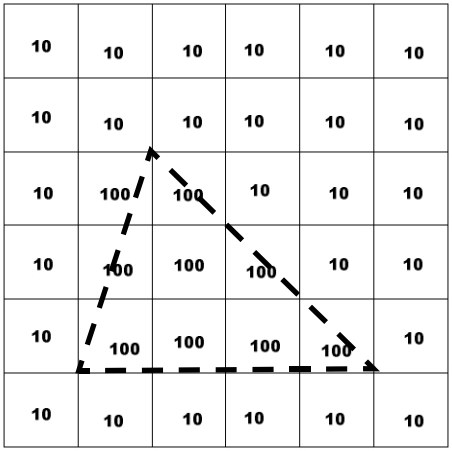
The *boundaryFillMode* is specified as the fourth parameter passed to **cfRasterize()**.



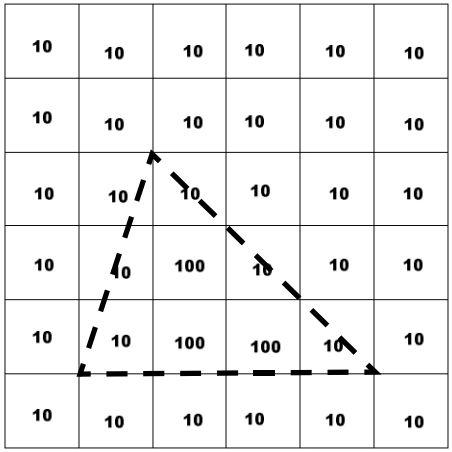
This figure shows the result of using an interpolated value for pels that are on the boundary between solid and hole regions. The interpolated value is a grey level that interpolates the existing grey level and the foreground level using the fraction of the pixel area that the region tree covers. This is the anti-aliasing mode; it is also the default.You would achieve this effect by calling **cfRasterize(region, buffer, 100, ccRasterizationDefs::eUseInterpolatedPelValue)**.



This figure shows the result of using the value covering the largest portion of the pixel for pels that are on the boundary between solid and hole regions. This setting uses the foreground level if at least half of the boundary pixel is covered by the region tree to be rasterized. Otherwise, the value is not changed. You would achieve this effect by calling **cfRasterize(region, buffer, 100, ccRasterizationDefs::eUseLargestPortionPelValue)** .



This figure shows the result of using the foreground value for pels that are on the boundary between solid and hole regions. You would achieve this effect by calling **cfRasterize(region, buffer, 100, ccRasterizationDefs::eUseForegroundPelValue)**.



This figure shows the result of using the background value for pels that are on the boundary between solid and hole regions. You would achieve this effect by calling **cfRasterize(region, buffer, 100, ccRasterizationDefs::eUseBackgroundPelValue)**.

cfRasterize

```
void cfRasterize(const ccRegionTree &region,
  const ccPelBuffer<c_UInt8> &pelbuf,
  c_UInt8 fg,
  ccRasterizationDefs::BoundaryFillMode boundaryFillMode =
    ccRasterizationDefs::kDefaultBoundaryFillMode,
  const ccShape::ccSampleParams & samplingParams =
    ccRasterizationDefs::RasterizeSampParams());
```

Parameters

region The region tree to draw, specified in client coordinates.

pelbuf The pel buffer into which to draw the region tree.

fg Foreground grey level. This value is assigned to pixels of solid regions.

boundaryFillMode

Specifies how to handle pixel values that are on the boundary between solid and hole regions. Possible values:

Value	Meaning
ccRasterizationDefs:: eUseInterpolatedPelValue	Use a grey level that interpolates the existing grey level and *fg* using the fraction of the pixel area that the region tree covers. This is the anti-aliasing mode. This mode is also the default.
ccRasterizationDefs:: eUseLargestPortionPelValue	Use *fg* if at least half of the boundary pixel is covered by *region*. Otherwise, don't change the pel value.
ccRasterizationDefs:: eUseForegroundPelValue	Use *fg* for boundary pixels.
ccRasterizationDefs:: eUseBackgroundPelValue	Do not change boundary pixel values. Existing pixel values remain unchanged.

samplingParams Parameters used to sample the shape.

Throws

ccPel::UnboundWindow
pelbuf is unbound.

ccShapesError::SampleOverflow
Possible throw from **ccShape::sample()**. See **ccShape::sample()** for details.

Notes

This function requires the boundary and children of the region to be non-self-intersecting. Otherwise, its behavior is not defined.

This function respects the client transform of the supplied pel buffer. Always specify the region in client coordinates.

cfRasterizeContour()

```
#include <ch_cvl/raster.h>

cfRasterizeContour();
```

Global function to rasterize the sampled contour of the specified shape on the specified pel buffer using the specified grey level and thickness values. The shape is sampled in image coordinates by the **ccShape::sample()** method using the specified sampling parameters.

To *rasterize* means to scan the image rows (or columns) and calculate the grey level of each pixel individually. The **cfRasterizeContour()** function performs this process by logically scanning each image row and determining whether each pixel should be assigned a new value.

The **cfRasterizeContour()** function creates a circular stencil with a diameter of *thickness* centered around each sampled point on the pel buffer and slides it along the line between this point and the next sampled point. Any pixels that are touching this stencil are assigned the foreground color value *fg*. The remaining pixels are not changed. Any pixels that are outside the pel buffer window and touching the circular stencil are ignored by means of clipping the circular stencil by the pel buffer window.

cfRasterizeContour

```
void cfRasterizeContour(const ccShape &shape,
  const ccPelBuffer<c_UInt8> &pelbuf,
  c_UInt8 fg,
  double thickness,
  const ccShape::ccSampleParams & samplingParams =
    ccRasterizationDefs::RasterizeSampParams());
```

Parameters

shape	The shape to draw, specified in client coordinates.
pelbuf	The pel buffer into which to draw the sampled shape.
fg	Foreground grey level. This value is assigned to any pixel of the pel buffer that is covered by the stencil.
thickness	Diameter of the circular stencil centered around the sampled points and the connecting lines between them, specified in client coordinates.
samplingParams	Parameters used to sample the shape.

Throws

ccPel::UnboundWindow
pelbuf is unbound.

ccShapesError::BadRadius
: *thickness* is less than or equal to 0.0.

ccShapesError::SampleOverflow
: Possible throw from **ccShape::sample()**. See **ccShape::sample()** for details.

Notes

This function respects the client transform of the supplied **ccPelBuffer**. Always specify the shape and thickness in client coordinates.

cfRealEq()

```
#include <ch_cvl/math.h> // for floating point values
#include <ch_cvl/vector.h> // for vectors
#include <ch_cvl/matrix.h> // for matrices
#include <ch_cvl/xform.h> // for transformations
#include <ch_cvl/units.h> // for angles
#include <ch_cvl/xflinear.h> // for linear transformations

cfRealEq();
```

Global function that tests whether two objects, that contain floating point values, are equal within a specified tolerance.

cfRealEq

```
bool cfRealEq(double x, double y, double epsilon = 1.e-15);

bool cfRealEq(const cc2Vect& v1, const cc2Vect &v2,
  double epsilon = 1.e-15);

bool cfRealEq(const cc3Vect& v1, const cc3Vect& v2,
  double epsilon = 1.e-15);

bool cfRealEq(const cc2Matrix& m1, const cc2Matrix& m2,
  double epsilon = 1.e-15);

bool cfRealEq(const cc1Xform& x1, const cc1Xform& x2,
  double epsilon = 1.e-15);

bool cfRealEq(const cc2Xform& x1, const cc2Xform& x2,
  double epsilon = 1.e-15);

bool cfRealEq(const cc2Rigid& x1, const cc2Rigid& x2,
  double epsilon = 1.e-15);

bool cfRealEq (ccRadian x, ccRadian y,
  ccRadian epsilon = ccRadian(1.e-15));

bool cfRealEq(const cc2XformLinear& x1,
  const cc2XformLinear& x2, double epsilon = 1e-15)
```

- `bool cfRealEq(double x, double y, double epsilon = 1.e-15);`

  Returns true if the two supplied values are equal to each other within the specified tolerance *epsilon*. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

Parameters

x	The first value to compare.
y	The second value to compare.
epsilon	The tolerance within which the two values must be equal.

- `bool cfRealEq(const cc2Vect& v1, const cc2Vect &v2, double epsilon = 1.e-15);`

Returns true if the corresponding elements of the two vectors are equal to each other within the specified tolerance *epsilon*. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

Parameters

v1	The first vector to test.
v2	The second vector to test.
epsilon	The tolerance within which the two vectors must be equal.

- `bool cfRealEq(const cc3Vect& v1, const cc3Vect& v2, double epsilon = 1.e-15);`

Returns true if the corresponding elements of the two vectors are equal to each other within the specified tolerance *epsilon*. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

Parameters

v1	The first vector to test.
v2	The second vector to test.
epsilon	The tolerance within which the two vectors must be equal.

- `bool cfRealEq(const cc2Matrix& m1, const cc2Matrix& m2, double epsilon = 1.e-15);`

Returns true if the corresponding elements of the two matrices are equal to each other within the specified tolerance *epsilon*. The default value of epsilon is 10^{-15}. You can override this value when you call the function.

Parameters

m1	The first matrix to test.
m2	The second matrix to test.

epsilon The tolerance within which the two matrices must be equal.

- ```
  bool cfRealEq(const cc1Xform& x1, const cc1Xform& x2,
    double epsilon = 1.e-15);
  ```

  Returns true if the corresponding elements of the two transformation objects (the scale and the offset values) are equal to each other within the specified tolerance *epsilon*. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

  Parameters

  x1 The first transformation object to test.

  x2 The second transformation object to test.

  epsilon The tolerance within which the two transformation objects must be equal.

- ```
  bool cfRealEq(const cc2Xform& x1, const cc2Xform& x2,
    double epsilon = 1.e-15);
  ```

  Returns true if the two transformation objects are equal to each other within the specified tolerance *epsilon.* In this case the function evaluates whether the corresponding elements of the matrix component of the two transformation objects and the corresponding elements of the vector component of the two transformation objects are the same within the specified tolerance. Default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

  Parameters

  x1 The first transformation object to test.

  x2 The second transformation object to test.

  epsilon The tolerance within which the two transformation objects must be equal.

- ```
  bool cfRealEq(const cc2Rigid& x1, const cc2Rigid& x2,
    double epsilon = 1.e-15);
  ```

  Returns true if the two transformation objects are equal to each other within the specified tolerance *epsilon.* In this case the function evaluates whether the corresponding elements of the vector component of the two transformation objects and the sine and cosine of the angular component of the two transformation objects are the same within the specified tolerance. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.
  ```

Parameters

x1	The first transformation object to test.
x2	The second transformation object to test.
epsilon	The tolerance within which the two transformation objects must be equal.

- ```
  bool cfRealEq (ccRadian x, ccRadian y,
    ccRadian epsilon = ccRadian(1.e-15));
  ```

  Returns true if the two supplied radians are equal to each other within the specified tolerance *epsilon*. The default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

  Parameters

x	The first value to compare.
y	The second value to compare.
epsilon	The tolerance within which the two values must be equal.

- ```
  bool cfRealEq(const cc2XformLinear& x1,
    const cc2XformLinear& x2, double epsilon = 1e-15)
  ```

  Returns true if the two transformation objects are equal to each other within the specified tolerance *epsilon.* In this case the function evaluates whether the corresponding elements of the matrix component of the two transformation objects and the corresponding elements of the vector component of the two transformation objects are the same within the specified tolerance. Default value of *epsilon* is 10^{-15}. You can override this value when you call the function.

  Parameters

x1	The first transformation object to test.
x2	The second transformation object to test.
epsilon	The tolerance within which the two transformation objects must be equal.

cfRegionize()

```
#include <ch_cvl/shapgeom.h>

cfRegionize();
```

Global function to convert a shape into a region tree when possible. If the shape is a closed contour, whether a primitive shape or contour tree, this function returns a singleton solid region tree with the contour as the root boundary. If the shape is a general shape tree, this function returns a new general shape tree generated by applying a regionizing algorithm to the shape's children (see *Regionizing General Shape Trees*, below). For all other shapes, including region trees themselves, this function simply returns a clone of the supplied shape.

Regionizing General Shape Trees

This function performs most of its work when the shape is a general shape tree. In this case, the function determines the nesting configuration of the closed contour children of the shape, merging such children into as few region trees as possible, and returning a new general shape tree made up of these region trees.

This function uses the following algorithm to regionize a shape:

1. Recursively regionize all children.
2. Insert regionized children that are not region trees as the final children of the result tree and do not consider them further.
3. The remaining children are all region trees. Among these, *unwrap* any phantom hole trees and replace them with their immediate children so that only solid region trees remain.
4. Determine the nesting structure and merge the region trees appropriately. What remains is a minimal set of region trees that contain exactly the same set of contours as the original set of region tree children, except for the discarded phantom hole contours. All of these region trees will have solid roots, as merging never introduces phantom holes.
5. Check the status of the *groupSeparateRegions* flag:
    - If *groupSeparateRegions* is false, or if there is only a single merged region tree, add the merged region trees directly as the intial children of the general shape tree result.
    - If *groupSeparateRegions* is true and there are multiple merged region trees, add the merged region trees as children to a newly created and appropriately sized phantom hole, and then add this single region tree as a child of the general shape tree result.

cfRegionize()

cfRegionize

```
ccShapePtrh cfRegionize(const ccShape &shape,
  bool groupSeparateRegions);
```

Parameters

shape The shape to be converted to a region tree.

groupSeparateRegions
Whether to group the merged region trees into a single region or to leave them as separate regions.

• If true (and there are multiple merged region trees):	The merged region trees are added as children to a newly created and appropriately sized phantom hole, and this single region tree is then added as a child to the general shape tree result. Phantom hole roots are automatically computed for sets of disjoint solid region trees. These holes will have **ccRect** boundaries that enclose all of the disjoint region trees, possibly with some padding.
• If false (or if there is only a single merged region tree):	The merged region trees are added directly as children to the general shape tree result.

See also *Regionizing General Shape Trees* on page 3831.

Notes

When regionizing general shape trees that contain region trees, the solid/hole status of the region tree boundaries is only used to detect and discard phantom holes. Beyond this, the solid/hole status is ignored as this function always treats the outermost enclosing boundary as a solid boundary when merging trees.

All closed contours within the shape, whether boundaries within region trees or stand-alone contours, must be non-intersecting. The function makes this assumption when determining the nesting structure of a set of contours. If this

assumption is violated, the resulting structure may be inconsistent. The exceptions to this rule are phantom hole boundaries of region trees. As these are discarded, it does not matter if they intersect other contours.

Shape model properties must not have been assigned to the supplied *shape* or any of its descendants. Always invoke this function *before* assigning model properties to a shape.

This function recursively processes an entire shape hierarchy. However, only region shapes that have the same general shape tree parent are candidates for merging into common region trees. Thus, you can use general shape tree nodes used to partition the merge candidates. In some applications, it may be useful to call **flatten()** before calling **cfRegionize()**.

cfRegionize()

cfRGBExtract()

```
#include <ch_cvl/rgbplane.h>

cfRGBExtract();
```

Global function to generate an 8-bit greyscale image from a 32-bit RGB image.

cfRGBExtract

```
void cfRGBExtract(
  const ccPelBuffer_const<ccPackedRGB32Pel> &src32,
  double rw, double gw, double bw,
  ccPelBuffer<c_UInt8>& dest);
```

Generates an 8-bit greyscale image from a 32-bit RGB image using a linear combination of the three component color planes.

If *dest* is unbound, it is allocated to the same size and offset of *src32*. Only the intersection of the *src32* and *dest* images is extracted.

The parameters *rw, gw*, and *bw* are the weights to be applied to each plane, where:

```
pel = rw*R + gw*G + bw*B
```

In general, rw + gw + bw = 1.0. However, this is not enforced and is not a requirement.

Parameters

src32	A 32-bit RGB color pel buffer.
rw	An double less than 32767 describing the weight to be applied to the red color plane when extracting from *src32*.
gw	An double less than 32767 describing the weight to be applied to the green color plane when extracting from *src32*.
bw	An double less than 32767 describing the weight to be applied to the blue color plane when extracting from *src32*.
dest	An 8-bit greyscale pel buffer with the same dimensions as *src32* to hold the extracted and combined image.

Throws

ccPel::BadParams
If any of *rw, gw,* or *bw* is > 32767.

Notes

This function is accelerated when run on a CPU that supports the MMX registers. However, MMX support is not required, the function runs on any CPU supported by CVL.

CPUs that support the MMX registers include the Intel Pentium II, Pentium III, Pentium 4, Xeon, and Celeron processors. Some but not all members of the original Pentium family included MMX support.

cfRGBPack()

```
#include <ch_cvl/rgbplane.h>

cfRGBPack();
```

Global function to generate a packed 32-bit or 16-bit RGB pel buffer from three separate 8-bit red, green, and blue pel buffers.

cfRGBPack

```
void cfRGBPack(
  const ccPelBuffer_const<c_UInt8>& red,
  const ccPelBuffer_const<c_UInt8>& green,
  const ccPelBuffer_const<c_UInt8>& blue,
  const ccPelBuffer<ccPackedRGB32Pel> &result,
  c_UInt8 alpha=0);

void cfRGBPack(
  const ccPelBuffer_const<c_UInt8>& red,
  const ccPelBuffer_const<c_UInt8>& green,
  const ccPelBuffer_const<c_UInt8>& blue,
  const ccPelBuffer<ccPackedRGB16Pel> &result);
```

This function accepts as input red, green, and blue color plane output from an RGB color camera and packs them into a 16-bit or 32-bit pel buffer.

For best performance:

- *result* should be 8-byte aligned
- *result* should be pre-allocated to the same size as the source color planes
- *red*, *green*, and *blue* should be 4-byte aligned.
- The width of all pel buffers should be multiple of 4.

Notes

This function is accelerated when run on a CPU that supports Intel SSE functionality. However, SSE support is not required, the function runs on any CPU supported by CVL.

CPUs that support SSE functionality include the Intel Pentium III, Pentium 4, Xeon, and Celeron processors.

cfRGBPack()

Parameters

result — A 16-bit or 32-bit RGB color pel buffer to contain the generated color image. By default, *result* will have same dimensions as *red, green,* and *blue* pel buffers. You can allocate a larger *result*, but the processing speed of this function is accelerated if you pre-allocate *result* the same size as *red, green,* and *blue*.

red — An 8-bit grey scale pel buffer that contains the red color channel of an RGB color camera.

green — An 8-bit grey scale pel buffer that contains the green color channel of an RGB color camera.

blue — An 8-bit grey scale pel buffer that contains the blue color channel of an RGB color camera.

alpha — Not currently implemented. Specify 0 or leave the default value of 0 in place.

Throws

ccPelFunc::BadParams
Any of the source pel bufffers is unbound, or their image sizes do not match.

cfRGBSeparateColorPlanes()

```
#include <ch_cvl/rgbplane.h>

cfRGBSeparateColorPlanes();
```

Global function to separate 32-bit RGB pel buffers into three 8-bit grey scale pel buffers.

cfRGBSeparateColorPlanes

```
void cfRGBSeparateColorPlanes(
  const ccPelBuffer_const<ccPackedRGB32Pel> &src32,
  ccPelBuffer<c_UInt8> *dstRed,
  ccPelBuffer<c_UInt8> *dstGreen,
  ccPelBuffer<c_UInt8> *dstBlue);
```

Separates the 32-bit RGB color pel buffer src32 into three 8-bit greyscale buffers that correspond to each of the red, green, and blue color planes.

For best performance

- *src32* should be 8-byte aligned.
- *dstRed*, *dstGreen*, *dstBlue* should be 4-byte aligned.
- The width of all pel buffers should be multiple of 4.

This function does not allocate the destination pel buffers. You must allocate a greyscale pel buffer for each color plane you wish to extract from the color pel buffer.

Notes

This function is accelerated when run on a CPU that supports the MMX registers. However, MMX support is not required, the function runs on any CPU supported by CVL.

CPUs that support the MMX registers include the Intel Pentium II, Pentium III, Pentium 4, Xeon, and Celeron processors. Some but not all members of the original Pentium family included MMX support.

cfRGBSeparateColorPlanes()

Parameters

src32 A 32-bit RGB color pel buffer.

dstRed A pointer to a 8-bit grey scale pel buffer with the same dimensions as *src32* to hold the red plane of the color pel buffer. If null, no color information for this plane is produced.

dstGreen A pointer to a 8-bit grey scale pel buffer with the same dimensions as *src32* to hold the green plane of the color pel buffer. If null, no color information for this plane is produced.

dstBlue A pointer to a 8-bit grey scale pel buffer with the same dimensions as *src32* to hold the blue plane of the color pel buffer. If null, no color information for this plane is produced.

Throws

ccPel::UnboundWindow

src32, dstRed, dstGreen, or *dstBlue* is unbound.

ccPel::BadWindow

One of the target pel buffers is bound but not the same size as the *src32*; or the three destination pel buffers do not have the same pitch.

Example

```
ccPelBuffer<ccPackedRGB32Pel> source32;
ccPelBuffer<c_Uint8> red(w,h), green(w,h), blue(w,h);
// w and h are the dimensions of the acquired images

// ...
// acquire 32-bit color image data into source32
// ...

// Separate source32 into all three color planes
cfRGBSeparateColorPlanes(source32, &red, &green, &blue);
```

cfSampleConvolve()

```
#include <ch_cvl/smplconv.h>

cfSampleConvolve();
```

Global function that performs smoothing and downsampling on the supplied 8-bit or 16-bit source image.

cfSampleConvolve

```
void cfSampleConvolve(
  const ccPelBuffer_const<c_UInt8> &src,
  const ccSampleConvolveParams &params,
  ccPelBuffer<c_UInt8> &dst);

ccPelBuffer<c_UInt8> cfSampleConvolve(
  const ccPelBuffer_const<c_UInt8> &src,
  const ccSampleConvolveParams &params);

void cfSampleConvolve(
  const ccPelBuffer_const<c_UInt16> &src,
  const ccSampleConvolveParams &params,
  ccPelBuffer<c_UInt16> &dst);

ccPelBuffer<c_UInt16> cfSampleConvolve(
  const ccPelBuffer_const<c_UInt16> &src,
  const ccSampleConvolveParams &params);
```

- ```
  void cfSampleConvolve(
    const ccPelBuffer_const<c_UInt8> &src,
    const ccSampleConvolveParams &params,
    ccPelBuffer<c_UInt8> &dst);
  ```

  Performs smoothing and downsampling on the supplied 8-bit image.

  Notes

  Non-integer *sampleStep* values are fully supported, but generally run slower than **FLOOR[***sampleStep***]** and much slower than **CEIL[***sampleStep***]**.

  The destination image respects client coordinates. The relationship of image and client coordinates of the result is determined by the sample.

  A default-constructed **ccSampleConvolveParams** object cannot be used to call this function. A valid kernel must be set, either directly with the **ccSampleConvolveParams::kernelX()** and **ccSampleConvolveParams::kernelY()** functions, or by using **ccSampleConvolveParams::setGaussSample()** or **ccSampleConvolveParams::setGaussSmoothing()**.
  ```

Parameters

src The 8-bit source image you supply.

params The sample convolve parameters.

dst The destination image.

Throws

ccPel::UnboundWindow
src is unbound.

ccPelFunc::Overlap
Source and destination images share pixels.

ccSampleConvolveDefs::BadParams
The (internally stored calculated or provided) kernelX_ or kernelY_ value has not been set (or both).

- ```
  ccPelBuffer<c_UInt8> cfSampleConvolve(
    const ccPelBuffer_const<c_UInt8> &src,
    const ccSampleConvolveParams &params);
  ```

  Performs smoothing and downsampling on the supplied 8-bit image. The functionality of this overload is the same as that of the first overload, with the difference that it does not return the destination image as an argument but as its return value.

  Parameters

  src The 8-bit source image you supply.

  params The sample convolve parameters.

- ```
  void cfSampleConvolve(
    const ccPelBuffer_const<c_UInt16> &src,
    const ccSampleConvolveParams &params,
    ccPelBuffer<c_UInt16> &dst);
  ```

  Performs smoothing and downsampling on the supplied 16-bit image. The functionality of this overload is the same as that of the first overload.

  Parameters

  src The 16-bit source image you supply.

  params The sample convolve parameters.

  dst The destination image.

- ```
  ccPelBuffer<c_UInt16> cfSampleConvolve(
    const ccPelBuffer_const<c_UInt16> &src,
    const ccSampleConvolveParams &params);
  ```

  Performs smoothing and downsampling on the supplied 16-bit image. The functionality of this overload is the same as that of the first overload, with the difference that it does not return the destination image as an argument but as its return value.

  Parameters

src	The 16-bit source image you supply.
params	The sample convolve parameters.
  ```

cfSampleConvolve()

cfSampledImageWarp()

```
#include <ch_cvl/simgwrp.h>

cfSampledImageWarp();
```

A global function that fills a destination image with grey values from a source image using a source image-from-destination image transform, and a destination image sampling rate.

cfSampledImageWarp

```
void cfSampledImageWarp(
  const ccPelBuffer_const<c_UInt8>& srcImage,
  ccPelBuffer<c_UInt8>& dstImage,
  const cc2XformBasePtrh_const& srcImageFromDstImage,
  c_Int32 samplingRate);
```

This function fills *dstImage* with grey values from *srcImage* using the *srcImageFromDstImage* transform. Each point in *destImage* is mapped by the *srcImageFromDstImage* transform to obtain locations in the *srcImage*. The bilinearly interpolated grey values associated with these positions are then assigned to their corresponding locations in *dstImage*.

cfSampledImageWarp() does not map every pixel in the *dstImage* with *dstImageFromSrcImage*. Instead, *dstImage* is sampled at a rate equal to the *sampingRate* (specified in image coordinates) in both its x- and y-directions. The mapped locations of all other pixels are then inferred from these mapped points. The *samplingRate* controls both the mapping accuracy and speed where smaller values correspond to higher accuracy at the cost of longer run times.

Notes

If points within *dstImage* map to locations outside of *srcImage*, a grey-value of 0 is used.

The *clientFromImageXform* transformation of *dstImage* is computed by the following:

(clientFromImageXform of dst) =
(clientFromImageXform of src)*(srcFromDstTransform provided)

srcImage and *dstImage* must not share pixels.

Parameters

srcImage The source image.

dstImage The destination image.

srcImageFromDstImage
The source image from destination image transform.

samplingRate The destination image sampling rate.

Throws

ccSampledImageWarpDefs::BadParams
If *samplingRate* < 1.

ccPel::UnboundWindow
If *srcImage* or *dstImage* are unbound.

ccPelFunc::Overlap
If *srcImage* and *dstImage* overlap.

cfSegmentColorImage

```
#include <ch_cvl/colsegm.h>
```

```
cfSegmentColorImage()
```

The Color Segmenter tool takes a vector of **ccColorRange**s and a color image, and segments the color image to produce a greyscale image in which the light pixels correspond to the colors in the color image that matched the color ranges.

Each **ccColorRange** value defines three fuzzy segmentation functions based on the nominal value and tolerances for the three color planes.

For each **ccColorRange** value, the Color Segmenter tool computes an intermediate image for each color plane using the corresponding fuzzy function, computes the product of the three images, and scales the values from 0 to 255. The final result is the maximum of all the segmentation images for the **ccColorRange** values in the vector.

cfSegmentColorImage

```
ccPelBuffer<c_UInt8> cfSegmentColorImage(
                const cc3PlanePelBuffer& colorImage,
                const cmStd vector<ccColorRange>& colors);

void cfSegmentColorImage(
                const cc3PlanePelBuffer& colorImage,
                const cmStd vector<ccColorRange>& colors,
                ccPelBuffer<c_UInt8>& result);
```

- ```
  ccPelBuffer<c_UInt8> cfSegmentColorImage(
                  const cc3PlanePelBuffer& colorImage,
                  const cmStd vector<ccColorRange>& colors);
  ```

  Segments the color image according to the collection of reference colors, and returns the segmentation in a result image.

  Parameters

  colorImage The image to segment.

  colors The reference colors.

  Throws

  ccColorSegmenterDefs::BadParams
  the size of *colors* is zero

  ccColorSegmenterDefs::BadImage
  colorImage is not bound
  ```

ccColorSegmenterDefs::BadColorSpace
colorImage's color space is **ccColorSpaceDefs::eUnknown** or an illegal value

ccColorSegmenterDefs::BadColorSpace
colors has a color with color space **ccColorSpaceDefs::eUnknown**.

ccColorSegmenterDefs::BadColorSpace
colorImage cannot be converted to the color space of one of the color ranges.

- ```
  void cfSegmentColorImage(
                  const cc3PlanePelBuffer& colorImage,
                  const cmStd vector<ccColorRange>& colors,
                  ccPelBuffer<c_UInt8>& result);
  ```

Segments the color image according to the collection of reference colors, and stores the result of the segmentation in *result*.

If *result* is not bound, it is allocated to be the same size as *colorImage*. If *result* is bound, only the area of *colorImage* and *result* that overlap is processed.

Parameters

colorImage The image to segment.

colors The reference colors.

result The grey scale pel buffer that holds the results.

Throws

ccColorSegmenterDefs::BadParams
the size of *colors* is zero

ccColorSegmenterDefs::BadImage
colorImage is not bound

ccColorSegmenterDefs::BadColorSpace
colorImage's color space is **ccColorSpaceDefs::eUnknown** or an illegal value

ccColorSegmenterDefs::BadColorSpace
colors has a color with color space **ccColorSpaceDefs::eUnknown**.
  ```

ccColorSegmenterDefs::BadColorSpace
colorImage cannot be converted to the color space of one of the color ranges.

cfSegmentColorImage

cfSegmentFeature()

```
#include <ch_cvl/pmifproc.h>

cfSegmentFeature();
```

Global function to segment a PatInspect feature into feature segments.

cfSegmentFeature

```
template <class BoundaryPoint>
cmStd vector<ccFeatureSegment> cfSegmentFeature(
  const cc_PMInspectFeature<BoundaryPoint>& feature,
  const ccRadian& maxAngle, c_Int32 minLength);
```

Segments the supplied **cc_PMInspectFeature** into one or more **ccFeatureSegment**s.

Parameters

feature	A PatInspect feature.
maxAngle	The maximum angle between adjacent boundary points permitted within a feature segment. *feature* will be segmented at boundary points with angles greater than *maxAngle*.
minLength	The minimum number of boundary points in a feature segment. Feature segments with fewer than *minLength* boundary points are discarded.

cfSegmentFeature()

cfSemiTrigger()

```
#include <ch_cvl/trigmodl.h>

cfSemiTrigger();
```

Global function to retrieve a semi trigger model object reference.

cfSemiTrigger

```
const ccTriggerModel& cfSemiTrigger();
```

When you specify **cfSemiTrigger()** as the trigger model, starting an acquisition is a two-step process:

1. You first prepare your application for acquisition by calling **ccAcqFifo::start()**. Each call to **ccAcqFifo::start()** prepares the hardware for one acquisition when there is a transition on the trigger input line.
2. The next transition on the trigger input line initiates the acquisition.

Notes

If **ccTriggerProp::triggerEnable()** is set to false, transitions on the trigger input line are ignored, and calls to **ccAcqFifo::start()** cause acquisition preparations to queue. **ccTriggerProp::triggerEnable()** must be true in order for acquisitions to proceed.

The default behavior is for a low-to-high transition on the trigger input line to trigger an acquisition. You can change this behavior to cause a high-to-low transition to trigger an acquisition by setting **ccTriggerProp::triggerLowToHigh()** to false.

cfSemiTrigger()

cfSetLanguage()

```
#include <ch_cvl/unicode.h>

cfSetLanguage();
```

Global function to select localized versions of resource DLLs to load. These DLLs are in the *\vision\bin\win32\cvl* directory and end with the three-letter code for the language. Cognex supplies only DLLs localized for US English (ENU).

There must be a complete set of resource files for each language. For example, if you want to localize only *cogstdENU.dll* to French (*cogstdFRA.dll*), you should make sure that you make copies of the other resource files and name them with the FRA suffix even if you do not localize them. If this function cannot find the complete set, it will throw an error.

For more information about localization, see *National Language Support* in the *Windows Base Services* section of the *Platform SDK* documentation.

cfSetLanguage

```
void cfSetLanguage(unsigned short languageId);
```

Selects which localized resource DLLs to load. If you do not call this function, CVL uses the US English resource DLLs whose names end in ENU.

You can call this function at any time to change languages while your application is running.

Parameters

languageId The language to use. Use the Windows **MAKELANGID()** macro to create a language ID.

Example

To use resource DLLs localized for Mexican Spanish (DLLs ending in ESM), you would call **cfSetLanguage()** like this:

```
cfSetLanguage(MAKELANGID(LANG_SPANISH,
                         SUBLANG_SPANISH_MEXICAN));
```

Throws

BadParams Localized versions of the resource DLLs for the language specified by *languageID* were not found. The *languageID* is set to its previous value.

cfSetLanguage()

cfSqr()

```
#include <ch_cvl/math.h>
```

```
cfSqr();
```

Global function that computes the square of a number (or a class that implements operator*).

cfSqr

```
template <class T> T cfSqr(T x);
```

Returns the square of the supplied value.

Parameters

T	The type of the value being squared.
x	The value to square.

cfSqr()

cfSetThreadPriority()

```
#include <ch_cvl/threads.h>

cfSetThreadPriority();
```

Global function that sets the thread priority of the current thread.

cfSetThreadPriority

```
void cfSetThreadPriority (cePriority newpri);
```

Parameters

newpri The new priority for this thread. *newpri* must be one of the following values:

cePriorityDefault
cePriorityIdle
cePriorityLowest
cePriorityBelowNormal
cePriorityNormal
cePriorityAboveNormal
cePriorityHighest
cePriorityTimeCritical

In CVL applications that will execute on the MVS-82400, do not raise the thread priority to *cePriorityTimeCritical*. If your application creates threads at this priority, your application on the embedded processor may experience problems with **ccTimer** objects and delays in image acquisition.

cfSetThreadPriority()

cfSlaveTrigger()

```
#include <ch_cvl/trigmodl.h>

cfSlaveTrigger();
```

Global function to retrieve a slave trigger model object reference.

cfSlaveTrigger

```
const ccTriggerModel& cfSlaveTrigger();
```

When you specify **cfSlaveTrigger()** as the trigger model, the acquisition FIFO becomes a slave to another acquisition FIFO. For each acquisition performed on a master FIFO, the slave FIFOs perform an acquisition at the same time. Master and slave FIFOs automatically coordinate with each other to ensure that all cameras capture images at the same time.

Master/slave FIFO configurations are also known as *synchronous* configurations. Configurations in which multiple FIFOs act independently of each other are known as *asynchronous* configurations.

In a synchronous configuration, a master FIFO can have more than one slave. The ability of a FIFO to act as master or slave depends on the frame grabber. Not all frame grabbers support the **cfSlaveTrigger()** trigger model, and those that do may have significant restrictions. For example, the FIFOs in a synchronous group must use consecutive camera ports, and the master FIFO must be associated with the first of those ports. Selecting an invalid synchronous group will not necessarily generate an exception, but will result in invalid results. Refer to the *Release Notes* for supported configurations.

Slaves cannot have other slaves. Use **ccTriggerProp::couldSlaveTo()** to check whether one FIFO can be slaved to another. **ccTriggerProp::couldSlaveTo()** indicates whether one FIFO can be a slave to another without taking into account current property settings. In particular, the master port property of the FIFOs must be set properly for synchronous configurations to work.

If a FIFO can be a slave to another FIFO, use **ccTriggerProp::triggerMaster()** to set the slave FIFO's master FIFO. Pointing **triggerMaster()** at another slave FIFO is not an error, and does not generate an exception, but the secondary slave will be unusable. A slave with an unbound **triggerMaster()** handle is also not considered an error, and is also effectively unusable.

If a synchronous configuration does not perform as expected, use **ccAcqFifo::isValid()** to check whether each FIFO is configured properly. If **isValid()** returns false, you can use the **ccAcqProblem** methods to determine the cause of the problem.

Notes

Starting with CVL 6.0, the **ccAcqProblem::hasInvalidMaster()** and **hasInvalidSlave()** methods are provided for backward compatibility only. Cognex recommends using other members of the **ccAcqProblem** class to obtain more

specific indications of which setup error was detected. For example, **slavePortInvalid()** says whether the camera port settings are valid, and **slaveNotSlaveTrigger()** says whether a FIFO has been assigned a trigger master but has not been assigned a slave trigger model. See the **ccAcqProblem** class for details.

Notes

If you call **ccAcqFifo::start()** when the slave trigger model is selected, your application will throw *ccAcqFifo::StartNotAllowed*.

Neither the **ccTriggerProp::triggerEnable()** nor the **ccTriggerProp::triggerLowToHigh()** property applies for this trigger model.

cfSystemTimeGet()

```
#include <ch_cvl/systime.h>

cfSystemTimeGet();
```

Global function to obtain the current system date and time.

cfSystemTimeGet

```
void cfSystemTimeGet(csSystemTime& time);
```

Obtains the current system date and time. When called from an application running on the host system, this function obtains the host system time.

The time is expressed in Coordinated Universal Time (UTC).

Parameters

time The current system time is placed in the supplied **csSystemTime** structure:

```
typedef struct
{
c_Int16 year; /* 1999, 2000 ... */
c_Int16 month; /* Jan = 1, Feb = 2 ... */
c_Int16 dayOfWeek; /* Sun = 0, Mon = 1 ... */
c_Int16 day; /* The day of the month. */
c_Int16 hour; /* The current hour (0-23). */
c_Int16 minute; /* The current minute (0-59). */
c_Int16 second; /* The current second (0-59). */
c_Int16 millisecond; /* Current msec (0-999) */
} csSystemTime;
```

cfSystemTimeGet()

cfSystemTimeSet()

```
#include <ch_cvl/systime.h>

cfSystemTimeSet();
```

Global function to set the current system date and time.

cfSystemTimeSet

```
bool cfSystemTimeSet(const csSystemTime& time);
```

Sets the current system date and time. When called from an application running on the host system, this function sets the host system time.

The time is expressed in Coordinated Universal Time (UTC).

This function returns a nonzero value to indicate success, zero to indicate failure.

Parameters

time The system time is set to the values in the supplied **csSystemTime** structure:

```
typedef struct
{
c_Int16 year; /* 1999, 2000 ... */
c_Int16 month; /* Jan = 1, Feb = 2 ... */
c_Int16 dayOfWeek; /* Sun = 0, Mon = 1 ... */
c_Int16 day; /* The day of the month. */
c_Int16 hour; /* The current hour (0-23). */
c_Int16 minute; /* The current minute (0-59). */
c_Int16 second; /* The current second (0-59). */
c_Int16 millisecond; /* Current msec (0-999) */
} csSystemTime;
```

Throws

ccSysTimeBadArgument::BadParams
One or more of the members of *time* is invalid.

Notes

The *dayOfWeek* member of *time* is ignored. The *year* member of *time* must be greater than or equal to 1980.

cfSystemTimeSet()

cfThreadCleanup()

```
#include <ch_cvl/threads.h>

cfThreadCleanup();
```

Global function that must be called at the termination of all threads that both

- Call CVL functions

  and

- Were not created using **cfCreateThread()**

You do not need to call this function for any threads that do not meet both of the requirements listed above.

This function does not need to be called for a program's main thread.

cfThreadCleanup

```
void cfThreadCleanup();
```

Caution

Once this function has been called within a thread, no further CVL calls can be made by that thread. This restriction includes the destructors for CVL objects. Accordingly, if you create a thread that creates any CVL objects, those objects must be destroyed before the thread calls **cfThreadCleanup()**.

If your thread creates CVL objects on the stack, you need to include an extra scope within your thread function, as shown below:

```
myThreadProc(void *arg)
{
  {
  ccPelBuffer<c_UInt8> myImage;

    ...

  } // End of extra scope -- myImage destroyed here

// Now safe to call cfThreadCleanup()
cfThreadCleanup()
}
```

cfThreadCleanup()

cfThresholdWGV()

```
#include <ch_cvl/thresh.h>

cfThresholdWGV();
```

Global function to calculate the threshold for a histogram by minimizing the within-group variance. This technique is particularly useful for obtaining a threshold value for noisy images, saturated images, or multimodal histograms. You typically determine the threshold before segmenting an image with the Blob tool.

cfThresholdWGV

```
void cfThresholdWGV(
  const cmStd vector<c_UInt32>& histogram,
  ccThresholdResult& result,
  c_Int32 leftIndex = 0,
  c_Int32 rightIndex = -1);
```

Computes the threshold for the specified range of bins by minimizing the within-group variance.

Parameters

histogram The histogram for which to compute a threshold. *histogram* must have a size greater than 0.

result A threshold result object.

leftIndex The index of the left pixel bin for the partial histogram. *leftIndex* is included in the threshold computation.

rightIndex The index of the right pixel bin for the partial histogram. *rightIndex* is excluded from the threshold computation. If you specify -1, **histogram.size()** is used as the value of *rightIndex*.

Throws

ccThresholdDefs::BadParams

leftIndex is less than 0; *rightIndex* is not -1 and is greater than the value returned by **histogram.size()**; *rightIndex* is not -1 and is less than or equal to *leftIndex*; or the partial histogram does not contain any nonzero values.

Notes

The within-group variance technique for calculating a threshold applies only to those partial histograms that have at least two nonzero bin values between *leftIndex* and *rightIndex*. In this case, **cfThresholdWGV()** calculates a threshold that lies between the indices and reports a nonzero score. The threshold computation includes the *leftIndex* value but excludes the *rightIndex* value. The two groups of bins created by the threshold have indices in the range *leftIndex*, inclusive, through

the threshold, exclusive, and the threshold, inclusive, through *rightIndex*, exclusive. When several possible thresholds minimize the within-group variance, **cfThresholdWGV()** returns the minimum threshold value.

If the histogram contains only one nonzero value, the within-group variance technique cannot be used. **cfThresholdWGV()** returns the index of the nonzero value and a score of 0.

cfTruePeak()

```
#include <ch_cvl/edge.h>

cfTruePeak();
```

Global function that performs whole-pixel peak detection on the supplied edge magnitude and edge angle images.

cfTruePeak

```
template<class T>
ccPelBuffer<T> cfTruePeak(
  const ccPelBuffer_const<T>& magImage,
  const ccPelBuffer_const<c_UInt8>& angImage,
  T magThreshold, c_Int32* pNPeaks = 0);

template<class T>
void cfTruePeak(const ccPelBuffer_const<T>& magImage,
  const ccPelBuffer_const<c_UInt8>& angImage,
  ccPelBuffer<T>& dstImage, T magThreshold,
  c_Int32* pNPeaks = 0);
```

-
```
template<class T>
ccPelBuffer<T> cfTruePeak(
  const ccPelBuffer_const<T>& magImage,
  const ccPelBuffer_const<c_UInt8>& angImage,
  T magThreshold, c_Int32* pNPeaks = 0);
```

Performs whole-pixel peak detection on the supplied edge magnitude and edge angle images and returns an edge magnitude image where pixels which are true edge peaks are set to the magnitude of the pixels in the input image, and all other pixels are set to 0.

For each pixel in *magImage* with a nonzero value and with a corresponding pixel in *angImage*, the Edge tool applies an angle-sensitive 3x1 neighborhood operator. Only those pixels which have a greater magnitude than both neighbors are included in the returned edge peak image.

Parameters

T	Template parameters specifying the type of the magnitude image and threshold. *T* must be of type **c_Uint8**.
magImage	The input edge magnitude image
angImage	The input edge angle image
magThreshold	A magnitude threshold. All pixels in *magImage* with a value less than *magThreshold* are discarded.
pNPeaks	If *pNPeaks* is not *NULL*, the total number of true peaks is written to the **c_Int32** pointed to by *pNPeaks*.

- ```
  template<class T>
  void cfTruePeak(const ccPelBuffer_const<T>& magImage,
    const ccPelBuffer_const<c_UInt8>& angImage,
    ccPelBuffer<T>& dstImage, T magThreshold,
    c_Int32* pNPeaks = 0);
  ```

  Performs whole-pixel peak detection on the supplied edge magnitude and edge angle images and returns an edge magnitude image where pixels which are true edge peaks are set to the magnitude of the pixels in the input image, and all other pixels are set to 0.

  For each pixel in *magImage* with a nonzero value and with a corresponding pixel in *angImage*, the Edge tool applies an angle-sensitive 3x1 neighborhood operator. Only those pixels which have a greater magnitude than both neighbors are included in the returned edge peak image.

  Parameters

T	Template parameters specifying the type of the magnitude image and threshold. *T* must be of type **c_Uint8**.
magImage	The input edge magnitude image
angImage	The input edge angle image
dstImage	The image into which the true edge peak output image is placed
magThreshold	A magnitude threshold. All pixels in *magImage* with a value less than *magThreshold* are discarded.
pNPeaks	If *pNPeaks* is not *NULL*, the total number of true peaks is written to the **c_Int32** pointed to by *pNPeaks*.
  ```

cfVerifyOcrChecksum()

```
#include <ch_cvl/acuread.h>

cfVerifyOcrChecksum();
```

Global function to verify that a string passes a checksum test.

cfVerifyOCRChecksum

```
bool cfVerifyOcrString(
   ccAcuReadDefs::Checksum checksum,
   const ccCvlString &str);
```

Returns true if the supplied string has the supplied checksum.

Parameters

checksum The checksum to verify. *checksum* must be one of the following values:

ccAcuReadDefs::eSemi
ccAcuReadDefs::eBC412
ccAcuReadDefs::eIBM412

str The string to validate.

Throws

ccAcuReadDefs::BadParams
The length of *str* is greater than *ccAcuReadDefs::kMaxStringLength*, *str* contains invalid characters, or *checksum* is *ccAcuReadDefs::eNone* or *ccAcuReadDefs::eVirtual*.

cfVerifyOcrChecksum()

cfVerifyOcrString()

```
#include <ch_cvl/acuread.h>

cfVerifyOcrString();
```

Global function to verify that a string is valid given a fielding string.

cfVerifyOCRString

```
bool cfVerifyOcrString(
   const cmStd vector<cccCvlString> &fieldMap,
   const ccCvlString &str);
```

Returns true if each character in *str* is one of the characters in the corresponding location in *fieldMap*, false otherwise.

Parameters

fieldMap A vector of **ccCvlString**s. Each vector contains all of the valid characters for that field position.

str The string to validate.

Throws

ccAcuReadDefs::BadParams
The size of *fieldMap* is greater than *ccAcuReadDefs::kMaxStringLength* + 1, the length of *str* is greater than *ccAcuReadDefs::kMaxStringLength*, the length of any of the strings in *fieldMap* is greater than *ccAcuReadDefs::kMaxFieldStringLength*, or *fieldMap* contains invalid characters.

cfVerifyOcrString()

cfWaitForContinue()

```
#include <ch_cvl/gui.h>

cfWaitForContinue();
```

Global function that displays a dialog box containing **Continue** and **Cancel** buttons on the host computer system, then waits for the user to click one of the two buttons.

cfWaitForContinue

```
bool cfWaitForContinue();

bool cfWaitForContinue(int xPos, int yPos);
```

- `bool cfWaitForContinue();`

  Displays the alert box in the center of the screen. Returns true if the user clicks **Continue** and false if he clicks **Cancel**.

- `bool cfWaitForContinue(int xPos, int yPos);`

  Displays the alert box at the specified location. Returns true if the user clicks **Continue** and false if he clicks **Cancel**.

  Parameters

xPos	The x-location of the upper-left corner of the alert box in host display pixels.
yPos	The y-location of the upper-left corner of the alert box in host display pixels.

cfWaitForContinue()

cfWaitForThreadTermination()

```
#include <ch_cvl/threads.h>

cfWaitForThreadTermination();
```

Global function that blocks until the supplied thread terminates.

cfWaitForThreadTermination

```
void cfWaitForThreadTermination(ccThreadID &thread);
```

Parameters

thread	The thread to wait for.

cfWaitForThreadTermination()

CompleteArgs

```
#include <ch_cvl/acqbase.h>

class ccAcqFifo::CompleteArgs;
```

CompleteArgs is a nested class defined within the scope of **ccAcqFifo**.

This class is used as the argument to the **ccAcqFifo::completeAcq()** method. The design of this class allows emulation of named parameters, where only the arguments with non-default values need to be specified, in any order.

Notes

Using **ccAcqFifo::complete()** in derived classes to handle acquired images is now replaced by **ccAcqFifo::completeAcq()**. The older method is retained for backward compatibility, but use **ccAcqFifo::completeAcq()** for all new code.

Class Properties

Copyable	No
Derivable	No
Archiveable	No

Constructors/Destructors

CompleteArgs

```
explicit inline CompleteArgs();
```

Constructs a **CompleteArgs** object that can be passed to **ccAcqFifo::completeAcq()** on an acquisition FIFO, or passed to an acquisition callback function. If not overridden, the arguments are initialized with the default values shown in this table:

Argument	Default Value
makeLocal()	true
maxWait()	HUGE_VAL
startReqStatus()	None
acquireInfo()	None
autoStart()	false

Public Member Functions

The member functions of **ccAcqFifo::CompleteArgs()** are used as if they were parameters to an invocation of **completeAcq()**. You only need to specify a parameter when changing a default value. If you wish to use a **ccAcquireInfo** object to contain the results of an image acquisition, you must specify the **acquireInfo()** parameter. If you wish to check the **start()** completion status, you must specify the **startReqStatus()** parameter.

There are two ways to specify the arguments to **completeAcq()** using a **CompleteArgs** object, the long form and the shortcut form. Cognex documentation shows the shortcut form in code examples, and recommends using it.

In the long form method, you instantiate a **CompleteArgs** object and use its member functions, one at a time, to override the default-constructed value for any argument you want to change, as shown in the following example.

```
ccAcquireInfo info;
ceStartReqStatus status;

ccAcqFifo::CompleteArgs args;

args.acquireInfo(&info);
args.startReqStatus(&status);
args.maxWait(5.0);
args.makeLocal(false);

ccPelBuffer<c_UInt8> pb = fifo->complete(args);
```

The shortcut form is made possible because all **CompleteArgs** member functions return a reference to the **CompleteArgs** object. For this reason, you can chain each member function off the constructor, resulting in a simple list of white-space separated **CompleteArgs** arguments, as shown in the following example. This example accomplishes exactly the same as the preceding example.

```
ccAcquireInfo info;
ceStartReqStatus status;
ccAcqImagePtrh img = fifo->completeAcq
          (ccAcqFifo::CompleteArgs().acquireInfo(&info)
                                    .startReqStatus(&status)
                                    .maxWait(5.0)
                                    .makeLocal(false));
```

The four parameters can be specified in any order.

The argument chaining makes *args* redundant, and it can be dropped. Using the shortcut form, all function-call arguments to **completeAcq()** are consolidated into a single statement.

As another example, if you want only to specify a **ccAcquireInfo** object, set **makeLocal()** false, and leave the other arguments in their default values, use code like the following:

```
ccAcquireInfo info;
ccPelBuffer<c_UInt8> pb = fifo->complete
          (ccAcqFifo::CompleteArgs().makeLocal(false)
                                    .acquireInfo(&info));
```

acquireInfo

```
ccAcquireInfo* acquireInfo() const;
CompleteArgs& acquireInfo();
```

- `ccAcquireInfo* acquireInfo() const;`

  Returns the **ccAcquireInfo** object, if one was set.

- `CompleteArgs& acquireInfo();`

  Specifies the use of a **ccAcquireInfo** object to contain the results of the image acquisition. **ccAcquireInfo** is a class that stores several pieces of information about each image acquisition. See **ccAcquireInfo** on page 261.

  Use this function as shown in this example:

```
ccAcquireInfo info;
ccPelBuffer<c_UInt8> pb = fifo->complete
(ccAcqFifo::CompleteArgs().acquireInfo(&info));
```

makeLocal

```
bool makeLocal() const;
CompleteArgs& makeLocal();
```

- `bool makeLocal() const;`

  Returns the current setting of the **makeLocal()** parameter.

- `CompleteArgs& makeLocal();`

  Sets the Boolean *makeLocal* parameter; the default value is true. Use this function as shown in this example:

```
ccPelBuffer<c_UInt8> pb = fifo->complete
          (ccAcqFifo::CompleteArgs().makeLocal(false));
```

Notes

The **makeLocal()** parameter is used in PC-based frame grabbers with the ability to store images on board. **makeLocal(true)** specifies that the image is to be automatically copied to PC memory. **makeLocal(false)** specifies that the image is to be left on the frame grabber. If the image is left on the board, it can be discarded, transferred to PC memory at a later time, or transferred directly to the PC's display adapter for display.

maxWait

```
double maxWait() const;

CompleteArgs& maxWait();
```

- `double maxWait() const;`

  Returns the current value of the **maxWait()** parameter.

- `CompleteArgs& maxWait();`

  Sets the **maxWait()** parameter, specified in seconds; the default value is HUGE_VAL. Use this function as shown in this example:

```
ccPelBuffer<c_UInt8> pb = fifo->complete
          (ccAcqFifo::CompleteArgs().maxWait(5.0));
```

Notes

The **maxWait()** parameter is the maximum number of seconds to wait for a completed image acquisition to become available. The special value HUGE_VAL means to wait indefinitely. If the time specified by **maxWait()** expires, **complete()** returns an unbound pel buffer, and **ccAcquireInfo()->failure().isIncomplete()** is true.

startReqStatus

```
ccAcqFifo::ceStartReqStatus* startReqStatus() const;

CompleteArgs& startReqStatus();
```

- `ccAcqFifo::ceStartReqStatus* startReqStatus() const;`

  Returns the current setting of the **ceStartReqStatus** parameter.

- `CompleteArgs& startReqStatus();`

  Specifies a pointer to **ccAcqFifo::ceStartReqStatus** to contain the **start()** completion status. Use this function as shown in this example:

```
ccAcqFifo::ceStartReqStatus status;
ccPelBuffer<c_UInt8> pb = fifo->complete

(ccAcqFifo::CompleteArgs().startReqStatus(&status));
```

Notes

If **startReqStatus()** is non-null, then upon acquisition completion, it contains the status of the **ccAcqFifo::start()** call that initiated the acquisition. This determines whether an additional call to **start()** is necessary to obtain the next image, whether the *appTag* is valid, and whether the FIFO is in sequence with the other FIFOs of a master-slave sequence. See the description of **ccAcqFifo::ceStartReqStatus()** on page 218 for further explanation.

---

autoStart

```
bool autoStart() const;

CompleteArgs& autoStart();
```

- `bool autoStart() const;`

  Returns the current setting of the **autoStart()** parameter.

- `CompleteArgs& autoStart();`

  Deprecated function, for backwards compatibility only.

Notes

If **autoStart()** is true and the current trigger model allows **start()** to be invoked, then **start()** is automatically invoked following this acquisition's completion, with an *appTag* of zero. If the acquisition was incomplete because the *maxWait* parameter timed out, (as reported by **ccAcquireInfo()->failure().isIncomplete()**) or if this function throws, **start()** is not invoked.
